Although recombination is still a theoretical possibility it would require all three packaging genes and the viral vector to combine to produce a replication competent virus. In this unlikely event such a recombinant virus would still lack all the genes required for the production of a complete intact virus. So in this instance no intact HIV virus will be produced.

In this particular instance we propose to create Master and Working cell banks for eight lentivirus packaging cell lines and three non-replication competent lentivirus producer cell lines. To test the viral potency of infection produced by conditioned - medium from the three producer lines using a standard viral titre assay in recipient cells.

### Recipient or parental organism

**Eight packaging cell lines.**

1. **STAR-G.** Human kidney epithelial cell line 293T transfected with HIV synthetic GAG-POL expressed from Murine Leukemia virus (MLV) vector; HIV REV gene expressed from a MLV vector; GALV envelope (with MLV c-tail) expressed from a plasmid.
2. **STAR-RD-pro.** Human kidney epithelial cell line 293T transfected with HIV synthetic GAG-POL expressed from Murine Leukemia virus (MLV) vector; HIV TAT gene expressed from MLV vector; HIV REV gene expressed from a MLV vector; RD114 envelope (with HIV protease cleavage site) expressed from a plasmid.
3. **STAR-A.** Human kidney epithelial cell line 293T transfected with HIV synthetic GAG-POL expressed from Murine Leukemia virus (MLV) vector; HIV TAT gene expressed from MLV vector; HIV REV gene expressed from a MLV vector; amphotropic envelope expressed from a plasmid.
4. **293T-GPRT1+R1.** Human kidney epithelial cell line 293T transfected with wild type HIV-GAG-POL; -TAT and -REV genes expressed from a MLV vector and amphotropic envelope expressed from a MLV vector.
5. **293T-GPRT1 +R1-A.** Human kidney epithelial cell line 293T transfected with wild type HIV-GAG-POL; -TAT and REV genes expressed from a MLV vector and wild type HIV-REV expressed from a MLV vector.
6. **STAR.** Human kidney epithelial cell line 293T transfected with HIV synthetic GAG-POL expressed from Murine Leukemia virus (MLV) vector; HIV TAT gene expressed from MLV vector; HIV REV gene expressed from a MLV vector.
7. **HT-STAR-A.** Human fibrosarcoma (HT1080) transfected with HIV synthetic GAG-POL expressed from Murine Leukemia virus (MLV) vector; HIV TAT gene expressed from MLV vector; HIV REV gene expressed from a MLV vector and amphotropic expressed from a MLV vector.
8. **HT-STAR.** Human fibrosarcoma (HT1080) transfected with HIV synthetic GAG-POL expressed from Murine Leukemia virus (MLV) vector; HIV TAT gene expressed from MLV vector; HIV REV gene expressed from a MLV vector.

**Three producer cell lines.**

1. **STAR-G-HV#2.** Human kidney epithelial cell line 293T transfected with HIV synthetic GAG-POL expressed from Murine Leukemia virus (MLV) vector; HIV TAT gene expressed from MLV vector; GALV envelope (with MLV c-rail) expressed from a plasmid and infected with an HIV vector.
expressing green fluorescent protein (GFP).
2. STAR-Rdpro-HV#1. Human kidney epithelial cell line 293T transfected with HIV synthetic GAG-POL expressed from Murine Leukemia virus (MLV) vector; HIV TAT gene expressed from MLV vector; HIV REV gene expressed from a MLV vector; RD114 envelope protein with HIV protease cleavage site expressed from a plasmid and infected with an HIV vector expressing green fluorescent protein (GFP).
3. STAR-A-HV#2. Human kidney epithelial cell line 293T transfected with HIV synthetic GAG-POL expressed from Murine Leukemia virus (MLV) vector; HIV TAT gene expressed from MLV vector; HIV REV gene expressed from a MLV vector; amphotrophic envelope protein expressed from a plasmid and infected with an HIV vector expressing green fluorescent protein (GFP).

Recipient cell lines: Human kidney epithelial cell line (293). Used in titering the supernatant from producer cell lines.

Host/vector system

The Moloney leukemia virus based vectors served as basic constructs for the generation of plasmids containing HIV gag-pol, Tat or Rev sequences. In particular the construct pCNC-MCS was used to generate the constructs pCNC-GPRT; pCNC-SYNGP; Pnc-Tat and pCNC-Rev.

To construct the producer lines 293T cells were transduced with pH7G; pHRSIN-CSGW and pHV. As described in Ikeda Y et al Nat. Biotechnol 2003 May 21(5): 569-572. UK patent application 0220467.5

Origin & function

The cell lines; STAR-G-HV#2; STAR-Rdpro-HV#1; STAR-A-HV#2; STAR-G; STAR-RDpro; STAR-A; 293TGPRT1+R1-A; 293TGPRT1+r1; star; ht-star-a AND ht-star; were provided by Department of Immunology and Molecular Pathology, Windeyer Institute of Medical Sciences, Windeyer Building, 46 Cleveland Street, London, W1T 4JF. Tel 020-7679-9343; Fax 020-7679-9652.

The packaging cell lines (STAR-G; STAR-RDpro; STAR-A; 293TGPRT1+R1-A; 293TGPRT1+r1; STAR; HT-STAR-A and HT-STAR) are intended as research tools in the production of non-replication competent lentiviruses. The producer cell lines (STAR-G-HV#2; STAR-Rdpro-HV#1; STAR-A-HV#2;) are meant to serve as sources of non-replication competent lentiviruses encoding the marker protein GFP for research studies involving cell tracking and identification.

Evaluation of foreseeable effects

As both cell type described here are intended for research purposes the foreseeable effects cannot be evaluated at this time. Details of the MLV constructs and demonstration that they do not give rise to replication competent MLV viruses are available in the publication; Soneoka Y. et al. Nucleic Acid Res. 23-628-633, 1995.

There is further evidence that such replication defective retroviruses are not pathogenic when tested in monkeys are presented in; Besnier C et al. Proc. Natl. Acad. Sci USA 99: 11920-11920 (2002).

Safety. Supernatants from the stable packaging cell lines and producer cell lines will be for the absence of replication competent virus using assays fro HIV-1 gag sequences and reverse transcriptase activity. Both of these assays are described in the publication Ikeda Y. et al. Nat Biotechnol. 2003 May 21(5): 569-572.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The packaging cell lines and producer clones are classified as ACDP Hazard Group 2. They are genetically modified cell lines developed for the production of non-replication competent viruses and are classified for use at ACGM level 2 and are worked with in Level 2 containment and conditions.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation from level 2 containment and use is expected. All activities with these cell lines will be performed in Lab 237 at the National Pathogenic Virus Collection located in the main building at CAMR.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Liquid waste generated in class-2 safety cabinet in Room 237:

1. Prior to work taking place, each cabinet is checked to see that it contains a ‘new’ or ‘in use’ liquid waste container. A ‘new’ liquid waste container comprises a 1L polypropylene bottle containing a single formulated tablet containing a chlorine-releasing agent sodium dichloroisocyanurate (NaDCC).

2. Add all liquid waste generated in the cabinet goes into this container, until a final volume of approximately 500 ml is reached (equivalent to a final concentration of 2,500ppm available Chlorine).

3. At the end of each working period, all surfaces of the open bottle are sprayed and wiped down with 0.25% v/v of NaDCC solution, equivalent to a final concentration of 2,500ppm available Chlorine.

4. After all work has finished the capped ‘full’ liquid waste bottle is removed from the cabinet (a ‘new’ waste bottle should be placed in the cabinet immediately).

5. The removed ‘full’ liquid waste bottle is allowed to stand for 24 hours.

6. The inactivated liquid waste can then be disposed of by laboratory personnel into a designated sink with running water.

Solid waste generated in class-2 safety cabinet:

1. All solid waste generated in the cabinet is placed in portex plastic bags.
2. The bagged waste is placed into an autoclave tin.
3. Once the autoclave tin is full. Spray and wipe the outside of the tin with 2,500ppm chlorine-based disinfectant.
4. Transfer the tin to the lobby area; notify Central Autoclaving Services of its presence and await collection.
5. The tin is autoclaved by Central Autoclaving Services.
6. After successful autoclaving, Central Autoclaving Services will return the tin to laboratory 237. Laboratory personnel will transfer the contents to yellow clinical waste sacks for incineration.
7. The waste in yellow sacks is then transferred to an on-site incineration plant for incineration. All steps in the disposal of waste from laboratory 237 must be recorded and signed off on the form shown below. A copy of the form must accompany the waste tin and be returned to the laboratory supervisor.

The use of chlorine-release tablets to make up disinfectant solutions is now well established. Formulated tablets using Sodium Dichloroisocyanurate (NaDCC) a potent chlorinating agent has been shown to be more effective than sodium hypochlorite solution or liquid bleaches where organic material is present.

Bloomfield S F. The bacterial capacity of Sodium dichloroisocyanurate formulations; the sterilisation of infant feeding bottles and teats. Lab Practice 1973. 22. 617-623.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

**Project Additional Information**

**Purposes of the contained use**

The European Collection of Animal Cell Cultures (ECACC) offers a service of safe storage, under appropriate conditions, for animal cell lines, viruses and bacteria as a back-up contingency to customers with their own storage facilities. A number of these deposits will be classified as genetically modified organism ACDP category 2 or 3 (GMO 2 or 3) by the depositor and as such will have already received HSE approval. ECACC requires submission of a biohazard risk assessment form with such deposits and evidence of HSE notification and approval prior to shipment from the owner to ECACC. These documents will be reviewed by the GMSC at HPA Porton Down before a deposit is accepted. The safe deposits are stored under appropriate conditions (either liquid nitrogen vapour or -80 degrees C freezer) in the secure ultra-low temperature.
cryostore facility at HPA Porton Down. Samples are always returned to the customer for disposal at the end of the storage period. For depositors outside the UK a biohazard risk assessment is required and, where available, a notification and approval by a national regulatory body with equivalent jurisdiction to the HSE will be sought.

ECACC also provides storage for patent deposits under the terms of the Budapest Treaty. The same requirements are made for these as for the safe deposits (see above). However, under the conditions of the Budapest Treaty, the contents of a representative ampoule has to be tested and shown to demonstrate viability and number of the contents of a representative ampoule thereby conforming with patent requirements. The purpose of this submission is to notify and obtain permission to store deposits (GMO class 2 & 3) at ECACC where the depositor has already demonstrated approval of a regulatory authority equivalent to the HSE for the work at their institution where the GMO was generated.

Further to notify the HSE that ECACC proposes to determine the viability and count the contents of a representative ampoule of a patent deposit under appropriate containment conditions by fully trained personnel. No additional genetic modification will be performed with the deposit at ECACC, HPA Porton Down in connection with the safes and patent storage facility.

Each customer will already have previously demonstrated notification of an appropriate regulatory body (eg HSE) and approval for the work that has generated the GMO class 2 or 3 patent deposit. Each customer will also provide ECACC with a detailed risk assessment for each type of patent deposit. These will be reviewed by the GMSC prior to any patent deposit being allowed on site. Any testing beyond the technical scope of the trained staff at ECACC will be contracted out to other department within the HPA or accredited external contractors.

Manipulation of patent deposits will be kept to a minimum and involve the determination of viability and number of content of a representative ampoule. This type of activity will result in no extensive cell culture, less than 72 hours; less than 100mls of culture medium or other liquid reagent.

ECACC expects the majority of the safes and patent deposits it will store and/or test will be mammalian or non-mammalian cell lines requiring bio-safety level containment up to and including ACDP containment levels 2 and 3. ECACC intends to test cell lines at ACDP 2, in room 237 located at the National Collection of Pathogenic Viruses (NCPV). ACDP 3 cell lines will be tested in the ACDP 3 laboratory (Room 237a) in the NCPV. In addition, room 21 in the ECACC main building is also equipped for ACDP level 2 work. Working with cell lines requiring ACDP2 containment ECACC would expect the most extreme hazard from such cell lines would be that they may produce mobile, self-replicating, transforming viruses or toxic agents. An extreme example of this would be the production of replication competent retrovirus with a broad tropism and containing a transforming gene, such as HPV16E6 and E7 or SV40 large T-antigen. The possibility of such an occurrence will be evaluated and assessed from the biohazard risk assessment and its review by the genetic-modification safety committee (GMSC).

The containment and waste management procedures described in sections 8 and 12 below are designed with this possibility in mind.

**Recipient or parental organism**

ECACC expects the majority of the safes and patent deposits it will store and/or test will be mammalian or non-mammalian cell lines requiring bio-safety level containment up to and including ACDP containment levels 2 and 3. ECACC intends to test cell lines at ACDP 2, in room 237 located at the National Collection of Pathogenic Viruses (NCPV). ACDP 3 cell lines will be tested in the ACDP 3 laboratory (Room 237a) in the NCPV. In addition, room 21 in the ECACC main building is also equipped for ACDP level 2 work. Working with cell lines requiring ACDP2 containment ECACC would expect the most extreme hazard from such cell lines would be that they may produce mobile, self-replicating, transforming viruses or toxic agents. An extreme example of this would be the production of replication competent retrovirus with a broad tropism and containing a transforming gene, such as HPV16E6 and E7 or SV40 large T-antigen. The possibility of such an occurrence will be evaluated and assessed from the biohazard risk assessment and its review by the genetic-modification safety committee (GMSC).

The containment and waste management procedures described in sections 8 and 12 below are designed with this possibility in mind.

**Host/vector system**

The possible cell lines that are anticipated to require storage or patent testing would include but not be limited to the following: animal stem cells, both embryonic and adult, (with current exception of human embryonic stem cells and related tissues); primary cultures derived from various tissues of animal and insect species; established/permanent cell lines (normal or spontaneously transformed; hybridomas or other cell hybrids derived from fusions; cell lines immortalised by introduction of transforming genes chemical mutagens or physical carcinogens (radiation); continuous cell lines produced by insertional mutagenesis; or animal and insect cell lines producing recombinant proteins, disabled or attenuated viruses, growth factors, antibodies, hormones, structural proteins or metabolites.

Animal cell lines described above further genetically modified by transfection or viral transduction to express non-endogenous genes or inactivate endogenous genes by homologous recombination.

**Origin & function**
In the instance where genetically modified cell lines are to be stored as a Safe or Patent deposit the origins and functions of the material introduced into the cell line will be diverse. It is anticipated that they will include but not be limited to: bacterial plasmid constructs containing homologous and heterologous regulatory sequences driving the expression of exogenous genes of bacterial, viral or animal origin. Retroviruses and adenoviruses containing similar genetic sequences as previously described may also be used to modify animal cell lines.

A full listing of most of the plasmid and viral systems commonly used to carry exogenous genes and genetically modified cell lines is given in the Advisory Committee on Genetic Modification Compendium of Guidance, Issue March 2000, Part 2A-Annex II.

Evaluation of foreseeable effects

These will have been evaluated by the depositor and communicated to ECACC in the form of the biohazard risk assessment. Additional guidance on cell lines that have undergone specific types of genetic modification can be sought in the Advisory Committee on Genetic Modification Compendium of Guidance, Issue March 2000, Part 2A-Annex II.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Containment and control measures are to include, but not be limited to, a separate laboratory with an appropriate air handling and monitoring systems for the level of containment. This laboratory will include a microbiological safety cabinet suitable for handling ACDP2 materials (or ACDP3 materials as appropriate), an incubator, if required, hand washing facilities, sink for disposal of disinfected liquid waste and a documented waste management scheme for the disposal of solid waste. Personal protection will consist of appropriate attire (gowns, gloves, hats and masks) which will be worn at all times thereby minimising risk. Further, operatives will be disqualified from working in the Level 2 or 3 containment facilities if they have any pre-existing condition that may render them susceptible to disease following any potential exposure to the biological being tested.

Safe and patent deposits will be supplied by laboratories and institutions outside HPA Porton Down, accordingly European and International regulations govern the packaging and shipment of such biological materials.

The supplier will be responsible for the shipment and will strictly follow the principle of triple packaging systems. This is absolutely necessary in the case of infectious and non-infectious biological substances. It is the obligation of the supplier to comply with the regulations relating to the biological material being transported.

Basic triple packaging system.

The system consists of three layers as follows:

1. Primary receptacle. A labelled primary watertight, leak-proof receptacle will be used to contain the cell lines or biological agents. The receptacle will be wrapped in enough absorbent material to absorb all fluid in case of breakage.
2. Secondary receptacle. A second durable, watertight, leak-proof receptacle to enclose and protect the primary receptacle(s) is to be used. Several wrapped primary receptacles may be placed in one secondary receptacle. Sufficient additional absorbent material will be used to cushion multiple primary receptacles.
3. Outer shipping package. The second receptacle will be placed in an outer shipping package, which will protect it and its contents from outside influences such as physical damage and water while in transit.

Specimen data forms, letters and other types of information that identify or describe the specimen and also identify the shipper and receiver will be taped to the outside. Accurate and informative signage on the outer shipping package is to be used.

2. Receiving broken or damaged specimen packages

If packages are received from the shipper and the contents are not intact, then the package and contents will be destroyed by disinfection and autoclaving. The shipper (and) courier will be notified and if necessary amendments made to the packaging. Records of destroyed specimens are to be kept.

Storage

Storage of cell lines (or viral isolates) in a state of cryopreservation will be in ampoules stored in liquid nitrogen vapour-phase in ACDP2 and ACDP3 designated tanks with appropriate inventory control. Cell lines up to and including ACDP2 and products derived from such are to be stored in liquid nitrogen vapour in warehouse at ECACC. The
warehouse at ECACC, located at the Health Protection Agency, Porton Down and is a secure site monitored on a 24 hour basis. Cell lines of ACDP2 and higher together with any products derived from such are to be stored in liquid nitrogen vapour in designated tanks at NCPV, room 237.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All activities with these cell lines will be performed in Lab 237/237A at the National Pathogenic Virus Collection located in the main building at HPA Porton Down in accordance with the Bio-hazard risk assessments. Alternatively Lab 21 located in the ECACC building sited next to the main building at HA Porton Down can be used for bio-safety level 2 only. No derogation from bio-safety level 2 or 3 containment and use is expected.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste will be decontaminated under the appropriate conditions in operation in that particular area of ECACC or the National Collection of Pathogenic Viruses. Currently all procedures requiring bio-safety level 2 containment are performed at Porton Down. Currently all procedures requiring bio-safety level 3 containment are performed in Porton Down. In addition, Lab 21 in the ECACC building is available for bio-safety level 2 work.

FOR BIO-SAFETY LEVEL 2 CONTAINMENT THE WASTE MANAGEMENT MEASURES ARE AS FOLLOWS:

Liquid waste generated in class-2 safety cabinet in Room 237:

1. Prior to work taking place, each cabinet is checked to see that it contains a 'new' or 'in use' liquid waste container. A 'new' liquid waste container comprises a 1L polypropylene bottle containing a formulated tablet containing a chlorine-releasing agent sodium dichloroisocyanurate (NaDCC) in water.
2. All liquid waste generated in the cabinet goes into this container, until a final volume of approximately 500ml is reached (equivalent to a final concentration of 10,000ppm available Chlorine). Four tablets per litre.
3. At the end of each working period, all surfaces of the open bottle are sprayed and wiped down with 0.25% v/v of NaDCC solution, equivalent to a final concentration of 2,500ppm available Chlorine. One tablet per litre of water.
4. After all work has finished the capped ‘full’ liquid waste bottle is removed from the cabinet (a ‘new’ waste bottle should be placed in the cabinet immediately).
5. The ‘full’ liquid waste bottle is allowed to stand for 24 hours.
6. Inactivated liquid waste can then be disposed of by laboratory personnel into a designated sink with running water.

Solid waste generated in class-2 safety cabinet:

1. Solid waste such as serological pipettes and pipette tips generated in the cabinet are disinfected by being immersed in an approximate 1 litre solution chlorine-releasing reagent at a final concentration of 2, 500ppm in container (1 litre polypropylene bottle).
2. All solid waste generated in the cabinet is placed in portex plastic bags.
3. The bagged waste is placed into an autoclave tin.
4. Once the autoclave tin is full. Spray and wipe the outside of the tin with 2,500ppm chlorine-based disinfectant.
5. Transfer the tin to the lobby area; notify Central Autoclaving Services of its presence and await collection.
6. The tin is autoclaved by Central Autoclaving Services.
7. After successful autoclaving, Central Autoclaving Services will return the tin to laboratory room 237.
8. Laboratory personnel will transfer the contents to yellow clinical waste sacks for incineration.
9. The waste in yellow sacks is then transferred to an on-site incineration plant for incineration.
10. All steps in the disposal of waste from laboratory 237 must be recorded and signed off on the form shown below.
11. A copy of the form must accompany the waste tin and be returned to the laboratory supervisor.

The use of chlorine-release tablets to make up disinfectant solutions is now well established. Formulated tablets using Sodium Dichloroisocyanurate (NaDCC) a potent chlorinating agent has been shown to be more effective than sodium hypochlorite solution or liquid bleaches where organic material is present.

Bloomfield S.F. The bacterial capacity of Sodium dichloroisocyanurate formulations; the sterilisation of infant feeding bottle and teats. Lab Practice 1973. 22. 617-623.
FOR BIO-SAFETY LEVEL 3 CONTAINMENT THE WASTE MANAGEMENT MEASURES ARE AS FOLLOWS:

It is a requirement of DEFRA that an audit trail of the waste generated in 237A is kept. (See Code of Safety Practice 1998 - Chapter 11; and COP 237A Addendum 1)

Liquid waste
All aqueous liquid waste generated within the ACDP3 containment laboratory, must be treated with Eegodor to a final concentration of not less than 3%. Prior to work taking place, each cabinet must be checked to see that it contains a 'new' or 'in use' liquid waste container. A 'new' liquid waste container comprises a 1L polypropylene bottle containing 50ml neat Tegador disinfectant.

Add all liquid waste generated in the cabinet to this container, until a final volume of approximately 500ml is reached (ie a final Tegador concentration of approximately 10% v/v)

At the end of each working period, all surfaces of the open bottle are sprayed and wiped down with 3% v/v Tegador, and the cabinet is fumigated as normal. Only after fumigation can the capped 'full' liquid waste bottle be removed from the cabinet (a 'new' waste bottle should be placed in the cabinet immediately).

After venting the fumigated cabinet, remove the 'full' liquid waste bottle and place into a rack within an autoclave tin.

Once the autoclave tin is full; unscrew each of the waste bottle caps by half a turn; place the lid on the autoclave tin; spray and wipe the outside of the tin with 2,500ppm chlorine-based disinfectant.

Transfer the tin to the lobby area; notify Central Autoclaving Services of its presence and await collection. This tin is autoclaved by Central Autoclaving Services on liquid cycle.

After successful autoclaving, Central Autoclaving Services will return the tin now that now contains the disinfected/fumigated/autoclaved liquid waste bottles. The inactivated liquid waste can be disposed of by laboratory personnel into designated Centre for Emergency Preparedness and Response (CEPR) effluent treatment plant for heat treatment prior to release.

Solid waste
All solid waste generated in the cabinet is placed in portex plastic bags and fumigated in the cabinet as normal.

Only after fumigation can the waste be removed from the cabinet after venting. The bagged waste is placed into an autoclave tin.

Once the autoclave tin is full; wipe the outside of the tin with 2,500ppm chlorine-based disinfectant. Transfer the tin to the lobby area; notify Central Autoclaving Services of its presence and await collection.

The tin is autoclaved by Central Autoclaving Services.
After successful autoclaving, CAS will return the tin to laboratory. Laboratory personnel will transfer the contents to yellow clinical waste sacks for incineration.

The waste in the yellow sacks are transferred to on-site incineration plant for incineration.

DOCUMENTATION
All steps in the disposal of waste from laboratory must be recorded and signed off on the form in appendix 1. A copy of the form must accompany the waste tin and be returned to the laboratory supervisor at step 17.2.9 or 17.3.6.
ORGANIC WASTE
All organic solvent liquid waste generated in the ACDP3 containment laboratory, must be treated with 40% formaldehyde (aqueous formalin) solution to a final concentration of not less than 4% (1:10 dilution). Solvent waste generated in the MSCs should be placed into 1L polypropylene bottles and fumigated before removal from the cabinet. Solvent liquid waste must be transferred to a specialist contractor via a SA.

GLASS SLIDES
Glass slides should be disposed of as ‘sharps’; laid out in CAMR Code of Safety Practice 1998 - Chapter 7, Section 5.3

DISINFECTANT
Chlorine-based disinfectants must not be used on metal surfaces as they will cause corrosion. Chlorine-based disinfectant, made up to 2,500 parts per million using Haz-tabs, is to be used for general disinfection of laboratory benches at the end of each work session and at the end of the day. It can be used, in conjunction with Haz-tab absorption granules, to deal with spillage and potentially infectious fluids eg serum etc.

Tegodor is a non-corrosive disinfectant. Tegor is a gluteraldehyde/formaldehyde based disinfectant with quaternary ammonium compounds plus a wetting agent. The concentrate is diluted with distilled water to give a working 3% or 10% solution. 3% Tegodor must be used to decontaminate laboratory equipment that may be attacked by chlorine based disinfectants, eg centrifuges or other apparatus containing metal, prior to servicing or as part of a regular cleaning program. 10% Regodor is used on heavily contaminated areas (eg a spill of virally infected liquid) within the MSC III. Tegador must only be used on a well-ventilated area in accordance with COSHH assessments NCPV/000.

Committee satisfied.

**Project Additional Information**

**Purposes of the contained use**

We are making a vaccine from a safe strain of influenza virus. The virus is inactivated with a chemical after production and before release to third parties. We are not doing any of the genetic manipulation at HPA-Porton Down. All safety checks will have been undertaken and validated before transfer from NIBSC to HPA-Porton Down under DEFRA licence.

**Recipient or parental organism**

The strain of influenza virus to be used is comprised of 6 genomic segments from the well-characterised PR8 strain (H1N1) and two segments derived from an avian pandemic strain (e.g. H5N1, H7N1, H7N7 or other currently circulating avian viruses). These 2 segments encode the haemagglutinin (HA) and neuraminidase (NA) genes. The HA gene has been genetically truncated which further reduces its pathogenicity. A reassorted virus has been generated based on the PR8 backbone with the modified HA and NA segments.

**Host/vector system**

See recipient or parental organism section above for full description.

**Origin & function**

Production of GMP seed-stock for manufacture of influenza vaccine.

**Evaluation of foreseeable effects**

Accidental release of the organism: This virus is incapable of entry into and replication in human cells, thus the risk is very low. Virus will be chemically inactivated before removal from the laboratory suite. Recombination with a Wild type Virus: there is a theoretical possibility of this, however the likelihood is extremely low as virus will only be
removed from the suite as killed suspension or in suitable containment. Staff who contract a WT virus will not be exposed to the PR8 reassorted virus as all manipulations are carried out in contained facilities.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No application for derogation is made.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste will be decontaminated using 3% (v/v) Kleencare prior to removal from the Class III Microbiological Safety Cabinet. Following disinfection, waste will be autoclaved using a validated destruction cycle and the autoclave waste finally incinerated. These procedures ensure that there can be no release of live virus from the laboratory facility.

Is an emergency plan required according to regulation 20? Y

If yes, tick to confirm that it is attached to this form Y

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

The committee had no objections to the risk assessment that had been undertaken.

CU2 Project Title Assessment of the viricidal potential of non-nucleoside reverse transcriptase inhibitors

Class 3

CultureVolClass2 25ml

CultureVolumeClass3-4
### Project Additional Information

**Purposes of the contained use**

The purpose of this work is to use a recombinant Simian Immunodeficiency Virus (SIV) containing a Human Immunodeficiency Virus (HIV) type 1 reverse transcriptase (RT/HSIV) in studies designed to investigate the efficacy of non-nucleoside reverse transcription inhibitors (NNRTI). The recombinant SHIV is non-infectious for humans, but susceptible to NNRTI and is therefore safer to work with.

**Recipient or parental organism**

Simian Immunodeficiency Virus

**Host/vector system**

No new constructs will be made, no new manipulations will be performed at the Centre for Emergency Preparedness and Response. GMO is a chimeric virus, SHIV which is a recombinant SIV expressing an HIV type 1 reverse transcriptase.

**Origin & function**

The recombinant Simian Immunodeficiency Virus containing a Human Immunodeficiency Virus (HIV) type 1 reverse transcriptase has been prepared by Dr L Alexander at Department of Epidemiology and Public Health, Yale University School of Medicine, New Haven, Connecticut, USA. No genetic modification will take place at The Centre of Emergency Preparedness and Response. The reverse transcriptase from HIV, unlike that of SIV, is sensitive to the NNRTI's, otherwise both reverse Transcriptases perform the same role and are equivalent. The recombinant SHIV is thus essential for these studies.

**Evaluation of foreseeable effects**

A breach of containment with release into the environment of the self-replicating recombinant:

The risk of this event occurring is negligible as all work will be carried out at containment level 3. The recombinant SHIV cannot survive outside the primate host. The SHIV is less fit than the parental strain of SIV, is unlikely to be pathogenic to humans and is susceptible to treatment with anti-retroviral drugs.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A
The Centre of Emergency Preparedness and Response (formally CAMR) applied for derogation from the requirement for autoclave destruction of CL3 laboratory waste to be carried out in the laboratory. The documents accompanying this notification should be consulted for further details of measures to be implemented. This derogation is in place for a number of projects and this application should be considered to be included in the derogation request.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Chemical disinfection and autoclaving procedures used with hazard group 3 work at CEPR are validated to give 100% kill efficiencies. Disposable plasticware will be used for all manipulation involving GMO's; these materials will be disposed of by autoclaving. Culture media and other liquids potentially containing GMOs will be pre-treated chemically (10% tegodor final conc.) for 24 h prior to autoclaving.

As indicated in detail in the derogation request accompanying this notification, GMO-containing waste will be transported in UN-approved purpose-designed sealed containers from the laboratory to the destruction autoclave, which is located in the CEPR main building, along with the laboratory in use for this project.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMSC were satisfied with the RA that had been undertaken.

</tbody>
</table>
Purposes of the contained use

The aim of this work is to generate a panel of non-toxic fragments derived from the toxins and other virulence factors of C. difficile and use these as tools for the study of pathogenesis of the disease and investigate therapy options for C. difficile-associated disease.

Recipient or parental organism

Derivatives of E.coli K12 or B (for example JM109, HMS 174, RV308, TOP10, ER2566, DH5a, BL21, Novablue) for the generation of plasmid stocks, general DNA manipulation, and protein expression. E.coli K12 strains are E.coli K12 derivatives that are recognised as non-colonising and disabled, and may be considered to be equivalent ACDP hazard group 1. They are not considered pathogenic to humans or animals, but are thought capable of surviving for up to seven days in the gut. They are expected to have limited survivability in the environment and often have auxotrophic requirements, which are unlikely to be satisfied outside of laboratory culture. BL 21 and derivatives have been demonstrated to be non-pathogenic according to Chart et al. 2000. An investigation into the pathogenic properties of Escherichia coli strains BLR, BL21, Dha, EQ1.J. Appl. Microbiol. 89, 1048-1058.

Host/vector system

The pMTL expression vectors contain a mutant form of the CoIE1 origin of replication and are Bom/Nic in addition to Mob and Tra, making them non-mobilisable.

The pMAL expression vector is derived from pBR322 and has been manipulated in house to ensure Bom/Nic in addition to Mob and Tra, making it non-mobilisable.

The pGEX expression vector is derived from pBR322 and is Bom/Nic in addition to Mob and Tra, making it mobilisation-defective.

The pET expression vector is derived from pBR322 and is Bom/Nic in addition to Mob and Tra, making it mobilisation-defective.

Origin & function

All protein sequences are in the public domain and genes will be produced by contract synthesis using these published protein sequences. The intended use of the proposed expression products is to investigate the pathogenesis and therapy of Clostridium difficile-related diseases.

Evaluation of foreseeable effects

The chosen hosts are non-infectious E.coli K12 and B derivatives which are incapable of surviving outside the laboratory environment for a prolonged period. Because of
these properties they can be considered non-hazardous.

The expressed proteins represent fragments of toxins which lack an essential domain(s) required for the expression of toxicity. All of the C. difficile toxins so far identified require entry into the mammalian cell to exert their toxic effects. The expressed constructs in the present proposal fall into two categories:

1. Protein domains which represent the enzymically active part of toxins but lack the domains which are essential for delivery of this effector into the mammalian cell
2. Protein domains which are the delivery vehicles for cellular effectors but which are expressed with the effector domain removed from the toxin structure.

Both these construct types are non-hazardous because they completely lack one or more protein domains essential for biological activity.

The above constructs will be inserted into hosts which are either mobilisation defective or non-mobilisable making the risk of gene transfer very low. It must also be stressed that genes encoding the complete toxins are already widespread in nature. In summary, the risk of harmful effects to either man or the environment is exceedingly small.

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

This proposal covers the generation by PCR, cloning and expression of non-toxic chimeric Botulinum type A toxins. The binding and translocation/catalytic (Hcand LHn) domains of BoNT/A toxin subtypes A1, A2, and A3 will be synthesised using E.coli codon bias to incorporate 2 separate mutations that remove function in each of the binding and catalytic domains. The purpose is to investigate the vaccine efficacy potential of chimeric toxins incorporating domains from different toxin subtypes. Custom gene synthesis and PCR using synthetic oligonucleotides will be used to construct clones of the various domains which will be cloned into disabled E.coli and sequenced. These genes will then be suncloned into non-mobilisable expression vectors (pMTL series etc.) for expression in disabled E.coli strains and purification. Fusion constructs between domains from different toxin subtypes will be constructed by PCR and the hybrid genes subcloned for sequencing and expression as described above.

**Recipient or parental organism**

Derivatives of E.coli K12 or B (JM109, HMS174, RV308, TOP10, ER2566, DH5a, BL21, Novablue) for the generation of plasmid stocks, general DNA manipulation and protein expression. These E.coli strains are recognised as non-colonising and disabled, and may be considered to be equivalent ACDP hazard group 1. They are not recognised pathogenic to humans or animals, but are thought capable of surviving in the gut for up to seven days. They have limited survivability in the environment and have auxotrophic requirements which are unlikely to be satisfied outside the laboratory.

**Host/vector system**

The initial synthesised genes will be cloned in the pCR series of vectors supplied by Invitrogen. These carry an E.coli origin of replication, multiple cloning site and
ampicillin and kanamycin resistance genes. The vectors are Bom, Nic, Mob and Tra, and therefore are non-mobilisable. These genes will be subcloned into expression vectors either as fusions with a variety of 5’ and 3’ affinity tags or without fusion partners to identify systems to give optimal yields of protein. Examples of affinity tags would be GST, (His)6, maltose binding protein (MBP) and GFP. Therefore, initially the expression vectors used will be pMAL-c2 (modified in house to be non-mobilisable) and the pMTL series (HPA-CEPR in house) and derivatives. These vectors are Bom, Nic, Mob, and Tra and therefore non-mobilisable. pET series expression vectors will also be used. These are Mob and Tra, but Bom and are therefore considered mobilisation defective.

Origin & function
The sequences of botulinum toxin genes are available in the public domain, as are the mutations required to render them non-toxic.

Evaluation of foreseeable effects
Since the chosen hosts are non-infectious E.coli K12 and B derivatives they are unable to survive outside the laboratory environment and are therefore regarded as non-hazardous. The DNA fragments inserted into the hosts encode non-toxic but nevertheless potentially biologically active proteins which have very low levels of toxicity. These sequences neither encode a pathogenicity determinant nor compensate for any host attenuation and therefore will not lead to an increase in the infectivity or pathogenicity of the host. The DNA fragments will be inserted into a range of non-mobilisable or mobilisation defective vectors such that the risk of gene transfer is negligible. The organism is neither pathogenic to man, animals nor plant, therefore the risk to the environment is effectively zero.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

A number of Tn5 transposon knock out mutants of Bordetella pertussis were produced at CAMR in the 1980s. These are currently stored as freeze dried organisms in a Bordetella pertussis culture collection at CEPR. They have not been cultered since the late 1980s or early 1990s. The strains are knock outs of the virulence components fimbriae (Fim), filamentous haemagglutinin (FHA), pertactin and adenylate cyclase. There is also a mutant with a disabled vir regulon that is unable to determine if the strains retain viability by culture on charcoal agar containing 25 ug/ml kanamycin and then in 100ml shake flask cultures containing the same concentration of Kan. The bacteria will then be stained with a fluorescent stain, killed and used in immunoassays. No further genetic manipulation is proposed.

Bordetella pertussis is a CL2 pathogen that requires containment where there is a potential risk of aerosol infection. The Tn5 mutants are likely to be attenuated in virulence but the Tn5 knockout strains will be handled in the same manner as wild type B pertussis using CL3 safety cabinet for all subculture procedures.

**Recipient or parental organism**

Bordetella pertussis strains

Background – ACDP hazard group 2. Humans can be infected and pertussis (whooping cough) develop. Transmission – B. pertussis is spread by inhalation of large aerosol droplets from infected persons.
Symptoms
- Incubation period approximately 10 days
- Catarrhal stage approximately 1-2 weeks Flu-like symptoms
- Paroxysmal stage approximately 1-6 weeks. Symptoms are forceful hacking successive coughs with paroxysms
- Complications include pneumonia and asthma

Treatment – Antimicrobials are only effective during incubation and catarrhal stage i.e before cough.

Vaccination – Effective pertussis vaccines are available and are part of the UK vaccination schedule.

Host/vector system
Previous produced Tn5 knock out mutants will be grown. No further genetic manipulation is proposed.

Origin & function
The Tn5 knock out strains were produced at Centre for Applied Microbiology and Research in the 1980s. Strains are described in:

A kanamycin resistance gene is included in the Tn5 transposon. This does not affect treatment options as other antibiotics such as azithromycin, clarithromycin or erythromycin are used.

We intend to determine if the strains retain viability by culture on charcoal agar containing 25ug/ml kanamycin and then in 100ml shake flask cultures. The bacteria will then be strained with a fluorescent stain. Killed and used in immunoassays to determine the role of the deleted antigens in the immune responses to current and new vaccines.

Evaluation of foreseeable effects
Accidental release: The genetically modified B. pertussis strains are unlikely to survive any better than wild type B pertussis which survives poorly outside the human host or on specific culture media. Available pertussis vaccines have shown efficacies exceeding 80% in clinical trials and the strains will be handled in a CL3 cabinet. Thus risks are no different from current wild type strains used.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
No application for derogation required

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All waste will be decontaminated using 1% SuperQ disinfectant solution prior to removal from the Class 3 Microbiological Safety Cabinet. Following disinfection, waste will be autoclaved and the autoclaved waste finally incinerated. Waste will be tracked through the destruction process according to standard procedures. These ensure that there can be no release of live organisms from the laboratory.

**Project Additional Information**

**Purposes of the contained use**

This project is part aimed at generating reagents and assays to efficiently and accurately detect and differentiate between alternative types of Filoviral infection. Essential to these goals are the generation of the purified structural proteins GP, NP, VP24 & VP40 and Virus like particles with analogous structure to mature filovirus virions. Due to their complex post-translational modification processes, these proteins will need to be expressed in a eukaryotic system to ensure they have the correct
modifications to allow relevant antibody generation downstream. As such, the purpose of this project is to create a panel of Baculoviruses, each expressing either GP, NP, VP24 or VP4O from a specific subtype of filovirus. In addition we will also create Virus Like Particles (i.e. VP4O and OP proteins) for each subtype by co-infection.

Recipient or parental organism

Sf9 insect cells from S. puclopterafrugiperda (cell culture adapted): Cell culture transformed insect cell line. Addition of Genetically modified material (BaculoDirect construct) will result in expression and assembly of recombinant Baculovirus. Not deleterious effects on environment or human health.

Infection of this cell line with the previously described recombinant Baculovirus will result in over expression of the corresponding structural protein, and eventual cell death. Of the over-expressed proteins the only foreseeable effects, from accidental exposure, would arise from the immunogenic nature of the OP gene product and from the VP4O/GP VLPs. Although these products have been previously shown to be immunogenic (resulting in protective antibody response and dendritic cell activation/endothelial inflammation) they will not have any other deleterious effects and are not classed as toxic or pathogenic in any way.

