Summary

The information in this document relates to Health and Safety statistics for 2013/14. The document can be found at: www.hse.gov.uk/statistics/causdis/pneumoconiosis/

Currently occurring cases and deaths from non-asbestos-related pneumoconiosis are mainly a result of past exposures to coal dust (coal worker’s pneumoconiosis) and silica (silicosis).

- There were 252 estimated new cases of pneumoconiosis seen by chest physicians in 2013 within the THOR-SWORD scheme compared with an average of about 170 per year over the previous 10 years.
- There were 275 new cases of coal worker’s pneumoconiosis assessed for Industrial Injuries and Disablement Benefit in 2013 compared to 265 in 2012.
- There were 45 new cases of silicosis assessed for Industrial Injuries Disablement Benefit in 2013 compared to 40 in 2012.
- These figures are likely to be underestimates of the annual number of new cases.
- The number of annual deaths from coal worker’s pneumoconiosis is now less than half that in the late 1990s, with 140 in 2012.
- There were 11 deaths due to silicosis in 2012, which is close to the annual average for the last 10 years.
- Pneumoconiosis usually takes many years to develop so most current cases of pneumoconiosis occur in retired workers and reflect industrial conditions of the past, particular in the coal mining industry.

Figure 1: Pneumoconiosis (other than asbestosis) in Great Britain, 1999-2013

This document is available from www.hse.gov.uk/statistics/
Introduction

The term "pneumoconiosis" refers to a group of lung diseases caused by the inhalation, and retention in the lungs, of dusts. The disease is characterised by scarring and inflammation of the lung tissue. It is an irreversible condition with no cure. Symptoms include, shortness of breath, persistent cough, fatigue, laboured and rapid breathing, chest pain. These can seriously affect normal daily activity and lead to various complications which can be fatal.

The main types of pneumoconiosis are coal workers' pneumoconiosis (caused by coal dust), asbestosis (caused by asbestos) and silicosis (caused by respirable crystalline silica (RCS)). These pages describe the latest available statistics for pneumoconiosis other than asbestosis which is described separately along with other asbestos related diseases – see www.hse.gov.uk/statistics/cause/cause_outcomes/asbestos/

There is usually a long delay of more than 10 years between first exposure to dust and the onset of symptoms of these diseases, though the disease process itself may start sooner that this, and if dust exposures are high symptoms may also emerge more quickly. However, most new cases or deaths from pneumoconiosis reflect the working conditions of the past and many cases occur in individuals who have retired.

Two main data sources provide information about annual numbers of newly diagnosed cases of pneumoconiosis (disease incidence) in Great Britain: the Department for Work and Pensions (DWP) Industrial Injuries and Disablement Benefit (IIDB) scheme and SWORD scheme within The Health and Occupation Reporting (THOR) network. The IIDB figures may underestimate incidence of pneumoconiosis since some individuals may not be aware of their entitlement to claim compensation or may not wish to do so. The figures are also subject to large fluctuations from time to time in response to changes to the administration of the compensation system or activity by DWP to encourage uptake. Incidence may be more substantially underestimated by THOR since the scheme will only include those cases that are serious enough to be seen by a chest consultant, or that occur in individuals with access to occupational physicians.

Overall Scale

New cases assessed for IIDB and cases recorded by respiratory physicians

IIDB pneumoconiosis cases can be readily classified into 3 groups:

1) coal worker’s pneumoconiosis,
2) asbestosis, and
3) other pneumoconiosis (mainly silicosis)

Causal agents other than coal or asbestos are not recorded, but details of the industrial setting in which cases occurred suggest that the majority of the cases in the third group (other pneumoconiosis) are in fact silicosis. For the SWORD statistics, the category “pneumoconiosis” includes all kinds of pneumoconiosis – including asbestosis.

- In 2013, there were 275 assessed cases of coal worker’s pneumoconiosis for IIDB compared with 265 in 2012; for the last 8 years the numbers have been well below the peak of over 1000 cases per year seen during 2002-2004. (See Table IIDB01 www.hse.gov.uk/statistics/tables/iidb01.xls).
- There were 45 assessed cases of other pneumoconiosis (mainly silicosis) in 2013 compared with 40 in 2012, slightly fewer than numbers in the previous five years (see Table IIDB01 www.hse.gov.uk/statistics/tables/iidb01.xls and Figure 1).
- There were 252 estimated new cases of pneumoconiosis seen by chest physicians in 2013 within the SWORD scheme compared with an average of about 180 per year over the last decade (Table THORR01 www.hse.gov.uk/statistics/tables/thorr01.xls and Figure 1).

Both the IIDB and THOR schemes indicate that most cases of pneumoconiosis occur in men over retirement age (see table IIDB07 www.hse.gov.uk/statistics/tables/iidb07.xls and THORR02 www.hse.gov.uk/statistics/tables/thorr02.xls). For example, approximately 80% of non-asbestos pneumoconiosis IIDB cases assessed in 2013 were over 65 years of age.

Both the IIDB and THOR data sources are likely to substantially underestimate the incidence of silicosis. If silicosis played a role in a substantial proportion of silica-related lung cancer cases, recent estimates of the
The current burden of lung cancer in GB due to past exposures to silica (nearly 800 deaths per year)\(^1\) would imply that the extent of underestimation of silicosis by IIDB and THOR was considerable. Available silicosis risk estimates for different exposure levels and durations\(^2\), together with estimates of the likely extent of past exposures in Britain also imply a much higher figure than recorded in the available statistics.

The role of silica exposure in work-related respiratory disease is supported by information about how individuals currently with “breathing or lung problems” thought that work had caused or made their illness worse, according to the LFS.

The most recent estimate of the annual prevalence of work-related respiratory disease (based on data from the LFS in 2010/11, 2011/12 and 2013/14) suggests that around 127 000 people who had ever worked currently had breathing or lung problems caused or made worse by work (95% Confidence Interval: 111 000 – 143 000). Based on questions about what respondents thought was the cause of their work related illness in the 2009/10/ 2010/11, and 2011/12 surveys, “Dusts from stone, cement, brick or concrete” contributed in 19% of estimated cases of breathing and lung problems.

### Trends in Incidence

Trends in the number of new IIDB pneumoconiosis cases are difficult to interpret. The substantially higher numbers of cases from 2002 shown in Figure 1 is likely to be due to a publicity campaign by the Department for Work and Pensions inviting people whose claims had been wrongly disallowed between 1994 and 1999 to re-claim, and also a more accurate method of data collection introduced in April 2002. Year on year changes in the estimated annual cases based on the THOR scheme are also difficult to interpret because the figures are affected by changes in the numbers and reporting habits of participating physicians.

Table DC01 (www.hse.gov.uk/statistics/tables/dc01.xls) and Figure 1 show deaths due to silicosis and other work-related pneumoconiosis (excluding asbestosis). The number of pneumoconiosis deaths is largely determined by changes in the size and employment conditions of the mining industry many years ago. A downward trend in the number of pneumoconiosis deaths other than silicosis or asbestosis is evident over the last few years: there were 140 such deaths recorded in 2012 compared to an average of 156 over the last decade. In 2012 there were 11 deaths in GB with silicosis recorded as the underlying cause of death, which is very close to the average of 13 deaths per year over the last 10 years.