Host/vector system

BaculoDirect baculovirus from Autogrepha california nuclear polyhedrosis virus (AcNPV Baculovirus): This vector, and the recombinant vectors created by insertion of the previously described filoviral structural genes, will only replicate/express viral proteins in insect cells due to the specific promoter/enhancer usage. They therefore pose no risk to the human health of the user or general public. Two of the products (OP and VLPs) resulting from infection with this vector are immunogenic as described above.

Origin & function

- **Glycoprotein (GP) and the (edited/full length) extracellular domain of GP:** The OP protein is responsible for Filoviruses binding to their specific cell surface receptors (e.g. DC-SIGN) allowing viral entry into target cells (1, 2, 3, 4).
- **VP24 and the extracellular domain of VP24:** The Filoviral VP24 protein or minor matrix protein is membrane associated and predicted to have a structural role in the formation of mature filovirus particles. (3,5).
- **VP4O Matrix protein:** The filoviral matrix protein is sufficient to drive the budding of VLP5 from the cell membrane and is responsible for the incorporation of Nucleocapsid/RNP into Virions. As such VP4O is the main driver for virion assembly and budding. (3,6).
- **Nucleoprotein (NP):** Filoviral Nucleoprotein is essential for RNA binding and incorporation into assembling virions. NP is the main constituent of filoviral nucleocapsid — implying an important structural role within mature virions. It is thought to be packaged into virions/VLPs via interactions with VP24/VP4O and VP35 (3,4,7) References for previous section (for gene function):
  4. Klenk, H. - D. 'Marburg & Ebola Viruses’1999; Springer publishing

Evaluation of foreseeable effects

The inserted gene products are non-hazardous structural proteins with no toxic, endogenic, or oncogenic properties. Any Minor risk associated with each of the resultant recombinant proteins, once over expressed by the vector-infected host cell line and purified, are described below:
• Glycoprotein (GP) and the (edited or full length) extracellular domain of QP. The GP protein is responsible for Filoviruses binding to their specific receptors allowing viral entry into cells. Although there are cytotoxic effects if over-expressed in cell lines, the purified protein has not been shown to have any pathogenic effects and the DNA constructs made in this project do not contain promoters that would all over-express in any mammalian cells (1, 2). No other pathological effects have been reported for OP. Although immunogenic (triggering antibody and inflammatory responses), it has no deleterious effects (3), however, the truncated ‘form of GP, sOP, has been shown to be immunosuppressive (4); it is not going to be expressed during this project (due to mutagenesis of the corresponding region in the OP ORF).

• 1P24 and the extracellular domain of VP24: The Filoviral VP24 protein predicted to have a structural role in the formation of mature filovirus particles (4). To date no Pathogenicity has been demonstrated for this protein when expressed recombinantly/purified. (4)

• VP40 Matrix protein: VP40 is the main driver for virion assembly and budding. To date no Pathogenicity has been demonstrated for this protein when expressed recombinantly/purified. (4)

• Nucleoprotein (NP): Filoviral Nucleoprotein is essential for RNA incorporation into virions and is the main constituent of filoviral. To date no Pathogenicity has been demonstrated for this protein when expressed recombinantly/purified. (4)

References for above:
4.Klenk, I-IL- 0. ‘Marburg & Ebola Viruses’ 1999; Springer publishing

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
The only GMO's Generated are micro-organisms (Baculovirus & Transformed Cell line) - no transgenic animal or plant work is associated with this project.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
No Derogation from Full ACGM level 2 and ACDP class 2 containment will be needed for this work. All work with the resultant GMMs will be conducted under level 2 conditions and in a class 2 cabinet. Any work that does derogate from full class 2 containment will only be carried out after appropriate de-activation/lysis of any GMM that may be in that sample.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Hypochlorite — Haztabs
For liquid waste with in the Class II safety cabinet, a solution of sodium hypochlorite is made by adding 1 HazTab tablet to 1 litre of water/liquid waste (2,500ppm available chlorine) in a waste pot. For non-infectious tissue culture this is transferred to drain with copious amounts of water. If virus-infected waste is produced, this is left in hypochlorite overnight, then transferred to drain with copious amounts of water.
70% Isopropanol
Isopropanol stock is 70% in purified water. It can be used to disinfect surfaces that are not heavily contaminated. All items of equipment taken out of the laboratory should be first sprayed with 70% Isopropanol. Its use should be avoided where bacterial spores, mycobacteria or non-enveloped viruses maybe present.
Formaldehyde
The Class II safety cabinet should be fumigated before servicing (or when bacterial/fungal contamination is observed) using 50% formalin (20% formaldehyde) diluted in deionised water. 30ml of 50% formalin is added to a boiling pot and allowed to evaporate in an enclosed cabinet. This is left for at least 6 hours, or preferably overnight before cabinet is switched on for reuse.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N

Host/vector system

The knock out delivery system (‘ClosTron’) is based on the shuttle vector pMTLO07C-E2 (depicted below) as described

Heap et al. (2007).

Origin & function

The DNA sequences for the C. difficile virulence factor genes are in the public domain (Sebaihia et al., 2006). The intended functions are to use these sequences to engineer knock out mutant derivatives of C. difficile 630SERM (Hussain et al., 2005).

Hussain et al. (2005) Generation of an erythromycin-sensitive derivative of Clostridium difficile strain 630 (630Deltaerm) and demonstration that the conjugative transposon Tn91 6DeltaE enters the genome of this strain at multiple sites. J. Med. Microbiol. 54, 137-141.

Evaluation of foreseeable effects

Foreseeable effects are expected to be the generation of C. difficile mutants with attenuated virulence profiles. The target genes
have been selected on the basis of known function and it is not anticipated that there would be any enhanced virulence of the wild type strain.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Liquid waste is treated with 10% sodium hypochlorite for 2 hours and autoclaved via centralised validated autoclave cycle. Solid waste is decontaminated by centralised validated autoclave cycle and incineration.

Is an emergency plan required according to regulation 20?  
If yes, tick to confirm that it is attached to this form
Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

The GM Safety Committee had no objection to the risk assessment that has been undertaken.

Project Ref  36/09.1

Date Ackn'd  19/03/2009  
CU2 Project Title The aim of this work is to evaluate a combined TB and malaria vaccine  
Class 2  Culture volume: Class 2 ≤ 1 Litre
Project Additional Information

Purposes of the contained use

In the work covered in this proposal, CEPR will carry out testing of a novel recombinant BCG vaccine expressing malarial antigens, followed by an adenovirus-malarial antigen boost, that may offer protection against both tuberculosis and malaria disease. The role of CEPR will be to provide vaccine evaluation of rBCG (+ malaria antigens) and Adenovirus (+ malaria antigens) constructs in the guinea pig model of tuberculosis to ensure that insertion of the malaria antigens into BCG has not diminished the potency of the BCG to protect against TB infection. The recombinant BCG and viruses have been prepared externally as a 'ready to test' formulation. No genetic modification will take place at HPA.

Recipient or parental organism

Mycobacterium Bovis BCG vaccine strain has multiple mutations rendering them unable to survive outside the laboratory.

Host/vector system

Mycobacterial shuttle vector PMV261 (derivative of pAL5000)

Origin & function

Mycobacterium bovis BCG vaccine strain has a listeriolysin gene (Hly) from L. monocytogenes inserted into its genome knocking out the BCG urease subunit C gene (ureC). The insertion increases the immunogenicity of BCG to the host without increasing virulence. In addition, up to three antigens from Plasmodium falciparum will be cloned into the rBCG:ureC:Hly BCG known to be immunogenic in humans.

Evaluation of foreseeable effects

Expression is performed in a recombinant M. bovis BCG vaccine strain. The addition of listeriolysin gene, from L. monocytogenes, into BCG, has proven not to increase its virulence and is unlikely to survive outside of the laboratory. Plasmodium falciparum do not possess the classical virulence factors such as toxins, capsules and fimbriae. Therefore, expression of a single component in BCG is unlikely to be toxic. The shuttle vector pMV261, a derivative of pAL5000, used to express the malaria antigens is non mobilisable. It is also unlikely that individual non-mycobacterial gene products are hazardous to the environment, being proteins they will be rapidly degraded outside stable laboratory storage.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Any potential shedding of the GMM by animals is controlled by the husbandry practices. Animals vaccinated with Class 2 GMM are housed in the containment facility.
section of animal wing and all material (bedding, waste food etc) is disposed via the facility autoclaves. Waste bags are autoclaved within the containment facility and then incinerated.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable - appropriate containment level being applied.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Waste will be treated according to the site waste management plan. For Class 2 material this would compromise autoclaving and disinfection of liquid waste with 2,500ppm available chlorine followed by autoclaving.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

**The committee had no objection to the risk assessment that had been undertaken**

</tbody>
</table>

---

02/03/2022
Essential to several ongoing virology projects is the ability to express antigenic viral proteins in a protein expression system that allows effective expression and post-translational modification. Expressing these viral antigens allows us to purify large amounts of protein that can be used in diagnostics (e.g. Antibody ELISAs/serology). Such proteins can then be used to raise antibodies and generate specific antibody reagents for the detection and differentiation of specific viral species/strains.

In order to obtain high yields of easily recoverable protein, we intend to express specific viral structural proteins, namely Envelope Glycoprotein (GP/env), Nucleoproteins (NP) and Matrix proteins (e.g. filovirus VP40) in individual (i.e. one per protein) Baculovirus vectors, to allow infection and subsequent over expression of both epitope tagged and native forms of the above proteins in insect (Sf9 or Sf21) cells. We also intend to express envelope proteins and matrix proteins in the same cells (infected with two baculoviral vectors simultaneously - one expressing each protein), to allow the production of virus-like particles (VLPs) that will be structurally analogous to whole virions but remain non-infectious, containing no genomic material or viral enzymes.

All this work will be sub-genomic; cloning only a single ORF from viral RNA (from previously infected cells) into Baculoviral transfer plasmids. At no time will full viral genomes be reconstructed.

Recipient or parental organism

Sf9, Tni.Hi5 and Sf21 insect cells from Spodoptera frugiperda (cell culture adapted)

Cell culture transformed insect cell lin. Addition of Genetically modified material will result in expression and assembly of recombinant Baculovirus. Not deleterious effects on environment or human health.

Infection of this cell line with the previously described recombinant Baculovirus will result in over expression of the corresponding structural protein, and eventual cell death. Of the over-expressed proteins the only foreseeable effects, from accidental exposure, would arise from the immunogenic nature of the Glycoprotein/Envelope gene product and from their corresponding VLPs. Although these products have been previously shown to be immunogenic (resulting inprotective antibody response and dendritic cell activation/endothelial inflammation) they will not have any other deleterious effects and are not classed as toxic or pathogenic in any way.

Host/vector system

Baculoviruses, modified from Autographa california nuclear polyhedrosis virus (AcNPV Baculovirus):

- Baculovirus entry vectors: are all simple cloning vectors allowing cloning, modification and recombination (into Baculoviral DNA) of gene of interest - all are non-mobilisable and contain modified pUC origins or replication. Namely, vectors used will include:
Origin & function

This scheme of work involves the insertion of three different genes into separate Baculoviral vectors, but from a range of viral pathogens. The functions of the genes is as detailed below, across the range of viral pathogens listed:

1. Envelope Glycoprotein: responsible for binding to specific cell surface proteins/receptors, allowing viral entry into target cells. As such these genes are responsible for viral tropism. Their exposed conformation on the viral envelope means they are heavily glycosylated but still are the main drivers of the host immune response to the virus.
2. Nucleoprotein: Viral Nucleoproteins are essential for ensuring viral genomes are packaged into progeny virions as the virus assembles. As such their main functions are binding to viral genomes and forming the main structural component of the viral core.
3. Matrix proteins: Viral Matrix proteins are important structural elements of enveloped viruses, bridging interactions between nucleocapsids and envelope glycoproteins. They are responsible for the incorporation of nucleoproteins into assembling viral particles. In many cases (e.g. filoviruses) they are responsible for driving viral budding.

Previous expression studies on such genes were performed at BSL/CL1-2

The above genes will be cloned into baculoviral vectors from the panel of viruses listed below:

- Filovirus (Strains of Ebola and Marburg viruses)
- Flaviviruses (including Dengue, Yellow fever, Japanese Encephalitis)
- Influenza viruses (included pandemic H1N1 and H5N1 influenza)
- Nairoviruses (e.g. Crimean-Congo Hemorrhagic Fever-CCHF)
- Arenaviruses (including strains of Lassa Fever virus and Lujo)
- Phlebovirus (e.g. Rift Valley fever)

Evaluation of foreseeable effects

Minimal hazards to human health: The inserted gene products are non-hazardous structural proteins with no toxic, endogenic, or oncogenic properties. Any Minor risk associated with each of the resultant recombinant proteins are described below:

- Matrix proteins and nucleoproteins: No pathogenicity or hazardous effects have been reported from the recombinant expression of viral Matrix or nucleoproteins, and previous expression studies on such proteins have been performed at BSL 1-2.
Envelope Glycoprotein: Some envelope glycoproteins give cytotoxic effects if over-expressed in cell lines, these proteins have not been shown to have any pathogenic effects, furthermore the DNA constructs made in this project do not contain promoters that would allow over-expression in any mammalian cells. No other pathological effects have been reported for viral glycoproteins. Glycoproteins are, by their nature and function, immunogenic (triggering antibody and inflammatory responses), previous expression studies on such proteins have been performed at BSL 1-2/CL1-2.

Recombinant baculovirus will not be able to establish an infection in human cells, they will not have altered host range or tissue tropism.

None of the gene products (described above) have any directly hazardous effects, baculovirus derived Virus Like Particles and heterologous protein from a range of these viruses (e.g. filoviruses) have been previously shown to illicit an immune response. Exposure to these proteins and VLPs, like many proteinaceous materials could have immuno-regulatory effects such as the generation of antibodies via Dendritic and B-cell activation and pro-inflammatory responses such as Endothelial cell activation. VLPs are not infectious and the expressed proteins are neither pathogenic nor toxic.

To minimise any risk, all handling of recombinant baculovirus, supernatants containing VLP's purified VLP's, expressed protein and co-infected cells will be carried out under level 2 containment conditions in class 2 cabinets, so affording suitable protection to the user. The fact that such VLP's are replication deficient ensures there is no risk of infection occurring and no wider risk to co-workers, etc.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The only GMO's Generated are micro-organisms (Baculovirus & Transformed Cell line) - no transgenic animal or plant work is associated with this project.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No Derogation from Full ACGM level 2 and ACDP class 2 containment will be needed for this work. All work with the resultant GMMs will be conducted under level 2 conditions and in a class 2 cabinet. All GMM's will be inactivated before removal from ACGM 2 licensed areas.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Hypochlorite - Haztabs
For liquid waste with in the Class II safety cabinet, a solution of sodium hypochlorite is made by adding 1 HazTab tablet to 1 litre of water/liquid waste (2,500ppm available chlorine) in a waste pot. For non-infectious tissue culture this is transferred to drain with copious amounts of water.

70% Isopropanol
Isopropanol stock is 70% in purified water. It can be used to disinfect surfaces that are not heavily contaminated. All items of equipment taken out of the laboratory should be first sprayed with 70% Isopropanol. Its use should be avoided where bacterial spores, mycobacteria or non-enveloped virus maybe present.

Formaldehyde
The Class II safety cabinet should be fumigated before servicing (or when bacterial/fungal contamination is observed) using 50% formalin (20% formaldehyde) diluted in deionised water. 30 ml of 50% formalin is added to a boiling pot and allowed to evaporate in an enclosed cabinet. This is left for at least 6 hours, or preferably overnight before cabinet is switched on for re-use.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [Y]

02/03/2022
The committee has no objections to the risk assessment that has been undertaken.

### Project Additional Information

**Purposes of the contained use**

The Yersinia strain will be grown and used as a reagent in cell based assays to determine the ability of a novel recombinant vaccine to generate functional immune responses in immunised subjects.

**Recipient or parental organism**
Yersinia pseudotuberculosis YpIII pIB19:

**Host/vector system**

pTrc99A containing the lcrV gene of Y. pestis

**Origin & function**

The recombinant lcrV is from Yersinia pestis. It has been introduced into a Y. pseudotuberculosis strain which has had its own lcrV gene deleted to enable the Y. pseudotuberculosis strain to act as a surrogate organism for Y. pestis in the cell based assay.

**Evaluation of foreseeable effects**

Insertion of the lcrV gene into a lcrV mutant of Y pseudotuberculosis will return the organism to the wt phenotype.

The inserted gene product, the V antigen of Y. pestis is unlikely to have a hazardous effect. It has been used in phase 1 clinical trials with no adverse effects (Williamson et al., Inf. Lmm., 73:3598).

Yersinia species harbouring the recombinant plasmid will gain resistance to ampicillin and kanamycin, however they remain sensitive to aminoglycosides, tetracycline, chloramphenicol and cephalosporins.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

NA

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be placed in clearly marked discard tins for autoclaving. After autoclaving, waste will be incinerated. Liquid waste will be decontaminated by treatment with a 10,000ppm available chlorine solution and left overnight before autoclaving. Decontaminated, autoclaved waste will be sent to drain before the containers are sent to wash up.

Project Ref 36/10.2

Cloning and expression of a type VI secretion system subunit Acinetobacter baumannii in E Coli

Class 2

< 1 Litre

Non-GMM

Consent Granted

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use

Generation of recombinant material to enable the purification and characterisation of the components of the Type VI secretion system.

Recipient or parental organism

Disabled strains of E. coli K12 derivatives (TOP10, DH5α and Novablue) will be used for the purposes of plasmid propagation with no foreseeable effects envisaged. For expression of the gene products, disabled E. coli K12 or B - derived host strains (JM109, RV308, HMS174±DE3, Novablue±DE3, ER2566±DE3 and BL21±DE3) will be employed. These E. coli strains are recognised as non-colonising and may be considered to be equivalent to ACDP hazard group 1. They are not considered pathogenic to humans or animals, but are thought capable of surviving in the gut for up to seven days. They have limited survivability in the environment and have auxotrophic...
requirements which are unlikely to be satisfied outside of the laboratory.

The genes to be cloned and expressed are the hep gene, AIS_1296 and the vgrI, vgrII & vgrIII genes AIS_0550, AIS_3364 & AIS_1288 respectively.

Host/vector system

The synthesised gene will be cloned in the pCR series of vectors supplied by Invitrogen. These carry an E. coli ColE1 origin of replication, multiple cloning site and ampicillin and kanamycin resistance genes. The vectors are Bom\(^{-}\), Nic\(^{-}\), Mob\(^{-}\) and Tra\(^{-}\), and therefore non-mobilisable.

The genes will be subcloned into expression vectors either as fusions with a variety of 5’ and 3’ affinity tags or without fusion partners to identify systems that give optimal yields of protein. Expression vectors that will be used include both non-mobilisable vectors, eg pMAL-c2 (modified in-house to be non-mobilisable), pMTL series (HPA-CEPR in-house), and mobilisable defective, eg the pET series, pMAL.

Origin & function

The DNA sequences for the A. baumannii genes are in the public domain (Pubmed). The intended functions are to use these sequences to maximise expression of the gene products in disabled E. coli host strains.

Evaluation of foreseeable effects

Forseeable effects are expected to be the generation of disabled E.coli variants with antibiotic resistance to either Ampicillin, or Kanamycin.

It is highly unlikely that the pathogenicity of the host will be attenuated by the expression of the above gene products as the individual subunits only form a small part of the type VI system and therefore are unable to form an active secretion system.

It can not be completely excluded, however, that the individual proteins may have some biological activity of their own although the potential to cause harm in isolation is very low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The only GMO's generated are micro-organisms - no animal or plant work is associated with this project.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste is treated with 10% sodium hyperchlorite for 12 hours and autoclaved via centralised validated autoclave cycle. Solid waste is decontaminated by centralised validated autoclave cycle and incineration.

### Project Additional Information

**Purposes of the contained use**

- Generation of knockout mutants to investigate the role of the Type VI secretion system in pathogenesis.
Recipient or parental organism

The recipient strain is K. pneumonia subsp. MGH 78578 (ATCC 700721). The organism was isolated from the sputum of a 66-year old ICU patient in 1994. The strain is resistant to ampicillin, ticarcillin, trimethoprim-sulfamethoxazole, and gentamicin, but I susceptible to amikacin, ciprofloxacin, and imipenem.

The genes to be knocked include:

Hcp1, Hcp2, vgr!, vgr2, vgr3, lcmF1, lcmF2, lcmF3, ClpV1, ClpV2

Host/vector system

Synthetic DNA sequences corresponding to subgene fragments (c. 300bp) of the knockout gene targets are cloned either side of a kanamycin resistance cassette and subcloned into the delivery plasmid, pJTOOL-3. This plasmid can only be propagated in specific E. coli K12 derived strains (egS17-1pi). The plasmid is introduced into the recipient strain by conjugation. The synthetic target DNA sequences introduced into the recipient are not genes but short (c.300bp) fragments that are partially homologous to regions of the genes being targeted in the chromosome.

Origin & function

The DNA sequence for the targeted genes are in the public domain (Pubmed). The intended functions are to use these gene fragments to knockout the corresponding genes in the recipients chromosome.

Evaluation of foreseeable effects

It is highly unlikely that the pathogenicity of the host will be attenuated as the knock out mutants are more likely to be rendered less virulent by preventing expression of key components of the Type VI secretion system (the Type VI system has been shown to be involved in pathogenesis in other Gram negative bacteria). The introduction og the synthesised genes into the recipients chromosome is highly unlikely to result in a harmful biological activity as they are subgene fragments that are homologous to existing regions in the chromosome.

Knockout mutants will be kanamycin resistant but this antibiotic is not the drug of choice for this organism

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The only GMO's generated are micro-organisms, however, Galleria mellonella insect larvae will be infected with the genetically modified bacteria. These will be handled and disposed of in the laboratory at containment level 2.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste is treated with 10% sodium hyperchlorite fo 12 hours and autoclaved via centralised validated autoclave cycle. Solid waste is incinerated.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N
The committee has no objections to the risk assessment that has been undertaken.

- **Class**: Class 2
- **Culture Vol Class 2**: < 1 Litre
- **Consent Granted**: Project notified under transitional arrangements

- **Significant Change ID**: 
- **Date of Significant Change**: 

- **Project Additional Information**

- **Purposes of the contained use**: Generation of recombinant material to enable the purification and characterisation of the OmpA protein
- **Recipient or parental organism**: 

02/03/2022
Disabled strains of E. coli K12 derivatives (TOP10, DH5α and Novablue) will be used for the purpose of plasmid propagation with no foreseeable effects envisaged. For expression of the gene products, disabled E. coli K12 or B-derived host strains (JM109, RV308, HMS174Δ3, NovablueΔDE3, ER2566ΔDE3 and BL21ΔDE3) will be employed. These E. coli strains are recognised as non-colonising and may be considered to be equivalent to ACDP hazard group 1. They are not considered pathogenic to humans or animals, but are thought capable of surviving in the gut for up to seven days. They have limited survivability in the environment and have auxotrophic requirements which are unlikely to be satisfied outside of the laboratory.

Host/vector system

The synthesised gene will be cloned in the pCR series of vectors supplied by Invitrogen. These carry an E. coli ColE1 origin of replication, multiple cloning site and ampicillin and kanamycin resistance genes. The vectors are Bom-, Nic-, Mob- and Tra-, and therefore non-mobilisble. The genes will be subcloned into expression vectors either as fusions with a variety of 5’ and 3’ affinity tags or without fusion partners to identify systems that give optimal yields of protein. Expression vectors that will be used will be non-mobilisble eg pMAL-c2 (modified in-house to be non-mobilisble) or the pMTL series (HPA-PORTON in-house).

Origin & function

The OmpA genes to be cloned and expressed will be sourced from strains of A. calcoaceticus and A. Iwoffi which are opportunistic pathogens of low virulence.

Evaluation of foreseeable effects

Forseeable effects are expected to be the generation of disabled E. coli variants with antibiotic resistance to either Ampicillin or Kanamycin.

The OmpA protein from A. baumannii has been shown to possess a relatively low toxicity against mammalian cell lines. It is therefore proposed to carry out the work at containment level 2 to provide adequate protection from disabled E. coli strains that have acquired a biologically active protein that shows a low level of cytotoxicity against mammalian cell lines.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The only GMO’s generated are micro-organisms - no animal or plant work is associated with this project.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste is treated with 10% sodium hyperchlorite for 12 hours and autoclaved via centralised validated autoclave cycle. Solid waste is incinerated.

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

The Committee has no objections to the risk assessment that has been undertaken.
**Project Additional Information**

**Purposes of the contained use**

The purpose of this work is to facilitate robust characterisation of previously constructed Clostridium difficile gene knockout mutants by re-introducing wild type copies of the inactivated genes. These mutants will be used to investigate colonisation factors which may be targets for Clostridium difficile infection.

**Recipient or parental organism**

Clostridium difficile 630 knockout strains, in which the chromosomal copy of the gene of interest has ben previously inactivated by targeted insertion of a group II intron.

**Host/vector system**
Wild type genes will be amplified from C. difficile genomic DNA and cloned into a mobilisation defective E. coli/C. difficile shuttle vector. Genes will be introduced into C. difficile knockout strains by conjugation from E. coli CA343, a K-12 derivative carrying a plasmid which provides mob+ functionality in trans.

**Origin & function**

**Evaluation of foreseeable effects**

The complemented C. difficile mutants are expected to have an identical phenotype to the wild type organism, as the inserted plasmid-borne gene will simply replace the inactivated chromosomal copy. The complemented mutants are therefore not expected to be any more hazardous than the parental wild type strain.

These are four genes we specifically exclude from this work - genes encoding the classical C. difficile toxins tcdA, tcdB, and those encoding the binary toxin ctdA and ctdB. There is therefore no risk of creating strains more toxigenic than the wild type.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

In accordance with the HPA code of safety practice liquid waste is treated with 10% sodium hypochlorite for 12 hours or autoclaved via centralised validated autoclave cycle. Solid waste is decontaminated be centralised validated autoclave cycle and incineration.

Is an emergency plan required according to regulation 20? Y

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

**Please enter comments on the GM safety committee on the risk assessment**

The proposal was reviewed by the local GM safety committee. They were confident that the risk assessment was appropriate and comprehensive and approved it with no concerns and where happy for the work to proceed.

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

Burkholderia thailandensis is a non-pathogenic relative of Burkholderia pseudomallei and Burkholderia mallei which has significant genetic homology to both pathogenic species (B. pseudomallei and B. mallei). We propose to use genetically modified strains supplied by Dstl to allow expression of putative vaccine candidates (polysaccharides). Dstl will provide HPA with genetically modified B. thailandensis strains. In these strains one of the genes involved in the biosynthesis of the O-antigen of lipopolysaccharide (LPS) is inactivated, either through insertion of mutation or in-frame gene deletion. This results in abrogation of O-antigen biosynthesis. These strains will be grown at HPA to enable production and ultimately purification of B. thailandensis capsular polysaccharide which is not contaminated with LPS. The purified material will be shipped to Dstl for further treatment to develop vaccines.

**Recipient or parental organism**

No GMMs will be constructed at HPA. Strains will be received from dstl and handled in an ACDP/ACGM II laboratory. The strains to be used all lack O-antigen biosynthesis, either through insertion of inactivation of selected genes or in-frame deletion of selected genes. The wild type host is B. thailandensis E555. It was isolated from the environment and has not been modified beyond the modification reported here.

**Host/vector system**

The only vector DNA present in the GM organisms is integrated into the chromosome. It contains the DNA sequences for kanamycin resistance, the R6K origin or replication and the RP4 origin of transfer. The functions of the latter two markers are rendered redundant by their integration into the host chromosome.
The recombinant DNA in these organisms, beyond those found in the vector detailed above, lead to gene inactivation. These all encode metabolic proteins involved in polysaccharide biosynthesis. Please note that gene numbering is based on strain E264 (ATCC700388) since E555 genes have not been assigned numbers. The genes in E555 are all more than 90% identical to the E264 genes.

Evaluation of foreseeable effects

The genetically modified B. thailandensis strains in this protocol will be provided by dstl; none are deemed more hazardous than the other and no further modifications are being undertaken. All of the GM organisms contain inactivating mutations resulting in abrogation of O-antigen biosynthesis. Thus, the strains are likely to be phenotypically indistinguishable.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid and liquid waste will be removed from the laboratory according to the local GM procedure for waste removal; 10% sodium hypochlorite solution

Is an emergency plan required according to regulation 20? N

Project Additional Information

Purposes of the contained use
Transformation of Neisseria with chlamydial genes. Preparation of outer membrane vesicles containing chlamydial proteins.

Recipient or parental organism
For conjugation experiments the donor strain will be E. coli disabled laboratory strains derived from K12:
E. coli S17-I carries the transfer genes of the broadhost-range INcP-type plasmid RP4 integrated into the chromosome (Simon, R et al. 1983).
E. coli S18 is a hemA deletion mutant E. coli S17-I. This strain requires 5-aminolevulinic acid (ALA) for growth. (Thoma, S et al. 2009).

Commensal Neisseria recipient strains; N. lactamica, N. cinerea, N. flavescens, N. flava, and N.subflava. These are not pathogenic to humans or animals and have limited survivability in the environment (the neisserial comensals are only able to colonise humans).

Host/vector system
The E. coli to Neisseria shuttle vector, pMIDG, will be used for transfer of chlamydial constructs into commensal Neisseria. pMIDG was initially developed from the fusion of a 4.2 kb gonococcal cryptic plasmid and a 7.0 kb beta-lactamase plasmid. pMIDG contains a kanamycin resistance cassette as a selectable marker.
pMIDG is not self-mobilising. Although it contains an origin of transfer it does not carry the additional genes (mating-pair formation & DNA processing and transport genes) for self-mobilisation.

Chlamydial genes will be cloned into pMIDG via the use of subcloning vectors that have been developed from pUC vectors, are non-mobilizable, and can only be...
Origin & function

The DNA sequences for the chlamydial genes are in the public domain (Pubmed/JCVI). MOMP: (JCVI annotated locus name: NT01CT0727)
The chlamydial MOMP is a porin that is both structurally and immunologically the dominant protein in the chlamydial outer membrane complex. It is a well defined chlamydial antigen with both T and B cell epitopes identified. It does not appear to have any virulence capabilities.

Polymorphic membrane proteins (Pmps); (JCVI annotated locus names: NT01CT0435, NT01CT0436, NT01CT0437, NT01CT0868, NT01CT0929, NT01CT0930, NT01CT0931, NT01CT0932, NT01CT0935)
The Pmps are a family of 9 genes (A-I) encoding outer membrane proteins. These proteins contain auto-transporter domain allowing secretion via a type V pathway. Pmps represent 13.6% of the coding capacity of the C. trachomatis genome, suggesting they have a critical role in chlamydial biology. However, the role of Pmps in chlamydial virulence is not well understood.

Evaluation of foreseeable effects

The family of chlamydial polymorphic membrane proteins (Pmps) have been shown to be immuno-dominant with certain members demonstrating an ability to induce protective immunity against genital tract infection (Eko FO, Okenu DN et al. 2011) (Eko FO et al. 2011)(Yu H et al. 2010)(Patent No. US 6,642,023). All nine Pmps are expressed on the surface of chlamydial elementary bodies (EB) and C. trachomatis-infected patients can produce antibodies to each Pmp subtype. However, the role of Pmps in chlamydial virulence is not completely understood. Recently it has been found that PmpD may act as an adhesion (Swanson KA et al. 2009) (Crane, D. D et al. 2006). Therefore, it is possible a Neiseria GMM could be created expressing a possible Chlamydia adhesin factor.

Although there is a potential role for Pmp proteins in chlamydial pathogenesis, it is currently thought that the full complement of Pmp genes would be required for any virulence traits to be achieved (Carrasco JA et al. 2011). There is also no evidence that these genes are directly toxic and by ensuring that only one gene is transformed per host cell we will be removing any possibility of any combined virulence being transferred to the host. In addition, these genes are unique to members of the order Chlamydiales. Due to lack of evidence for horizontal gene transfer in the Chlamydiales the Pmps are likely to have evolved specifically for the unique biphasic life cycle of the chlamydial organisms, and their unique intracellular niche of the inclusion body. Thus, it is highly unlikely that they will be capable of making the recipient commensal Neisseria strains pathogenic.

The use of a mobilizable plasmid for the transfer of the chlamydial genes into commensal Neisseria may appear as though it could be possible for this plasmid to undergo further mobilisation, and transfer chlamydial genes to other bacteria. However this is deemed highly unlikely due to pMIDG not being self mobilizing, unlikely to be able to persist outside of laboratory cultures due to a lack of selection pressure. Kanamycin resistance will not allow for stabilisation of the transferred plasmid in natural populations of the nasopharynx as this antibiotic is not used in a clinical setting for neisserial disease, thus there will be no selection pressure.

Finally, there is a possibility that the E. coli donor may be able to mobilise pMIDG to other bacteria. Again, this is considered to be highly unlikely as the E. coli donor strains S17 and S18 are K12 derivatives that have limited survivability in the environment (Isaza LA et al, 2011) (Simon R et al. 1983) (Thoma S et al. s009). More specifically the strain S18 has an auxotrophic requirement for 5-aminolevulic acid that will not be satisfied outside laboratory culture (Thoma S et al. 2009). Furthermore, any additional concerns regarding expression of chlamydial proteins in the E. coli donor strains can also be considered insignificant as the chlamydial genes will be driven by a neisserial promoter, and contain a neisserial signal peptide sequence.

Page 1651 of 15326
**Purposes of the contained use**

With a view to developing improved vaccines and or immunological assays, the GMMs will be used to investigate the role of functional antibodies to the conserved NTHi outer membrane proteins PD, LicD, PilA and PE using target strains that are deleted in these antigens.

**Recipient or parental organism**

The strains of non-typeable Haemophilus influenzae (NTHi) to be modified are those of MPJ003, 3224A and 3655. All strains used are ACDP 2 organisms specific to humans. Associated disease includes sinusitis, otis media, chronic bronchitis, and in very rare cases meningitis and septicaemia.

Modifications to strains were made by allelic exchange, using antibiotic resistance cassettes to replace the knocked out NTHi genes. The knockout phenotypes are stable in the absence of antibiotic selection demonstrating that allelic exchange has gone to completion so as to leave behind no plasmid relics.

Antibiotic resistance genes have been integrated for kanamycin, spectinomycin or both.

The knocked out genes include:

hpd, licD, pe and pilA

**Host/vector system**

Modifications to strains are made by allelic exchange, using antibiotic resistance cassettes to replace the knockout NTHi genes. No plasmid remains and the knockout phenotypes are stable in the absence of antibiotic selection as the sequences have been integrated into the host chromosome.

**Origin & function**

This genetic material involved will be used in immunological assays that will have been developed (using the wild type organisms) as part of this study to investigate the role of functional antibodies to the conserved NTHi outer membrane proteins PD, LicD, PilA and PE using target strains that are deleted in these antigens. The strains deficient in the proteins of interest will be produced by our collaborator on this study, therefore this proposal is strictly directed at growth and manipulation of the mutant strains for use in assays.

**Evaluation of foreseeable effects**

The modifications that will be made to the host strain involve the deletion of NTHi surface proteins. Proteins PD, PilA and PE have either been shown or suspected of playing a pathogenic role in adhesion and entry into upper respiratory epithelial cells. LicD is another conserved protein phosphorylchlorine (PCho) to LOS. The presence of the PCho epitope as part of the outer membrane LOS results in the promotion of NYHi infection and persistence by reducing the host inflammatory response. Deletion of the genes expressing these proteins will therefore not result in any increased hazard to human health.

The use of kanamycin or spectinomycin resistance as a selection marker will not have any impact in a clinical setting owing to these antibiotics no being used in the treatment of NTHi disease.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid cultures will be disposed of via the site incineration service (yellow clinical waste sacks). Liquid waste will be treated using 2.5% sodium hypochlorite and disposed of via the site autoclaving service (autoclave tins). Waste disposal procedures do not need to be amended to accommodate the genetic modifications (ACGM 2 activity).

CU2 Project Title Recombinant influenza strains based on attenuated influenza A virus PR8 (H1N1) vectoring vaccine antigens

Class CultureVol

Class 2 < 1 Litre

Non-GMM Consent Granted

Project notified under transitional arrangements N
**Project Additional Information**

**Purposes of the contained use**
- Evaluation of novel vaccine candidates

**Recipient or parental organism**
- Attenuated Influenza A virus PR8 (H1N1)

**Host/vector system**
- N/A No vectors are used; recombinant strain(s) are received ready to evaluate

**Origin & function**
- Well characterised bacterial antigens serving as vaccine candidates

**Evaluation of foreseeable effects**

The host strain is attenuated and there is no reason to believe that the inserts will increase the hazards to human health or the environment: Attenuated Influenza A virus PR8 (H1N1)

This virus was passaged over 100 times in mice, ferrets and embryonated chicken eggs. As a result of this passage history a complete attenuated virus was generated unable to replicate in humans (WHO Technical Report Series No 941, 2007 Annex 5, WHO biosafety risk assessment and guidelines for the production and quality control of human influenza pandemic vaccines).

The infectivity absence in humans was attributed to the surface glycoproteins of the PR8 virus; the Haemagglutinin (HA) and Neuraminidase (NA) (Beare AS, Schild GC, Craig JW (1975) Trials in man with live recombinants made from A/PR/8/34 (H0 N1) and wild H3 N2 influenza viruses. Lancet 2: 729-732).

The inserted gene products (vaccine antigens) are not harmful. This has been shown in preclinical and clinical studies. There is also preclinical and clinical evidence for their not being harmful when delivered in a viral vector.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID
**Project Additional Information**

**Purposes of the contained use**
HIV-1-based plasmids will be adapted to allow the cloning and study of viral genes from HIV-1. These genes can be sequences derived from lab adapted viruses, molecular clones, partial clones or clinical HIV material. The plasmids contain all the necessary HIV-1 genes required for HIV-1 replication in a single vector. Therefore the transfection the plasmids into cells produces viruses that are replication competent and capable of multiple rounds of replication in susceptible host cells. The viruses will then be used in cell-based drug susceptibility and replication fitness and drug selection studies.

**Recipient or parental organism**
Bacterial or eukaryotic transformed or primary human or animal cell lines.

**Host/vector system**
The plasmids have a standard antibiotic resistance backbone and therefore do not constitute any more hazard than any other cloning or expression plasmids containing genes of HIV origin. The plasmids are maintained in disabled E. coli strains such as HB101 and DH5α. The plasmids promoter are eukaryotic hence not specific for expression within the bacterial cells. The plasmids are transfected into eukaryotic transformed human or animal cell lines such as HEK293T cells. Upon transfection, viral particles will be produced and secreted into the tissue culture medium.

**Origin & function**
The genetic material to be used will be derived from laboratory adapted viruses, full or partial molecular clones or clinical HIV material.

**Evaluation of foreseeable effects**
The recombinant viruses produced are capable of multiple rounds of infection in HIV-1 susceptible cells and will be used in replication fitness and drug selection assays where viral production will be quantified using indicator cell lines or by ELISA. Exposure of a lab worker could lead to infection and integration of the packaged HIV-1 genome and expression of HIV-1 genes. Thus hazards associated with the recombinant viruses are through the risk from accidental infection resulting in HIV-1 infection and/or insertional mutagenesis causing over-expression of cellular genes by random integration. The main risk is to the laboratory personnel directly handling the recombinant viruses and the risk is equivalent to that of a laboratory worker handling clinical specimens from HIV-infected individuals. The final GMM is not a risk to the environment as the recombinant viruses are extremely susceptible to desiccation and will only survive a few hours at room temperature.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
Autoclave sterilisation of all solid waste and residual fluid waste. Autoclave waste programmed to 134°C for 40 minutes, with 100% kill., Autoclave validation by thermocouples in every load.
Some liquid culture waste disinfected with proprietary disinfectant containing 2500ppm available chlorine over 2 hours or more. Disinfection validated by demonstrating presence of available chlorine after disinfection time.
Two comments were made:
1. If the volume and concentration handled is to be greater than that expected in clinical samples, an additional risk assessment would be required to address this. GMSC has been informed that this will not be the case, and that the risk assessment is therefore sufficient.

2. The risk assessment submitted to the GMSC should include, in the environmental section, information about storage of the material and shipment arrangements. This additional information has been added to the risk assessment and returned to the GMSC (see attached copy).

Please enter comments on the GM safety committee on the risk assessment

Project Ref 36/14.1

Date Ackn'd 22/01/2014  CU2 Project Title Production of pseudotype viruses in mammalian cell lines for identification of therapeutic antibodies

Class 2  CultureVolClass2 < 1 Litre  Consent Granted Not Applicable

Project notified under transitional arrangements N

Tick if notifying a connected programme of work N
**Project Additional Information**

**Purposes of the contained use**

This project is aimed at generating reagents and assays to efficiently and accurately detect antibodies with neutralising properties to Hazard Group (HG) 3 and 4 virus pathogens.

Essential to these goals are the generation of the Human Immunodeficiency Virus 1 (HIV-1) replication deficient pseudoviruses (PV) that display HG3 and 4 surfaces proteins (glycoproteins, GP). Due to their complex post-translational modification processes, these proteins will need to be expressed in a eukaryotic system to ensure they have the correct folding and modifications to determine cellular tropism for downstream applications (virus neutralisation assay).

As such, the purpose of this project is to create a panel of PV, each expressing a GP from a range of HG3 and 4 viruses, which can be used to assess antibodies for virus neutralising properties.

**Recipient or parental organism**

Mammalian cell lines (culture adapted):

- Vero cells;
- Vero E6 cells;
- Human Embryonic Kidney 293 and derivatives;
- SW13 (adrenal cortex from human);
- Multicystic dysplastic kidney (MCDK) cells;
- Chinese hamster ovary (CHO) cells and derivatives;
- COS cells (CV-1 (simian) in Origin, and carrying the SV40 genetic material);
- HeLa cells.

The cell lines will be used for two applications:

1. Transfection with plasmids (DNA) for production of PV. Depending on the cell line chosen, transfected cell lines will either amplify plasmid DNA and over-express the heterologous genes, or over-express the heterologous genes from the transfected plasmids. The over-expressed gene products include, HG3 or 4 surface GP, HIV-1 gag
[capsid protein [p24], nucleocapsid protein [p9], matrix protein [p17], p6), pol (reverse transcriptase, protease, Rnase H, Integrase), tat, rev (only the regions needed for the tat and rev genes are maintained) and a reporter gene (green fluorescent protein (GFP) or luciferase). The production of these proteins in combination with HIV-1 regulatory and packaging material will self-assemble to form replication deficient HIV-1 pseudoviruses, which display a heterologous HG3 or 4GP.

2. Infection with PV to screen for virus neutralisation. Cells are infected with a pseudovirus, if the virus enters the cell it cannot replicate at it's replication deficient; however, once in the cell and unpackaged the modified viral genome can integrate into the hosts genome and over-express a reporter gene.

The forseeable effects from accidental exposure to a laboratory worker would arise from over-expression of the immunogenic protein GP, which is present in and on the host cell, and the surface of PVs. The GP also determines cellular tropism, enabling PVs to infect humans and animal cells, although the likelihood is extremely low and considered to be non-hazardous.

Virus GPs have been shown to be immunogenic (resulting in protective antibody response and dendritic cell activation/endothelial inflammation), however, they are considered to have no deleterious effects and are not classed as toxic or pathogenic to humans, or hazardous to the environment.

The PV system described here is well established in the US and the UK for producing high titre retroviral vectors. There is a very low likelihood that exposure to any components of this project will cause harm. The risk of accidental transfer of reporter gene to the host is extremely low but in the event of such a transmission the potential for harm would be by insertional mutagenesis/over-expression of a reporter gene by random integration acting to deregulate normal cell function. Again the likelihood that this will cause harm is low as the vector is replication defective and therefore will not spread within or between individuals; also more than one genetic lesion is required for most cell transforming and altering events. We will use the retroviral vector system to transduce cell lines. The main risk is to the laboratory personal directly handling the retroviral vectors. The risk attached to using replication defective HIV vectors is minimised because these viruses are extremely susceptible to desiccation and will only survive a few hours at room temperature. In addition, the replication defective nature of the HIV vectors ensures that even in the case of a breach of containment, no virus can spread within the individual or from individual to individual.

The PV intended for experimental use will be produced using an adapted version of the HIV-1 gene therapy vector system; this system comprises three plasmids:

Plasmid 1 (p8.91 or p8.9NSX) - packaging construct, supplies the structural (gag), transcriptional (pol) and regulatory (tat and rev) proteins to form a HIV-1 core particle.

Plasmid 2 (pMDG, pcDNA3.1, pCAGGS, pCI or pSI containing a HG3 or 4 GP) - envelope construct, produces a foreign surface envelope protein (e.g. VSV-G), provides virus identity for cell recognition.

Plasmid 3 (pHIR-SIN-CSHW or pCSFLW) - expression construct, this supplies the HIV-1 RNA packaging signals, regulatory elements and reporter gene; this is the genetic material that will be carried by the PV for cell entry studies.

To produce PVs, all three plasmids must be delivered into the host (mammalian cells); plasmids are delivered into the host by transfection. Once in the cell the packaging plasmid produces structural proteins required to make virions; however, it also produces viral transcription and regulatory proteins that are required by the PV for infectivity studies. The expression construct produces a modified RNA HIV-1 defective genome, which is packaged into the virions; no viral structural genes are packaged into the virions. The envelope plasmid produces a foreign GP, which is incorporated into the surface of the virions; the GP subsequently determines the type of cell the PV can enter.

The PVs produced can be used to infect a broad-spectrum or specific cell line depending on the GP it carries, once cells are infected with a PV the genetic material (RNA defective reporter genome) is released and the transcription protein (reverse transcriptase) processes the RNA genome into a DNA form, which is then integrated into the host cells genome. Once intergraded, regulatory elements transcribe the reporter gene into its protein constituen (e.g. GFP), providing a quantifiable readout for analysis.
Plasmids:

p8.91 or p8.9NSX (and derivatives of) encoding HIV-1 gag-pol, tat and rev but with virulence genes vif, vpu and nef deleted as well as deletion of env (only the regions needed for the tat and rev genes are maintained) - Naldini, L. et al (1996) Science 272, 263-7.

pHR-SIN-CSGW encoding GFP, and derivatives of that encode alternative reporter genes, including pCSGW-YFP encoding Yellow Fluorescent Protein and pCSFLW encoding firefly luciferase. These all have the HIV-1 packaging sequence and the SFFV promoter leading to the expression of the reporter gene, flanked by self inactivating HIV-1 Long Terminal Repeats.

Envelope glycoprotein (GP) is responsible for binding to specific cell surface proteins/receptors, allowing viral entry into target cells. As such these genes are responsible for viral tropism. Their exposed conformation on the viral envelope means they are heavily glycosylated but still are the main drivers of the host immune response to the virus.

Gag contains around 1500 nucleotides, and encodes four separate proteins which form the building blocks for the HIV viral core:

- Capsid protein, CA, p24
- Nucleocapsid protein, NC, p9

Viral capsid and nucleoproteins are essential for ensuring viral genomes are packaged into progeny virions as the virus assembles. As such their main functions are binding to viral genomes and forming the main structural component of the viral core.

- Matrix protein, MA, p17 (this protein isn’t actually part of the viral core but the “matrix” which anchors the core to the viral envelope).
- p6 - The protein p6, one of the products of the gag gene, helps vpr to be incorporated into newly-made virus particles.

The most significant role of the gag gene is therefore to encode important proteins which will make up the viral core.

Pol is one of the main retroviral genes. It encodes four proteins, of which the most important is Reverse Transcriptase. Reverse Transcriptase performs a job which is unique to retroviruses, in that it copies the virus’ RNA genome into DNA. Since most organisms and viruses keep their genes in DNA form in the first place, they have no need to perform this task. The copying of the HIV genome into DNA form is one of the key stages of the HIV life-cycle. The other three products of pol are:

- Protease - which processes proteins made from HIV’s genome so that they can become part of new fully-functioning HIV particles.
- RNAse H - which breaks down the retroviral genome following infection of a cell
- Integrase - which integrates the DNA copy of HIV’s genome into the host DAN

"tat" is short for “transactivator” - its’ a regulatory gene which accelerates the production of more HIV virus. Infact, it's crucial to HIV, because HIV completely fails to replicate itself without it.

HIV regulator gene "rev" stimulates the production of HIV proteins, but suppresses the expression of other HIV's regulatory genes, rev helps intact mRNA to be exported from the cell nucleus. It binds to the mRNA at a specific point (the Rev-Responsive Element or RRE), and this complex of RNA and rev is sent out of the nucleus. A molecule of rev can "shuttle" in and out of the nucleus, potentially taking a new set of RNA out each time it leaves the nucleus. The RRE is not present in completely-spliced HIV mRNA - it will have been chopped out.
5' and delta 3' Long Terminal Repeats (LTR) and self-inactivating (SIN) - the LTRs function in packaging to create lentiviral particles, but are self-inactivating after integration into the target cell genome and thus render the integrated lentiviral construct incapable of being mobilised into infectious particles even in the presence of active endogenous or exogenous retrovirus.

Central polypurine tract (cPPT) serves to enhance the efficiency of integration and insert gene expression by facilitating nuclear translocation of pre-integration complexes.

Spleen focus-forming virus promoter (SFFV) - drives expression of reporter genes, upon host integration of the defective modified HIV-1 genome.

Woodchuck Hepatitis Virus Post-transcriptional Regulatory Element (WPRE) - enhance expression of the genes harboured in the expression construct. Its mechanism of action is unclear, but may involve the facilitation of nuclear export and/or stability of viral mRNA, or enhanced transcriptional termination and avoidance of read-through beyond the construct. This element was first described in Donello et al., 1998 and in Zuffrey et al., 1999 and there has been a good deal of work on it since. Kingsman et al., 2005 wrote a summary highlighting the concerns about the presence of a promoter and partial (60 amino acids) coding sequence of the WHV X protein within the first generation WPRE element. Protein X has been reported to be a major factor in the increased incidence of liver cancer after infection by natural routes with Hepatitis B-type hepadnaviruses. It is unclear whether there is any real evidence that this 60 amino acid N-terminal fragment of protein X is directly oncogenic, although it may act as a cofactor for oncolycygenicity with weak effect. It also seems that partial-Protein X cannot be expressed under the control of the promoter in the WPRE element, even in lentiviral constructs, except in the presence of a second enhancer, examples of which are not present in the WPRE construct. It could potentially be expressed as a result of read-through from endogenous genes through effects would be reduced by the deliberate inclusion of insulator elements flanking the expressed portions of the integrated construct. It is also possible to abrogate the potential expression from the included protein X promoter using newer generation WPRE elements lacking all or part of this promoter, and/or by site-directed mutagenesis to using newer generation WPRE elements lacking all or part of this promoter, and/or by site-directed mutagenesis to remove the start codon or other portions of the coding sequence. These modifications have been shown not to affect the efficiency of the WPRE element in enhancing expression of genes contained within the lentiviral construct.

The green fluorescent protein (GFP) is a protein composed of 238 amino acid residues (26.9kDa) that exhibits bright green fluorescence when exposed to light in the blue to ultraviolet range. Although many other marine organisms have similar green fluorescent proteins, GFP traditionally refers to the protein first isolated from the jellyfish Aequorea victoria.

Luciferase is a generic term for the class of oxidative enzymes used in bioluminescence and is distinct from a laboratory reagent often refers to P. pyralis luciferase although recombinant luciferases from several other species of fireflies are also commercially available.

An application of GFP and luciferase for virology, cell and molecular biology includes reporters of expression.

- Bainbridge, J. et al. (2001) Gene Therapy 8, 1665-8

Evaluation of foreseeable effects

Minimal hazards: the inserted gene products are non-hazardous structural proteins with no toxic or oncogenic properties. Any minor risk associated with each of the resultant recombinant protein or PV are described below.

Envelope Glycoprotein: Some envelope glycoproteins give cytotoxic effects if over-expressed in cell lines, these proteins have not been shown to have any pathogenic effects. No other pathological effects have been reported for glycoproteins. Glycoproteins are, by their nature and function, immunogenic (triggering antibody and inflammatory responses), previous expression studies on such proteins have been performed at CL2 (GM36/09.2).

pP8.9NSX (and derivatives of) encoding HIV-1 Gag-Pol, Tat and Rev but with virulence genes vif, vpu and nef deleted as well as deletion of env (only the regions needed for the tat and rev genes are maintained). The combination of these genes will produce empty virions; however, the virions will not possess a surface GP and are not considered hazardous.
pHR-SIN-CSGW encoding GFP (and derivatives of that encode alternative reporter genes, including pCSFLW encoding firefly luciferase). These all have the HIV-1 packaging sequence and the SFFV promoter leading to the expression of the reporter gene, flanked by self inactivating HIV-1 LTR. The products from this construct is not considered hazardous.

Combination of gene products from p8.9NSX, pHR-SIN-CSGW and pMDG-GP (GP of interest) will produce a replication deficient PV capable of entering human and animal organs specific to the tropism of the GP displayed. This is considered highly unlikely, but if in the event this was to happen then no pathogenic affects are expected; the modified genetic material carried by the PV has the potential to be integrated into host cells and over-express the inserted reporter gene. The nature of this insertion and expression is also considered non-hazardous as the inserted genetic information cannot be mobilised due to the presence of the SIN and partially deleted LTR. Production and handling of PVs should be performed at Containment Level 2 (CL2).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The only GMO's generated are micro-organisms - no transgenic animal or plant work is associated with this project

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No Derogation from Full ACGM level 2 and ACDP class 2 containment will be needed for this work. All work with the resultant GMMs will be conducted under level 2 conditions and in a class 2 cabinet. Any work that does derogate from full class 2 containment will only be carried out after appropriate de-activation/lysis of any GMM that may be in that sample.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Hypochlorite - Haztabs
For liquid waste with in the Class II safety cabinet, a solution of sodium hypochlorite is made by adding 1 HazTab tablet to 1 litre of water/liquid waste (2,500ppm available chlorine) in a waste pot. For non-infectious tissue culture this is transferred to drain with copious amounts of water. If virus-infected waste is produced, this is left in hypochlorite overnight, then transferred to drain with copious amounts of water.

70% Isopropanol
Isopropanol stock is 70% in purified water. It can be used to disinfect surfaces that are not heavily contaminated. All items of equipment taken out of the laboratory should be first sprayed with 70% Isopropanol. Its use should be avoided where bacterial spores, mycobacteria or non-enveloped viruses maybe present.

Formaldehyde
The Class II safety cabinet should be fumigated before servicing (or when bacteria/fungal contamination is observed) using 50% formalin (20% formaldehyde) diluted in deionised water. 30ml of 50% formalin is added to a boiling pot and allowed to evaporate in an enclosed cabinet. This is left for at least 6hours, or preferably overnight before cabinet is switched on for re-use.

Autoclave sterilisation and incinderation of all solid waste.

Is an emergency plan required according to regulation 20?  
No

If yes, tick to confirm that it is attached to this form

### Project Additional Information

#### Purposes of the contained use

The work proposed covers the genetic manipulation of ACDP2 Gram-negative bacteria, specifically targeted gene knock-outs and knock-ins in Enterobacteriaceae (e.g. Klebsiella pneumoniae, ACDP2 Escherichia coli, Enterobacter spp, Serratia, Citrobacter) and Pseudomonads (e.g. Pseudomonas aeruginosa, Stenorophomonas maltophilia). The main goal of the project is to generate site specific gene knock out derivatives in order to assess their susceptibility to common clinical disinfectants and to define the function of specific genes within the related stress response. The project will also generate fluorescent and bioluminescent derivative strains which can be used to develop more rapid measurements of microbial growth.
**Recipient or parental organism**

Klebsiella pneumoniae:
Clinical strains (e.g. TW3, M3, M6; Wand et al 2013; Complex interactions of Klebsiella pneumoniae with the host immune system in a Galleria mellonella infection model. J MedMicrobiol, 62:1790-8) and library isolates (e.g. NCTC13368, MGH78578)
Murray strains; isolated from the 1920s to the 1950s and available from PHE Culture collections.

Pseudomonas aeruginosa
PA01, NCTC 13359 and 372261 (resistant to chloramphenicol and the penicillin class of antibiotics).

Clinical and type isolates of Escherichia coli (acdp-2), Enterobacter spp, Serratia, Citrobacter and Stenotrophomoas maltophilia ). Details of specific strains or additional ACDP-2 bacteria will not be notified to the local GMSC committee.

**Host/vector system**

Vectors:
Suicide plasmids:
- pKOV suicide plasmid (Link et al, 1997) temperature sensitive Psc101 replication origin; CmR, SacB counter selection marker.
- pK0V has a temperature sensitive Psc101 replication origin. Strains harboring the plasmid must be grown at 30°C under chloramphenicol selection.
- pDM4 suicide plasmid, mobRP4; oriR6K; CmR; sacB counter selection marker;

The origin of replication (oriR6K) requires for its function the pi protein. This gene product is not present on the vector. It is supplied by specific E. coli strains that have had the prophage (lambda pir) introduced. It is therefore unable to replicate in strains that do not express the pi protein.

For plasmid complementation:
- pET-28a(+) expression plasmid (mobilisation defective). (Novagen) T7 promoter and terminator, pBR322 origin, f1 origin, iacI coding sequence, KanR
- pMF230 pTrc vector pKK233-2, oriVSF oriT Aor GFP mut2 (Nivens et al 2001; J Bac 183p1047) (mobilisation defective)
- pACYC184 broad host range plasmid (mobilisation defective; Change and Cohen, Construction and characterisation of amplifiable multicopy DNA cloning vehicles derived from the P15A cryptic miniplasmid, J Bacteriology 1978)

**Origin & function**

The functions of many of the genes to be targeted for knock-out and/or introduced for complementation are in the stress or stringent response. The upstream and downstream fragments are to allow insertion of the knock-out construct and are for the purpose of targeting only. They are extremely unlikely to encode peptides with any deleterious biological activity, and no attempt will be made to construct these fragments in a way that would allow high level expression.

Full length genes used to complement knock-out mutants will be inserted under the control of their own native promoter either back into their original chromosomal position or onto an expression plasmid. Doing this will not generate any deleterious biological activity beyond normal wild-type phenotype.

Genes expressing fluorescent proteins such as the gfp gene and its derivative e.g. egfp, bfp, rfp, cfp, etc will also be inserted either into the chromosome or onto an expression plasmid. Again there is no evidence to suggest that expression of these genes leads to any deleterious biological activity. The Photorhabdus luminescens lux genes encoding for the luciferin-luciferase system will be used to generate bioluminescent strains.

**Evaluation of foreseeable effects**

The expectation is that the majority of the knock-out mutants generated in the study would be attenuated to some degree, compared to their parental strains. There is no expectation that the traits being modified would generate clones that were significantly more virulent than their parental strains. The aim of the project is to understand the role of specific genes in the ability of the organisms to adapt to biocide or other environmental stresses. As such it would be expected that the knock-outs would either increase the susceptibility to specific biocides and/or prevent the organisms from acquiring resistance. The introduction of wild type genes to complement the knock-out strains, even where this is achieved using an intact plasmid copy of the gene of interest on a multicopy plasmid, would not be expected to have a significant effect on the range of biocides that are effective against the organism, although it might affect the relative level of susceptibility compared to parental strains.

See Derogation GM36/15.3a
Current whooping cough vaccines are either whole cell formulations (wP) containing killed/detoxified Bordetella pertussis cells, or acellular formulations (aP) containing up to five purified B. pertussis proteins. Acellular pertussis vaccines were introduced in response to concerns about the reactogenicity of wP, but it is now apparent that aP vaccination has accelerated the emergence of new alleles of the vaccine antigens. There is also evidence that the immunity elicited by aP is shorter-lasting and less effective at blocking transmission compared to that elicited by wP. The allelic exchange and knockout strains described here are of value in distinguishing the contribution made by each of the proteins encoding by the deleted and/or allelic-exchanged genes to host immunity or to immune evasion. Their purpose is thus to aid the development of improved vaccines that overcome the shortcoming of existing wP and aP.

Bordetella pertussis. All available strains were isolated from whooping cough patients and are handled as virulent strains. B. pertussis is a respiratory pathogen transmitted from person to person via aerosol drops. There is evidence that asymptomatic (or mildly symptomatic) carriage may occur in persons who have received current acellular vaccines. Containment measures must therefore be sufficient to prevent un-noticed dissemination via vaccinated laboratory workers.

E. coli ST18 is used as a conjugation donor for construction of new GM B. pertussis strains. E. coli ST18 is a derivative of widely used non-colonising K12 strains. E. coli ST18 has chromosomally integrated tra genes from plasmid RP4, and a markerless deletion of hemA (these two modifications fall within the exemption in Schedule 2 Part lll of the Contained Use Regulations 2000). The hemA deletion prevents this strain from growing without supplementary 5-aminolevulinic acid (required at concentrations exceeding those in the human respiratory tract), and thus effects additional attenuation.

The hemA deletion prevents this strain from growing without supplementary 5-aminolevulinic acid (required at concentrations exceeding those in the human respiratory tract), and thus effects additional attenuation.

Host/vector system

Allelic exchange vectors pSS4940 and PSS4894:

These were constructed elsewhere from a pUC replication origin, an RP4 origin of transfer, a selectable marker (gentamycin resistance in pSS4940, streptomycin resistance in pSS4894), and a counterselectable marker (the coding sequence for restriction enzyme I-SceI under the control of a Bordetella promoter). These vectors replicate episomally in E. coli, but after conjugation into B. pertussis, can persist only as chromosomal cointegrates via recombination between chromosomal sequences and homologous insert sequences.

Episomal vector pBBR1GW-Tet:

pBBRGWTet is a GATEWAY®-adapted derivative of the natural Bordetella bronchiseptica S87 plasmid pBBR1, with tetracyclin resistance added as a selectable marker.
The original pBBR1 is a 2.6kb plasmid that can replicate episomally in the genera Bordetella, Escherichia, Pseudomonas, Rhizobium and Vibrio, with 30-40 copies per cell in B. pertussis and E. coli. It can co-exist with incompatibility groups IncP, IncQ and IncW, and it can be mobilised by any host that provides RP4 tra function in trans (including E. coli ST18).

Origin & function

Transposon knockouts: The heterologous genetic material (Tn5) has no function other than to disrupt endogenous B. pertussis genes. The sole phenotypic side-effect is kanamycin resistance.

Cointegrates (transient intermediates in allelic exchange process); the heterologous genetic material is the backbone of pSS4940 or pSS4984 (see above).

Markerless knockouts: No heterologous genetic material present. B. pertussis genes cleanly deleted.

Allelic exchange mutants: No heterologous material present. Alleles with >80% amino acid similarly have been shuffled between different isolates of the same species.

Strains with upregulated antigen production: Limited to endogenous gene relocation within the B. pertussis chromosome or in to pBBRGWTet, i.e. no heterologous material other than the vector pBBRGWTet (described above)

Evaluation of foreseeable effects

Transposon knockout and markerless knockouts may be attenuated relative to the wild-type organism, but the cautious assumption is that they are still able to cause disease. The possibility of upregulated toxin expression arising from altered transcriptional context has been examined and discounted for each knockout.

Allelic exchange mutants are unlikely to pose new hazards because diversification of these genes into alleles is driven by immunological pressure, and the encoded products of different alleles are functionally equivalent. Similarly, strains with upregulated antigen expression are unlikely to have gained virulence since natural selection ensures that these antigens are already expressed at optimum levels (for the organism) in disease isolates. Upregulation of toxin genes has not been attempted and is not proposed.

Horizontal transfer risks: The risk of horizontal transfer of pBBRGWTet constructs is low because hosts strain of B. pertussis do not have RP4 tra function (checked from genome sequences). For cointegrates of pSS4940 or pSS4894, this risk is minimised by the transient nature of these constructs (~5 days agar plate culture before cointegrate resolution).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation is sought

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Microbiologically contaminated liquids are treated with sodium hypochlorite or Super Q™, to produce a final concentration of no less than 2.5% (v/v) and left for 30 minutes before removing from the flexible film isolator or microbiological safety cabinet. These liquids are then autoclaved by the site autoclaving service prior to disposal to drain.

Solid waste is discarded into a nylon autoclave bag, sealed with a swan-neck bend, secured with a cable tie and sprayed with 2.5% sodium hypochlorite or Super Q™ (v/v) prior to being bagged into a second nylon autoclave bag sealed using a swan-neck bend secured with cable-tie. This is then sprayed with 2.5 sodium hypochlorite or Super Q™ (v/v) and left to vent in the flexible film isolator pass box or microbiological safety cabinet for 5 minutes prior to removal. The double-bagged waste is then placed in waxed paper-lined autoclave tins, autoclaved by the site autoclaving service and finally incinerated. Autoclave tins are surface-decontaminated prior to removal from the laboratory.
Waste is tracked throughout the destruction process according to standard site-wide procedures.

**Project Ref**  36/15.2

- **Date Ackn'd**: 18/11/2015
- **CU2 Project Title**: A rescue system for Hazara virus
- **Class**: Non-GMM
- **Consent Granted**: Consent Granted

**Project notified under transitional arrangements**  N

- **Withdrawn**: N
- **Tick if notifying a connected programme of work**: N

**Historical Significant Changes**

**Historical Date of Additional Info**

02/03/2022
The development of a rescue system for HAZV will enable the replication cycle of HAZV to be studied in much greater detail. The HAZV rescue system will enable us to make (i) precise mutations, (ii) deletions and (iii) gene fusions in the support proteins and or genome of HAZV. These will permit a molecular understanding of Hazara virus biology through subsequent experiments in comparison to wild type virus. We aim to use site directed mutagenesis to modify amino acid residues in the L-protein, N-protein, and the viral glycoproteins to determine the roles of these residues within the function of the protein and the replication cycle of the virus. We also aim to modify the viral glycoproteins and/or nucleocapsid protein through the addition of an EGFP tag to enable better visualisation of viral replication. This system will also allow the modification of the viral 3' and 5' UTRs to determine the minimum cis-acting factors required for viral replication, and the testing of anti-viral compounds. Initially wild-type (unmodified) infectious HAZV will be recovered from BSRT7 cells following transfection of plasmids encoding cDNA corresponding to the viral L-, M-, and S-segments. We will then generate plasmids encoding the following specific point mutations:

1) In the L segment plasmid, D685A, G710A and K726A These amino acid mutations will eliminate the putative endonuclease site responsible for cap-snatching during the replication cycle of HAZV, and should result in no or significantly decreased virus replication. Mutation of the equivalent amino acids (0693,0718 and K734) in the CCHFV virus-like particle system (which uses the CCHFV Nand L- proteins in trans to support transcription and replication of a CCHFV minigenome, and co-expression of the viral glycoproteins to create virus-like particles) abrogates minigenome transcription (0693A and K734A) or significantly reduces it (D718A). Oevignot S, Bergeron E, Nichol S, Mirazimi A, Weber F. 2015. A Virus-Like particle system identifies the endonuclease domain of CrimeanCongo hemorrhagic fever virus. J Virol. 89(11):5957-67.

An EGFP and other fluorescent reporter tags will be inserted into the viral glycoprotein precursor and N protein to determine whether the protein can tolerate the insert, and to better visualise HAZV replication. This insertion will either not affect, or will detrimentally affect HAZV replication. Shi X, van Mierlo JT, French A, Elliot RM. 2010. Visualising the replication cycle of bunyamwera orthobunyavirus expressing fluorescent protein-tagged Gc glycoprotein. J Virol. 84(17):8460-9.

The genetic changes proposed in this work will be detrimental to the WT version of HAZV and they will result in no or negligible risk to human health and the environment.
Recipient or parental organism

The recipient organism is Hazara virus. HAZV is listed by the ACDP in hazard group 2 and is used in a containment level 2 environment. HAZV is not known to cause any disease in humans or animals (other than severely debilitated transgenic mice which lack an interferon response) and does not pose a risk to the environment or community. HAZV has been isolated from Ixodes redikorzevi licks in Pakistan, and antibodies against Hazara virus have been detected in wild rodent sera. Transmission of HAZV is therefore thought to be through the bite of an infected tick.

Host/vector system

The vectors for the rescue system are all simple cloning vectors that allow the site directed mutagenesis of their inserts, but are non mobilisable and contain a Cot E1 origin of replication along with an antibiotic resistance gene. The vectors for the plasmids are:
- pOK (HAZV L-segment and M-segment rescue)
- pMK-RQ (HAZV S-segment rescue)
- pMK-RQ (HAZV L segment support and N support)
The plasmids will be propagated in and purified from the E.coli strain DH5a. The plasmids will be transfected into BSRT7 cells, which are modified BHK21 cells (an immortalised cell line originally derived from baby hamster kidney cells) that have been stably transfected with a plasmid encoding the T7 polymerase, which is constitutively expressed in BSRT7 cells. The rescue system plasmids contain a T7 promoter, which will allow the initiation of transcription of the HAZV genomic segments and support plasmid open reading frames in the cytoplasm of transfected cells by the T7 polymerase.

Origin & function

The genetic material (rescue plasmids encoding cDNA corresponding to the Hazara virus genomic segments, as well as support plasmids encoding the open reading frames of the HAZV L- and N- proteins) was originally synthesised by GeneArt (Thermo Fisher). The functions of the proteins encoded by these plasmids are detailed below.
The L segment rescue and the L segment support plasmid encode the HAZV RNA dependent RNA polymerase. This enzyme is responsible for transcription and replication of all three segments of the HAZV RNA genome. The M segment rescue plasmid encodes the viral glycoproteins Gn and Gc. Gn and Gc are the viral envelope glycoproteins that form a heterodimer on the virion surface. The function of Gn and Gc is to bind to mammalian cell surface receptors and facilitate entry of virions into cells. The S segment rescue and S segment support plasmid encode the viral nucleocapsid protein (N protein). The N protein binds to and encapsidates the viral RNA segments, protecting them from degradation, and forming ribonucleoprotein particles which are essential for both transcription and replication of the viral RNA genome.

Evaluation of foreseeable effects

The proposed HAZV rescue system poses minimal hazards to human health. All of the planned mutations have been previously generated in equivalent amino acid residues in related viruses, and have been shown to be detrimental to replication either of the rescued virus itself, or in a minireplicon system. Therefore we predict that the planned mutations will be detrimental to HAZV replication, and will result in a virus that is replication-comprised in comparison to wild type. These mutations will not increase the hazard of HAZV, they will not result in HAZV being turned into a pathogen. The planned mutations are not in the M segment which encodes the viral glycoproteins and therefore will not affect the tropism of HAZV or the immunogenic properties of the virions. None of the proposed mutations in the Nand L protein alter known virulence determinants or immunogenic properties of HAZV, and there are no hazardous properties associated with the proposed gene insert (EGFP). Also, none of the gene products
(described above) have been shown to have any directly hazardous effects. In accordance with wild type HAZV being classified as a hazard group 2 pathogen by the ACDP, all handling of supernatents from transfected cells, supernatent containing rescued virus and purified rescued virus will be carried out under containment level 2 conditions in MSC class 2 cabinets. This provides suitable protection to the user and minimises the risk of co-workers and the wider community being exposed to any GMOs.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

| N/A - no transgenic animal or plant work is associated with this project. |

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

| N/A - no derogation from full containment level 2 procedures applicable to work with any ACDP classified hazard group 2 organisms will be required for this project. All work with the resultant GMMs will be conducted under containment level 2 conditions in an MSC class 2 cabinet and all GMMs will be inactivated before removal from ACGM 2 licensed areas. |

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| Liquid laboratory waste will be disinfected with 1% virkon solution overnight and diluted to drain with copious water (or other approved disinfectants such as sodium hypochlorite, or sodium dichloroisocyanurate can be used at a concentration of 2,500 ppm available chlorine). Solid laboratory waste will be discarded in yellow sacks for incineration. Virkon has been validated as an effective disinfectant for other members of the Bunyavirus family by the manufacturers (DuPont Rely+on virkon efficacy data) and by other groups (Evaluation of the efficacy of disinfectants against Puumala hantavirus by real time RT-PCR. Journal of virological methods. Maes, Li et al. December 2006) and is active in the presence of organic material. Sodium Dichloroisocyanurate (Haz-Tabs) have also been validated as an effective virus disinfectant. 70% isopropanol (100% isopropanol diluted in purified water) will be used as a surface and equipment disinfectant. when these are not heavily contaminated. 70% isopropanol will also be used to spray all items of equipment taken out of the laboratory. The MSC class 2 cabinet will be fumigated before servicing (or when fungal or bacterial contamination is observed) using 50% formalin (20% formaldehyde) diluted in deionised water to minimise the risk of exposure of GMMs to co-workers. |

<td>Expression of Clostridium difficile virulence factors in Bacillus Megaterium</td>
<td>Class 2</td>
<td>&lt; 1 Litre</td>
<td></td>
</tr>
</tbody>
</table>
We propose to express DNA encoding whole or parts of virulence factors from C. difficile in Bacillus megaterium, as part of a commercial expression kit from MobiTec using standard techniques. This will involve inserting the relevant genets into a plasmid which can be propagated in E. coli cloning strain(s). This plasmid will then be harvested, and transferred to B. megaterium via transformation of protoplasts. Following this the genes will be expressed in B. megaterium under the control of a xylose inducible promoter.

Recipient or parental organism
B. megaterium - Host strains
MoBiTec™ offers three different B. megaterium strains (WH320, MS941, and YYBm1) for protein production. All strains are supplied as protoplasts, ready-to-use for transformation.
1. The strain WH320 is a chemical mutant of strain DSM319, which is deficient in the production of betagalactosidase (β-lacZ). It was described by Rygus and Hillen (1991).
2. The strain YYBm1 carries the nprM deletion and an additional deletion of the xylose isomerase gene xylA. It is thus unable to metabolize xylose, which is used as inducer for gene activation (Yang et al. 2006). (Genotype: Defined deletion mutant of wild type strain DSM319: ΔnprM, ΔxylA)
3. The strain MS941 was generated from the Wild-type strain DSM319 by deletion of major extracellular protease gene nprM (Wittchen and Meinhardt 1995). Because of reduced extracellular protease activity, this strain is well suited for extracellular protein production.

DSM319 been a workhorse in food and pharmaceutical production processes for decades (i.e., a and β-amylases used for starch modification in the baking industry and penicillin acylases essential for the synthesis of novel 3-lactam antibiotics, among others).
MoBiTec host strains are asporogenic on common media (vegetative cells die on plates kept at 4°C within two weeks) and are therefore not expected to persist in the environment.
B. megaterium is ubiquitous in the environment. These asporogenic mutants have a long history of safe use.

E. coli - Host strains
Derivatives of E. coli K12 or B (for example JM109, TOP10, ER2566, DH5alpha/10-beta, Novablu) will be used for the generation of plasmid stocks, general DNA manipulation. E. coli K12 strains are E. coli K-12 derivatives that are
recognised as non-colonising and disabled, and may be considered to be equivalent ACDP hazard group 1. They are not considered pathogenic to humans or animals, but are thought capable of surviving for up to seven days in the gut. They are expected to have limited survivability in the environment and often have auxotrophic requirements, which are unlikely to be satisfied outside of laboratory culture.

### Host/vector system

**Expression vectors**

**Health and Safety**

Executive

With exception of pMGBm19, all shuttle vectors are derived from the original pWH1520 vector (Rygus and Hillen, 1991) with following features:

- Xylose-inducible expression system: strong PxylA promoter and repressor gene xylR; after xylose addition, the repressor is released from the PxylA that activates transcription initiation
- Ribosomal binding site (RBS) and start codon (ATG) upstream of the multiple cloning site (MCS)
- The MCS is located within the xylA' reading frame and allows easy cloning due to identical restriction sites in all vectors (from BglII to Nael, except for the pWH1520)
- Replication origins: CoIE1 ori (E. coli) and pBC16 ori (Bacillus)
- repU gene encoding for the replication protein RepU of Staphylococcus aureus, necessary for replication in Bacillus
- Resistance genes for selection: J3-1actamase (ampicillin resistance for E. coli), tetl encoding a tetracycline efflux pump (tetracycline resistance for Bacillus)

There are two kinds of vector series available:

- vectors of the 1520 series: with a) far-off located stop codon (> 120 bp downstream of start codon or b) stop codon directly downstream of an existing C-terminal tag
- vectors of the 1622 series: size-reduced vector variants with a) closely located stop codon directly downstream of the MCS or b) stop codon directly downstream of an existing C-terminal tag (Malten et al., 2006)

- pWH1520
- pMM1522
- pMM1525
- pHIS1522
- pHIS1525
- pSTREP1525
- pSTREPHTS 1525

- pN-His-TEV1622
- pN-Strep-TEV1622
- pN-Strep-Xa1622

Vectors for special requirements

- pMMEc4

### Origin & function

The genes to be cloned and expressed will be sourced from either directly from C.difficile or synthetically synthesised based on genes available in the public domain.
The proposed inserted genes will be C. difficile toxins A (TcdA) and B (TcdB), and C. difficile transferase toxin (COT). The single-chain toxins TcdA and TcdB are the main virulence factors. They bind to cell membrane receptors and are internalized. The N-terminal gluCoQsyltransferase and autoprotease domains of the toxins translocate from low-pH endosomes into the cytosol. After activation by inositol hexakisphosphate (InsP6), the autoprotease cleaves and releases the glucosyltransferase domain into the cytosol, where GTP-binding proteins of the Rho/Ras family are mono-O-glucosylated and, thereby, inactivated. Inactivation of Rho proteins disturbs the organization of the cytoskeleton and affects multiple Rho-dependent cellular processes, including loss of epithelial barrier functions, induction of apoptosis, and inflammation. COT, the third C. difficile toxin, is a binary actin-ADP-ribosylating toxin that causes depolymerization of actin, thereby inducing formation of the microtubule-based protrusions.

Evaluation of foreseeable effects

The most hazardous GMM constructed will express active proteins which have the functions defined in Section 6 iii. The primary potential hazard is therefore towards human health. Toxins (TcdA and TcdB) are the main virulence factors of C. difficile (though there is no real difference in the virulence of these two). The most hazardous GMO produced here will therefore be Bacillus megaterium expressing high levels of one of these toxins. Although Knoblock et al (2011) reports expression of genes under the xyiA promotor in E.coli. The GMM produced here (E.coli and B. megaterium) are producing active toxin, as such will be handled in the same way as the native pathogen to mitigate any risks associated with the expression of biologically active virulence factors.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste is treated with 10% sodium hyperchlorite for 12 hours and autoclaved via centralised validated autoclave cycle. Solid waste is incinerated.

Project Additional Information

**Purposes of the contained use**

The particular micro-organisms for this Notification are genetically-modified derivatives of Aspergillus fumigatus. They are null/knockout mutants for transcription factors were generated by means of homologous recombination. The genetically-modified derivatives 01 Aspergillus fumigatus will be delivered to CC-PHE in preformatted and packaged multi-well plates frozen and in double-barrier containment packaging. They will be stored at -BOC in the ultra-low temperature storage facility Building 17, Culture Collections-Public Health England at Porton Down. These genetically-modified derivatives of Aspergillus fumigatus will be stored and shipped from Building 17, Culture Collections-Public Health England and Porton Down.

We will only store and distribute these strains. No laboratory work will be performed.

Risk Assessments to be used: BA100419. These GM strains have been developed and deposited with Culture Collections-PHE by COFUN 2.30D Core Technology Facility, Grafton Street, School of Biological Science* Faculty of Biology, Medicine and Health, University of Manchester, M13 9NT* UK.
Recipient or parental organism

The strain used to create the library of null mutants strains in a genetically modified strain with the designation A1160P+ (MF1G001). This strain has virulence levels indistinguishable from the isogenic wild-type clinical isolate CEAIO.

Host/vector system

Vectors containing hygromycin cassettes were constructed using the Gateway™ pDONR221 Vector (Thermo Fisher) and the hygroR cassette from pCBI003 Knock out vectors pDONR HPH A and pDONR HPH B vectors (plasmid A and plasmid B), representing two orientations of the hygroR cassette were constructed

These vectors were used to construct the knockout vectors

The generation of Knockout cassettes in A. fumigatus was performed using a generic methodology for the generation of gene KO cassettes using PCR fusion and these constructs.

PCR fusion and Aspergillus transformation has been described in detail by Berl Oakley's group (Nat. Protoc. 2006;1 (6):3111-20. Szewczyk E).

Origin & function

The selectable marker hph, which confers hygromycin resistance. The genetically-modified derivatives of Aspergillus fumigatus that have been constructed are null/knockout mutants for transcription factors generated by means of homologous recombination. The genetic KO constructs comprise the selectable marker hph, which confers hygromycin resistance, flanked by 1 kb fragments upstream and downstream of the gene to be removed. The hygromycin cassette was delivered into A. fumigatus and transforming colonies were selected using hygromycin at 200mg/L. Transformants have been validated by PCR to confirm insertion of the cassette into the specified locus.

Evaluation of foreseeable effects

Consequences to Risk Assessment for Human Health:

Aspergillus fumigatus is an opportunist pathogen. Individuals with a normal immune system are not at risk from systemic aspergillosis. Severe immunological defects are required for individuals to become infected [Singh & Paterson, Clin. Microbiol. Rev. (2005) 1 B: 44-69].

Aspergillus fumigatus is found as a normal component of the microflora of the atmosphere and no systemic disease is seen in the healthy population. It is therefore very unlikely that Aspergillus fumigatus poses a significant risk to immune-competent laboratory workers or other support staff.

Although genetically-modified Aspergillus strains produced pose no significant threat to healthy immunocompetent individuals. Immunocompromised individuals or women of childbearing age who are expecting a child or planning a pregnancy will be excluded from handling these pre-packaged Aspergillus strains.

Risk: Low

The stock held at CC-PHE will consist of preformatted and packaged multi-well plates containing the genetically modified strains of A. fumagatus will be delivered to Culture Collection-PHE frozen and in double-barrier containment packaging. They will be stored at -BOC in the ultra-low temperature storage facility Building 17, Culture Collections Porton Down. The stock held will consist of ten batches of five x 96 multiwell plates (containing a total of 400 individual strains of GM Aspergillus).

We will not propose to perform any laboratory work with these strains. Storage and distribution only

Shipping: Aspergillus Fumigatus is a Hg2 fungus whether wild type or genetically modified these will be shipped as UN3373 - Biological substance Category B and would be packaged according to Packing Instruction 650.
We have consulted the Mycology Reference Laboratory, Public Health England, Bristol. Their recommendation for handling the Aspergillus strains are: Aspergillus fumigatus is a HG2 pathogen and is manipulated on the bench at CL2. A 0.5% Virusolve + solution is used with a contact time of more than 1 minute for local disinfection where a reduction of spore numbers is adequate to limit contamination.

Total elimination of genetically-modified A. fumigatus spores, for example, a spill in a MSC, would be fumigation with formaldehyde. This is the routine procedure at the Mycology Reference Laboratory. Spillage outside of the MSC would probably require fumigation of entire the laboratory.

As no culture work is proposed we need only consider the release of fungal strains in the event of breach of the packaging.

The disinfection procedures in the event of a breach of the packaging will be as follows:

Spillage: allow aerosols of dry spores or spore suspensions to settle; wearing protective clothing, gently cover spill with paper towels and apply 0.5% Virusolve +. After 30 minutes clean entire area with 0.5% Virusolve + and dispose of all materials by steam sterilization.

Liquid waste to be inactivated with 0.5% Virusolve +.

All waste materials (solid and liquid) will be initially autoclaved followed by incineration.

Contaminated equipment, e.g., freezer, would be cleaned using 5% Virusolve + solution.

(Virusolve + is supplied by Amity International). This reagent is 1509001 &13485 compliant, Certificate Numbers: GB06/69741 & GB0669740. Basic fungicidal and anti-yeast activity has been tested in accordance with BS EN 1275 (European Suspension Test) and demonstrates a > log.5 reduction in counts at 20°C after 1,2, and 5 minute contact times.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We will not propose to Rerorm any laboratory work with these strains. Storage and distribution only. No derogation is requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Control and Waste Management procedures

Health and Safety Executive

After 30 minutes clean entire area with 0.5% Virusolve + and dispose of all materials by steam sterilization. Liquid waste to be inactivated with 0.5% Virusolve +. All waste materials (solid and liquid) will be initially autoclaved followed by incineration. Contaminated equipment, e.g., freezer, would be cleaned using 5% Virusolve + solution. (Virusolve + is supplied by Amity International). This reagent is ISO9001 & 13485 compliant. Certificate Numbers: GB06/69741 & GB0669740. Basic fungicidal and anti-yeast activity has been tested in accordance with BS EN 1275 (European Suspension Test) and demonstrates a > log.5 reduction in counts at 20C after 1, 2, and 5 minute contact times

Non-GMM Consent Granted

02/03/2022
The work proposed covers the genetic manipulation of Candida species to enable studies on new antifungal agents. Much of the genetic engineering will be carried out by our collaborators at King's College London (KCL) but 1 strains will be transferred to the organisation for use in drug screening, mechanisms of action studies and for virulence studies in Galleria mellonella infection models. Studies focus particularly on Candida albicans, as the most common cause of candidiasis, and the recently emerged species C.aurantis. Additional species, such as C.glabrata, C.tropicalis, may be used to answer specific questions about drug resistance mechanisms in these species. A specific objective of the work is to generate strains with single and multiple deletions in the efflux pump genes, associated with resistance to antifungal agents and genes affecting cell wall permeability. These mutants will help in defining how specific efflux pumps contribute to resistance and to improve initial drug screening. These strains also help validate these targets for the development of new antifungals, acting either directly on the cell wall/membrane or as “resistance breaking” adjuvants targeting efflux pump.

C. auris strains TIDG1912, NCPF8985, NCPF8971, and NCPF8977 from Public Health England (now UKHSA) and NCTC. Strains are resistant to fluconazole and voriconazole, variably resistant to echinocandins, but sensitive to caspofungin and amphotericin B (according to broth dilution and presumptive EUCAST breakpoints). The strains is also sensitive to nourseothricin used as a selectable marker in these studies. C. albicans strain SC5314 (the wild-type strain sequenced by the Candida genome sequencing project), was provided by King's College London (Odds et al 2004). The strains is susceptible to all antifungal agents tested. The strains is also sensitive to nourseothricin.

Genetic modification of Candida strains is achieved using CreLoxP systems based in intergration cassettes carrying a selectable marker, which can subsequently be excised from the genome. In the GMOs covered here there are no vectors used.

Efflux pump genes and regulators.
Genes that appeared to be significantly upregulated in fluconazole-resistant isolates of C. albicans or C. auris were CDR1 and CDR2 (multidrug transporter of ABC superfamily), MDR1 and MD2 (MFS family multidrug efflux pump) and MLT1 (vacuolar membrane transporter of ABC family) will be deleted.

Metabolic genes.
Metabolic genes will be deleted to demonstrate utility of the knockout process and to generate auxotrophic variants for some applications. Selected genes will include:

- URA3 encodes orotidine-5'-phosphate (OMP) decarboxylase, an enzyme required for the biosynthesis of uracil.
- ADE2 encodes phosphoribosylaminomimidazole carboxylase, an enzyme involved in the catalysis of 'de novo' purine nucleotide biosynthesis.

Cell wall / membrane biosynthetic genes.

- ss-(1,3)-glucan synthase (GS): involved in biosynthesis of ss-(1,3)-glucan, the major component of the fungal cell wall. Molecular targets of echinocandins
- Cell wall kinase Yck2
- Trehalose synthases: involved in synthesis of trehalose
- Gwt1, a key component of GPI anchor protein biosynthesis
- Chitin synthase involved in synthesis of chitin, one of the key cell wall components in fungi.

Putative virulence genes.

- Hog1-related stress-activated protein kinase (SAPK), is a known stress-response gene linked to virulence in Candida and other fungal pathogens; Day et al 2018.

Peptide tags.

- C-myc, 6-HA and 6-His tags are short peptides recognised by antibodies and have no biological function in their own right.
- HiBiT is a short 11 amino acid peptide which combines with LgBiT to form a functional luciferase for ultrasensitive bioluminescent detection.

Evaluation of foreseeable effects

The expectation is that the majority of the knock-out mutants generated in the study would be attenuated to some degree, compared to their parental strains, either in terms of reduced fitness/virulence and/or by reducing their resistance to antifungal agents. There is no expectation that the traits being modified would generate clones that were more virulent than their parental strains. The aim of the project is to understand the role of specific genes in the antifungal resistance of the organisms and to generate strains to improve initial stages of antifungal screening. As such it would be expected that the knock-outs would either increase the susceptibility to specific antifungals and/or prevent the organism from acquiring resistance. Specific knockouts might also have reduced virulence traits, such as the ability to infect Galleria mellonella as a model host, or to form biofilms as an important facet of infection.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The only GMMs generated are micro-organisms - no transgenic animal or plant work is associated with this project.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No Derogation from Full ACGM level 2 and ACDP class 2 containment will be needed for this work. All work with the resultant GMMs will be conducted under level 2 conditions and in a class 2 cabinet.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Hypochlorite — Haztabs

For liquid waste with in the Class II safety cabinet, a solution of sodium hypochlorite is made by adding 1 HazTab tablet to 1 litre of water/liquid waste (2,500ppm available chlorine) in a waste pot. For non-infectious tissue culture this is transferred to drain with copious amounts of water. If virus-infected waste is produced, this is left in hypochlorite overnight, then transferred to drain with copious amounts of water.

70% Ethanol

isopropanol stock is 70% in purified water. It can be used to disinfect surfaces that are not heavily contaminated. All items of equipment taken out of the laboratory should be first sprayed with 70% Isopropanol. Its use should be avoided where bacterial spores, mycobacteria or non-enveloped viruses maybe present.

Formaldehyde

The Class II safety cabinet should be fumigated before servicing (or when bacterial/fungal contamination is observed) using 50% formalin (20% formaldehyde) diluted in deionised water. 30ml of 50% formalin is added to a boiling pot and allowed to evaporate in an enclosed cabinet. This is left for at least 6 hours, or preferably overnight before cabinet is switched on for re-use.

Autoclave sterilisation and incineration of all solid waste.

Is an emergency plan required according to regulation 20? N

**Project Additional Information**

**Purposes of the contained use**

P. falciparum is a serious human pathogen classified by ACDP as Group III* (derogation applies such that they can be handled in category II facilities, with no requirement for positive pressure of HEPA filtration, since there is no risk of airborne contamination.).

No significant additional hazards have been identified above and so it is appropriate to assign the same containment level as that required for the non-GM organism. This is categorised by ACDP as Class III, but derogation is permitted to allow work to proceed under containment level 2. A COSHH form pertaining to P. falciparum cultures has been signed by all relevant personnel.

**Recipient or parental organism**

The function of the inserted parasite gene product will frequently be unknown, or can only be implied through homology with other organisms. Gene knockout experiments targeting genes linked to invasion should result in parasites with lowered invasion potential. Knockouts of potential drug targets (e.g., protein kinases) are aimed at reducing the fitness of the knockout parasites, preferably to produce non-viable or severely functionally-impaired parasites. Allelic replacement of protein kinase genes with those exhibiting hypersensitivity to inhibitors should result in parasites with increased sensitivity to these inhibitors. Growth rates are not expected to be affected, other than negatively, in any of these experiments.

**Host/vector system**

Growth of *Plasmodium falciparum* in human red blood cells.

**Origin & function**

Stable transfection systems for the human malaria parasites have only recently become available, and provide a means to investigate gene function using gene...
modification or ablation ("knockout") 2. Transfection is achieved through electroporation of either red blood cells prior to infection by the parasite, or ring-stage parasites (asexual development cycle in the blood), using in vitro cultured parasites grown in human erythrocytes, with specific plasmid vectors such as pHRPCAT. These vectors contain a drug-selectable marker, usually the dihydrofolate resistance gene (DHFR) from pyrimethamine-resistant strains of either P. falciparum or Toxoplasma gondii, for selection with pyrimethamine, or the human DHFR for selection with the antifolate drug WR99210 3. We will also use plasmids based on the pHHT-TK vector 4, which allows negative selection using gancyclovir.

Transient transfection (without permanent modification of the parasite;"s genome) will be performed using plasmids encoding reporter genes such as GFP, luciferase or CAT. The mRNA levels of specific genes will be targeted by RNAi.

Plasmodium genes considered for possible GM work:

* Protein kinases (a preliminary examination of the PlasmoDB database indicated the presence of approximately 60 genes of this family in the parasite's genome, any of which can be of interest in the context of our work).
* Cyclins (pfcyc-1, -2, -3, -4)
* Apical complex proteins (esp. pFRH1, -2A, -2B, -3, and -4)

Evaluation of foreseeable effects

Any environmental risk is more likely due to the organism itself rather than the genetic modification. Because we will not be using mosquitoes, the release of the parasite in to the environment is exceedingly unlikely.

The function of the inserted parasite gene product will frequently be unknown, or can only be implied through homology with other organisms. Gene knockout experiments targeting genes linked to invasion should result in parasites with lowered invasion potential. Knockouts of potential drug targets (eg protein kinases) are aimed at reducing the fitness of the knockout parasites, preferably to produce non-viable or severely functionally-impaired parasites. Allelic replacement of protein kinase genes with those exhibiting hypersensitivity to inhibitors should result in parasites with increased sensitivity to these inhibitors. Growth rates are not expected to be affected, other than negatively, in any of these experiments. For all new transgenic strains, growth rates will be checked as part of phenotypic characterisation.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Similar containment requirements are for unmodified P. falciparum. As for unmodified P. falciparum, derogation from various aspects of Level 3 containment is appropriate. The reasons for derogation relate to the fact that infection by aerosol or ingestion does not occur, and spread of the disease requires the appropriate vector species of mosquitoes, which are absent in the area where the work will occur.

We request derogation from standard level three containment on the three points detailed below. Plasmodium cannot be transmitted by aerosol. The normal route of transmission is by mosquito bite. In laboratory conditions, the only means of infection is by an accidental puncture wound, for example with a contaminated syringe needle. Also, plasmodium is exceptionally fragile. To survive outside its host species (humans and mosquitoes), it must be kept in complex media. Plasmodium dies instantly if placed in water and is also killed by drying.

1. Negative pressure relative to the pressure of immediate surrounds. Derogation requested. Plasmodium transmission by aerosol does not occur.
2. Extract and input air from the laboratory should be HEPA filtered. Derogation requested. Plasmodium transmission by aerosol does not occur.
3. Protective footwear. Derogation requested for footwear. The risk of live/infectious parasites escaping to the environment in this way is nil as they cannot survive outside the host in the environment - not necessary as this requirement is is only where and to the extent the risk assessment shows it to be required.
4. Autoclave required in the laboratory suite.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid and liquid waste is inactivated using HibiTane prior to disposal. Solid waste for autoclaving will be double-bagged and transported to the autoclave room in a plastic

02/03/2022
The culture room is kept locked and access is restricted to trained personnel. Written training and culture records are maintained. The sensitivity of new transgenic strains to killing by hibitane will be tested.

We feel this is a good and well thought out risk assessment. From an original discussion of the proposal, the committee raised a variety of questions, all of which have been answered to our satisfaction, by the principle investigators. In particular, we feel that the areas of derogation from level 3 are appropriate because of the extremely low risk of spread of plasmodium into the wider community and environment. We believe the only significant risk is to the actual individuals involved in the project where infection as a result of a puncture wound could theoretically occur. The risk of a puncture wound occurring is minimised by avoiding the use of sharps in handling transgenic plasmodium.

### Purposes of the contained use

To overexpress membrane proteins of interest in sufficient quantities as to provide the necessary material for subsequent purification and crystallisation experiments.

### Recipient or parental organism

CHO, BHK cells

### Host/vector system

Semliki Forest Virus (SFV)

### Origin & function

Receptors (in particular G-protein coupled receptors (GPCR), ion channels (both voltage - and ligand-gated) and transporters from the human, rat, mouse Drosophila, C. elegans, yeast and higher plant genomes.

### Evaluation of foreseeable effects

The consequence of escape to the operator is low: If the worker is exposed to virus or virus infected cells, the likelihood of disease is very low. Any gene expression that does occur would be restricted in its duration and limited to those cells that have been infected. The only potential hazard associated with this possibility depends upon whether or not the transgene is toxic. The genes that we intend to express, even though some maybe from organisms that are non-human are non-toxic. As 'live' virus can, theoretically, be produced by RNA recombination events, there exists a very small possibility that a user could become infected with replication-competent virus. This would result in mild disease symptoms before the immune system restores the person to full health. Given that the major carrier of SFV is the mosquito, infections with SFV arising from natural sources in the UK are infrequent. This means that the possibility of generating replication-competent virus within an SFV-infected human through RNA recombination events, between wild-type and recombinant RNAs, are next to zero. The possibility of an infected operator infecting other people is also very low.

The consequence of escape to the environment is low: If virus was to be removed from the lab (e.g. for shipment or transfer to another lab), it would be the inactive form of the virus that would be sent. Activation of the virus with a-chymotrypsin will always occur in a class II hood, prior to infection of the mammalian cells. Even if the virus escaped by accidental damage to its container during transit, it would remain non-infectious.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Cell suspensions infected with recombinant SFV will be grown in a purpose built incubator for up to 48 hours, during which time expression of the transgene will occur. This is an absolute requirement as optimal gene expression usually occurs at temperatures between 30-40C. The bio-reactors will be autoclaved after they have been used. Following the period of gene expression, the cells will be harvested by centrifugation in a stand-alone centrifuge. The cell suspension will be poured into sealed containers, which will be autoclaved after use.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated tips and tubes will be placed in autoclave bags situated within a metal bin. The bin has a metal lid, and the whole bin will be replaced into the autoclave without removing the bag from it. Centrifuge pots and bioreactors will be autoclaved directly after use.

**Is an emergency plan required according to regulation 20?**

N

**If yes, tick to confirm that it is attached to this form**

N
This application proposes to use an attenuated Semliki Forest Virus Vector to overexpress a variety of proteins. Since SFV is a category 2 pathogen a full RA and notification to HSE is required. The vector system is an off-the-shelf one that utilises defective strains of the virus. Live virus should not be produced. In the unlikely event of live virus being generated by RNA recombination, a mild and short lived human infection might be produced. The committee were satisfied that the probability of this occurring was low and that the consequences unlikely to be serious. The recommendation of the committee was that the application be approved and forwarded to HSE.

### Project Additional Information

#### Purposes of the contained use

The purpose of these experiments is to drive high level expression in cellular populations to determine the physiological role of these proteins in either insulin signalling or regulated membrane trafficking. These are the two main areas of research activity in this lab.

We seek to use Adenovirus as it is an established method for high efficiency infection of adipocytes in culture (which cannot be achieved by other means), and because such high levels of expression can be reached, it offers advantages for other cellular systems over more standard transfection approaches.

#### Recipient or parental organism

- Murine 3T3-L1 adipocytes, Chinese Hamster Ovary cells, Rat pheochromocytoma cells (PC12 cells), HeLa cells.
- Rat L6 muscle cells, Human Endothelial Artery cells (commercial - not primary isolated cells) and similar cells.

All cells will be purchased from commercial suppliers.

#### Host/vector system

Serotype 5 replication-deficient/E1-deleted adenoviruses

The adenoviral vectors will be purchased from commercial suppliers of these (Invitrogen).

Intended function is to use these viruses to delivery foreign genes into cells. These genes include components of membrane trafficking pathways (syntaxins, components of the so-called exocyst complex (sec6, sec8, sec10 and sec15), cysteine string proteins, domains of trafficking proteins (such as Hrs domains, ear domains of adaptins) and Arf protein effectors. In addition, we will express some components of signalling cascades which impinge on membrane traffic, specifically IKK kinase isoforms alpha and beta, protein kinase B and dominant negative mutants of protein kinase B.

#### Origin & function

The viral vectors are replication deficient, and cannot replicate in the cell lines to be used. Infection of humans is highly unlikely to result in replication as the viruses are E1 deficient.

The consequences of escape to the operator are mild. If the worker is exposed to virus or viral infected cells, the likelihood of disease is very low. Any gene expression which may occur will be restricted to the infected cells and its duration of expression would be short. The only potential hazard could be if the transgene is toxic.

The consequences of escape to the environment are minimal, as the proteins being expressed using these viral vectors are non-toxic or pathogenic and there is no potential for any of the defective isolates recombining with wild type adenovirus present in the human population.

#### Evaluation of foreseeable effects

The consequences of escape to the operator are mild. If the worker is exposed to virus or viral infected cells, the likelihood of disease is very low. Any gene expression which may occur will be restricted to the infected cells and its duration of expression would be short. The only potential hazard could be if the transgene is toxic.

The consequences of escape to the environment are minimal, as the proteins being expressed using these viral vectors are non-toxic or pathogenic and there is no potential for any of the defective isolates recombining with wild type adenovirus present in the human population.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
All replication of viruses will be performed under level 2 containment. All infections of cells for experimental analysis will be performed in level 2 facilities. Once infection is completed, media containing viruses will be removed from cells, the cells will be washed and at that stage manipulations will involve washing in different buffers, stimulation of cells with insulin or other agonists, treatments with inhibitors etc. These require incubations in defined buffers on a hot-plate or on ice, depending on the experiment, and cannot be performed in level 2 hoods. We will therefore carry them out with the derogations from level 2 detailed below. Subsequent disruption (eg homogenisation of lysis) will, however, be performed in level 2 hoods to minimise any risk from aerosols. Subsequent fractionation of homogenates or lysates will be carried out with the derogations detailed below.

It must be emphasised that all cell lines proposed for these experiments do not support replication of the infectious virus.

Derogations from level 2 for manipulation of cells and subsequent fractionation of homogenates or lysates: Numbers refer to Part II, Table 1a, pp 80-82.

5. Negative pressure relative to surroundings: Not required by RA.
7. Microbiological Safety Cabinet. Not required by RA for these procedures.
9. Access to authorised personnel. Work to be carried out, and stocks to be kept in room with restricted access to authorised personnel. No public access to labs within the building.
10. Specific measures to control aerosols. Not required for these handling procedures. Required for cell disruption (to be carried out in level 2 hood).
14. Efficient control of disease vectors. Not required as adenovirus is not spread by vectors. Defective virus used for GMM not infectious to rodents.
15. Specific disinfection procedures in place. Specific procedures not required by RA.

Written records of Staff Training. All workers covered by COSSH and must be adequately trained and complete COSSH records, all GM workers registered locally with GMSC. Specific records not required.

Media derived from cells (HEK293 cells) producing virus will be immediately mixed with strong bleaching agents (such as chloros) prior to disposal. Media from cells after infection (test cell lines which do not support viral replication) will likewise be treated with bleach then disposed of in designated sink/drain area.

All contaminated plasticware will be rinsed in chloros prior to autoclaving and disposal.
All contaminated pipettes will be autoclaved.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Following prior consultation the GM Safety Committee (Assessment Subcommittee) met on 06/12/01 to consider this proposal. The subcommittee was satisfied that the proposal meets the safety criteria for a class 2 project.

Streptococcus pneumoniae
Neisseria meningitidis
Staphylococcus aureus

Host/vector system
Introduction of linear DNA generated by polymerase chain reaction (PCR)
Transposon Tn917 for gene inactivation
Plasmid pMTL23 for gene inactivation in Neisseria

Purposes of the contained use
Construction of gene detection mutants or gene replacement mutants. Analysis of phenotype of altered mutants in invitro and in vivo (animal) systems.
Modified genes from the pathogens including virulence factors such as toxins, surface proteins and signalling molecules.

**Origin & function**

All the organisms used are carried as commensals in the normal human population. All genetic alterations involve the removal of genes or protein function such that the GMO will be no more harmful to people or the environment than the parental organism. In most cases the risk will decrease in the GMO due to the genetic modification partially disabling the organism. Antibiotic resistance markers will only be used if they are associated with the normally occurring population.

**Evaluation of foreseeable effects**

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

none

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GMO Liquid cultures (volume up to 100ml) will be autoclaved. Following autoclaving cultures will be sterile. Other material (equipment etc) will be sterilized by disinfection. Animals infected with GMOs are incinerated. No GMO will be released into the environment.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

USE OF ADENOVIRUSES (SEROTYPE 5 REPLICATION-DEFICIENT/E1-DELETED ADENOVIRUSES) TO DELIVER FOREIGN GENES INTO CELLS

The purpose of these experiments is to drive high level expression in cellular populations to determine the physiological role of these proteins in cell signalling. This is the main area of research activity in this lab.

We seek to use Adenovirus as it is an established method for high efficiency infection of various cells in culture, in particular, cardiac myocytes, human vascular endothelial cells, and vascular smooth muscle cells which cannot be achieved by other means. Because such high levels of expression can be reached, this offers many advantages for analysing these various cellular systems over more standard transfection approaches.

Recipient or parental organism

Murine 3T3-L1 adipocytes, murine F442A adipocytes, Chinese Hamster Ovary cells, rat cardiac myocytes (primary isolates), human arterial endothelial cells (commercial - not primary isolated cells), monkey kidney cells (COS1 and COS7), Rat1 fibroblasts, human umbilical vein endothelial cells, human pulmonary artery smooth muscle cells (commercial).

All cells apart from the rat cardiac myocytes will be purchased from commercial suppliers.

Host/vector system

Serotype 5 replication-deficient/E1-deleted adenoviruses - see risk assessment.

Origin & function

The adenoviral vectors will be purchased from commercial suppliers of these (Invitrogen)
Intended function is to use these viruses to deliver foreign genes into cells. These genes include the following G-protein-coupled receptors:

Human: EDG1, EDG2 and EDG3 lipid receptors. A1, A2A and A3 adenosine receptors.

AND catalytically inactive forms of all the above AND other forms engineered to have disruptions in intracellular targeting and phosphorylation.

Also Green Fluorescent Protein (GFP) and receptor-GFP chimeras.

Evaluation of foreseeable effects

The viral vectors are replication deficient, and cannot replicate in the cell lines to be used. Infection of humans is highly unlikely to result in replication as the viruses are E1-deficient.

The consequences of escape to the operator are mild. If the worker is exposed to virus or viral infection cells, the likelihood of disease is very low. Any gene expression which may occur will be restricted to the infected cells and its duration of expression would be short. The only potential hazard could be if the transgene is toxic. Further details are in the enclosed risk assessment.

The consequences of escape to the environment are minimal, as the proteins being expressed using these viral vectors are non-toxic or pathogenic and there is no potential for any of the defective isolates recombining the wild type adenovirus present in the human population.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

Date Project Ceased: 02/03/2022
The purpose of these experiments is to drive high level expression in cellular populations to determine the physiological role of these proteins in cell signalling. This is the main area of research activity in this lab.

We seek to use Adenovirus as it is an established method for high efficiency infection of various cells in culture, in particular, cardiac myocytes, human vascular endothelial cells, and vascular smooth muscle cells which cannot be achieved by other means. Because such high levels of expression can be reached, this offers many advantages for analysing these various cellular systems over more standard transfection approaches.

Recipient or parental organism

Murine 3T3-L1 adipocytes, murine F442A adipocytes, Chinese Hamster Ovary cells, Rat pheochromocytoma cells (PC12 cells), HeLa cells, rat cardiac myocytes (primary isolates).

Rat L6 muscle cells, Human Endothelial Artery cells (commercial - not primary isolated cells) and similar cells. Monkey kidney cells (COS1 and COS7), Rat1 fibroblasts, SK-N-SH neuroblastoma (human), HUVEC human umbilical cord endothelial cells, human pulmonary artery smooth muscle cells (commercial)

All cells apart from the rat cardiac myocytes will be purchased from commercial suppliers.

Host/vector system

Serotype 5 replication-deficient/E1-deleted adenoviruses - see risk assessment.

Origin & function

The adenoviral vectors will be purchased from commercial suppliers of these (Invitrogen). Intended function is to use these viruses to delivery foreign genes into cells.

These genes include the following PDE4s

Human: 4A1, 4A4, 4A10, TM3, 2el, 4B1, 4B3, 4B4, 4C1, 4C2, 4C3, 4D1, 4D2, 4D3, 4D4, 4D5.

Rat: 4A8, 4A5.

Human: EDG1, EDG3, and A2A adenosine receptors.

AND catalytically inactive forms of all the above AND other forms engineered to have disruptions in intracellular targeting and phosphorylation.
Also green fluorescent protein (GFP) PDE4-GFP and receptor-GFP chimeras.

Evaluation of foreseeable effects

The viral vectors are replication deficient and cannot replicate in the cell lines to be used. Infection of humans is highly unlikely to result in replication as the viruses are E1-deficient.

The consequences of escape to the operator are mild. If the worker is exposed to virus or viral infected cells, the likelihood of disease is very low. **Project Ref** 37/02.5

**Date Ackn'd** 07/08/2002

**CU2 Project Title** GENETIC MODIFICATION OF HUMAN MALARIA PARASITES FOR FUNCTIONAL GENETIC ANALYSES

**Class** Class 3

**CultureVolClass2** 200ml

**Consent Granted** yes

**Non-GMM**

**Project notified under transitional arrangements** N

**Withdrawn** N

**Tick if notifying a connected programme of work** N
**Project Additional Information**

**Purposes of the contained use**

**Recipient or parental organism**

Plasmodium falciparum - ACDP Class 111 (derogated to Class 11)
Plasmodium vivax - ACDP Class 11

**Host/vector system**

Plasmid pHRPCAT is modified pBluescript (Strategene) with DHFR-TS gene as selectable marker flanked 5’ and 3’ by regions of the gene of interest. This allows recombination of the selectable marker gene into the gene of interest, thereby disrupting it and ablating the function of the protein encoded.

E. coli XL1-Blue MRF’ is host for pBluescript

Human malaria parasites grow in human erythrocytes in vitro and infect mosquitoes of genus Anopheles

**Origin & function**

Gene disruption (knockout) of parasite genes thought to be important in mosquito infection processes. Genes are those known to be expressed in mosquito life-cycle stages, or in transmission stages (gametocytes), or which have been identified by linkage analysis studies. Allelic replacement of these genes from different cloned lines of P. falciparum or from P. vivax.

Investigation of novel potential anti-material drug targets, including protein kinases, cyclins, DNA polymerases, by gene disruption and replacement of wild-type with alternative alleles (naturally occurring).

Localisation of parasites or proteins using green fluorescent protein-tags or purification of epitope-tagged parasite proteins.

Inserted material

DHFR-TS selectable marker is from P. falciparum or Toxoplasma gondii (for selection with pyrimethamine)

DHFR selectable marker is from Homo sapiens (for selection with WR99210).

Green Fluorescent Protein gene is from Aequorea victoria (jellyfish).

Epitope tags are synthetic.

**Evaluation of foreseeable effects**

Genetically transformed parasites will be resistant to the antifolate drug pyrimethamine or to the drug WR99210.

GMM is unlikely to be more harmful to humans or the environment than the parental organism.

It is more likely that the GMM will be of reduced fitness (lowered transmission success to mosquitoes, increased susceptibility to inhibitory compounds, slower growth rates, reduced or non-viability) than of increased fitness relative to the parental parasite.

Transmission of antifolate resistance genes to other species is unlikely due to the strict containment measures applied for this pathogen.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

The GM parasites will be used to infect mosquitoes. These are not GM mosquitoes. Infected mosquitoes are maintained in a secure insectary at a containment level appropriate to the pathogenic nature of the parasites. Access to the insectary is through a sealed anteroom and all doors have rubber seals and brushes to prevent
mosquitoes escaping from the insectary area. Within the inner insectary, mosquitoes are kept inside secure escape-proof containers. A copy of the mosquito protocols (for COSHH purposes) is attached which gives details of safety measures in place to ensure no mosquito leaves the secure insectary alive.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Plasmodium falciparum has been specifically exempted from full ACDP Class 11 containment. This formal derogation has been applied because the risk of airborne transmission is deemed to be low.

For in vitro culture of GM P. falciparum, the following derogation from full Class 3 containment are requested.
1. The laboratory is not sealable for fumigation
2. Entry to lab via airlock is not required
3. There is no negative pressure relative to the immediate surroundings
4. Extract and input air are not HEPA filtered
5. Autoclave is not required in the laboratory suite
6. Inactivation of GMMs in effluent from handwashing sinks and showers and similar effluents is not required

Justification: Infection of human or vector is not via aerosol or skin contact but requires direct blood stream (human) or stomach (ingestion by mosquito) contact. Parasites cannot survive desiccation and there is no air-borne infection route. Parasites are inactivated by bleach, detergent or disinfectant.

For work with GM P. falciparum parasite-infected mosquitoes the following derogation from full Class 3 containment are requested (the insect facility is classified as an animal facility)
1. The laboratory is not sealable for fumigation
2. Entry to lab via airlock is not required.
3. There is no negative pressure relative to the immediate surroundings
4. Extract and input air are not HEPA filtered
5. Autoclave is not required in the laboratory suite
6. Inactivation of GMMs in effluent from handwashing sinks and showers and similar effluents is not required
7. Incinerator for disposal of animal carcasses is not required (mosquitoes)

Justification: A 14-day developmental period is required within the mosquito post-infection before parasites are capable of infecting humans. At this point direct inoculation of the parasites into the human blood is required, through the bite of the insect. There is no air-borne route of infection. There is no aerosol formation. Parasites are inactivated by bleach, detergent, disinfectant, or desiccation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste management suitable for ACDP Class 111 (derogated) will be applied.
Solid waste, e.g. contaminated paper towels, plastic tissue culture flasks and pipettes, microscope slides, infected mosquitoes:
Autoclaved prior to disposal.

Liquid waste e.g. spent culture medium, waste culture: Inactivated by bleach or an appropriate detergent or disinfectant.
Parasites are lysed (killed) by water or mild detergent. Infected mosquitoes are killed by deep freezing at -20 degree C for 24 hours, or by exposure to chloroform vapour and ethanol immersion. The former process kills both parasite and mosquito. The latter kills only the mosquito, allowing viable parasites to be examined. The parasites are subsequently killed by detergent lysis.

All mosquito waste contaminated with GM parasite material is autoclaved prior to disposal.

Tick to confirm that you have attached a risk assessment to this form Y
This proposal has been carefully evaluated. We sought advice from HSE as to the class under which the proposal would be submitted and were advised that although many of the activities could be derogated to Cat 2 containment, the nature of the GMO indicated that the proposal should be submitted as Class 3. The GMSC is satisfied that the containment proposed can be achieved with the facilities available.

Date of Significant Change

Project Additional Information
## Purposes of the contained use

The purpose of these experiments is to drive high level expression in cellular population to determine the physiological role of these proteins in either cell signalling cascades or either cell cycle and the subsequent effect on protein synthesis and transcription by RNA polymerase (pol) and pol III. These are the main areas of research activity in the lab.

We seek to use adenovirus as it is an established method for high efficiency infection of fibroblast cells and cardiomyocytes in culture (which cannot be achieved by other means). Because such high levels of expression can be reached, it offers advantages for cellular systems over more standard transfection approaches.

## Recipient or parental organism

Murine Balb/c 3T3 fibroblasts, Chinese Hamster Ovary cells, Human embryonic kidney 293 cells, HeLa cells and similar cells.

All of these cells will be purchased from commercial suppliers.

In addition, primary cultures of neonatal rat cardiac myocytes will also be utilised for our studies.

## Host/vector system

Serotype 5 replication-deficient/E1-deleted adenoviruses - see risk assessment.

## Origin & function

The adenoviral vectors will be purchased from commercial suppliers of these (Invitrogen)

Intended function is to use these viruses to deliver foreign genes into cells. These genes include components of signalling cascades which impinge on RNA polymerase III transcription such as CKII, mitogen-activated protein kinase (ERK) and dominant negative mutants of this as well as protein kinase B and dominant negative mutants of protein kinase B. In addition, RNA pol III is regulated during the cell cycle and genes that encode components of the cell cycle machinery will also be delivered into host cells including retinoblastoma protein RB, as well as cell cycle inhibitory proteins (p27kip1 and p16). In addition, we will express some components of the basal RNA pol I and pol III transcriptional machineries such as the transcription factors UBF, TFIIIB and TFIIIC. In addition, p53 has been found to regulate pol I and pol III and wild-type and inactive constructs of p53 can also be delivered to host cells.

## Evaluation of foreseeable effects

The viral vectors are replication deficient, and cannot replicate in the cell lines to be used. Infection of humans is highly unlikely to result in replication as the viruses are E1-deficient.

The consequences of escape to the operator are mild. If the worker is exposed to virus or viral infected cells, the likelihood of disease is very low. Any gene expression which may occur will be restricted to the infected cells and its duration of expression would be short. The only potential hazard could be if the transgene is toxic. Further details are in the enclosed risk assessment.

The consequences of escape to the environment are minimal, as the proteins being expressed using these viral vectors are neither non-toxic nor pathogenic and there is no potential for any of the defective isolates recombining with wild type adenovirus present in the human population.

## Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.
will, however, be performed in level 2 hoods to minimise any risk from aerosols. Subsequent fractionation of homogenates or lysates will be carried out with the derogations detailed below. However, it must be emphasised that apart from the HEK293 cells that will be used for amplification of adenovirus preparations, none of the other cell lines proposed for these experiments support replication of the infectious virus.

Derogations from level 2 for manipulation of cells and subsequent fractionation of homogenates or lysates: numbers refer to Part II, Table 1a, pp80-82.

5. Negative pressure relative to surroundings. Not required by RA.
7. Microbiological safety cabinet. Not required by RA for these procedures.
10. Specific measures to control aerosols. Not required for these handling procedures. Required for cell disruption (to be carried out in level 2 hood).
14. Efficient control of disease vectors. Not required as adenovirus is not spread by vectors. Defective virus used for GMM not infectious to rodents.
15. Specific disinfection procedures in place. Specific procedures not required by Ra.
21. Written records of staff training. All workers covered by COSHH and must be adequately trained and complete COSSH records. All GM workers registered locally with GMSC. Specific records not required.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Media derived from cells (HEK293 cells) producing virus will be immediately mixed with strong bleaching agents (such as chloros) prior to disposal. Media from cells after infection (test cell lines which do not support viral replication) will likewise be treated with bleach then disposed of in designated sink/drain area.

All contaminated plasticware will be rinsed in chloros prior to autoclaving and disposal.
All contaminated pipettes will be autoclaved.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

This project is very similar to three previous projects, 37/02.1, 37/02.3 and 37/02.5 all of which involve the use of the same defective adenovirus vector. The GMSC did not consider that the proposed sequences to be clones offered any greater risk that the previous three projects, all of which were approved for submission to HSE.

**Large Scale Activities**

**Human Clinical Applications**
Genetic and phenotypic studies of enteropathogenic (EPEC) enterohaemorrhagic Escherichia coli EHEC), Salmonella enterica, Citrobacter rodentium and other enteropathogenic bacteria. Genetic and phenotypic studies of Clostridium.

The work involves dissecting the molecular basis of virulence of the listed enteric pathogens by targeted mutation of bacterial genes and analysis of wild-type, mutant and trans-complemented strains in vitro and in vivo. The cellular localisation and expression of proteins is also determined using green fluorescent-tagged and epitope-tagged constructs.

The GMOs are likely to be less virulent or of comparable virulence compared with the parent strain. Deletion of genes involved with virulence or the regulation of virulence generally leads to a reduction in pathogenicity. The complementation of genes on plasmids or by chromosomal exchange using alternative promoters may lead to higher copy number of compared with the parental strain but, in isolation, this step is unlikely to increase pathogenicity. Furthermore, the stringent disposal and handling of all material should effectively limit any chance of infection.

For EHEC, pACYC184 and 177: medium copy vectors used for promoter::reporter (GFP/lacZ) fusions to determine gene expression. Also used to generate complements of specific deletions. pUC1S: used to carry/express gene::GFP translational fusion constructs. p18307: low copy number, temperature sensitive vector used to create specific gene deletions using allelic exchange. pKD201: expresses lambda red recombinase enzyme, used to create specific gene disruptions For C.difficile, ClosTron or alternative transconjugative plasmid will be used.
Inserted material: the majority of material cloned and expressed on the plasmids is derived from the host (pathogen) strain itself. Typically, these are promoter regions of genes or regulators that have been deleted in order to study their function. The fact that the genes are from sequenced strains allows excellent bioinformatic based analyses before any cloning takes place which informs the researcher of the likely function of the target gene. Promoter fusions drive known and well characterised reporter genes.

Some exogeneous material is used: green fluorescent protein is from Aequorea victoria Ocell's fish) and epitope tags are synthetic in origin.

**Project Additional Information**

Purposes of the contained use

The work involves the investigation of metabolism of T. vaginalis in order to identify novel biochemical pathways that might be suitable for therapeutic intervention. The essentiality of potential drug targets will be analysed by gene knockout (either by gene deletion or RNAi). The cellular localisation and expression of proteins will also be determined using epitope-tagged constructs.
Recipient or parental organism
The parental organism is Trichomonas vaginalis, which is listed in ACDP hazard group 2. The parasite infects the human urogenital tract and is sexually transmitted — there are no other known routes of transmission.

Host/vector system
Reticulation of T. vaginalis will be derived from the non-mobilisable E. coli vectors. They will contain well characterized T. vaginalis promoters such as the ap65-1 or SCS promoters to direct expression of homologous and heterologous genes. Vectors for gene deletion will contain a selectable marker gene flanked by sequences homologous to sequences of the target gene. RNAi methods will use a tetracycline inducible system.

Origin & function
Inserted material: the majority of material cloned and expressed on the plasmids is derived from T. vaginalis. Typically, these are genes that will have been deleted in order to study their function. The fact that the genes are from the genome strain of the parasite (for which a draft genome is available) allows excellent bioinformatic based analyses before any cloning takes place, which informs the researcher of the likely function of the target gene. Promoter fusions drive known and well characterised reporter genes (such as Green Fluorescent Protein and its derivatives) and epitope tags of synthetic origin.

Evaluation of foreseeable effects
Trichomonas vaginalis is listed in ACDP hazard group 2. The parasite infects the human urogenital tract and is sexually transmitted — there are no other known routes of transmission. Infections are asymptomatic to mild (vaginitis or urethritis) and are successfully treated with the nitroimidazole drugs, metronidazole and tinidazole. The parasite has no cyst stage and the organism has no capacity for survival in the environment. Humans are its only natural host. The genetic manipulations in this study are not envisioned to lead to over-expression of proteins or other metabolites that are harmful to humans. None of the genes in this study are thought to encode proteins that are sufficient to alter the pathogenic properties of T. vaginalis with respect to host range or tissue tropism. The genetic manipulations planned in this study are intended to lead to either no change in virulence or a loss of virulence. The antibiotic resistance genes used to select genetically modified parasites (such as puromycin acetyl transferase (PAC) in combination with puromycin) do not confer resistance to drugs used in the treatment of T. vaginalis infections (metronidazole or tinidazole). Genetically modified T. vaginalis strains will be propagated in-vitro as trophozoites in complex defined medium. They are not able to survive in the environment. Sexual exchange of genetic information has not been reported for this organism. Genetic exchange between T. vaginalis and other microorganisms has not been reported. It is envisioned that the genetically modified T. vaginalis strains will be either less hazardous or about the same as the parental organism (ACDP Hazard group 2). The containment level required is ACDP laboratory containment level 2. No additional measures above ACDP laboratory containment level 2 are required.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Project Ref 37/10.1

Date Ackn'd 22/02/2010

Date Project Ceased

CU2 Project Title

Molecular biology of Toxoplasma gondii. Systematic analysis of essential parasite genes linked to invasion of the host cell by Toxoplasma gondii

Class 2

Consent Granted

Project notified under transitional arrangements N

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

22/02/2010
**Project Additional Information**

**Purposes of the contained use**

Toxoplasma gondii is an obligate intracellular parasite that can invade basically every warm blooded, nucleated cell. The aim of this project is to study the formation, maintenance and regulation of the complex machinery the parasite has evolved in order to actively invade its host cell. To do so, forward and reverse genetic approaches will be combined to identify and characterise factors believed to play a critical role in host cell invasion. We have previously demonstrated that parasites mutated in some of these factors are unable to invade the host and can be used as experimental live vaccines. Furthermore this study will allow the validation of potential drug targets.

**Recipient or parental organism**

Toxoplasma gondii is capable of infecting a wide range of warm blooded animals, including man, cattle and rodents. Transmission is through ingestion. Symptoms are normally mild to asymptomatic although congenital transmission can be serious. Infection with the RH strain (virulent) may be serious if left untreated.

Toxoplasma gondii is classed as ACDP hazard group 2. Both non-genetically modified parasites and genetically modified parasites are handled in accordance with ACDP guidelines. It is considered unlikely that genetically modified parasites T. gondii will cause harm to humans or the environment above that inherent in the pathogenicity of the wild type parasites themselves.

**Host/vector system**

The host for genetic manipulation will be T. gondii. Genetic manipulation of the parasite will exclusively be performed in cell culture, propagating the parasite in a variety of mammalian cell lines. Drug resistance genes that will be used to generate stable transfected parasites include:

- DHFR (confers resistance to pyrimethamine) (see: Donal and Roos (1993), PNAS 15;90(24):11703-7)
- HXGPRT (positive selection under mycophenolic acid and negative selection under 6-thioxanthine) (Donald and Roos (1993), Molec.Biochem.Parasitol. 91, 295-305) This system has the benefit of not introducing any resistance genes into the T. gondii.
- Green fluorescent protein and resistance genes of prokaryotic origin (Ble, CAT)

**Origin & function**

Selection methods for gene knockout studies and stable transfection and gene expression in T. gondii require plasmid vectors that can be amplified in bacteria (Escherichia coli) and are based on pBluescript. In addition vectors contain selectable markers as described above for stable transfection of the parasite. The intended applications are to either remove or overexpress a gene of interest (including mutants of the respective gene) in T. gondii.

DNA encoding genes of the parasites (and mutated versions) and in some instances heterologous genes from other organisms (e.g. Plasmodium may be expressed in the parasites in order to characterise the function of the respective gene during the asexual life cycle of the parasite.

It is the aim to identify genes required for host cell invasion. To do so, libraries of parasite mutants will be established by two complementary strategies:

1) Transfection of an inducible overexpression library (normalised cDNA fused to the ddFKBP-regulation system (see Herm-Gotz et al., 2007). In case parasites will be transfected in a medium throughput format and subsequently standard screening procedures will be applied to identify loss and gain of function mutants.

2) Random integration mutagenesis. It is possible to generate parasite mutants by transfection with linear DNA fragments, containing a selectable marker (see above). These fragments will integrate into the genome of the parasite at random positions at high frequency. Thus it is possible to generate random parasite mutants that can subsequently be screened for certain phenotypes (for and example see: Meissner et al., 2002)

For the reverse genetic screen, the focus will be on homologous of factors involved in vesicular traffic, like RabGTPases, Dynamins, Motor proteins and Syntaxins. All these candidates will be expressed under control of an inducible system as trans-dominant mutants (see above for an example of the respective plasmids employed). (see: Agop-Nersesian et al., 2009 or Breinich et al., 2009)

**Evaluation of foreseeable effects**

The overall aim of this project is to perform a systematic, functional analysis of important parasite genes linked to host cell invasion. Therefore a combination of
bioinformatics, forward and reverse genetics will be employed to:
- Generate and analyse parasite mutants unable to invade the host cell
- Establish and open access database of characterised genes of interest (GOIs) as a community resource
- Screen for chemical inhibitors (drug development) for the most promising GOIs

This should facilitate drug target identification, validation and future design.

The main interest of this project is the mechanisms involved in host cell invasion by Toxoplasma gondii, with a special focus on the biogenesis and maintenance of specialised organelles linked to invasion. In the past we isolated and characterised several mutants that were deficient in host cell invasion (Meissner et al., 2002; Kessler et al., 2008, Agop-Nersesian et al., 2009, Breinich et al., Current Biology 2009). All of these mutants have reduced virulence and are unable to grow, when the respective protein is depleted or expressed as a trans-dominant mutant. Genes to be analysed in Toxoplasma include:
- mutants obtained from forward genetic screens
- trafficking factors, such as Rab-proteins, dynamins, motor proteins, kinases and syntaxins.

Foreseeable effects of gene disruption or overexpression of a GOI

(i) Considerations relating to whether the product of the inserted gene has a biological activity

Three types of genetic modification are envisaged.

(a) Gene disruption.
Generation of mutant parasites by removing a GOI via homologous recombination (exchange of the GOI for a selectable marker by homologous recombination). It is considered likely that gene disruptions will be detrimental to parasite survival or will have no phenotypic difference from wild type cells. The selectable markers mentioned above will be used (DHFR, HXGPRT; CAT, Ble).

(b) Homologous and heterologous gene expression.
The expression of genes in T. gondii will be achieved after integration of a expression vector into the genome. These experiments are designed to test for cross species complementation (eg. Homologous genes from Plasmodium) and for generation of overexpression phenotypes (to identify genes required for host cell invasion, etc.). Other heterologous genes include reporter genes such as green fluorescent protein (GFP) from the jelly fish Aequorea victoria (including mutants of this protein engineered to give greater fluorescent or a different colour of light emission) and luciferase from the firefly Photinus pyralis (or mutant versions of this gene from this or other organisms).
The heterologous DNAs to be used for transfection of the parasited do not encode a toxin, oncogenic protein, allergen or other protein with a potentially harmful biological activity.
Risk assessment. As access will be restricted to contained handling in a containment level 2 laboratory and expressed genes will be non-toxic, risk levels are kept to a minimum.

(ii) Considerations relating to whether the inserted gene encoded a product that might act alongside the existing characteristics of the recipient micro-organism, so as to endow the GMM with altered pathogenic properties.
It is possible that disruption of genes will alter the pathogenicity of the parasited. It is envisaged that genes modified in this project will lead to either no change in virulence or a loss of virulence. Drug resistance genes of prokaryotic origin, such as Ble or CAT will be used. These drug resistance genes do not confer resistance to drugs commonly used to treat T.gondii, in man or animals. DHFR selection confers resistance to pyrimethamine one of the current drugs used for treatment of T. gondii. Alternatives are available (eg. Sulphadiazine)

(iii) Consideration of the most hazardous GMM to be created
The most hazardous GMM to be generated are pyrimethamine resistant T. gondii (see above). With alternatives to pyrimethamine available (Sulphadiazine) and the unlikeliness of environmental release (see below), the hazard is very low.
Most of the proposed genetic modifications are expected to produce attenuated organisms lacking one or more genes or that express trans-dominant versions of an
essential protein.

(iv) Considerations relating to wether an inserted sequence, that does no give rise to a harmful phenotype in the recipient micro-organism, could give rise to harm as a result of natural gene transfer to another, possibly related, organism. T.gondii can reproduce sexually but this only happens in the domestic cat. Genetic exchange with other organisms has not been reported for T. gondii.

The genetically modified parasited will be contained with ACDP containment level 2 facilities. The chance of escape into the environment is negligible. The details of the appropriate systems of work are held within the appropriate COSHH risk assements and standard operating procedures.

Part 2 Animal work
Genetically modified T. gondii will be grown in mice. The University of G;asgow has an animal facility with ACDP containment level 2 classification. It is not envisaged that genetically modified T. gondii will present any additional environmental hazard risk envisaged in using the genetically modified micro-organisms rather than the parental micro-organisms in genetically modified animals.

GM modified T. gondii may be inoculated into wild type or KO mice (of various backgrounds eg. BALB/c) to analyse their virulence. These animals will be housed in a security monitored home office licensed facility in appropriate surroundings at containment level 2. The risk of these reaching the external environment is negligible. All animal tissue will be incinerated (by the Universiyt appointed contractors) and spillage of body fluids and surfaces that have been in contact with tissue will be treated with Virkon. All animal handling will involve the use of gloves. All workers should have tetanus vaccination up to date. Bites and scratches should be squeezed to allow blood flow, treated with 70% ethanol, dried and covered with an antiseptic plaster. Toxoplasma cannot be transmitted by bites or scratches.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All parasite manipulation will be conducted in accordance with ACDP guidelines. T. gondii will be handled under containment level 2.

1) Are any of the work procedures likely to generate aerosols?
Aerosols are unlikely since most work with the parasite will be performed in a class II hood. Aerosols could be generated if, for example, a tube of T. gondii was dropped during FACS analysis of live cells. However, the volumes of material would be small (1-2ml) and T. gondii infection cannot be spread by aerosols.

2) How will you dispose of waste materials?
Animal waste will be disposed of through an authorised waste disposal company, provided through the Clinical Waste Service. Solid waste is stored in small waste bins within the laboratory. The bins have lids and hold inner liners, which are autoclave bags. When the liners are no more than 3/4 full, they are removed from the bin, loosely sealed with autoclave tape (to allow steam penetration during autoclaving ), labelled with lab number, operator and date and then transported to the autoclave room on a trolley. The bags are logged into the room and autoclaved on the same day that they are delivered. The bags and the logging procedure designates them 'GM', which results in their inclusion on a 'run' on the validated autoclave with recorder. The record is inspected to ensure that the correct temperature has been reached for sufficient time. The record is kept on file by the autoclave room staff. The autoclaved material is disposed of in solid waste by an authorised waste disposal company, provided through the Clinical Waste Service. The routine autoclave regime will be 126°C for 30 min, which has previously been established to produce a 100% kill (British Pharmacopeia 2005, Vol IV, Appendix XVIII A385-A388).

Liquid waste (e.g cultures in flasks or 'spent broth' wherein the cells have been seperated from the culture broth by centrifugation) will be sterilised in the culture flasks the same day by addition of Virkon® to a final concentration of 1% w/v, and left overnight. Virkon-disinfected solutions will be disposed of into the waste water supply. Virkon solutions are stable for up to 7 days (manufacturer's data), and thereafter disinfectant solutions will be discarded (the pink colouration fades). Virkon is a peroxygen compound and disinfection requires a contact period of at least 10 min for 1% w/v solution: see http://www.antechh.com/frameset.html.
Contaminated glassware and centrifugation buckets from cultures will be disinfected by complete submersion in 1% w/v Virkon® overnight (polypropylene and polystyrene centrifugation buckets, steel and glass are not corroded by 1% w/v Virkon). Glassware and buckets will then be rinsed in tap-water and dried.

Small volume spills (up to 100ml) on hard surfaces (floors, work benches, trolleys) will be disinfected by mopping up the spill with absorbent tissue paper and spraying the surface with a 1% w/v Virkon solution or sprinkling the area with powder Virkon and leaving for at least 20 minutes and drying with paper towel to remove any remaining white deposit. Paper towels will then be bagged for disposal as solid waste (above).

Large volume spills (100ml to 0.5l) on hard surfaces (floors, work benches, trolleys): Absorbent granules will be used to cover the spill, if necessary, contained using absorbent booms. Granules and booms will be bagged for disposal as solid waste (above). The contaminated area will then be disinfected by wiping or spraying the surface with a 1% w/v Virkon solution or sprinkling the area with powder Virkon and leaving for at least 20 minutes and drying with paper towel to remove any remaining white deposit. Paper towels will then be bagged for disposal as solid waste.

3) Does your laboratory avoid sharps?
Yes, where possible. However, where it is necessary to use sharps, the laboratory provides Sharps containers and has guidelines for the use and safe disposal after use.

4) Has the disinfectant been validated?
Yes, Virkon kill has been validated in house to kill 100% of the Toxoplasma when used as per manufacturer's instructions (1% weight/volume). When genetically modified organisms are created these will also be tested. This is done by incubation in Virkon at different concentrations for different lengths of time and examination by microscopy. The autoclave has also been validated.

5) Does the nature of the work preclude it being undertaken by any workers who have a serious skin condition?
No. All workers must wear adequate protective clothing, including laboratory coats and disposable gloves, safety glasses,

6) Will workers receive any vaccination?
No vaccinations are currently available for toxoplasmosis

7) Is the recipient micro-organism controlled by DEFRA?
No

ASSIGNMENT OF CONTROL MEASURES
It is believed that the genetically modified T. gondii provide no significant additional risk over and above the wild type parasites. Non-genetically modified T. gondii are handled at Containment level 2. All genetically modified T. gondii, will also be handled in Containment 2 facilities only.

Project Additional Information

Purposes of the contained use
Sub-project 1 - Dr R is investigating how neurons and nerves can be repaired after injury and will use lenti constructs to express marker protein in cells around the injury site and in cells transplanted into the injury site. Proteins potentially involved in regulating nerve regeneration, differentiation and plasticity would also be expressed. Sub-project 2 - Drs C and B are investigating therapeutic avenues for Rett syndrome, a neurodevelopmental disorder and will use lentiviral constructs to deliver wild-type Mecp2 to mice deficient in this gene or cre to reactivate the gene in targeted mice to look for restoration of normal neuronal functioning in a regulated manner.

Recipient or parental organism
Recipients - Mouse, Rat
Parental organisms - transgenes with biological activity will be rodent or human-specific cDNAs

Host/vector system

4th generation lentiviral vector systems based on pLenti and pLentiLox4.0 (pLL4.0) and pLentiLox4.2 (pLL4.2). Three plasmid packaging system (pLP from Invitrogen or pMD series). VSV-G envelope. Can infect all mammalian cells.

Origin & function

The inserted transgenes will compromise full length cDNAs encoding plasticity-related proteins (including Mecp2-e1), neurotrophins (e.g. Ngf, Bdnf, Cntf, Gdnf), and chemorepulsive factors (e.g. semaphorins, ephrins, Slit, Neureilin). Constructs containing cre recombinase will be used in some experiments to reactivate Lox-STOP-inactivated targeted genes. Some constructs will also employ fusions with eGFP and RFP, FLAG and MYC tags, HS4 insulators (chicken-derived), WPRE (encoding non-expressible portion of N-term fragment of WHV-X protein). A variety of nervous system-specific and ubiquitous promoters will be employed to express the transgenes/fusions/markers, including CMV, UbiC, U6, CamKII, PGK, synapsin 1, Tau. All are intended to influence neurite-extension, maturation and mature functioning/plasticity properties of neurons in the central and peripheral nervous system.

Evaluation of foreseeable effects

Risk to experimenter and other co-workers involved in the delivery of lentiviral particles to the experimental animals - there is a small risk that the experimenter and associated lab workers present in the room during the surgery and lentiviral particle delivery phase will be exposed to viral particles via inadvertent or accidental needlestick injury. The viruses cannot survive for more than a few hours in the environment and are easily inactivated by use of standard antiviral reagents and cleaning regimes. If needlestick injury does occur, it could lead to two consequences. Firstly, lentiviral particles will infect cells local to the injury and may provoke inflammatory responses or immune responses to the infected cells. Such responses are likely to be mild and not prolonged. Exposure volumes would be tiny, and infections are unlikely to become established locally or by spreading away from the needlestick injury site. Secondly, integration of the construct may cause mutagenic effects on the genome in infected cells local to the delivery site. The chances of insertional inactivation of a tumour suppressor gene are very low, but finite. If the construct inserts adjacent to cellular oncogene, there is a very low but finite risk of disruption of the normal regulation of the Tumourigenesis, if it did occur, could be of 'mild' consequence, if localised, benign, or succesfully treated, or 'sever' consequence if malignant and untreated. Recombination between natural lentiviruses and constructs in an exposed worker is of negligible likelihood. Virus particles will become inactive within a few hours and no viable virus should remain by 48 hours. No virus shedding is expected from the GM rodents created. There will be no germline integration of lentiviral construct. We have no reason to believe that the GM animals produced by lentiviral infection and/or transplantation of infected exogenous cells will be any more aggressive or likely to bite handlers, or more anxious and prone to escape, than mice and rats not undergoing the infection procedure.

Risk of altering or affecting other conspecifics and other species - the mice and rats used in vivo work are either wild type inbred (or partially outbred) lines with poor ability to compete in the environment, or genetically modified (knockout) mice with low or reduced fitness relative to WT. None of the constructs or their use increases the risk that GMOs or GMMs will escape into the environment or come into contact with non-GM organisms, and there is no reason to believe that escape of GMOs/GMMs would affect the environment in deleterious ways.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Containment of infected animals will be as per the standard GM rodent containment risk assessment used by Biological Services. Essentially, all GM rodents are identified by methods appropriate for the species and records of disposal and experimental use are kept electronically in the unit. All animals are kept in secured, labeled cages with a record card containing the number of animals kept in each cage. If escape from the cages occurs, this can be readily identified and dealt with accordingly. A count of the animals held within the animal unit is carried out routinely on a weekly basis. During animal handling the holding room door is kept closed. A knee high rodent barrier is also fitted to each animal holding room door to contain any animals that may have escaped during husbandry or procedural activities. This barrier can be removed for cleaning but is kept in place at all other times. The layout of the animals unit is such that there are multiple doors separating the animal/procedure rooms from the outside (emergency exits excpeted). Live rodent traps are placed in rooms when working with GM rodents to assist in the recapture of escaped animals. All these measures are more than the minimum appropriate for the planned activities and the nature of the GMOs.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
In survival experiments, viral particles are not expected to survive in infectious form by the time the recipient animals are sacrificed. Where animals die unexpectedly within 48 hours, or in acute application experiments where recipients animals are sacrificed within 48 hours, carcasses will be autoclaved and bedding and absorbent towels treated with Virkon and autoclaved, as is routine for all GM animals. Cages and incubators used to house treated animals within 48 hours of infection will be sprayed with Virkon and/or fumigated after removal and disposal of bedding. Unused aliquots of packaged viral particles will be inactivated using Virkon and autoclaved. Kill is expected to be 100% complete in all these circumstances, so no special monitoring is planned.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

This is a well constructed proposal using the most up-to-date and safest lentiviral vector system. The committee was satisfied that had the project been confined to cell lines, it would clearly have fallen into category 1. The project falls into category 2 solely because of the intention to use live animals and the consequental risk to the experimenter in carrying out injection procedures as defined under SACGM discussion paper 20/11/08

Pectobacterium spp. are phytopathogenic bacteria that cause soft rot, stem rot, bacterial wilt and black leg disease in angiosperm species. The aim of this work is to identify genes that may be involved in iron uptake and susceptibility to protein antibiotics. This work could ultimately lead to better control strategies against this important plant pathogen.

Recipient or parental organism
Pectobacterium spp. are major pathogens of potatoes and other field vegetables causing blackleg, aerial stem rot, and tuber soft rot. P. carotovorum is very common and has an extensive host range, including most fleshy vegetables, whereas P. atrosepticum is associated mostly with potatoes. Tuber soft rot can be caused by either of these bacteria and blackleg is usually caused by P. atrosepticum carried on contaminated seed tubers. Most lots of seed tubers are contaminated to some degree. In contrast, aerial stem rot is usually caused by P. carotovorum contained in infested soil or introduced to the crop by irrigation water. Other sources of bacteria include infected plant debris and contaminated potting media, tools or soil. However, Pectobacterium spp. do not cause disease unless environmental conditions are favourable and amount of bacterial disease that actually develops in a crop is strongly influenced by factors such as soil moisture and temperature.

Host/vector system
The suicide plasmid pMRS101 will be used for the creation of deletion mutants in Pectobacterium spp. This vector is derived from pKNG101 with the addition of the high copy number CoIE1 origin of replication on a NotI fragment to increase plasmid yield and to allow initial manipulations in E. coli DH5α. pKNG101 has a conditional origin of replication requiring the replication factor *pir for propagation and thus is unable to replicate in most Gram-negative bacteria. For complementation we will clone relevant iron uptake related genes into a standard expression vector (pUC, pET or pJexpress) and transform this vector into Pectobacterium strains by electroporation with ampicillin selection.
The origin of the genetic material to be transferred is the host Pectobacterium species. Thus genes or fragments of genes encoding putative proteins involved in iron uptake will be transferred. Typically the encoded protein will be TonB-dependent outer membrane receptors, inner membrane ABC transporters, periplasmic binding proteins or homologues of TonB. The intended function of the transferred material in the deletion mutants is to enable the construction of the deletion mutant by homologous recombination. For plasmid based complementation, the purpose of the genetic material is to allow production of the putative iron uptake protein to complement the loss of function of the deletion mutant.

Evaluation of foreseeable effects

Since the recipient organisms are UK field isolates the capacity of the GMM to cause disease, given favourable environmental conditions is high. However, this would not be expected to be increased over and above the parent strain as virulence would not be expected to be increased. Indeed, since the acquisition of iron is a critical factor in the bacterial infection of plants the capacity of some of the deletion mutants to cause disease may be reduced, although possible redundancy in iron acquisition genes does not make this a certainty. In the case of the complemented deletion mutants, which may show higher expression levels of complemented gene products, it is again unlikely that this will lead to increased virulence since they will be only one component of a multi-component iron uptake system. There is also no reason to suspect that the proposed genetic modification would have an impact on host range since Pectobacterium spp. are necrotrophic pathogens with an already broad host range. Therefore accidental release would not be expected to impact on other environmentally sensitive plant species. In addition, since Pectobacterium spp. are already present in high numbers in the environment, the very low bacterial numbers that might be released would be expected to have a negligible impact on the environment. Since most crop losses are due to contamination of seed tubers or existing soil contamination where host plants have been grown, there is also a very low probability that any accidently released GMM would find a route to infect crop plants.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The GMSC has agreed that work need not be undertaken in a microbiological safety cabinet, since the proposed experiments (which do not include infection of live plants) are physically easy to contain. The maximum culture volume will be 50 ml and aerosols will be kept to a minimum. A designated area will be assigned for this GMM work when in progress and this are will be thoroughly disinfected after use. Specified measures to control aerosol dissemination will include avoidance of vigorous mixing or shaking of cultures and the avoidance of vigorous pipetting. The GMM will be stored in a secure area. Good microbiological practice will be followed at all times.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile. After inactivation as described above, waste will undergo conventional disposal. These procedures are appropriate for the disposal of Class 2 containment material.
This application was submitted to the GM safety committee on 21/08/15. The application was discussed at the committee meeting held on 09/09/15 and some minor clarifications sought. The amended version was circulated to the committee who were satisfied that these met the requests for clarification. The application was approved for submission to HSE and signed by the GMBSO on 19/11/15.

Project Ref: 37/17.1

Date Ackn’ed: 02/08/2017

CU2 Project Title:
- Investigating virulence and transmission in malaria parasites using wild type and genetically modified Class 2/Hazard Group 2 Plasmodium species

Class: Class 2

CultureVolClass2: < 1 Litre

Consent Granted

Non-GMM: Consent Granted

Project notified under transitional arrangements: N
### Purposes of the contained use

Overall the goal is to understand the biology of Plasmodium blood stages using molecular, biochemical, cellular and omics tools. In vitro and in vivo (rodents) experiments with Plasmodium blood stages will be performed to study parasite host interactions, gene and protein expression, and subcellular localization of proteins. Only Class 2/Hazard Group 2 Plasmodium species will be used in this work, for example P. berghei, P. knowlesi, P. cynomolgi. Wild type and genetically modified strains will be used.

### Recipient or parental organism

Class 2 and Hazard Group 2 Plasmodium species will be used in this work, for example P. berghei, P. knowlesi, P. cynomolgi. Wild type and genetically modified strains will be used.

### Host/vector system

Shuttle vectors include those for genetic knock-outs (Maier et al, Cell 2008), epitope tagging by 3’ replacement (Dvorin et al, Science 2009) and overexpression (Buchholz et al, JID 2011), and for conditional knockdown (Coleman et al, CHM 2014). The vectors may also contain promoter DNA to drive expression of the genes of interest, DNA to confer resistance to specific drugs for selection purposes, and DNA to express specific markers for protein identification. Vectors developed for other Plasmodium species, eg P. falciparum, P. berghei, and P. vivax, may be used, as evidence to date suggests that Plasmodium is a universal acceptor for DNA from other Plasmodium species.

### Origin & function

Plasmodium is generally the source of the DNA for integration, eg P. berghei, P. falciparum, P. vivax. Additionally genetic elements that find general use in genetic transformation systems (e.g. Crispr/CASS, Cre-recombinase, AID degron, fluorescent/bioluminescent protein encoding genes) will be employed (see below). There are a number of specific elements to this work:

1. The cloning of promoter regions and gene fragments to create transcriptional and translational reporter fusions. This will be achieved using standard molecular techniques to analyse the expression and regulation of genes. The promoter regions of genes will be PCR amplified from the target genome and cloned into reporter vectors (pDEFhDHFR or pDEFSSUhDHFR(RV) derivatives, published Franke Fayard et al (2004) Mol.Biochem. Parasitol 137. 23-33) to produce promoter-reporter gene fusions for expression studies. These plasmids would be then be transformed into host strains to allow expression of the gene to be monitored by measuring reporter activity. The protein product of individual genes may be analysed through the creation of fusion genes where the open reading frame (ORF) of the gene of study (GoS) may be fused to a reporter gene, such as the gene encoding green fluorescent protein, a non-toxic and well studied reporter gene. Additional reporters include red fluorescent protein, luciferase (both firefly and Renilla), CFP, YFP, mCherry (from the mFruit series), and beta-galactosidase. All these products have been used extensively in numerous studies and are non-toxic. These foreign (eg human, toxoplasma gondii) DNA sequences have been used extensively in malaria parasites without negative consequences.

2. Specific gene deletions. These will be achieved using standard molecular techniques to analyse the role of specific genes in pathogenesis.

3. Complementation of specific gene deletions. This will be achieved using the appropriate standard techniques.

Plasmid vectors have been obtained from commercial sources - pET (Stratagene), pcAL-N-FLAG (Stratagene), peGFP (Clontech), or from a former laboratory in Leiden (http://www.lumc.nl/1040/research/malaria/malaria.html) where a database of vectors with sequence and maps is available.
available and can be supplied if required. The database is password protected (User: Waters. Password: mal-2008) All vectors will be engineered and amplified inside of E.coli plasmids. Plasmogem vectors from a publicly available resource (http://plasmogem.sanger.ac.uk/) will also be used.

**Evaluation of foreseeable effects**

*P. berghei* is a rodent malaria pathogen and does not infect humans. During the proposed experiments with *P. berghei*, exposure of humans to the infectious stage of the parasite would require either a bite by an infected escapee mosquito or an injection of the infected rodent blood. Both events can be easily prevented by appropriate laboratory practice. Moreover, even in the event of such exposure *P. berghei* would be extremely unlikely to invade and replicate in human cells. Successful invasion of human erythrocytes by *Plasmodium* was studied extensively and was shown to require multiple species-specific ligand-receptor interactions, which are present in human parasites but not in *P. berghei*. Additionally, despite presumably multiple accidental exposures of humans to *P. berghei* in its natural environment, no human *P. berghei* infection has ever been reported in the literature and a phylogenetic tree of *Plasmodium* parasites shows no evidence of frequent crossing of the host-species barrier.

Simian *Plasmodium* Hazard Group 2 species e.g. *P. knowlesi*, *P. cynomolgi*, predominantly infect simians but can infect humans and cause malaria. Human *Plasmodium* Hazard Group 2 species e.g. *P. vivax* also cause malaria. Exposure to humans of the infectious stage of the parasite during our proposed experiments would require either a bite by an infected escapee mosquito or an injection of the infected human blood. Appropriate laboratory practice should reduce the likelihood of these events from happening, such as by avoiding the use of any sharps whenever possible. However, in the event of such an occurrence the individual will be treated with anti-malarials (Singh et al, Lancet 2004; Ta et al, Malar J. 2014). There are no known instances of human-mosquito-human transmission of simian *Plasmodium* species. Only monkey-mosquito-human. All species to be employed in the laboratory are sensitive to common anti-malarials e.g. chloroquine. The sources of inserted gene products are as described above. The resultant genetically modified organisms, including those overexpressing target genes, are not expected to be any more virulent than the unmodified host organism. DNA when introduced into *Plasmodium* overwhelmingly interacts with the target genome and integrates through mechanisms of homologous recombination. Random integration into the genome is not observed and therefore unexpected mutant parasites are generally not generated unless through specific experimental design and the use of integrases of low target site specificity (e.g. piggyBac).

The risk that insertion of foreign DNA, especially that from *P. falciparum* or *P. vivax* DNA into rodent or simian *Plasmodium* species will confer pathogenicity to humans is very low as the genes that we are interested in are not known to play any part in the infectivity of the organism. Invasion of human erythrocytes by *Plasmodium* has been studied extensively and it is known that species-specific ligand-receptor interactions are required. We are not working on any of these proteins and therefore should not confer an increase in infectivity to humans. The gene products we are investigating are not known toxins or allergens.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Parasites are completely inactivated by desiccation, or by the addition of detergent, bleach, or even water to culture material. All *P. berghei* liquid waste is inactivated by the addition of detergent or 5% Chemgene for a minimum of 16 hours (overnight) and then flushed down the sink with copious amounts of water. All *P. berghei* solid waste is either autoclaved or incinerated. Since the cultured material for any of the simian *Plasmodium* species, eg *P. knowlesi* and *P. cynomolgi*, also contains human blood and serum, an autoclaving step is necessary to prevent any infection by viruses etc, which are not inactivated by detergent, bleach or desiccation. It would also have the effect, in GM parasites, of denaturing the genetic material. All solid waste used with simian *Plasmodium* species is soaked in detergent or bleach for the
same minimal period before autoclaving. GMO infected mice carcasses are autoclaved and then frozen until removal for incineration by an appropriate waste disposal company following procedures described in the Biological Services risk assessment 334. The above procedures are common practice in Plasmodium laboratories as a reliable method for 100% kill.

### Project Additional Information

**Purposes of the contained use**

We intend to use type strains of *Mycobacterium smegmatis* (Class 1), *Mycobacterium haemophilum* (Class 2), *Mycobacterium abscessus* (Class 2), *Mycobacterium avium* (Class 2), *Mycobacterium bovis BCG* (Class 2), and *Mycobacterium Aurum* (Class 2) to carry out genotypic and phenotypic studies of identified proteins involved in growth and virulence by targeted mutation of bacterial genes and analysis of wild-type, mutant, and complemented strains in vitro.

**Recipient or parental organism**

The GMOs are likely to be less virulent or of comparable virulence with the parent strain; deletion of genes involved with virulence or the regulation of virulence generally leads to a reduction in pathogenicity. The complementation of genes on plasmids using alternative promoters may lead to higher copy number of proteins compared with the parental strain but, in isolation, this is unlikely to increase pathogenicity. Furthermore, stringent disposal and handling of all materials should effectively limit any chance of infection.

**Host/vector system**

- *Mycobacterium smegmatis* (Class 1) is an acid-fast bacillus commonly found in the environmental habitats, mainly soil. It is a fast-growing non-pathogenic bacterium commonly used in the laboratory for genetic studies of mycobacteria.
- *Mycobacterium haemophilum* (Class 2) is an acid-fast bacillus commonly found in the environmental habitats, mainly water. It is a slow-growing opportunistic pathogenic C bacterium that could colonize immunocompromised hosts (humans and animals), but rarely in immunologically competent individuals.
- *Mycobacterium abscessus* (Class 2) is an acid-fast bacillus commonly found in the environmental habitats, mainly soil and water. It is a slow-growing opportunistic pathogenic C bacterium that could colonize immunocompromised hosts (mammals and animals), but rarely in immunologically competent individuals.
- *Mycobacterium avium* (Class 2) is an acid-fast bacillus found in the environmental habitats, such as soil and water. It is a slow-growing opportunistic pathogenic bacterium that could colonize immunocompromised hosts and cause Mycobacterium intracellulare, Mycobacterium Avium Complex (MAC) infection, but rarely in immunologically competent individuals.
- *Mycobacterium bovis BCG* (Class 2) is the attenuated form of the *Mycobacterium bovis* strain Calmette-Guerin (BCG), an acid-fast bacillus, that is currently used as a vaccine for *Mycobacterium tuberculosis* (causative agent of tuberculosis).
Mycobacterium aurum (Class 2) is an acid-fast bacillus commonly found in the environmental habitats, mainly soil and water. It is a slow-growing opportunistic pathogenic bacterium that could colonize immunocompromised hosts (humans) resulting in bacteremia, but rarely in immunologically competent individuals.

pML1335-GFP or pML 1357 was a gift from Michael Niederweis (Addgene plasmid # 32378; http://n2t.net/addgene:32378; RRID:Addgene_32378). The intended function is to introduce GFP gene into the to re-introduce gene back to a mutant organism.

pKM444 was a gift from Kenan Murphy (Addgene plasmid # 108319 ; http://n2t.net/addgene:108319; RRID:Addgene_1 08319). The intended function is for creating knockouts of target genes by oligonucleotide-mediated recombineering of bacterial chromosomes. This shuttle vector expresses the Che9c phage RecT annealase and the Bxb1 phage integrase (Int) from an anhydrotetracycline (ATc)-inducible Ptet promoter.

pKM464 was a gift from Kenan Murphy (Addgene plasmid # 108322; http://n2t.net/addgene:108322; RRID: Addgene_108322). The intended function is for creating knockouts of target genes by oligonucleotide-mediated recombineering of bacterial chromosomes. This is a payload plasmid that does not replicate in mycobacteria and includes a hyg resistance marker for selection in mycobacteria and a Bxb1 attB site.

pKM468-EGFP was a gift from Kenan Murphy (Addgene plasmid # 108434; http://n2t.net/addgene:108434; RRID: Addgene_108434). The intended function is for creating EGFP-His fusions to target genes by oligonucleotide-mediated recombineering of bacterial chromosomes. C-terminal tag: EGFP-4xGly-TEV-Flag-6xHis.

pKM491-Flag-His was a gift from Kenan Murphy (Addgene plasmid # 109282 ; http://n2t.net/addgene:109282; RRID: Addgene_1 09282). The intended function is for creating Flag-His fusions to target genes by oligonucleotide-mediated recombineering of bacterial chromosomes. C-terminal tag: 4xGly-TEV-Flag-6xHis.

pKM493. The plasmid is not yet available, but will be used in the future. The intended function is for creating FlagEGFP fusions to target genes by oligonucleotide-mediated recombinering of bacterial chromosomes. C-terminal tag: TEV-Flag-4xGly-EGFP.

Origin & function

Materials are obtained from Group Leader of the Mycobacterial Metabolism and Antibiotic Research Laboratory and Group Leader of the Host-Pathogen Interactions in Tuberculosis Laboratory, at The Francis Crick Institute, 1 Midland Road, London NW1 1AT, UK. Inserted gene products are all from mycobacterial origin. In most cases, the inserted gene will be the same previously deleted, to demonstrate rescue of the phenotype.

Evaluation of foreseeable effects

Deletion, mutation or introduction of genes, is unlikely to alter its ability to infect humans and cause disease as usually these are dependent on several genes acting in concert. Alteration would likely reduce the pathogenic traits. Most mutants generated will contain gene deletions or mutations which are associated with a fitness cost. Therefore, these strains will be further attenuated and less fit to survive in the environment. Strains that carry cloned genes for complementation work should be equivalent to parental strains or less harmful.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Disinfection and autoclaving will be carried out where required. All waste materials will be disposed of into the autoclave bags, yellow clinical waste bags or sharps bins as required. All used sharps will be placed immediately after use into a sharps bin. Sharps bins will be located on the bench where the sharps are used so that they can be disposed of directly after use.

All disposable consumables that come into contact with mycobacteria will be chemically inactivated by soaking in 10% Surfanios for at least 15 minutes. All other surfaces will also be chemically inactivated by spraying with Amphospray and left to air dry for at least 5 minutes. This include the external surface of rubbish bags used to collect the waste.

The chemically-inactivated waste will then be heat-inactivated by autoclaving at 121°C for 20 minutes.

Disinfectant:

10% surfanios in a tub inside the microbiological safety cabinets (MBSC) will be used for decontamination of plastics.

Stripettes will be decontaminated by flushing with 10% surfanios;

Soaked for a minimum of 15 minutes and placed in a bag to prevent piercing of the autoclave bag.

• The liquid waste from the tub should be poured down a sink;

Pouring this through a sieve device (colander) to collect the decontaminated items which can then be put in the autoclave bags.

For mycobacterial cultures, surfanios is added to obtain a 10% concentration. A minimum of 15 minutes contact time should be allowed for decontamination.

Amphospray 41 can be used for surface decontamination.

All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile or chemical indicators (eg Browne TST indicator test strips). This is carried out within the Institute of Infection, Immunity and Inflammation general waste protocol.

(1) Solid waste: where practicable, solid waste should be chemically disinfected prior to disposal in autoclave bag for autoclaving.

(2) Liquid waste: all liquid waste must be thoroughly treated with the disinfectant appropriate for killing the specified organism.

(3) Glassware: the use of glassware should be avoided if at all possible. If the use of glassware is unavoidable then glassware used as a container for infectious materials must be;

a. Thoroughly disinfected inside and out using the approved disinfectant, Amphospray or Surfanios.

b. Glassware is to be rinsed with water once after disinfection.

c. If the glassware has not been in contact with infectious materials then all outer surfaces must be disinfected using an appropriated approved diSInfectant, Amphospray or Surfanios.

d. Disinfected glassware should be placed in the glassware collection tray situated in the lab for Glass wash & Media Preparation staff to collect.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
The mycobacterial species are normally found in the environmental habitats, and our mutants will not likely to affect other organisms. No potential hazards to the environment and other organisms associated with the recipient mycobacteria can be predicted. Again, most mutants generated will contain gene deletions or mutations which are associated with a fitness cost. Therefore, the mutant strains will be further attenuated and less fit to survive in the environment.

Project Additional Information
Purposes of the contained use

Aims:

Contained Use Notification
Plasmodium falciparum is one of the parasites responsible for human malaria. The aim of this study is to establish the role of protein phosphorylation in maintaining the blood stage of the parasite and the essential processes involved in progressing the parasite through the blood stage. For this we will be generating and importing mutant parasite strains where certain protein kinase genes have been mutated as well as other genes involved in invasion and gametogenesis.

General overview of the project:
It is estimated that 300-500 million people worldwide suffer from malaria with over 2 million deaths per year, mostly in children under the age of 5 (Breman, 2001). The most severe cases of malaria are caused by the parasite Plasmodium falciparum. This parasite is transmitted to humans in the saliva of an infected mosquito. Once in the bloodstream, the parasite makes its way to the liver where it invades liver cells. Inside liver cells the parasite divides and changes into a form that is able to infect red blood cells. The infected liver cells eventually release parasites into the bloodstream where they quickly invade red blood cells. Once inside the red blood cells the parasite once again divides filling the red blood cells with new parasites which are released when the cell membrane eventually ruptures. These released parasites invade other red blood cells and the cycle is repeated.

Many studies aimed at developing novel treatments for malaria focus on the blood stage form of P. falciparum (Pleass and Holder, 2005). Hence a detailed understanding of this stage in the life cycle will provide robust targets for further drug discovery.

We will study the biochemical processes of invasion of P. falciparum into human red blood cells, progression of the parasite through the red blood cell cycle and gametogenesis with particular focus on the role of protein phosphorylation. The following will be undertaken:

1. Investigation of novel potential drug targets including protein kinases and signalling molecules involved in parasite development and gametogenesis. Gene knockout experiments have demonstrated that certain proteins are essential for viability of malaria parasites. Among these genes are those that encode for protein kinases. Therefore, replacement of wild-type alleles of protein kinases with alleles carrying a mutation conferring hypersensitivity to inhibitors will allow validation of these proteins as potential drug targets.

2. Localisation and purification of tagged proteins/parasites: Subcellular localisation of Plasmodium proteins is important for determining how they may be pharmacologically targeted. Localisation of potential drug targets to different parts of the cells will be achieved through GFP or epitope-tag gene constructs. The addition of tags (such as 6-His, HA) to proteins such as kinases, cyclins and metabolic enzymes will allow direct purification of these proteins complexed with their natural protein partners, which can then be analysed further. Such purified proteins can also be used to directly screen against potential drug compounds in luminescent assays.

3. Investigation of erythrocyte invasion by malaria parasites. Gene knock-out of Plasmodium genes of the EBA family presumed to be involved in invasion will determine the role of individual proteins in this process.

4. Determination of the phospho-proteome of plasmodium falciparum using wild-type and genetically-modified parasitoids in comparative studies.

We will be looking at mutants of various protein kinases and signalling proteins including PfCPDK1, PfCLK1, PfCLK3, PfGSK3, PfPK6 and the gale keeper mutant of PfPKG and NEK family (PfNEK1-4) kinase mutants as well as mutants in invasion-related proteins (such as the EBAs) and regulatory proteins including K13-propeller and PfRh protein.

Recipient or parental organism
Host/vector system

DNA vector to be used will be pHH1
This vector will confer ampicillin resistance

Origin & function

The genetic material used has its origin in an eDNA library obtained from the reverse transcription of mRNA derived from the schizont stage of P. falciparum.

The specific genetic material is discussed below:

Dominant negative mutants of:

- PfGSK3 (+GTP/HA/His tagged versions)
- PfPK6 (+GTP/HA/His tagged versions)

We will inhibit the action of specific protein kinases by over expression of dominant negative mutants. These will include dominant negative mutants to GSK3 and PK6.

PfGSK3 is a protein kinase. The normal function of this kinase in malaria is unknown other than it is an essential kinase to maintain the blood stage of the parasite.

PfPK6 is a protein kinase. This kinase is homologous to the cyclin-dependent kinase and therefore likely to be involved in the cell cycle.

Gate keeper mutant of:

PfPKG (+GTP/HA/His tagged versions)

Mutants of the essential protein kinase PKG that render the parasite insensitive to inhibitors of PKG will be used to dissect the role of this kinase in the survival of the parasite.

PfPKG is a protein kinase. It is an essential kinase for parasite survival and is involved in parasite development in the red blood cell, egress and invasion into red blood cells. This kinase is also involved in formation of gametocytes.

Protein kinases:

- CDPK1 (HA-tagged)
- NEK kinase family (NEK1 -4)(HA and GFP tagged)
- CLK1 and CLK3 (+GTP/HA/His tagged versions)

Wild type and mutants of a number of protein kinases that are essential for the progression of the parasite through the erythrocytic cycle will be investigated to establish the role played by these kinases in maintaining the viability of the parasite. The mutations to be introduced either involve epitope tags or removal of regulatory phosphorylation sites or introducing mutations that change sensitivity to protein kinase inhibitors.

PfCLK1/3 are protein kinases. They are involved in RNA processing in the parasite

Invasion proteins

- EBA family (e.g. EBA-175)
- K13-propeller. This is a transcriptional regulator of unknown function.

Drug resistance is a major problem in malaria. It is becoming clear that a number of proteins including K13-propeller proteins are mutated in drug resistant parasites. We will use mutants of these proteins to establish what mechanisms are in play during drug resistance.
The PfRH-family are a group of rhoptry proteins which are released from the parasite during invasion and are essential for the invasion process.

**Evaluation of foreseeable effects**

P. falciparum is a serious human pathogen but the parasite is unable to infect any vertebrate species apart from man and certain primates, and can only infect certain species of Anopheles mosquitoes. Natural infection of humans occurs through the bite of an infected mosquito vector of the genus Anopheles. The research programmes that will be implemented in the Cat3 facilities do not involve mosquito vectors, so the risk of insect-borne inoculation is very low. The only way that the GM could enter the environment and survive is if a mosquito able to transmit malaria was to enter the lab, feed on the culture and pick up from the culture gametocytes. This is almost impossible for the following reasons: Firstly there are only a few species of mosquito in the UK able to act as the vector for P. falciparum, of those that do exist they are in very low numbers in Leicestershire. • The mosquito would then have to enter the closed environment of the malaria lab and gain access to the class 2 hood, or the incubator, which is extremely unlikely. The mosquito would have to feed on the culture (which it is unlikely since it is only 10% human blood) In the meal the mosquito would need to pick up gametocytes which are in extremely low numbers in Pf in vitro cultures (less the 0.5% of the infected red blood cells) After all this it is almost impossible for a single infected mosquito to successful propagate malaria. For this to happen a large number of mosquitoes would have to go through the above process. In the laboratory environment, infection of humans may take place by direct inoculation of infected blood (cultured material) into the bloodstream of the laboratory worker, e.g. through contaminated hypodermic needle. This risk is minimal since no needles or any glass are used in the dedicated culture room. Since the parasite may enter through a cut in the skin then any skin abrasions should be cover in a plaster and the operator where gloves and appropriate PPE. This should reduce any risk of infection to close to zero. The only parasite lines which will be used in this programme (307, NF54) are all susceptible to chloroquine and, importantly, the effectiveness of commonly used antimalarial drugs, e.g. chloroquine, is unaffected by the genetic modification. The function of the inserted parasite gene product will frequently be unknown, or can only be implied through homology with other organisms. Knockouts of potential drug targets (e.g. protein kinases) are aimed at reducing the fitness of the knockout parasites, preferably to produce non-viable or severely functionally-impaired parasites. Allelic replacement of protein kinase genes with those exhibiting hypersensitivity to inhibitors should result in parasites with increased sensitivity to these inhibitors. Growth rates are not expected to be affected, other than negatively, in any of these experiments. The GMM is very unlikely to be more harmful to humans than the parental organism. Pathogenicity in Plasmodium does not depend on any known toxin or clonable agent. Malaria parasites are extremely host-specific and there have been no reports of malaria parasites crossing species barriers, with the exception of some non-human primate malarias that are able to establish very mild infection in humans, and experimental infection of certain non-human primates with human malarias. It is not possible for the human malarias to establish infection in any other vertebrates.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

P. falciparum is a parasite responsible for human malaria. As such this organism is categorised by ACOP as a Hazard
group 3 parasite but handling without negative pressure/HEPA filler is permitted (appendix 3.2 Biological agents managing the risks in laboratories and healthcare premise). This is justified on the following grounds:

- The only way to contract malaria from an in vitro erythrocytic culture of P. falciparum is through a puncture wound of the skin. It is not possible, for example, to gain infection via spillage on the skin, touching contaminated cloths or by touching or rubbing eyes with contaminated hands or tissues.
- It is not possible to be infected by inhalation of parasites contained in aerosols, for example caused by centrifugation or by pipetting, or from evaporation from culture media.
- It is not possible to be infected by contaminated clothing.
- It is not possible to become infected by spillages unless some how the spillage was able to enter the body through punctured skin.

Since the parasite may enter through a cut in the skin then any skin abrasions should be cover in a plaster and the operator where gloves and appropriate PPE. This should reduce any risk of infection to close to zero.

For these reasons it is not necessary to implement full cat 3 containment. Specifically the following key elements of cat 3 contained are not required for P. falciparum in vitro culturing for the following reasons:

- **The laboratory is sealable of fumigation:**
  - This is not necessary as there is no inherent risk of infection from P. falciparum through inhalation. Hence fumigation does not present any inherent risk of parasite infection. Thus, it is not necessary to conduct fumigation in a sealed room. It would seem that this would in fact seriously increase the risk associated with the fumigation procedure with no benefit in decreasing the risk of parasite infection.

- **There is an autoclave available within the laboratory suite:**
  - It is not possible to become infected by the parasite culture other than through a puncture wound. Thus, the solid waste is currently double bagged and autoclaved in the building autoclave facility because it is not possible to contract an infection through accidental contact of any residual waste culture material with the skin, by inhalation or ingestion. There is no justification therefore for autoclaving in the malaria lab. In fact having an additional autoclave would increase risk of injury through autoclaving.

- **Note that all liquid waste is decontaminated in the malaria lab and disposed of in the malaria lab therefore is not autoclaved.**

- **Entry to the lab is via an airlock:**
  - This is unnecessary since it is not possible to be infected by the malaria parasite from inhalation or from aerosols or vapour or any airborne source. Hence an airlock is not necessary.

- **The lab is at negative pressure relative to the pressure of the immediate surroundings:**
  - This is not necessary for the same reasons as described above for the airlock.

- **Extract and input air from the laboratory must be HEPA filtered:**
  - This is not necessary for the same reasons as described above for the airlock/negative pressure.

Controls to mitigate risk of infection from in vitro P. falciparum cultures.

To mitigate the risk of infection from a puncture wound the following standard operating procedure for P. falciparum in vitro culture has been in operation for some time in line with the recommendations from the University and MRC safety office and as approved by the HSE.

- **a) Only the culture of P. falciparum is permitted in this laboratory.**
- **b) Each culture batch will be up to 30ml**
- **c) Only staff that have gone through the appropriate safety training and that have been approved by the University**
and MRC safety officers will be allowed to work in lab 201.
d) Access to lab 201 will be limited to personnel who have received training and approval by the supervisor/group leader.
e) Only trained personnel will be given the access code to enter the lab that will be locked at all times with a swipe card entry lock.
f) All the equipment required for the culture of P. falciparum will be contained in lab 201. This includes the class 2 microbiological cabinet, incubator, centrifuge and microscope.
g) Liquid tissue culture medium is stored in lab 202/209.
h) The use of sharps is strictly forbidden. This includes in particular glass pipettes and glass bollies. Glass slides will, however, be permitted for the staining of parasites in culture.
i) Liquid waste will be inactivated with presept (1,000ppm equivalent to 4 x 2.5g tablet per 500ml) and disposed of down the designated sink.
j) All solid waste will be double bagged and autoclaved.
k) Gloves will be worn at all times.
l) Safety glasses to be worn at all times.
m) Dedicated blue lab coats will be worn at all times.
n) Buckets in the centrifuge must be capped when spinning tubes containing the parasite cultures.
o) In the event of spillage, liquid waste will be absorbed onto CLAN Unisafe absorbent granules and placed in solid waste and autoclaved. Area will then be washed with presept (10,000ppm equivalent to 4 x 2.5g tablet per 500ml) for disinfecting.
p) In the event of centrifuge disruption or if a spill is suspected then the following procedure must be adhered to:
1. Leave 20 minutes before opening
2. If the integrity of the buckets is not comprised, these (with caps) will be moved into the class II microbiological cabinet and opened.
3. Liquid will be disposed of in liquid waste container, treated with presept (1,000ppm equivalent to 4 x 2.5g tablet per 500ml) and disposed of in the designated sink. Solid waste will be disposed of in the solid waste disposal bin and autoclaved.
4. If the integrity of the buckets is comprised, then liquid waste will be absorbed onto CLAN Unisafe absorbent granules and placed in solid waste and autoclaved.
5. The centrifuge should then be thoroughly cleaned with presept (10,000ppm equivalent to 4 x 2.59 tablet per 500ml) and all waste disposed of as solid waste and autoclaved.
q) Transport of potentially infected material from laboratory 201 (e.g. cell lines, frozen ampoules, serum etc.) will be done in an approved sealed vessel clearly labeled and a trolley will be used.
r) All solid waste is autoclaved.
s) Eating, chewing, drinking, smoking, taking medication, storing food and applying cosmetics is forbidden in the laboratory.
t) Mouth pipetting is forbidden.
u) In case of a spillage of P. falciparum on broken skin or a puncture wound (from for example a contaminated slide) the wound should be washed thoroughly under running water and Occupational Health consulted.
v) When leaving the malaria lab (room 201) with malaria samples gloves and lab coats need to be changed.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be inactivated by addition of Presept (Johnson & Johnson Medical) - 4x2.5g tablet per 500ml (equivalent to 10,000ppm*) - overnight and disposed of down the designated sink.
In the event of a large spillage, liquid waste will be absorbed onto CLAN Unisafe absorbent granules and placed in
solid waste and autoclaved. Area will then be washed with Presept (10,000ppm equivalent to 2.59 tablet in 500ml). In the event of small spillages or splashes, the surface should be cleaned with 70% IMS. All solid waste will be placed in an appropriate autoclave bag, taped closed and autoclaved at 133°C for 12 mins. It is handled as detailed in the appropriate standard operating procedure for the Hodgkin Building. All pipettes will be placed in a sealed orange topped 7L sharps bin and autoclaved at 133°C for 12 mins. All waste will then be incinerated by an approved contractor. *Note: Presept data - a solution of presept was made up in water where the presept concentration was 10,000 ppm. 1ml of this solution was added per 10ml 307 or NF54 P. falciparum culture for 24 hours (final concentration was 1,000 ppm). In the control culture parasitemia was 1% and in the presept treated culture, no live parasites were observed. Therefore a final concentration of 10,000 ppm is deemed far higher than necessary to kill the parasites.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The genetic modification safety committee have agreed the following:

i. That a designation of Class 2 is appropriate
ii. That the risk assessment is sound and that work should be carried out at Containment Level 3 but can be handled without negative pressure/HEPA filter
iii. That the project will be notified to the HSE, and, further, they have noted:
   i. That the proposer will contact HSE to notify the work as a new project.

CU2 Project Title

TRANSFORMATION OF THE POWDERY MILDEW FUNGUS Erysiphe graminis WITH A GREEN FLUORESCENT PROTEIN (GFP) CONSTRUCT TARGETED TO THE MITOCHONDRIA.

Class  Class 2
CultureVolClass2 < 1 litre
CultureVolumeClass3-4

Non-GMM  Consent Granted
not applicable
Purposes of the contained use

To investigate the sexual reproduction of the fungus Erysiphe graminis with particular reference to the inheritance of nuclei and mitochondria. The mitochondria of the two mating fungi will be differentially recognised using two forms of green fluorescent protein (GFP). The mitochondria cannot be transformed directly, so we will transform nuclear DNA using a GFP construct with a mitochondrial-targeting signal. Positive selection of transformants will use bialophos (BASTA), which since E. graminis is an obligate biotroph will also require a susceptible wheat line to be bialophos resistant. A bialophos resistant wheat variety (Bobwhite) has already been generated at the John Innes Centre. This procedure will enable us to establish the mechanism by which mitochondria, but not the nucleus, from the male parent are excluded from the developing progeny.

Recipient or parental organism

The recipients will be two isolates (Fe109 and J1W2) of the powdery mildew fungus Erysiphe graminis f. sp. tritici.

Host/vector system

The plasmids used will be derivatives of the pBT-BAR plasmid. This plasmid contains the bialophos resistance gene (bar) (for positive selection of fungal transformants) bordered by fungal promoter and terminator sequences. The rest of the vector consists of the plasmid pBLUESCRIPT KS(-) available from Stratagene. pBLUESCRIPT contains a bacterial promoter plus ampicillin resistance genes to enable positive selection of bacterial transformants during plasmid propagation. These will be disabled Escherichia coli strains such as DH5-a.

A GFP construct with a mitochondrial-targeting signal will be engineered into the above background.

Origin & function

The different components of the above vector have the following origins:

i) The bar gene is isolated from the bialophos-producing Streptomyces hygroscopicus. The bar gene encodes a phosphinothricin acetyl transferase which inactivates the antibiotic bialophos.

ii) The fungal promoter and terminator sequences are derived from the B-tubulin gene from E. graminis.

iii) pBLUESCRIPT is a commercially available plasmid from Stratagene.

iv) The GFP gene originates from the jellyfish Aequoria victoria and is commercially available.

v) The mitochondrial-targeting signal will be the 5' end of the citrate synthase gene from either Aspergillus niger or E. graminis.

The modified pBT-BAR plasmid will be transformed into nuclear DNA of Erysiphe graminis f.sp. tritici using biolistic transformation. The mitochondrial-targeting signal will then enable GFP to be specifically expressed in the fungal mitochondria, where under appropriate conditions it will cause the mitochondria to fluoresce. These isolates will
then be studied microscopically. The bialophos resistance genes will be expressed conferring bialophos resistance upon the host organism for selection purposes only. All transformants are for experimental purposes only.

**Environmental Risk**

Plant, fungal and bacterial colonies will be killed by autoclaving prior to disposal, eliminating risk of environmental contamination by this route. Likewise all compost and residual plant material generated in containment glasshouses is autoclaved prior to disposal. Infected plants growing in containment glasshouses will be contained in plastic tubes, sealed at the bottom to the plant pots, and at the top to hoods prepared from a double layer of tea bag paper. This system has been routinely tested for escape of contaminating spores and has proved highly effective. In addition, containment glasshouses are MAFF-approved and have an air filter system, which prevents accidental release of airborne spores into the environment. The air filter system is tested at regular intervals (every 4 months) using rust fungal spores and the filters changed regularly. The soiled filters are bagged and autoclaved prior to disposal. In the highly unlikely event of accidental release no adverse effects are likely, as E. graminis is an obligate biotroph and will not survive long in the absence of a susceptible wheat host. Laboratory manipulations will be performed in sterilised airflow cabinets and isolates stored in sealed plastic boxes. Transformants will be resistant to the herbicide bialophos, which non-transformed isolates are susceptible to; however, bialophos is not used to control fungi, nor indeed is it used as a herbicide in the UK.

**Human Health Risk**

The plasmids used are geared for expression in bacteria and fungi and should have no expression potential in humans. The transformed organisms are for experimental purposes only and are not intended for human consumption. The bacterial hosts are disabled laboratory strains with negligible risk to human health.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Containment level 2 is appropriate for activities involving plant manipulations.

The susceptible wheat line (Bobwhite) which has been previously transformed with the bialophos resistant gene at the John Innes Centre will be grown in MAFF-approved containment level 2 glasshouses. The plants will be grown to seedling stage (10 day old) and inch long leaf segments removed for infection with the transformed E. graminis isolates in the laboratory (G31 Bateson Building). Transfer of the transformed isolates between the laboratory and glasshouses will be in sealed containers to prevent dissemination. Plant material infected by E. graminis will be contained in plastic tubes, sealed at the bottom to the plant pots, and at the top to hoods prepared from a double layer of tea bag paper. This system has been routinely tested for escape of contaminating spores and has proved highly effective. This infected plant material will be grown in containment glasshouses and transported to the laboratory in sealed plastic bags. Laboratory manipulations will be completed in airflow cabinets, which are sterilised before and after use. Material stored in the laboratory will be in sealed plastic boxes. All residual plant material (both infected and uninfected) will be disposed of by autoclaving. Autoclaving facilities are present within the containment glasshouse facilities and within the laboratory (G68) adjoining G31.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

No derogation from containment level 2 required.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Waste material generated will be in different forms:

i) Residual plant material and soil will be disposed of by autoclaving.

ii) Plant material infected with transformed E. graminis isolates will be stored in sealed boxes which will be disposed of by autoclaving.
iii) Liquid cultures generated by bacterial propagation will be autoclaved prior to disposal. Plasmid manipulations of bacterial cultures will be completed in disposable plastic vessels, which will be autoclaved prior to disposal.

All autoclaving results in 100% kill. Autoclave procedures are as follows:
1. Soil is autoclaved in stainless steel containers for 1.5 hours (15 min vent, 30 min sterilisation at 7 vacuums). Resultant waste is transported in trailers to a farm site where it stands for a 3 year period prior to disposal.
2. Plant waste generated in the glasshouses is autoclaved for 1.33 hours (15 min vent, 45 min sterilisation at 2 vacuums).
3. Laboratory material will be autoclaved in room G68 (adjoining room G31) at 121 degrees C for 18 minutes.
Routine monitoring of autoclave efficiency is completed using Thermolog S strips.

Run-off from containment glasshouses is channelled to a filtration plant with a 5000 L holding tank. 1500 L aliquots are removed and treated with sodium hypochlorite and circulated in the tank for a 24 hour period, following this treatment is with sodium thiosulfate. The water is then filtered and disposed of.

Human Clinical Applications

Project Ref  38/01.2

Date Ackn’d  11/05/2001  CU2 Project Title  INFECTION OF ARABIDOPSIS WITH PSEUDOMONAS SYRINGAE SPP  Class  2  CultureVolClass2  < 1 litre  CultureVolumeClass3-4

02/03/2022  Page 1758 of 1532
EXPRESSING RECOMBINANT AVIRULENCE PROTEINS.

Purposes of the contained use

To investigate the plant resistance response to bacterial pathogens expressing or lacking specific avirulence determinants. Pseudomonas syringae episomally expressing recombinant avirulence determinants derived from related Pseudomonads will be infiltrated directly into Arabidopsis leaves. Leaves will be subsequently harvested and analysed for bacterial growth, defence gene induction, and physiological changes.

Bacterial tagged with the lux operon will be used in viability studies.

Recipient or parental organism

Recipients will be Pseudomonas syringae pv maculicola, pv.tomato, pv.lachrymans, pv.pisi, pv.phaseolicola, pv.glycinea, and pv.apii.

Host/vector system

The plasmids used will be derivatives of pRK2 and pRSF1010. In both cases modified derivatives of these plasmids will be used that are defective in mobilisation (mob). The plasmids are also replication defective and are rapidly lost in the absence of antibiotic selection in vitro. These plasmids contain genes encoding resistance to tetracycline (RK2) and kanamycin (RSF1010) for selection in vitro. These plasmids contain lac promoter to drive expression of introduced avirulence genes. Manipulation of these plasmids and avirulence genes will be performed in non-colonising rec derivatives of E.coli K12.

The lux operon of Photohabdus luminescens will be introduced by Transposition insertion with a disabled mini-Tn5 construct.

Origin & function

1. The avirulence genes to be used are derived from Pseudomonas pathovars as follows: avrA, B, C (pv glycinea), avrRpt2 (pv.tomato), avrRpm1 (pv maculicola), avrRps4 (pv.pisi), avrPphB (phaseolicola). Additionally, the lux operon from Photohabdus luminescens will be used in some viability studies.

2. The tetracycline resistance gene is native to the parental RK2 plasmid.

3. The kanamyycin resistance gene is native to the parental RSF1010 plasmid.

4. pBluescript is commercially available from Stratagene.
All constructs will be introduced into the respective Pseudomonas pathovars via electroporation and maintained episomally in plasmids under antibiotic selection with the exception of the lux operon which will be maintained chromosomally after plasmid integration. The lux operon will enable the direct determination of viability to be made by scoring for relative luminescence.

Evaluation of foreseeable effects

The transformed Pseudomonads will be essentially identical to their non-transformed parents except for the expression of avirulence proteins. These avirulence proteins are well characterised molecules that are known to elicit specific plant defence responses. These Pseudomonads are expected to be equal or less virulent than their parental counterparts as they will be expressing specific molecules that enable a plant response.

Environment risk:

The bacteria and infected plant material will be killed by autoclaving prior to disposal. Likewise all compost and residual plant material generated in the containment glasshouses is autoclaved prior to disposal. Containment glasshouses are MAFF approved and have an air filter system (the filters are changed regularly and autoclaved prior to disposal) which prevents accidental release of aerosols. These are non-spore forming bacterial and hence such risks are negligible.

In the event of release:

In the event of an accidental release no adverse effects are expected. The recombinant avirulence proteins used in these experiments are common in their wild-type counterparts and are being expressed on unstable plasmids that are rapidly lost in the absence of persistent antibiotic selection in vitro.

Human health risk:

The plasmids and constructs being used are directed for bacterial expression only. The E.coli hosts used are disabled non-colonising rec derivatives of E.coli K12. The Pseudomonads in use are unable to colonise humans as they cannot replicate at 37 deg. No adverse human health effects are foreseen.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Level 1

Level 2 where infected with GMM

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Class 2 GMM (plant pathogen) (containment level 2). All GMM material handled using good microbial practice. All GMM material autoclaved prior to disposal.

Residual lant material will be stored in sealed containers and disposed of by autoclaving.

Liquid bacterial cultures will be chemically inactivated using Hycolin or autoclaved prior to disposal.

Autoclave procedures are as follows: Soil is autoclaved in stainless steel containers for 1.5 hours (15 min vent, 30 min sterilisation at 15 psi). Resultant waste is transported in trailers to a farm site where it stands for a 3 year prior prior to disposal.

Plant waste generated in the glasshouses and growth rooms is autoclaved for 1.33 hours (15 min vent, 45 min sterilisation at 15 psi).
Routine monitoring of autoclave efficiency is completed using Thermolog S strips.

Run-off from containment glasshouses is channelled to a filtration plant with a 5000 L holding tank. 1500 L aliquots are removed and treated with sodium hypochlorite and circulated in the tank for a 24 hour period followed by a treatment with sodium thiosulfate. The water is then filtered and disposed. Plants in the growth rooms will be watered by sub-irrigation in leak proof trays such that no run-off is generated.

The RAs indicate that level 2 containment is required for GMM work. The BSC agree that this is appropriate and that the facilities are available to ensure containment is effective.

Please enter comments on the GM safety committee on the risk assessment

The RAs indicate that level 2 containment is required for GMM work. The BSC agree that this is appropriate and that the facilities are available to ensure containment is effective.

**Project Additional Information**

**Purposes of the contained use**

To investigate plant-virus interactions - in particular, the plant genes involved in virus infection and changes in plant gene expression in response to virus infection. We will introduce transgene or virus constructs into non-transformed or transformed plants (Arabidopsis or tobacco) using Agro-inoculation, rub-inoculation, particle bombardment or stable transformation using Agrobacterium. The virus constructs will be wild-type or recombinant ie tagged with reporter genes or parts of plant genes.

**Recipient or parental organism**

Plant viruses: eg potato virus X (PVX); tobacco rattle virus (TRV); tobacco etch virus (TEV); tobacco mosaic virus (TMV); tomato golden mosaic virus (TGMV). These viruses will be tagged with reporter genes eg beta-glucuronidase; green fluorescent protein. TGMV, PVX and TRV will have parts of plant sequences inserted into their genomes. These sequences will not encode plant proteins.

**Host/vector system**

**Plant Hosts**: Arabidopsis thaliana and Nicotiana spps.

The plasmids used will be derivatives of the binary vectors pBIN19, pSLJ729/2, pSLJ75515/6, pGreen or derivatives of pUC18/19, pBLUESCRIPT KS, pGEM-T.

**Bacteria hosts**: Escherichia coli DH10B (Disabled); Agrobacterium tumefaciens GV3101, LBA4404, C58C1 (pCH32) - all disarmed.

**Origin & function**

The reporter genes will be commonly used markers such as the uidA gene from E. coli, that encodes beta-glucuronidase (GUS); the green fluorescent protein (GFP) from the jellyfish Aequoria victoria. The plant sequences will be from A. thaliana or Nicotiana spps. and will not encode proteins. The transgenes will be GFP or GUS reporter genes or viral genes expressed from generally used promoters eg the cauliflower mosaic virus 35S promoter, the nopaline synthase promoter.

**Evaluation of foreseeable effects**

**Environmental risks**: None expected.

There is no evidence that the host range of the recombinant viruses can be increased by insertion of a reporter gene or by insertion of part of a plant gene sequence. Symptoms of the recombinant viruses are very similar to those produced by the non-recombinant (wild-type) virus. The inserted sequences are rapidly lost through recombination through duplicated viral sequences. The agrobacterium is disarmed and therefore not oncogenic. Agrobacterium may survive in the environment as a free-living soil microbe but the binary vector would be lost in nature very quickly in the absence of antibiotic selection. Transfer and expression of the constructs requires the presence of a chemical that induces T-DNA transfer. Agro-inoculation will only be used as a delivery system for what are already mechanically transmitted viruses. The plant hosts are not wind pollinated. All wild-type and recombinant viruses will be propagated in Class 2 containment glasshouses. All transgenic plants will be grown in Class 2 containment glasshouses or a Weiss controlled environment room (CER).

**Human health risks**: None expected.
The marker genes have no known toxicity and have a history of safe usage over the previous 5-10 years. The plant sequences used in the viruses will not encode proteins. The plant viruses do not cause infection in humans. The bacteria are disabled and do not cause infection in humans.

All manipulations of GMOs will be performed in laboratories which comply with HSE level 2 containment facilities. All agro-inoculations will be performed in Class 2 containment glasshouses. All virus inoculations will be performed in Class 2 containment glasshouses or a Weiss CER.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Containment level 2 is appropriate for activities involving plant manipulations.

All GM plants will be grown in Class 2 containment glasshouses or a Weiss CER.

Glasshouse: All run-off water is sterilised before discharge into the sewerage system. Access is restricted to named personnel and monitored. Entry is via a sterilisation foot mat. The glasshouses are physically protected against insect ingress and a solid floor prevents insect or nematode vectors. Unrelated experiments are segregated.

Weiss CER: All run-off water is collected in trays below the benching and evaporates. The chamber is sterilised at the end of each experiment. Access is limited to named personnel only and the chamber is locked. Entry is via a sterilisation foot mat. Entry to the area housing the CER is via several closed doors. Flowering is prevented because the CER is run at short day length and plants are removed at about 3 weeks post pricking out. Non-GMO work is not performed in the chamber.

All pots, soil, plant material are autoclaved after each experiment.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All manipulations of GMMs will be performed in the laboratory with GMP. The laboratories comply with HSE level 2 containment facilities. All materials coming in contact with the GMO and all biological waste is inactivated by autoclaving (121C for 18 min) or verified chemical means before leaving the building.

All experiments using GMMs will be performed in Class 2 containment glasshouse or Weiss CER. The glasshouse run-off water is sterilised before discharge into the sewerage system (using hypochlorite solution circulated for 24h, followed by sodium thiosulfate treatment and filtration). The CER water is collected in trays and evaporates. The trays are sterilised at the end of each experiment. All plant material and soil is autoclaved after use (Soil: 15 min vent, 30 min. sterilisation at 7 facuums; plant material: 15 min. vent, 45 min sterilisation at 2 vacuums). All autoclaving results in 100% kill. Routine monitoring of autoclave efficiency is completed using Thermolog S strips.

Is an emergency plan required according to regulation 20? Y

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

**Please enter comments on the GM safety committee on the risk assessment**

This work has been reviewed by the local JIC Biological Safety Committee. The modified organisms should be no fitter than the wild-type and are probably less fit. Given the containment levels, environmental hazards are minimal.
**Project Additional Information**

**Purposes of the contained use**

To transform avirulent isolates of powdery mildew to virulence, and hence identify avirulence genes which are specifically recognised by the corresponding resistance gene in plants.

**Recipient or parental organism**

The recipients will be isolates of powdery mildew fungi, (*Blumeria graminis*).

**Host/vector system**
The plasmids used will be derivatives of pCAMBIA and they will be grown in Agrobacterium for transformation. Initial experiments to establish transformation efficiency will require the resistance gene (bar) for the antibiotic bialophos, and will require susceptible barley or wheat line to be bialophos resistant. However, the experiment to isolate avirulence genes will not require bialophos resistance since selection of transformants will be directly on cereal plants containing the corresponding resistance gene. The plasmids contain a kanamycin resistance gene to ensure that the bacterium can be grown without contamination.

Origin & function

The pCAMBIA series of plasmids are available from the Centre for the Application of Molecular Biology to International Agriculture (CAMBIA), Canberra, Australia. The bar gene is isolated from the bialophos-producing Streptomyces hygroscopicus. The bar gene encodes a phosphinothricin acetyl transferase which inactivates the antibiotic bialophos.

A pCAMBIA vector will be delivered to the nuclear DNA of Blumeria graminis by incubation of growing colonies of mildew with the Agrobacterium strain AGCI 563 containing the vector. In the initial experiment to establish efficiency of transformation, the mildew colonies will be inoculated onto a bialophos-resistant line of barley or wheat and sprayed with bialophos. In the experiment to isolate avirulence genes, a derivative of the pCAMBIA vector with the bar gene removed will be used. Selection will be directly onto commercially available cultivars of wheat or barley with the corresponding resistance gene. Any colonies that grow can be expected to disrupted in their ability to produce the avirulence gene specifically recognised by the resistance gene, enabling the avirulence gene to be isolated. All transformants are for experimental purposes only.

Evaluation of foreseeable effects

The purpose of the experiment is not to introduce foreign genes into powdery mildew, but to disrupt the expression of a functional avirulence gene by random insertion of the Agrobacterium T-DNA into the genome. This make the fungus become virulent on a wheat or barley plant carrying the corresponding resistance gene, and will enable us to establish the genetic location of the avirulence gene. Selection is highly specific for disruption in the target avirulence gene, and transformants with altered expression in non-target genes will be recognised by the plant and will die. Mutation to virulence in cereal powdery mildew occurs frequently in nature, and we will use R genes which have already ‘broken down’ in the field, ie for which matching virulence is common in European populations of the fungus. Thus the transformed fungus will not be any more pathogenic than naturally-occurring isolates.

Even though transformed mildew is not expected to be any more pathogenic than naturally-occurring isolates, procedures to minimise risk of escape into the environment will be implemented. Plant, fungal and bacterial colonies will be killed prior to disposal in an autoclave located in the laboratory where the transformants are generated. Laboratory manipulations will be performed in sterilised airflow cabinets and isolates stored in sealed plastic boxes. During the initial experiment to investigate transformation efficiency, transformants will be resistant to the herbicide bialophos. However, bialophos is not used to control fungi, nor indeed is it used as a herbicide in the UK.

The plasmids are geared for expression in bacteria and fungi, and will have no expression potential in humans. The transformed mildew will be used for experimental purposes only and are not intended for human consumption.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Susceptible wheat and barley lines (Bobwhite and Golden Promise respectively) which have been transformed with the bialophos resistance gene will be used during the initial experiment to assess transformation efficiency. These will be grown in DEFRA-approved containment level 2 glasshouses. The plants will be grown to seedling stage (10 day-old) and inch long sections removed and taken to the laboratory (G31 Bateson building) in sealed plastic containers for infection with the transformed mildew isolates. The experiments to isolate avirulence genes will not require any genetically-modified plants.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation from containment level 2 required.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Waste material generated will be in different forms:

1. Residual plant material and soil will be disposed of by autoclaving.
2. Plant material infected with transformed Blumeria graminis isolates will be stored in sealed plastic boxes which will be disposed of by autoclaving.
3. Liquid cultures generated by bacterial propagation will be autoclaved prior to disposal. Plasmid manipulations of bacterial cultures will be completed in glass or disposable plastic vessels, which will be autoclaved prior to disposal.

All autoclaving results in 100% kill. Autoclave procedures are as follows.

1. Soil is autoclaved in stainless steel containers for 1.5 hours (15 min. vent, 30 min. sterilisation at 7 vacuums). Resultant waste is transported in trailers to a farm site where it stands for a 3 year period prior to disposal.
2. Plant waste generated in the glasshouses is autoclaved for 1.33 hours (15 min. vent, 45 min. sterilisation at 2 vacuums).
3. Laboratory material will be autoclaved in Room G68 (adjoining room G31) at 121 degrees C for 18 minutes.

Routine monitoring of autoclave efficiency is completed using thermolog S strips.

Run-off from containment glasshouses is channelled to a filtration plant with a 5000 litre holding tank. 1500 litre aliquots are removed and treated with sodium hypochlorite and circulated in the tank for a 24 hour period, after which they are treated with sodium thiosulphate. The water is then filtered and disposed of.

Details of how the facilities at the John Innes Centre reduce the risk to effectively zero have been supplied, and more details of the experience of the researchers has been provided. Although there is no environmental of human risk, this procedure has been classified as a category 2 activity because it involves work with the powdery mildew fungus, which is a plant pathogen. Under DEFRA guidelines, all work involving plant pathogens is a category 2 activity. Experiments to identify multiple tDNA insertions and insertion of vector backbone have been described in accordance with the recommendations of the safety committee.

Please enter comments on the GM safety committee on the risk assessment

Animal Units  Large Scale Activities  Human Clinical Applications
Project Additional Information

Purposes of the contained use

To characterise signal transduction events in the interactions between plants and their pathogens, particularly disease resistance conferred by the tomato Pto gene in response to strains of Pseudomonas carrying the avrPto gene. The GM organisms described here have been constructed to 1) provide identical strains of Pseudomonas syringae differing only for the presence of avrPto, and 2) to allow transgenic expression of Pto or avrPto in the tomato relative Nicotiana benthamiana for experimental purposes. The GM organisms will be imported from a laboratory in the USA under DEFRA Plant Health License PHL 161/3914.

Recipient or parental organism

1) Pseudomonas syringae pathovar tomato strains DC3000 (unmodified) and T1 (modified).
2) Nicotiana benthamiana (wild tobacco).

Host/vector system

1) Pseudomonas strains have been modified with the derivatives of the broad host-range vector (pDSK519 (Gene 1988) 70, 191-197). Some of the constructs express the avrPto gene from Pseudomonas syringae pv tomato strain TO, from its genomic promoter.
2) N. benthamiana has been modified by Agrobacterium-mediated transformation to express 1) Pto from the 35S promoter, or 2) avrPto from a dexamethasone-inducible promoter.

Origin & function

1) pDSK519 is a derivative of the broad host-range vector RSF1010 (Gene (1983) 24, 299-308). The vector carries the Kan gene for kanamycin resistance, the lacZ gene
and multiple cloning site from pUC18, and where indicated, the avrPto gene with 0.5 Kb of genomic promoter sequence. The broad host range origin allows propagation of
the vector in both E. coli and Pseudomonas. The lacZ<CS facilitates cloning of genes to be expressed, and avrPto confers avirulence to Pseudomonas on hosts carrying
the Pto gene.

2. The Pto gene was cloned into the standard binary vector pB1121 and is expressed from the strong, constitutive 35S promoter. The vector also carries the Kan gene on
the T-DNA. Transgenic plants thus constitutively express Pto from the 35S promoter and are resistant to kanamycin.

3. The avrPto gene was cloned into the binary vector pTA7002 (Curr Opin Biotechnol (2000) 11(2): 146-51) and is expressed conditionally in the presence of
dexamethasone. pTA7002 contains the mammalian GVG gene under control of the constitutive 35S promoter. The T-DNA also contains the HPT gene for resistance to
hygromycin. Thus transgenic plants express GVG and hygromycin resistance constitutively. avrPto expression is silent until specifically induced with the glucocorticoid
dexamethasone.

All GM organisms described here are for experimental procedures only.

**Evaluation of foreseeable effects**

1. Pseudomonas strains carrying pDSK519 will be resistant to the antibiotic kanamycin. Kanamycin is not used to control the bacteria in the field and so this will not add
fitness to the genetically modified organism. Genetically modified Pseudomonas carrying pDSK519 are expected to be slightly less fit than the unmodified bacteria because
of the metabolic cost in replicating the vector. Pseudomonas carrying pDSK519 modified to express the avrPto gene will be avirulent (non-infectious) on hosts expressing
the Pto gene. Therefore, Pseudomonas strains expressing avrPto are expected to be considerably less fit than the unmodified organism. The protein encoded by AvrPto is
only known to be active within the plant cell, and is not known ro have any biological effects on humans. The sequence of the avrPto gene does not suggest any
relationship with known toxins. The Pseudomonas strains used here are not known to be pathogenic on humans. AvrPto is not known to increase the virulence of
Pseudomonas, and in fact should decrease the host range of the modified bacteria. Therefore, Pseudomonas carrying pDSK519 expressing the avrPto gene should be
less fit than the unmodified organism.

2. Transgenic Nicotiana benthamiana 38-12 expressing 35S:pto will be resistant to Kanamycin. Kanamycin is not used to control plants in the field and this is not expected
to make any difference to the fitness of the organism. Plants expressing 35S:Pto will be resistant to bacteria that contain the avrPto gene. The resistance is specific to
micro-organisms and will not cause the plant to become more toxic to humans or animals. The resistance will not be selected against in the wild so the transgenic plants
will not be fitter than unmodified plants. Therefore I foresee no potential for these plants to pose a hazard as weeds.

3. Transgenic Nicotiana benthamiana containing the T-DNA derived from vector pTA7002, or this vector containing the avrPto gene, will be resistant to hygromycin, a
herbicide. Thus the plants will no longer be susceptible to this herbicide, but can still be contained by application of unrelated herbicides (multiple herbicide resistance will
not be a result of the modification). The modified plants are not expected to be fitter than unmodified plants. Transgenic N. benthamiana containing the PTA7002 T-DNA
containing the avrPto gene will express AvrPto protein only when induced with the specific chemical inducer, dexamethasone. AvrPto protein will not be expressed under
any other conditions so the chance of expression of AvrPto after escape to the wild is negligible. AvrPto is not knonw to be toxic to humans or animals, and is only known
to be active when expressed within the plant cell. Expression of AvrPto will activate plant defences only in the presence of the host resistance gene, Pto. Plants modified
with the capability to express AvrPto upon induction with dexamethasone are not expected to be fitter than unmodified plants, and do not possess greater potential to be
weeds than the unmodified plant.

**ENVIRONMENTAL RISK**

Plant and bacterial material will be killed by autoclaving prior to disposal, eliminating risk of environmental contamination by this route. Laboratory surfaces exposed to
genetically modified micro-organisms will be decontaminated by treatment with bleach or 70% ethanol. All compost and residual plant material generated in containment
glasshouses is also autoclaved prior to disposal. Containment glasshouses are DEFRA-approved and have air filter and waste-water treatment systems. The GMMs
described here are expected to be less fit than unmodified bacteria.

**HUMAN HEALTH RISK**

The plasmids used are designed for bacterial use and should have no expression potential in humans. The transformed organisms are for experimental purposes only and
are not intended for human consumption or environmental release. The bacterial hosts are not pathogenic to humans.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Containment level 2 is appropriate for GM plants that are imported under a DEFRA Plant Health License (PHL 161/3914). All GM material will be imported as seed in sealed vials.

Transformed plants will be grown in DEFRA-approved containment level 2 glasshouses. Transfer of the GM material between the laboratory and glasshouses will be in sealed plastic bags to prevent dissemination of the material. Plants will be grown to 4-6 weeks old prior to infection or sampling for biochemical analyses. Where infection of plants with GMMs is necessary, infected plants growing in containment glasshouse will be maintained free from invertebrates. Infected plants will be grown on saucers to prevent spillage of soil or drainage water, and inflorescences will be bagged to contain pollen and seed, which will be destroyed by autoclaving or stored within the glasshouse in a suitably labelled, secure container. Plant material infected with GM bacteria may be transported from containment facilities to the laboratory in sealed plastic bags, however most material will not leave the glasshouse but be destroyed by autoclaving of plants, soil, and contaminated material, in the dedicated autoclave within the glasshouse.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Waste material generate will be in different forms:

(i) Residual plant material and soil will be disposed of by autoclaving.
(ii) Plant material infected with transformed P. syringae strains will be stored in sealed boxes which will be disposed of by autoclaving.
(iii) Liquid cultures generated by bacterial propagation will be autoclaved prior to disposal.

All autoclaving results in 100% kill. Autoclave procedures are as follows:

1. Soil is autoclaved in stainless steel containers for 1.5 hours (15 min vent, 30 min sterilisation at 7 vacuums). Resultant waste is transported in trailers to a farm site where it stands for a 3 year period prior to disposal.
2. Plant waste generated in the glasshouses is autoclaved for 1.33 hours (15 min vent, 45 min sterilisation at 2 vacuums).
3. Laboratory material will be sealed in plastic bags and boxed, before being autoclaved in room G68 (adjoining room G31) at 121 degrees C for 18 minutes.

Routine monitoring of autoclave efficiency is completed using Thermolog S strips.

Run-off from containment glasshouses is channelled to filtration plant with a 5000L holding tank. 1500 L aliquots are removed and treated with sodium hypochlorite and circulated in the tank for a 24 hour period, following this treatment is with sodium thiosulfate. The water is then filtered and disposed of.

Project Additional Information

Purposes of the contained use

Turnip crinkle virus cDNA clones were obtained from Dr Dan Klessig, Boyce Thompson Institute, Ithaca, NY, USA under DEFRA license PHL 161A/4391 (01/2003). The cDNA will be inoculated either as cDNA or as in vitro transcripts to arabidopsis plants. The level of accumulation will indicate whether the virus is able to accumulate either in the presence or absence of HRT.
The experiments will generate TCV that are as virulent or less virulent than the wild type constructs. The most virulent constructs would have the ability to survive, establish and disseminate in the environment. However, given the use of containment there is only a low hazard from these experiments.

Turnip crinkle virus is not known as a hazard to human health and nor is there any reason to suppose that it could be unless specifically modified to express toxic proteins or proteins that produce toxic products.

Host/vector system

Origin & function

Turnip crinkle virus cDNA clones were obtained from Dr Dan Klessig, Boyce Thompson Institute, Ithaca, NY, USA under DEFRA license PHL161A/4391 (01/2003). The cDNA will be inoculated either as cDNA or as in vitro transcripts to Arabidopsis plants. The level of accumulation will indicate whether the virus is able to accumulate either in the presence or absence of HRT.

Evaluation of foreseeable effects

Turnip crinkle virus is not known as a hazard to human health and nor is there any reason to suppose that it could be unless specifically modified to express toxic proteins or proteins that produce toxic products. To eliminate this hazard we shall not express toxic proteins or proteins known to produce toxic products. The host plants used in the experimental work include Arabidopsis, potato, tomato, Nicotiana species, Chenopodium species, Gomphrena globosa. None of these experimental plants is a human health hazard under the conditions used in our experimentation. There is no reason known to me why infection with wild type or modified forms of turnip crinkle virus should cause these plants to be a human health hazard under the conditions used in our experimentation.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Bacterial cultures containing the TCV clones will be propagated in the laboratory in axenic culture and will be disposed of by autoclaving. All materials in contact with these cultures will also be sterilized to give 100% kill before disposal. Infected plants will be maintained in the containment glasshouse at the John Innes Centre. Standard operating procedures for the glasshouse and for disposal of glasshouse waste will be strictly adhered to. These procedures provide physical containment, biological containment by minimising opportunities for unwanted spread of the virus infection and for disposal of waste after sterilization by autoclaving.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Autoclaving of all materials to give 100% kill. Autoclaves are regularly monitored with Thermalogues. All inactivated waste is sent to landfill.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The background to the proposed work is a project in which the inf1 extracellular protein of P. infestans was identified as an avirulence determinant on N. benthamiana (Kamoun et al., 1998). P. infestans strains that produce this protein do not exhibit extensive growth or sporulation whereas strains in which the inf1 protein are not produced exhibit extensive hyphal growth and do sporulate whereas strains in which the inf1 protein are not produced exhibit extensive hyphal growth and do sporulate. The role of inf1 as an avirulence determinant is associated with its ability to elicit a hypersensitive necrotic response in N. benthamiana (Kamoun et al., 1997). This hypersensitive response is manifested in a simple assay in which a solution of the inf1 protein is infiltrated into leaves of N. benthamiana. After 2-3 days the infiltrated patch becomes...
necrotic and eventually dies. We shall be using the genetically modified isolate of P. infestans that does not produce inf1 as a control in tests of N. benthamiana genes that may be involved in the resistance pathway.

Recipient or parental organism

The modified strains of P. infestans will carry antisense transgenes to suppress expression of inf1. These strains also carry a kanamycin resistance gene that was used as a selectable marker in the production of the strains. We intend to use these strains as a negative control in the experiments described above. If we have completed ablated the resistance against P. infestans in N. benthamiana the wild type strains will grow as well and will sporulate at the same level as the inf1 strains. There is no reason to suppose that there is a human health risk since P infestans is not known as a human pathogen and the genetic modification will have resulted in loss of gene expression. The genetic modification in P. infestans transformants isolates 88069 Y15, PY23 and PY37 results in the ability of the strain to overcome natural resistance in N. benthamiana. However this modification does not affect the pathogen on potato, tomato or tobacco. (Kamoun, S., vanWest, P., Vleeshouwers, V., deGroot, K.E. and Govers, F (1998). Resistance of Nicotiana benthamiana to Phytophthora infestans is mediated by the recognition of the elicitor protein INF1. Plant Cell 10, 1413-1425.). Since N. benthamiana is not a UK species (it is from Australia) there is no reason to think that the gm strains would pose an environmental hazard.

Host/vector system

Not applicable.

Origin & function

The P. infestans isolates were imported under DEFRA licence from Wageningen, The Netherlands

Evaluation of foreseeable effects

The most severe consequences that could be envisaged would be a novel pathogen of N. benthamiana species that are used for experiments in the JIC. However as no experiments will be carried out in glasshouses this is an unlikely scenario. All proposed experiments will be carried out on detached leaves of plants maintained in propagators that are kept in incubators with illumination.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All proposed experiments with infected plants will be carried out on detached leaves of plants maintained in incubators in the laboratory. The level 2 containment measures will include:

* the use of microbiological safety cabinets when handling cultures of the isolates
* autoclaving to be carried out in the laboratory building
* all handling of liquid cultures and samples in microbiological safety cabinets and using procedures that minimise aerosol production.
* cultures to be handled only by named personnel
* laboratory coats to be worn at all times when handling cultures and samples
* disinfectant procedures as specified in standard operating procedures
* inactivation of contaminated material and waste by autoclaving prior to disposal
* cultures will be maintained in designated freezers and storage areas.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1. SECURITY
   a) Areas containing quarantine material: all bioassays should be carried out in the laboratory under the following conditions: inoculations of agar plates and plant tissue with licensed isolates of P. infestans should be performed in microbiological safety cabinets designed for experiments dealing with fungi. For long-term storage, stocks of P
infestans zoospores in 15% DMSO are stored in cryotubes in a -80 degrees C freezer. Regarding the bioassays, mycelium should be grown on appropriate agar medium in petri dishes sealed with parafilm. Bioassays will be carried out on plant detached leaves that will be placed in screw-capped plastic containers or sealed petri dishes. Plates and plants should be kept in sealed containers at 18 degrees C in a growth chamber designated for P infestans bioassay experiments located in the laboratory.

b) Access to quarantine areas: the growth chamber is used exclusively for experiments using licensed isolates of P infestans, therefore only those persons working with these isolates will be authorised to use this facility. One person will be in charge of monitoring whether standard operating procedures are followed.

c) Quarantine areas should be labelled clearly with the following information: this facility is to be used for P infestans work only, with a description of the licensed material, the name of the persons authorised to use the growth chamber and the name of the person in charge of the project. Information on the type of work that is being carried out at any one time should also be listed.

d) Authorised personnel will have to read and sign the operating procedures before they can work on the licensed material.

2. ADMINISTRATION AND RECORDING:

a) Dated records of all introductions of licensed material and description of the work will be kept in a log book.

b) Licensed material should be labelled as such together with the name of the corresponding P infestans isolate, the date and the name of the user, through all stages of experimentation.

c) Inventories of stocks will indicate that the material is held under licence and that users should be authorised.

3. TRANSPORT BETWEEN AND WITHIN LICENSED AREAS

a) Infected material should be kept at all times in sealed containers and transported in these containers between the microbiological safety cabinet and the growth chamber or -80 degrees C freezer so that escape of the pathogen is prevented.

b) The licensed material should be sent as rye-agar slants of pure P. infestans mycelium covered with mineral oil, in screw-capped tubes placed in a metal container to avoid the possibility of damage. To eliminate any fungal or bacterial contaminants, P. infestans isolates should initially be grown on clean-up media containing a cocktail of antibacterial and antifungal agents prior to starting any other manipulation.

4. CONTAINMENT FACILITIES

a) All experiments should be carried out in the laboratory using three types of facilities: a -80 degrees C freezer, a growth chamber and a microbiological safety cabinet. It should be noted that the latter will not be used for storage of material but for inoculation experiments only.

b) The -80degree C freezer and the growth chamber (Sanyo versatile environmental test chamber) are located on the first floor of the Sainsbury Laboratory in room SL1-40. The microbiological safety cabinet is located on the second floor of the Sainsbury Laboratory in room 241.

c) Licensed facilities can be used by authorised staff as many times as required provided that they follow strictly the procedures described here.

d) The growth chamber should not be overcrowded, no more than 200 leaf samples and no more than 20 mycelium plates should be kept at any one time. Up to 100 cryotubes containing stocks P. infestans will be stored in the -80 degrees C freezer. The microbiological safety cabinet will only be used for inoculation experiments.
typically inoculations of 50 samples can be done at any one time.

e) Sharing of the facilities: the growth chamber will only be used for growing licensed material whereas the -80 degrees C freezer and the microbiological safety cabinet will be shared between licensed and non-licensed material.

f) Type of work to take place in each area:
- microbiological safety cabinet: inoculations of agar plates and plant tissue with P. infestans. Preparation of infected leaf samples for microscopy and extraction of nucleic acids.
- growth chamber: incubation of P. infestans and infected leaves in sealed containers at 18 degrees C.
- -80 degrees C freezer: storage of pathogen material.

g) The licensed material will not include plants for planting.
h) There are no traps to detect any escapes of the licensed organism.

5. EXPERIMENTAL PROCEDURES

a) Protocol: Inoculations of agar plates and plant tissue with P. infestans are performed in a microbiological safety cabinet designed for experiments dealing with fungi. Stocks of P. infestans zoospores will be stored in cryo-containers at -80 degrees C. To carry out bioassays, mycelium will be grown from single zoospores taken from the cryotubes in petri dishes containing the appropriate growth medium (typically rye-agar or pea-agar). Plates will be sealed with parafilm and incubated at 18 degrees C in the growth chamber for us to three weeks. Isolation of P infestans zoospores will be done by adding cold water on the surface of the mycelium that is growing on the agar plate and incubating the plate at 4-8 degrees C in an ice box. After 1-2h, water suspension containing zoospores is collected and filtered through cheesecloth to separate the zoospores from the mycelium. Bioassays are carried out on detached leaves from Nicotiana benthamiana, potato and tomato plants. Aliquots of zoospores from the water suspension are taken with a Gilson pipette fitted with filtered tips and placed on the surface of the leaves. Typically, each leaf will is inoculated with 20ul droplets containing between 100 and 1000 zoospores. Leaves are placed in sealed containers and incubated at 18 degrees C in the growth chamber for up to 8 days. To assess biotrophic growth of the pathogen, pieces of leaf are cut with a scalpel at different days and placed immediately in screw-capped tubes containing a fixing solution (1 volume of chloroform, 3 volumes of acetic acid, 6 volumes of ethanol), such a treatment will neutralise the pathogen and bleach the leaves so that they can be used for microscopy analyses. For DNA analyses, plant tissue is placed directly in a lysis solution that will also neutralise the pathogen. The scalpel will be sterilised by dipping into ethanol and flaming, it will be kept in the microbiological safety cabinet in ethanol at all times.

b) Staff should wear lab coats and gloves at all times. Gloves will be disposed of immediately after use and autoclaved.

c) Infected material should be kept at all times in sealed containers and transported in these containers between the microbiological safety cabinet and the growth chamber or -80 degrees C freezer so that escape of the pathogen is minimised.

6. HYGIENE AND DISPOSAL

a) Infected areas will be disinfected with 70% ethanol.

b) Disposal of waste: waste will consist of sealed petri dishes containing mycelium, screw-capped tubes containing zoospores/sporangia in water, gloves, screw-capped plastic containers containing infected plant tissue, pipette tips used for inoculation of plant tissue. All contaminated material will be placed in autoclave bags in closed containers and autoclaved immediately after use using autoclaves that are located on the first floor of the Sainsbury Laboratory or other locations that can be reached through indoor corridors and passageways.
Approved November 7th 2003.

Project Ref 38/04.3

Date Ackn'd 04/02/2004
CU2 Project Title THE AIM OF THE WORK IS TO INVESTIGATE VIRUS ENCODED PROTEINS AS SUPPRESSORS OF GENE SILENCING.

Class 2 Culture Vol Class 2 Culture Volume Class 3-4
Class 2 < 1 litre

Non-GMM Consent Granted not applicable

Project notified under transitional arrangements N
**Project Additional Information**

**Purposes of the contained use**

The experiments will involve expression of these viral proteins in plants in a transient expression system in transgenic plants. The findings will be informative about the mechanisms of silencing and, through the identification of host proteins that interact with the suppressors, about the host proteins involved. In addition by coexpression of viral suppressors and non viral transgenes encoding foreign proteins, it will be possible to enhance expression of these foreign proteins in plants.

The coexpression experiments will be carried out using agrobacterium transient expression in leaves of Nicotiana species. These experiments will not generate transformed plants - the agrobacterium strains are unfiltrated into leaves and expression of the suppressor and the foreign protein is assayed within 14d.

Transgenic Arabidopsis and solanaceous plants will be developed to express these suppressor proteins as part of our work to investigate the mechanism of silencing.

**Recipient or parental organism**

The viral suppressors will be derived from beet western yellows virus, cotton leaf curl virus, African cassava mosaic virus, tomato bushy stunt virus, cucumber mosaic virus. None of these viruses is known as a hazard to human health and nor is there any reason to suppose that they could be in the proposed experiments. The experiments will not involve expression of these viruses as infectious agents - the isolated genes for the suppressor proteins will be used.

PO from beet western yellows virus (Pfeffer et al., 2002)
beta C1 protein from cotton leaf curl virus (Briddon et al., 2001)
p19 from tomato busy stunt virus (Silhavy et al., 2002)
2b from cucumber mosaic virus (Ji and Ding, 2001)
AC2 from african cassava mosaic virus (Voinnet et al., 1999)

**Host/vector system**

The cDNA clones of the suppressor proteins will be maintained in bacterial plasmids maintained either in E. coli or A. tumefaciens. The E. coli strains will be standard laboratory strains and the A. tumefaciens will be standard non oncogenic isolates used for plant transformation.

**Origin & function**

The cDNA clones were obtained under DEFRA license PHL161A/4391(01/2003)

**Evaluation of foreseeable effects**

It is unlikely that accidental release of transgenic plants expressing these suppressor proteins would have a harmful effect because the proteins are not known to be toxic.
and because the plants are normally impaired in growth and development and because they are hypersusceptible to virus disease.

The effects of the potyvirus suppressors on development is described (Anandalakshmi et al., 2000; Kasschau et al., 2003) and it likely to be a guide for the effects of other suppressors in transgenic plants. The effect of p189 on arabidopsis development has been described by Dunoyer et al (2004) and is described in a paper in press. The hypersusceptibility phenotypes to virus disease are described for a potyvirus suppressor of silencing (Pruss et al., 1997) and for the 2b protein of cucumber mosaic virus (Li et al., 1999).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Bacterial cultures containing the suppressor clones will be propagated in the laboratory in axenic culture and will be disposed of by autoclaving. All materials in contact with these cultures will also be sterilized to give 100% kill before disposal. Plant tissues that are transiently expressing these proteins or that are stably transformed to express these proteins will be maintained in the containment glasshouse at the John Innes Centre. Standard operating procedures for the glasshouse and for disposal of glasshouse waste will be strictly adhered to. These procedures provide physical containment, biological containment by minimising opportunities for disposal of waste after sterilization by autoclaving.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Autoclaving of all materials to give 100% kill. Autoclaves are regularly monitored with Thermalogues. All inactivated waste is sent to landfill.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form  

Tick to confirm that you have attached a risk assessment to this form  

Tick if you are claiming exemption from disclosure for section of the risk assessment  

Please enter comments on the GM safety committee on the risk assessment
Approved November 7th 2003 and revised after request from HSE for more information and decision by investigator to remove PVX expression experiments. The BSC made the following comments on the revised risk assessment.

Two points:
Section B(ii) of the GMRA - the same paragraph appears twice.
Section 12 of the Notifications suggest the following:
Autoclaving of all materials to give 100% kill. Autoclaves are regularly monitored with Thermalogues. All inactivated laboratory waste is sent to landfill and inactivated soil waste is composted on site for 2 years prior to use on JIC field plots.

I've had a look at bogh assessments and they look fine. The previous comments concerned the problems which might arise if suppressors of silencing were expressed from a viral vector (PVX) and resulted in increased virulence. The PVX expression work is no longer requested and the new versions appear to have assessed the potential hazards correctly.

I found one typographical error in GMRA 154 Revised: The paragraph starting: "The Agrobacterium strains and Arabidopsis and Nicotiana species would survive in the environment but neither are likely to cause damage…" In Part B (ii) is repeated twice.

This revised version appears to be OK. Only one minor point: Section (ii) of the GMRA refers to African cassava mosaic virus but, unlike other viruses mentioned, there is no reference (Voinnet et al., 1999) provided. This also applies to section 7 of the HSE Notification.

Everything appears to be in order.
The appropriate minor corrections were made to the GMRA and HSE notification form in response to these comments.

**Date Ackn'd**  19/01/2007

**Date Project Ceased**  02/03/2022

**CU2 Project Title**  Expression of candidate oomycete and fungal effector proteins in planta, in Agrobacterium sp., Xanthomonas spp., Erwinia sp. And in Pseudomonas syringae.

**Class**  Class 2

**CultureVolClass2**  < 1 Litre

**CultureVolumeClass3-4**

**Non-GMM**  Not Applicable

**Consent Granted**
**Project Additional Information**

**Purposes of the contained use**

Please see page 10 for section 6. (additional comments page).

**Recipient or parental organism**

Recipients will be standard laboratory strains of Escherichia coli, disarmed or non-oncogenic isolates of Agrobacterium tumefaciens, Pseudomonas syringae (all pathovars), Xanthomonas campestris pv. vesicatoria (=Xanthomonas axonopodis pv. vesicatoria), Xanthomonas translucens pv. hordei (Xanthomonas translucens pv. Translucens) and Xanthomonas campestris pv. campestris and Erwinia carotovora. These experiments may generate transgenic plant pathogenic bacteria with altered host ranges or pathogenicity.

**Host/vector system**

Plasmids used will be recombinant pBBR, pVS1, pVSP61 (a derivative of pVS1), pGreen, pRK290 derived binary vector plasmids, pBIN19 and pTA7002 (a derivative of pBIN19). These plasmids are either non-mobilisable or non self-mobilisable and encode genes for resistance to gentamycin, spectinomycin, kanamycin and tetracycline for selection in vitro. Recombinant plasmids may carry effector fusions that could deliver oomycete or fungal effector proteins into plant cells.

**Origin & function**

Candidate plant pathogen effector molecules will be identified and genes cloned from the oomycete pathogens; Hyaloperonospora parasitica (Hp), Albugo candida (Ac), Phytophthora infestans (Pi), Phytophthora capsici, phytophthora sojae and from the fungal pathogens; Golovinomyces spp., Erysiphe spp., Blumeria spp. and Colletotrichum spp.

Many of these candidate effectors from Hp.Ac.Pi, Phytophthora capsici, Phytophthora sojae, Golovinomyces spp. Erysiphe spp., Blumeria spp. Or Collectotrichum spp. Will be fused to the N terminal TTSS secretion signal of a Pseudomonas,Erwinia or Xanthomonas TTSS- secreted protein, introduced into Pseudomonas, Erwinia, Agrobacterium or Xanthomonas, and then tested for their phenotypes on various species and strains of Arbidopsis, Medicago, Tricitcum, Brassica, Solanum, Lycopersicon, Horedonium, Brachypodium, Oriya and Nicotiana whole plants grown in Glasshouses and CERS.

**Evaluation of foreseeable effects**

Human Health and Environment

The E.coli to be used in this study are rec-non-colonising derivatives of K-12. The Pseudomonas, Erwinia and Xanthomonas phytopathogens in this study are endemic in the UK and have specific host-ranges as indicated by their pathovar designations. The genetic manipulation of these bacteria will be performed using replication-compromised plasmids that are unstable and lost in the absence of persistent antibiotic selection. The transformedPseudomonas, Agrobacterium, Erwinia and Xanthornonas spp. Will be essentially identical to their non-transformed parents except for the expression of pathogens effector molecules. These bacteria are
non-sporulating water-borne organisms that are readily contained using standard microbiological practices. The genetic manipulations in this study may alter the pathogenic properties of the bacteria, but these changes are as likely to result in reduced host range as in increased host range, because bacteria regularly exchange plasmids that encode effector proteins that plants have evolved the capacity to recognize, and plants have resistance proteins that recognize effectors from diverse microbes. Because of the narrow host range of these bacteria and the genetic instability of these vectors outside the laboratory, no adverse environmental effects are expected.

The Pseudomonas, Xanthomonas and Agrobacterium strains to be used are unable to colonise humans, as they are incapable of growth at 37°C. The Erwinia species used are not human pathogens. No adverse human health effects are foreseen. It is not foreseen that plant infected with any of these transgenic plant pathogenic bacteria would constitute a human health hazard.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For plant material infected with GMM, containment level 2 is appropriate. Infected plants will be maintained in containment level 2 growth facilities at the John Innes Centre. Standard operating procedures for the use of plant growth facilities and for the disposal of waste will be strictly adhered to.

The bacteria infected plant material and compost will be killed by autoclaving prior to disposal. The containment glasshouses have an approved air filter system to minimise the accidental release of aerosols, and as these are non-spore forming bacteria, such as risks are negligible.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Class 2 GMM (plant pathogen) (containment level 2). All GMM material will be handled using good microbiological practice (GMP). All GMM material will be autoclaved prior to disposal.

Residual plant material will be stored in sealed containers and disposed of by autoclaving. Liquid bacterial cultures will be autoclaved prior to disposal.

Autoclave procedures are as follows: Soil and plant waste generated in glasshouses and growth rooms is autoclaved in stainless steel containers for 1.5 hours (15 minutes vent, 30 minutes sterilisation at 15 p.s.i) Resultant waste is transported to a farm site where it is left to stand for three years prior to disposal. The compost banks are inspected twice yearly and sprayed with a general purpose herbicide.

Routine monitoring of autoclave efficiency is completed using Thermolog S strips.

Run-off from containment glasshouses is collected into 5000L tank. 1500L aliquots are removed and treated with sodium hypochlorite and circulated in the tank 24 hours followed by a treatment with sodium thiosulphate. The water is then filtered and disposed. Plants in growth rooms will be sub-irrigated in teak proof trays such that minimal run-off is generated.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The John Innes Centre GM Safety Committee have reviewed the risk assessment and the HSE notification both electronically via e-mail and also at a general meeting on the 6th November 2006. A series of minor improvements and text additions were recommended and incorporated by the group leader. The classification for the containment were agreed.

### Project Additional Information

**Purposes of the contained use**

The purpose of this project is the use of plant virus-based vectors for analysis of monocotyledonous plant gene function through silencing. Plant viral cDNAs, under the control of bacteriophage promoters for in vitro transcription, will be genetically modified through the insertion of cereal derived genes to determine the effects of silencing on...
Recipient or parental organism

Barley stripe mosaic virus (BSMV) gene silencing vector
As tested by SCRI, Dundee (HSE centre number GM 250)

Host/vector system

Virus induced gene silencing (VIGS) using the BSMV-based gene silencing vector will be performed in different cereal species (intially with Hordeum and Triticum aestivum). BSMV vector viral cDNAs will be contained in plasmids (such as pUC-based plasmids) under the control of bacteriophage or plant promoters. Plasmids will be cultured in disabled Escherichia coli strains (such as XL1-Blue and DH5a).

Origin & function

VIGS of cereal genes will be performed using partial cDNAs of candidate genes isolated from different cereal species (such as Hordeum vulgare and Triticum aestivum) inserted into the BSMV vector. Also reported genes such as Green fluorescent protein (GFP) from Aequorea and ß-glucuronidase (GUS) from Escherichia coli will be used.

Evaluation of foreseeable effects

The viral proteins produced by the recombinant viruses occur in nature and have no known risks to human health. The reporter proteins GFP and GUS have been expressed in a wide range of experimental systems and do not present a risk to human health. BSMV is non-indigenous plant pathogen and thus subject to legislative control and is a cause of disease in wheat and barley. In order to provide robust biological containment, portions of the coat protein genes of BSMV have been deleted to render them non-transmissible by mechanical routes (system developed by Holzberg et al 2002). Previous insertion of reporter protein genes into plant viral genomes has resulted in the creation of attenuated viruses and no mechanism for enhanced pathogenicity can be foreseen. Overall the coat-protein disabled BSMV can be considered to present less risk to the environment than the natural progenitor viruses.

The modified BSMV strain has been used successfully in several labs (Lacomme et al 2003, Hein et al 2005, Scofield et al 2005 and Cloutier et al 2007) to silence targeted genes, both reporter genes and partial cDNAs from cereals. The vector to be used for this study will be obtained from the Scottish Crop Research Centres (SCRI) in Dundee where the BSMV based VIGS system is used under CL2.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All materials in contact with viral material will be sterilized to give 100% kill before disposal. Sterilization will be carried out when plants are four weeks old. Plant tissues that are transiently silenced will be maintained in the containment glasshouse at the John Innes Centre. Standard operating procedures for the glasshouse and for disposal of glasshouse waste will be strictly adhered to. These procedures provide physical containment, biological containment by minimising opportunities for disposal of waste after sterilization by autoclaving.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Infected plants and associated materials (soil, plants, gloves) will be autoclaved using a protocol validated to give 100% kill. Plant extracts prepared in the laboratory and material derived from them will be autoclaved using a protocol validated to give 100% kill. Containment surfaces will be disinfected with a proprietary validated viricide.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
John Innes Centre Biological (GM) Safety Committee agrees with the containment level 2 classification. Main Comment:

Although BSMV can infect many different species of plants from a range of plant families, it may be that this virus and vectors derived from it would not necessarily be able to trigger gene silencing in all of them. This is the case for PVX induced plant gene silencing. One could say that the native virus poses a greater risk to the environment than the proposed genetic modification. It is necessary to address the risk of silencing genes in plants from the same or other plant family, which may include plants in the neighbouring environment. In the absence of pollen transfer this virus would be contained absolutely, since it can no longer be mechanically transmitted.

The risk assessment states that silencing of endogenous genes could result in more severe infection symptoms (if host defence genes are silenced. The notification to the HSE states that no mechanism for enhanced pathogenicity can be foreseen with reference to viral genomes with inserted reporter protein genes. If silencing of endogenous genes could result in greater disease symptoms, then include it in the HSE notification (the logic being that a pathogen will be more pathogenic on a plant that is less fit). It could be that no known host defence genes will be targeted for silencing and say so if that is indeed the case. It would probably be useful to indicate the nature of the genes to be silenced in the Project Description Overview.

**Project Ref** 38/11.1

**Date Ackn'd** 03/05/2011

**CU2 Project Title**
Virus induced gene silencing (VIGS) and virus-mediated heterologous gene overexpression in the Graminae: Aegilops spp., Triticum spp., Hordeum spp. and Brachypodium distachyon and virus induced gene silencing (VIGS) in the Fabaceae

**Date Project Ceased**

**Class** Class 2
**CultureVolClass2** < 1 Litre

**Non-GMM Consent Granted**

**Project notified under transitional arrangements** N
Project A;
Virus induced gene silencing (VIGS) and virus-mediated heterologous gene overexpression in the Poaceae; Aegilops spp., Triticum spp., Hordeum spp., Avena spp., and Brachypodium distachyon.

This project aims to establish protocols for: (1) virus-induced gene silencing (VIGS) and (2) virus-mediated gene overexpression in Aegilops sharonensis, (Sharon goatgrass), Ae. Longissima, Ae. Bicornis, Ae. Searssii and Ae. Speltoides, Triticum species, especially Triticum aestivum (bread wheat), T. durum (pasta wheat), T. boeoticum (domesticated Einkorn wheat), T. monococccum (wild Einkorn wheat), T. diococum (domesticated Emmer wheat) and T. dicoccoides (wild Emmer wheat), Hordeum vulgare (Barley) and Hordeu, valgare subsp. Spontaneum (wild Barley), Avena sativa (oat) and Brachypodium distachyon. VIGS, if achieved, would be a useful tool to test the function of candidate wheat stem rust (Puccinia gramiis f.sp tritici) and wheat yellow rust/stripe rust (Puccinia striiformis f. sp. Tritic) resistance genes. We will test cloned viruses with a proven potential above all in monocots, including brome mosaic virus (BMV), barley stripe mosaic virus (BSMV), tomato yellow leaf curl virus: (TYLCV), and soil-borne wheat mosaic virus (SBWMV).

The same viruses identified in the screen above will also be tested for their ability to over express candidate effector genes from wheat stem rust and wheat stripe rust.

Project B;
Virus induced gene silencing (VIGS) in the Fabaceae.
Bean pod mottle virus (BPMV) and tomato yellow leaf curl virus; (TYLCV)

This project aims to establish protocols for and identify whether either of these viruses are suitable vectors in order to achieve virus induced gene silencing (VIGS) and/or virus-mediated heterologous overexpression in the Fabaceae.

Virus osolates we will use are infectious modified clones. They are full length clones that have had certain restriction enzyme sites modified or introduced (to facilitate cloning) and also in some cases have been engineered to carry foreign "marker" gene(s), including the green fluorescent protein (GFP), b-glucoronidase (GUS), the bar gene from Streptomyces hygrosporius coding for phosphimothricin (PPT) acetyltransferase, and a fragment of wheat and or barley pds (phytoene desaturase) for gene silencing. In the case of BSMVb we also plan to employ a widely used clone, BSMVbDa, that has the ba gene (coat protein) deleted (Holzberg et al., 2002). The modified tri-partite virus (longhand, BSMV a::bDba::g) spreads systemically better within barley (Holzberg et al., 2002) but considering that seed transmission determinants map to RNAa and RNAg (Edwards, 1995) it is conceivable that such a mutant would display reduced seed transmission.

The identified hazards would be the escape of GM virus that could silence wheat stem rust and/or stripe rust resistance genes in plants in the local environment, thereby rendering infected plants more susceptible to these fungal pathogens or the GM virus could cause plants in the local environment to die, probably not as a result of the pathogenicity of the virus, but as a result of the host plant's recognition of fungal effector proteins. The GM virus will likely be more pathogenic on plants with compromised...
host defence mechanism. Viral vectors expressing genes such as fluorescent or antibiotic resistance markers will have a neutral effect on their host plant in that the genetic modification will not affect viral pathogenicity. Recombinant viruses could survive in the environment, but the genetic modification is unlikely to persist due to the instability of recombinant viral vector genomes.

Host/vector system

The genetically modified viruses will be the vectors for the delivery of gene constructs that would direct either the overexpression or silencing of wheat stem/stripe rust genes and/or host plant resistance genes. We may consider cloning the virus in the T-DNA of a standard laboratory binary vector, such as pBIN19 but not exclusive to, and delivered from a disarmed Agrobacterium strain.

Origin & function

We may engineer BSMV (or other viral) infectious clones expressing putative fungal stem rust and/or stripe rust effector(s) (some of which will have been identified in the lab of Fumiaki Katagiri, J G and L S, University of Minnesota, USA; and in the lab of Sophien Kamoun and Cristobal Uauy, The Sainsbury Laboratory, The John Innes Centre, Norwich, UK)

The identification of novel eukaryotic plant pathogen effector molecules from wheat stem and stripe rust and the identification of host plant resistance genes will lead to novel strategies for the control of these and other emerging crop pathogens.

Evaluation of foreseeable effects

Human Health;

None of the recipient organisms used in these projects is a human pathogen and does not, therefore, constitute a hazard to human health. The proposed genetic modifications of plant viruses here described will not cause the modified viral vectors to become human or animal pathogens and are therefore of no risk to human or animal health. None of the host plants used in the experimental work, is nor is likely to become, a human health hazard under the conditions used in our experimentation.

Environmental Safety;

Virus-Induced Gene Silencing (VIGS)
The silencing of endogenous plant gene(s) may compromise host defence, enabling the virus to be more virulent than the corresponding wild type isolate. The GM-virus infected plants will be more susceptible to wheat stem rust and stripe rust. The identified hazard would be the escape of GM virus that could silence wheat stem rust and/or stripe rust resistance genes in plants in the local environment, thereby rendering infected plants more susceptible to these fungal pathogens.

Virus-Mediated Gene Over expression (VMGO)
The virus mediated overexpression of plant fungal pathogen effector proteins may cause the infected plants to grow more slowly or even lead to plant death. The identified hazard would be the escape of GM virus that could cause plants in the local environment to die, not as a result of the pathogenicity of the virus, but as a result of the host plant's recognition of fungal effector proteins. The GM virus will likely be more pathogenic on plants with compromised host defence mechanisms.

The endogenes that will be silenced or the transgenes that will be overexpressed with virus vectors will be candidates for either wheat stem rust/stripe rust resistance or wheat stem rust/stripe rust avirulence determinants.

It is unlikely that either the overexpression of avirulence determinants from these plant fungal pathogens or the silencing or wheat stem rust/stripe rust resistance genes will pose a threat to UK farming or the natural environment. Wheat stem rust has only been found in the south coast of the UK well after normal harvesting time for cereals, it was last identified in 1981 and has never been observed spreading into the UK in the last century (R B, personal communication) and wheat stripe rust is routinely controlled with fungicides

Survival of GM virus in the local environment

Since all the viruses that will be genetically modified have broad host ranges, there is a high likelihood that GM virus could find a suitable host in the local environment. The
insertion of genes into the viral genome is extremely unlikely to affect the virus host range, viral pathogenicity or means of transmission. Only BSMV is pollen transmissible and such virus infected plants will not be allowed to flower. BMV, TYLCV and BPMV are primarily transmitted by insects and therefore plants infected with these viruses will be kept in the containment glasshouse block under positive pressure (B41). SBWMV is transmitted by zoospores of the soil borne fungus, Polymyxa graminis. All wastewater run off is treated within B41. Virus infected plants contained in B35 room 505 produce no waste water run-off.

It is generally the case that when foreign transgenes are inserted into viral vector genomes, these modified forms tend to be much less stable than wild type virus. Continued passage of the virus through successive host plants will select for deletion variants. There is therefore a degree of biological containment inherent with working with such types of modified virus. Genetic stability of the virus will cause loss of the insert and of the corresponding hazard. This has been demonstrated for PVX (Avesani et al., 2007) and BSMV (Bruun-Rasmussen M. et al., 2007).

The plant viral pathogens; BSMV, BMV, TYLCV and SBWMV are widely distributed and very likely to be present in the local environment, even if the unmodified recipient strains here used may be imported from outside of the UK and held under licence from DEFRA. Therefore the risk posed by their potential accidental escape is not related to the introduction of a new plant disease, but rather to factors that relate to their genetic modification(s) BPMV is from the USA and widespread in soya bean growing areas. This virus vector will be used to infect members of the FABaceae with transgenes to silence marker proteins/genes only.

</tr>
</tbody>
</table>

**Is an emergency plan required according to regulation 20?** N

**If yes, tick to confirm that it is attached to this form** N
Members of the Biological Safety Committee reviewed the risk assessment along with the HSE Notification form and were generally very satisfied with the standard and contents of the documents. These were considered to be very comprehensive. Two typographical errors were pointed out and corrected.

It was stressed that it is imperative to ensure that good procedures are in place to kill BSMV plants before they are allowed to flower including a reasonable margin of safety.

## Purposes of the contained use

The aim of our work is to dissect the resistance mechanisms in Solanaceous plants (tomato, potato, and Nicotiana spp.), sweet potato (Ipomoea batatas), cereals (wheat and barley), Brassicas including Arabidopsis thaliana that operate against eukaryotic plant pathogens such as the oomycetes Phytophthora infestans and/or Phytophthora brassicae, Phytophthora capsici, Phytophthora ipomoeae, Phytophthora palmivora, Albugo candida and Albugo laibachii, as well as ascomycete fungi such as Blumeria spp., Mycosphaerella graminicola, M. brassicicola, Leptosphaeria maculans, Botrytis cinerea, Sclerotinia sclerotiorum, Fusarium spp., Pyrenophora spp., Phaeosphaeria nodorum, Oculimacula spp. and Ramularia colo-cygni.

## Recipients or parental organism

Recipients will be wild type strains of eukaryotic plant pathogens (oomycetes and fungi), some of which will be native to the UK environment, some of which will have been imported and held under Plant Health Licence from FERA/DEFRA. These experiments may generate transgenic eukaryotic plant pathogens with altered host ranges, pathogenicity and/or insensitivity to fungicides.

## Host/vector system

Plasmids used will be recombinant pTOR and its derivatives, including the pTOR derivative pNC2. It is identical to pTOR apart from the MCS which is replaced by a Gateway MCS. Also, pAN7, pAN5 or pCamb, pCAMDsRed, pCAMBgf, and pCamb-CYP51-2. These plasmids encode genes for resistance to kanamycin/geneticin G418 or hygromycin. Recombinant plasmids may carry plant pathogen effectors and/or effector fusions as well as effector hairpin constructs and fungicide insensitivity genes that will be delivered and integrated into eukaryotic plant pathogen genomes.

## Origin & function

Candidate eukaryotic plant pathogen effector molecules and genes that encode insensitivity to fungicides will be identified and cloned from the oomycete pathogens; Phytophthora infestans, Ohytophthora brassicae, Phytophthora capsici, Phytophthora ipomoeae, Phytophthora palmivora, Albugo candida and Albugo laibachii and the ascomyte fungi such as Blumeria spp., Mycosphaerella graminicola, M. brassicicola, Leptosphaeria maculans, Botrytis cinerea Sclerotinia sclerotiorum, Fusarium spp., Pyrenophora spp., Phaeosphaeria nodorum, Oculimacula spp. and Ramularia colo-cygni.

Many of these genes will be transferred back into various recipient strains which may be of the same or different species of plant pathogen. Stably transformed genetically modified eukaryotic plant pathogens will be inoculated onto host plants and tested for pathogenicity and/or insensitivity to fungicides. Host plants include tomato, potato, and Nicotiana spp., sweet potato (Ipomoea batatas), cereals (wheat and barley), Brassicas including Arabidopsis thaliana. Other species of plants may be tested for resistance.

## Evaluation of foreseeable effects

### Human Health;

None of the recipient organisms used in these projects is a human pathogen and does not, therefore constitute a hazard to human health. The proposed genetic modifications of eukaryotic plant pathogens will not cause the modified strains to become human or animal pathogens and are therefore of no risk to human or animal health.

### Environmental Safety;

The eukaryotic plant pathogens; P infestans, P. brassicae, Albugo candida, Albugo laibachii, Blumeria sp., Mycosphaerella graminicola, M. brassicicola, Leptosphaeria maculans, Botrytis cinerea, Sclerotinia sclerotiorum Fusarium spp., Pyrenophora spp., Phaeosphaeria nodorum, Oculimacula spp. and Ramularia colo-cygni are all present.
in the local environment, even if the unmodified recipient strains here used may be imported from outside of the UK and held under licence from DEFRA. Therefore the risk posed by their potential accidental escape is not related to the introduction of a new plant disease, but rather to factors that relate to their genetic modification. The graminicola, M. brassicicola, Leptosphaeria maculans, Botrytis cinerea, Sclerotinia sclerotiorum Fusarium spp., Pyrenophora spp., Phaeosphaeria nodorum, Oculimacula spp and Ramularia collo-cygni will result in GM plant pathogens that could survive in the local environment. Some of the genetic modifications will result in pathogens that are more virulent than the recipient strain, but are nonetheless unlikely to be significantly more virulent than naturally occurring isolates.

The eukaryotic plant pathogens; P. capsici, P ipomoeae and P. palmivora are unlikely to be present in the local environment since they are pathogens of subtropical/tropical plants and are unable to survive in the local environment, due both to the absence of suitable hosts and environmental adversity. P. capsici will be used as a model organism, receiving candidate effector genes from different donor oomycete plant pathogens. The hazard identified is that GM-P. capsici may have an altered host range and be able to infect plants that may grow in the local environment. However, it is extremely unlikely that the genetically modified P. capsici will differ from wild type strains in its ability to survive in the UK environment. Moreover, P. capsici is not likely to be present in the UK and therefore not able to reproduce sexually with the GM strain.

The silencing of candidate plant pathogen effector genes could lead to growth of the GM-pathogen on an otherwise resistant plant host, especially if the silencing resulted in a loss of avirulence determinants. However, potato varieties harbouring genes conferring P. infestans resistance remain susceptible to other diverse naturally occurring virulent races of the pathogen.

It has been demonstrated that the Phytophthora infestans a virulence protein Avr3a is required for full virulence of the pathogen. The silencing of effector genes is not likely to alter the GM-pathogen’s host range, but is likely to have a negative effect on virulence.

Where eukaryotic plant pathogen genomes receive genes that are suspected to be involved in reducing sensitivity to fungicides, the hazard identified is the production of genetically modified plant pathogens that are more able to establish in the UK environment. The choice of fungicides insensitivity genes will be made to ensure that there is no additional risk from fungi transformed with these genes. For example, fungicide insensitivity genes used to transform B. graminis will only be those that have already been shown to be present in the UK population of this fungus. There would therefore be no risk of releasing alien genes into the UK environment.

For genetically modified plant pathogens that could survive in the UK environment, it is envisaged that none of the modifications will lead to races off pathogen that are more virulent than naturally occurring races; the recipient strains are not the most virulent and the most virulent naturally occurring strains will not be modified, except to receive GM marker genes. Moreover since the primary objective of these investigations is to monitor the virulence of eukaryotic plant pathogens, any pathogens where the genetic modifications lead to a significant increase in virulence will be killed by autoclaving.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For plant material infected with GMMs, containment level 2 is appropriate. Infected plants will be maintained in containment level 2 growth facilities at the John Innes Centre. Standard operating procedures for the use of plant growth facilities and for the disposal of waste will be strictly adhered to.

Plant pathogens, infected plant material and compost will be killed by autoclaving prior to disposal.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

A derogation is requested for the use of an autoclave in a building other than the building where the work is conducted. The transport distance between the building where the work is conducted and the building housing the autoclave is short, both buildings are located on the same site. The waste materials would be transported from the building where the work is conducted to the autoclave in bags inside sealed plastic boxes, the boxes have locking lids to prevent the accidental release of waste materials during transportation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Class 2 GMM (plant pathogen) (containment level 2). All GMM material will be handled using good microbiological practice (GMP). All GMM material will be stored in sealed containers and disposed of by autoclaving.
Oomycete and fungal cultures and culture plates will be autoclaved prior to disposal. The compost banks are inspected twice yearly and sprayed with a general purpose herbicide.

Routine monitoring of autoclave efficiency is completed using Thermalog S strips.

Run-off from containment glasshouses is collected into a 5000L tank. 1500 L aliquots are removed and treated with sodium hypochlorite and circulated in the tank for 24 hour, followed by a treatment with sodium thiosulphate. The water is then filtered and disposed. Plants in growth rooms will be sub-irrigated in leak proof trays such that minimal run-off is generated.

Autoclave procedures are as follows; Soil and plant waste generated in glasshouses and growth rooms is autoclaved in stainless steel containers for 1.5 hours (15 minutes vent, 30 minutes sterilisation at 15 p.s.i). Resultant waste is transported to a farm site where it is left to stand for three years prior to disposal.

Members of the Biological Safety Committee reviewed the risk assessments along with the HSE Notification form and were generally very satisfied with the standard and contents of the documents. These were considered to be well written, covering the necessary points.

It was suggested that the original HSE Notification title be changed from "The expression of fluorescent marker...” to "The expression of GM marker genes...”, to cover GUS, hph, nptII etc., used in experiments, and this suggestion was accepted.

In Section C of the GMRAs (Provisional Assessment), in both cases it was stated that the experiments are "excluded from Class 1" but did not actually propose which class they should be in. Although it was stated later that Class 2 is appropriate, it was suggested this should be stated in the provisional assessment as well. The GMRAs were amended accordingly.

Please enter comments on the GM safety committee on the risk assessment

The aim of our work is to dissect the resistance mechanisms in monocotyledonous plants such as wheat, barley, Brachypodium and Aegilops spp. that operate against, among others, the fungal plant pathogens Puccinia striiformis and P. graminis. This will be done by expressing candidate plant pathogen effector genes in B. glumae.

The characterisation of capsular polysaccharide prepared from genetically modified B. thailandensis will be used to further research the production of a vaccine for B. pseudomallei.

Exopolysaccharides purified from genetically modified P. aeruginosa will be used to probe the PAMP (pathogen associated molecular patterns)-triggered immune response in Nicotiana benthamiana and Arabidopsis thaliana.

Deletion mutants of P. aeruginosa will be constructed by allelic exchange and examined for attenuated/enhanced PAMP triggered immune responses in N. benthamiana and A. thaliana.

The recipient strain of B. glumae, the bacterial panicle blight pathogen of rice, was isolated from a rice paddy field from outside the UK and, as a non-native plant pathogen, will be held under Plant Health Licence from FERA/DEFRA. The genetic modification of B. glumae will allow it to operate as an effector delivery system capable of delivering filamentous phytopathogen effectors into monocotyledonous plants under controlled laboratory conditions.

B. thailandensis, strain E555 occurs naturally in the soils as a soil saprophyte and was isolated from the soil in Cambodia. It is an opportunistic human pathogen affecting only immuno-compromised individuals. The characteristics of the genetically modified strain will likely render it between one tenth and one hundreth of the virulence of wild type and it is essentially avirulent in mammals.
P. aeruginosa PAO1 used in this study was isolated from an infected human patient. PAO1 is a commonly used strain for research purposes and is an opportunistic human pathogen affecting immuno-compromised individuals. Any mutants used in this study will likely have a reduced fitness.

P. aeruginosa strains have been reported as an opportunistic pathogen in Arabidopsis and lettuce, however, as in humans this would be as a secondary opportunistic infection.

**Host/vector system**

Plasmids used to genetically modify B. glumae will be largely derived form the broad-host range cloning vector pBGR1MCS. Recombinant plasmids will harbour genes encoding for putative plant phytopathogen effectors. The genetically modified B. thailandensis carries the pKock plasmid inserted in to the wbl gene, abrogating LPS 0-antigen synthesis and conferring kanamycin resistance.

**Origin & function**

Candidate filamentous phytopathogen effector molecules will be identified and cloned from, in the first instance, Puccinia striiformis and P. graminis. These genes will then be fused to the N terminal type III secretion signal of a Pseudomomas type III secreted protein, introduced into Burkholderia glumae and used in plant infections assays.

Burkholderia thailandensis strain E555 wbl (knock-KmR) is a kanamycin resistant derivative of E555, isolated from the soil in Cambodia. Characterisation of capsular polysaccharide produced by this strain of bacteria will be used to advance research in to the production of a carbohydrate vaccine against Burkholderia pseudomallei.

Pseudomonas aeruginosa strain PAO1 is a domesticated laboratory strain originally isolated from the wound of a patient in Australia. Lipo/exopolysaccharides produced from mutant strains of this bacterium will be used to investigate PAMP-triggered immune responses in Nicotiana benthamiana and Arabidopsis thaliana.

**Evaluation of foreseeable effects**

**Human Health:**

The bacterial genus Burkholderia comprises in excess of 40 species most of which are typically non-pathogenic for humans. B. glumae is a plant pathogen of rice (Oryza sativa) and considered to be an organism with extremely low human virulence. Only one case of human infection has been reported in an infant with chronic granulomatous disease (Weinberg et al., 2006). As this case was associated with a pre-existing complication this suggests that immune-competent humans are not at risk of infection.

B. glumae strain 106619 was isolated from wild paddy field rice (Oryza sativa). The genetic modification(s) of this strain, here described will likely have no effect on its virulence in humans.

B. thailandensis is a soil-saprophyte and is considered to be an organism with extremely low virulence. Only four human infections with B. thailandensis have been recorded, two in Southeast Asia and two in the United States, suggesting that it is much less virulent than B. pseudomallei (Dharakul et al. 1999; Lertpatanasuwan et al. 1999). Indeed, these cases have been in immuno-compromised individuals. The characteristics of the genetically modified strain will likely render it between one tenth and one hundredth of the virulence of wild type and it is essentially avirulent in mammals.

P. aeruginosa rarely causes disease in healthy humans; however it is an opportunistic nosocomial pathogen of immuno-compromised individuals. Diseases caused by P. aeruginosa include skin and soft tissue infections in burns victims and patients with wound infections, outer ear and urinary tract infections, colonisation of medical devices (e.g. catheters), and diffuse bronchopneumonia in cystic fibrosis patients (Lowbury, 1975).

Strain PAO1 is a domesticated laboratory strain originally isolated from the wound of a patient in Australia (Holloway, 1955). It is perhaps the most widely studied laboratory strain of P. aeruginosa at present. PAO1 is known to be less virulent than PA14, the other extensively studied laboratory strain (Mikkelsen et al., 2011).

The genetically modified strains of P. aeruginosa here described will likely be unaffected with respect to their virulence in humans.
Environmental Safety:

Bacterial panicle blight of rice, which is caused by B. glumae, has been reported in Central and South America and Asia. B. glumae strain 106619 will be imported from outside of the UK and held under licence from DEFRA.

B. glumae is unlikely to survive in the local environment, due both to the absence of suitable hosts and environmental adversity.

B. glumae will be used as a system for the delivery of filamentous phytopathogen effectors to monototyledonous plants. It is not envisaged that there would be any expansion in B. glumae host range outside controlled laboratory conditions. The recipient strains are not the most virulent and the most virulent naturally occurring strains will not be modified. This strain will be used in pathogenicity assays and any alterations in pathogenicity will be closely monitored.

The genetically modified P. aeruginosa strains used to infect plants will not be more virulent than the wild type strain and as they are opportunistic plant pathogens they do not present a hazard to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For plant material infected with GMMs. Containment level 2 is appropriate. Infected plants will be maintained in containment level 2 growth facilities at the John Innes Centre. Standard operating procedures for the use of plant growth facilities and for the disposal of waste will be strictly adhered to.

Genetically modified micro-organisms, infected plant material and compost will be inactivated by autoclaving prior to disposal.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMM material will be handled using good microbiological practice (GMP). All GMM material will be inactivated by autoclaving prior to disposal.

All residual plant material will be stored in sealed containers and disposed of by autoclaving.

Autoclave procedures are as follows; Soil and plant waste generated in glasshouses and growth rooms is sterilised by autoclaving at 121 degrees C for a minimum of 30 minutes at 15p.s.i.

Routine monitoring of autoclave efficiency is completed using Thermalog S strips. Annual 12 point validation of autoclaves is performed.

Run-off from containment glasshouses is collected into a 5000L tank. 15000L aliquots are removed and treated with sodium hypochlorite and circulated in the tank for 24 hours, followed by a treatment with sodium thiosulphate. The water is then filtered and disposed. Plants in growth rooms will be sub-irrigated in leak proof trays such that minimal run-off is generated.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]
Two risk assessments attached (GM RA 175 and GM RA 176):

Caps/LPS gene-deletion mutants. (Reference GM RA 175) and Genetic modification of Burkholderia glumae (Reference GM RA 176).

The risk assessments were reviewed by members of the Biological Safety Committee.

For GM RA 175, the following observations were made during the review process:

It looks informative, clear and accurate in its risk assessment. It would be good to define IN (by the IN route, page 3) for clarity, or write in full. The GM RA was amended accordingly.

On considering the potential hazards to the environment for the HSE notification, I noticed that in Part B; Project Description (i) Overview, the modified P. aeruginosa will be tested in plants for PAMP-triggered immune responses. I understand that P. aeruginosa/plant infection(s) can be used as a model to understand animal infections. However, since P. aeruginosa can be pathogenic on Arabidopsis in nature. I think that there should be a statement in (ii) Hazard identification in respect of human health and environmental safety that relates to the effect of the genetic modification(s) on the virulence in plants. One sentence should suffice to demonstrate that the risk has been assessed-something along the lines; The modified P. aeruginosa used to infect plants will not be significantly more virulent than the wild type strain and does not present a hazard to the environment. The GM RA was amended.

Project Ref 38/15.1

Date Ackn'd 05/11/2015

CU2 Project Title Examining the contribution of various Pseudomonas syringae and Streptomyces loci to infection and colonisation in model plant systems

Class 2

Consent Granted
The work will include the development of genetic tools including vectors and gene replacement systems and the subsequent expression, deletion and modification of bacterial genes and pathways in P. syringae and plant pathogenic Streptomyces strains, plant infection assays in model systems including Arabidopsis thaliana, tomato and potato, comparative genomics and other whole-cell techniques, biochemical analysis of purified proteins, and the study of signalling pathways, secondary metabolism, and bacterial behaviour in different plant-associated environments (including plants and soil).

P. syringae is an ubiquitous and widespread phytopathogen that is responsible for a range of important plant diseases including tomato speck, bleeding canker and halo blight. It is an aggressive plant pathogen that uses a combination of secreted phytotoxins and effectors to subvert plant defences and kill host cells. There are over 50 known pathovars of P. syringae, which specifically infect a wide range of different plant species depending on their particular encoded effector proteins. The most commonly employed pathovar in this project will be Pto DC3000, which infects A. thaliana and tomato, and as such has become a model organism for plant-pathogen interaction studies.

The genetically modified P. syringae strains used in this work will be no more virulent (and are highly likely to be less virulent) than the wild type strain. Furthermore, as these variants will be compromised for important signalling and phenotypic output operons they are unlikely to thrive outside of a protective and defined laboratory environment. As such, it is unlikely that they will present a hazard to the wider environment.

Streptomyces plant pathogens are prevalent all over the world and infect tuber and root crops. The most well characterised is S. scabies, which is one of the causative agents of potato scab, where it forms lesions on the potato surface, which decreases the quality of the crop but is not destructive. Other closely related Streptomyces strains include S. reticuliscabiei, S. turgidiscabies, S. acidiscabies and S. europaeiscabiei. These all form similar lesions on tubers and roots. The most commonly used strains for this project will be S. scabies DSM 41658, which is the type strain, and S. scabies 87-22, which is the best characterised S. scabies strain and has become the model organism for the study of potato scab.

Mutations will be made to Streptomyces strains to inactivate biosynthetic pathways that make natural products. It is therefore highly likely that the strains will be less virulent than the wild type strains, as natural products have been shown to be important determinants of S. scabies pathogenicity.
Various plasmid-based systems will be used to delete or complement P. syringae genes. These will include the broad host-range vectors pME6032, pBBR-MCS2-5, pME3087, pUC18-miniTn7-Gm, and derivatives of these. These plasmids will confer resistance to gentamycin, kanamycin, tetracycline and other antibiotics in common laboratory use. Genes in Streptomyces strains will be mutated or complemented using standard vectors and methodology developed for the genetic modification of Streptomyces strains. These will include pYH7, pKC1132, pSET152, p1J10257, pIB139 and derivatives of these, which confer resistance to apramycin, hygromycin or kanamycin. These will be introduced into Streptomyces strains by intergeneric conjugation from E. coli ET12567 harbouring a plasmid required for the conjugalltransfer of DNA, such as pUZ8002.

**Origin & function**

P. syringae are a widespread species group of phytopathogenic, Gram negative bacteria. Pathogenic Streptomyces strains are a closely related widespread group of Gram-positive bacteria. They have been isolated from around the world, and both the DSM 41658 and 87-22 strains were originally isolated in the USA. All genes manipulated in these experiments will either be derived from the species under observation, or will be wellcharacterised genes that will not affect the pathogenicity or virulence of the species under investigation (e.g. GFP, antibiotic cassettes used in cloning).

**Evaluation of foreseeable effects**

**Environmental Safety:**
Pseudomonas syringae is already ubiquitous in the environment, including in the soil and on plant surfaces. The genetically modified P. syringae strains used in this work will be no more virulent (and are highly likely to be less virulent) than the wild type strain. Furthermore, as these variants will be compromised for important signalling and phenotypic output operons they are unlikely to thrive outside of a protective and defined laboratory environment. As such, it is unlikely that they will present a hazard to the wider environment.

Streptomyces are one of the most common bacterial genera found in the soil, and pathogenic variants are prevalent in all fields that contain root or tuber crops. They mainly affect the appearance of potatoes rather than the yield and the genetic modifications made in this work will not increase the virulence of these strains. It is therefore unlikely that they would present a hazard to the wider environment.

**Human Health:**
Neither organism is able to infect humans, except under very exceptional circumstances where susceptible individuals would be severely immuno-suppressed. Such individuals would not be present in the workplace. There is consequently no appreciable risk to human health.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For plant material infected with GMMs, containment level 2 is appropriate. Infected plants will be maintained in containment level 2 growth facilities at the John Innes Centre. Standard operating procedures for the use of plant growth facilities and for the disposal of waste will be strictly adhered to.

Genetically modified micro-organisms, infected plant material and compost will be inactivated by autoclaving prior to disposal.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMM material will be handled using good microbiological practice (GMP). All GMM material will be inactivated by
autoclaving prior to disposal. All residual plant material will be stored in sealed containers and disposed of by autoclaving. Autoclave procedures are as follows; Soil and plant waste generated in glasshouses and growth rooms is sterilised by autoclaving at 121 degreesC for a minimum of 30 minutes at 15p.s.i. Routine monitoring of autoclave efficiency is completed using Thermalog S strips. Annual 12 point validation of autoclaves is performed. Run off water from watering plants in the containment glasshouse is collected and treated using a thermal treatment system at 1210C, 15 psi for 15 minutes.

**Project Additional Information**

**Purposes of the contained use**

The work will include the development of genetic tools (vectors and gene replacement systems) for the deletion and modification of bacterial genes and pathways in *S. aureus*, for microscopy experiments, and for biochemical analysis of purified proteins, with an overall aim of understanding the mechanism of chromosome segregation and cell division in *S. aureus*.

**Recipient or parental organism**

*S. aureus* is the most common pathogenic staphylococcus, which is often part of the normal human microflora and linked to opportunistic infections. It is a pathogen of man and other mammals. Around one third of healthy individuals carry this bacteria in their noses, pharynx and on their skin. In normal healthy and immunocompetent person, *S. aureus* colonization of the skin, intestinal tract, or nasopharynx does not lead to any symptoms or disease. However, in immunocompromised people, *S. aureus* may cause: minor skin infections, such as pimples, impetigo etc.; boils (furuncles), cellulitis folliculitis, carbuncles; scalded skin syndrome and abscesses. Moreover, it may lead to lung infections or pneumonia; brain infections or meningitis; bone infections or osteomyelitis; heart infections or endocarditis; generalized life threatening blood infections or Toxic shock syndrome (TSS), bacteremia and septicaemia.

The genetically modified *S. aures* strains used in this work will be no more virulent (and are highly likely to be less virulent) than the wild type strain. Furthermore, as these mutants will be compromised for important mechanisms necessary for cell division and chromosome segregation they are unlikely to thrive outside of a protective and defined laboratory environment. As such, it is unlikely that they will present a hazard to the wider environment.

**Host/vector system**

Various plasmid-based systems will be used to delete or complement *S. aureus* genes. These will include the broad host-range vectors such as pIMAY, pRAB11, and derivatives of these. These plasmids will confer resistance to cloramphenicol, ampicillin and other antibiotics in common laboratory use. Plasmids will be constructed in JM110 *E. coli* strain and introduced to *S. aureus* strains by electroporation or conjugation. The *S. aureus* bacteriophage 11 will be used for DNA transduction as well.

**Origin & function**

*S. aureus* is a Gram-positive spherical bacteria, member of the Firmicutes of important clinical and biotechnological relevance. It is frequently found in the nose, respiratory tract and on the skin. *Staphylococcus* was first identified in 1880 in Aberdeen, Scotland, by surgeon Sir Alexander Ogston in pus from a surgical abscess in a knee joint. It has been estimated that 20% to 30% of the human population are long-term carriers of *S. aureus*. Pathogenic *S. aureus* strains have been isolated from around the world.

*S. aureus* RN6390 and RN4220 strains are laboratory strains derivatives of NCTC8325-4 (RN450), a modified *S. aureus* NCTC8325 strain originally isolated in 1960 from a sepsis patient and primarily utilized in the laboratory for the study of *S. aureus* genetics. While RN6390 was generated via sequential phage transduction (Peng et al., 1988), RN4220 was mutagenized via nitroguanoside to enrich for mutants that would efficiently accept plasmid DNA from *E. coli* (Kreiswirth et al., 1983; Herbert et al., 2010).

All genes manipulated in these experiments will either be derived from the species under observation, or will be well-characterised genes that will not affect the
pathogenicity or virulence of the species under investigation e.g. GFP, antibiotic cassettes used in cloning, or genes that encode proteins that are important for chromosome segregation such as parB, smc, scpA and scpB. Other related genes may be used, these would present no greater risk to the environment, humans or animals.

Evaluation of foreseeable effects

Environmental Safety:
Staphylococcus aureus is already ubiquitous in the environment, it is part of the human microbiota and it colonises about the 30% of human population. The genetically modified S. aureus strains used in this work will be no more virulent (and are highly likely to be less virulent) than the wild type strain. Furthermore, as these mutants will be compromised for important phenotypic output operons they are unlikely to thrive outside of a protective and defined laboratory environment. As such, it is unlikely that they will present a hazard to the wider environment.

Human Health:
S. aureus is a human pathogen, however it doesn't lead any symptoms or diseases when it colonizes healthy and immuno-competent people. Only under very exceptional circumstances, where susceptible individuals would be severely immuno-suppressed it could represent a risk. Such individuals would not be present in the workplace. There is consequently no appreciable risk to human health in the workplace.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Genetically-modified S. aureus will be maintained in containment level 2 growth facilities at the John Innes Centre. Standard operating procedures for the use of the growth facilities and for the disposal of waste will be strictly adhered to.

Genetically modified micro-organisms will be inactivated by autoclaving prior to disposal.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All GMM material will be handled using good microbiological practice (GMP). All GMM material will be inactivated by autoclaving prior to disposal.
All residual microbiological material will be stored in sealed containers and disposed of by autoclaving
Autoclave procedures are as follows: Microbiological solid waste generated in growth rooms is sterilised by autoclaving at 121 degrees C for a minimum of 30 minutes at 15p.s.i.
Routine monitoring of autoclave efficiency is completed using Thermalog S strips. Annual 12 point validation of autoclaves is performed.

Is an emergency plan required according to regulation 20? [N]
If yes, tick to confirm that it is attached to this form [N]
Tick to confirm that you have attached a risk assessment to this form [Y]
Tick if you are claiming exemption from disclosure for section of the risk assessment [N]
The Genetic Modification Safety Committee requested that a list of genes the investigator intends to delete or express in the target strain is included in the GMRA and the HSE CU2 form.

**Project Ref** 38/21.1

- **Date Ackn'd**: 02/09/2021
- **CU2 Project Title**: Genetic modification of Enterococcus faecalis and other related hazard group 2 Enterococcus species using plasmids encoding antibiotic resistance and fluorescent markers
- **Class**: Class 2
- **Culture Volume Class 2**: ≤ 1 Litre

- **Non-GMM**: Consent Granted

- **Historical Significant Changes**: Withdrawn

**Project Additional Information**

**Purposes of the contained use**

The study will visualise how GM Enterococcus faecalis, and other related hazard group 2 Enterococcus species, colonise the larvae of the moth Galleria mellonella. This will be done through feeding and injection studies. The plasmid enables easier visualisation and differentiation between the E. faecalis colonising the larvae and the native bacteria of the larvae, which are also enterococci.

**Recipient or parental organism**

02/03/2022
Larvae of the moth Galleria mellonella will be colonised by GM Enterococcus carrying antibiotic resistance and fluorescent marker genes. Visualisation studies will be performed to study colonisation and to allow differentiation between the native enterococci and the GM E. faecalis and other related species. There are no harmful effects foreseen.

Host/vector system

E. faecalis is classified as being a Hazard Group 2 organism. It is a commensal bacterium inhabiting the gastrointestinal tract of healthy humans. They can be used as a probiotic. They are opportunistic human pathogens that would not present a problem to healthy individuals but could cause infection in immuno-compromised people. Treatment of infections caused by these organisms is well documented and effective antibiotic treatments are known.

The plasmid carried by E. faecalis confers antibiotic resistance and fluorescent markers for visualisation studies. The plasmid contains a spectinomycin resistance cassette; a commonly used antibiotic marker in research laboratories. The plasmid contains no other antibiotic resistance genes and is not considered to pose an additional hazard.

Origin & function

The GM Enterococcus faecalis will colonise Galleria mellonella larvae and the fluorescence marker carried on the plasmid will enable visualisation and differentiation between the E. faecalis colonising the larvae and the native bacteria of the larvae, which are also enterococci.

There is a theoretical possibility that the plasmid could be passed to the native bacteria in Galleria, these are generally E. gallinarum or E. casseliflavus which also belong to hazard group 2. They are less pathogenic than E. faecalis so this would not pose an additional hazard. Effective containment measure will prevent risk of un-authorised escape to the environment.

Infected Galleria larvae will maintained in a dedicated incubator in the lab, in Petri dishes closed with tape, and these will only be opened within biological safety cabinets. Galleria larvae will be destroyed by 24 hour freeze treatment, followed by autoclaving.

Evaluation of foreseeable effects

The GM Enterococcus faecalis will colonise Galleria mellonella larvae and the fluorescence marker carried on the plasmid will enable visualisation and differentiation between the E. faecalis colonising the larvae and the native bacteria of the larvae, which are also enterococci.

There is a theoretical possibility that the plasmid could be passed to the native bacteria in Galleria, these are generally E. gallinarum or E. casseliflavus which also belong to hazard group 2. They are less pathogenic than E. faecalis so this would not pose an additional hazard. Effective containment measure will prevent risk of un-authorised escape to the environment.

Infected Galleria larvae will maintained in a dedicated incubator in the lab, in Petri dishes closed with tape, and these will only be opened within biological safety cabinets. Galleria larvae will be destroyed by 24 hour freeze treatment, followed by autoclaving.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All routine studies involving the GM E. faecalis and the contained larvae of Galleria mellonella will be conducted within a Containment Level 2 laboratory.

Occasionally longitudinal multigeneration studies may be performed to see if the Galleria mellonella moths can transfer the bacterium E. faecalis to their offspring. These will be conducted in the designated Entomology Dept with appropriate containment facilities as required by the Genetically Modified Organisms (Contained Use) Regulations. Moths will also be destroyed by 24 hour freeze treatment, followed by autoclaving.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Infected Galleria larvae and moths will be treated by 24 hour freeze treatment, followed by autoclaving.

All solid biological waste will be sterilised by autoclaving at 121°C for 20 minutes, or 30 minutes for dense loads.

Liquid biological waste will be sterilised by autoclaving at 121°C for 20 minutes.

Routine monitoring of autoclave efficiency is completed using Thermalog strips and annual 12 point validation of autoclaves is performed.

All activities so far assessed and carried out at GM40 are class 1: Activities of no or negligible risk, for which containment level 1 is appropriate to protect human health and the environment. The scale of work carried out at present is small with GMM cultures of up to a maximum of 10L; GMO work with animals is on a much smaller scale and is limited to cell culture; GMO work with plant materials is on a slightly larger scale with several projects producing transgenic lines of up to a hundred plants grown in containment growth rooms or glasshouse facilities. Waste management for GMM and GMO cell culture materials is similar - microbial and cell cultures are pretreated with an effective disinfectant (usually a hypochlorite-type) prior to autoclaving and disposal as normal biological waste. Waste GM plant materials including all tissue culture media and compost are autoclaved on an extended cycle which has been checked to achieve and maintain the temperature/pressure necessary for deactivation of any microorganisms/plant pollen or seeds. Autoclaves used for waste processing are tested annually for maintenance of temperature and pressure cycles. Routine checks for waste deactivation include 'load-activated' temperature sensors which control the autoclaves as well as indicator tape or tabs (temptabs etc.).

For activities involving GMMs, describe the waste management measures which will apply to the activity

Project Ref 40/05.1
Structure/function analysis of Mononegavirales proteins with relation to their role in viral replication, assembly, virion morphology and host-pathogen interactions.

---

**Project Additional Information**

**Purposes of the contained use**

Academic research and training

**Recipient or parental organism**

Standard eukaryotic cell-lines (human and primate) such as A549s, HeLa, and 293Ts and CV-1 for the propagation of recombinant viruses.

The genes for insertion are derived from Human Respiratory Syncytial virus or Measles virus grown in standard mammalian cell-lines.

The recipient viruses are vaccinia, baculovirus, and lentivirus (HIV-1 derived) and mouse (MMLV) retroviruses.

**Host/vector system**

Vaccinia will use plasmids pTM-1, pTM-3 or similar for initial cloning systems, propagated in E.coli before use in targeted recombinant transference in mammalian cell-lines. Recombinant Respiratory syncytial virus generated using reverse genetics, the viruses will be generated and propagated in mammalian cells such as CV-1, A549s and other mammalian lines. The system was a gift from Hong Jin, Aviron Inc (USA)

Baculoviruses created in E.coli using the Bac-to Bac system (Invitrogen) using transfer vector based on pFastbac-1

A third generation Lentivirus system using plasmids pWPI and pMDL g/p RRE from Trono's lab in Geneva

A MMLV based system will use the shuttle vectors pNCLX and pNCLX2 or other related plasmids.

**Origin & function**

Vaccinia virus, a poxivirus, is used routinely to express or drive the expression of recombinant proteins in mammalian cells. The viruses, created using homologous recombination, will either contain the gene for the protein of for a polymerase, such as T7 RNA polymerase. The polymerase then drives the expression froma transfected plasmid containing the gene of interest downstream of a T7 polymerase promotor. The virus was the basis for the smallpox vaccine but infection can be problematical. Adverse effects were noticed in 1/50,000 vaccinations. Most of the viruses in the lab are based on the Copenhagen strain however the use of more attenuated strains.
(MVA) will be employed were possible. The Lentivirus system is a third generation expression system that has been developed to remove the possibility of recombination generating viable HIV. The virus particles produced from this system will not contain a viable genome as the L3 domain has been mutated prevent formation of the LTR at the 5' domain. The system will be used to express proteins in non-dividing cells, for example human primary cells.
The MMLV-derived retroviral system will be used to routinely express proteins in tissue culture.
Baculoviruses will be used for the large scale production of recombinant proteins, suitable for structural studies e.g. crystallography.
Recombinant RSV will be generated by cloning genes of interest into a plasmid containing the full length RSV genome. The recombinant plasmids will be used to transfect mammalian cells together with helper plasmids and vaccinia supplying T7 polymerase. The resultant viruses will be used in experimental procedures to determine the effect of mutating or deleting structural proteins that are important in replication and/or assembly.

Evaluation of foreseeable effects

The MMLV and Baculovirus systems have been used in many labs for a number of years and have demonstrated excellent biosafety. Baculovirus can infect mammalian cells but fail to replicate, if a mammalian promotor is present a transgene can be expressed, however there is practically no chance of propagation and spread of the vector. Each construct will therefore be assessed individually on the impact of the expression of the recombinant protein on a cell.

The Lentivirus system, whilst based on HIV-1 (HSE CAT 3) has been designed to maximise its biosafety, particularly with regard to the likelihood of producing infectious HIV-1 particles. The proposed system is a third generation series developed by the Trono lab (http://www.tronolab.unique.ch/x_hime2.htm) and the inherent design reduces the likelihood of this to near zero. The system comprises three main components, a transfer vector which the transgene is inserted. This is the component that will eventually be packaged into the virion and contains viral sequences such as the packaging signal for viral assembly and the LTRs need for integration of the proviral DNA. The 3' LTR has been modified such that the ability of the provirus to reconstitute active viral promoters is destroyed. Expression of the transgene is driven by an upstream mammalian promotor. The structural and enzymatic components of the viral particle are provided by a second plasmid containing the viral gag-pol genes. This plasmid cannot be packaged into the virion thus the virus does not contain the necessary resources to replicate upon subsequent infection of a cell. Finally the viral glycoprotein, gp169 has been replaced by vesicular stomatitis virus (VSV) G protein, provided in trans from a third plasmid which again cannot be packaged into nascent virions. Whilst there is a minimal chance of infecting a lab worker the ability to replicate, or recombine with endogenous retroviruses has been reduced to insignificant levels.

Vaccinia virus (HSE CAT 2), a poxvirus, is used routinely to express or drive the expression of recombinant proteins in mammalian cells. Recombinant viruses, created using homologous recombination, will either contain the gene for the protein or for a polymerase, such as T7 RNA polymerase. The polymerase then drives expression from a transfected plasmid containing the gene of interest downstream of a T7 polymerase promotor. The virus was the basis for the smallpox vaccine but infection can be problematical. Adverse effects were noticed in 1/50,000 vaccinations. Infections by vaccinia is still a possibility. Possible routes of infection for workers are ingestion, droplet spread and exposure to aerosols. The virus may cause a particularly severe skin disease in those suffering from eczema or other skin conditions. Most of the viruses in the lab are based on the Copenhagen strain however the use of more attenuated strains (MVA) will be employed when possible.

The risk of changing the glycoproteins of RSV using the rescue system may result in a change of cell tropism. However no work will be undertaken were both viral glycoproteins are changed, thus in the case of accidental exposure the worker is likely to be able to mount an effective immune response preventing any disease. As RSV is endemic to the general population no foreseeable risks are envisaged.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Individual schemes for dealing with the waste disposal from each expression system is described in the attached risk assessments. Also code of practice for the labs has been drawn up detailing the waste streams available in the CAT 2 labs in the Wolfson. Basically, all work is carried out in class II MSC's that are decontaminated before
and after use with either 70% ethanol or 1% Virkon. Before servicing the hood, or if there is a major spill, the hood can be sterilised by fumigation with Formaldehyde. Liquid waste will be treated with Virkon overnight before disposal as normal waste. Solid waste will be neutralised by autoclaving before disposal via the normal waste stream and removed by council/contractors to approved waste sites. Plasticware will be soaked overnight in 1% Chloros before disposal in the normal waste stream. In the advent of a large, unattended spill, solid Virkon will be added directly to the liquid and mopped up using absorbent tissue. The contaminated tissue will be autoclaved before disposal to ensure complete neutralisation of any biological material. At all times personnel will wear suitable safety gear, lab coats, gloves, eye protection etc. The autoclave is tested regularly to ensure it is functioning efficiently.

The above schemes represent procedures similar to that used in many labs. The efficiency of the above has been tested in the author's previous place of employment, the Medical Research Council's Virology Unit in Glasgow. The effect to reduce titre/infectivity was demonstrated to be suitable assays.

**Purpose of the contained use**

To prevent the operator infection by the viral systems used. Class 2 safety cabinet ensures appropriate protection and reduces to effectively zero the environmental risk for this project.

The project boundaries are set by the effect of disease causing mutations that cause the loss of function in neurones, astrocytes, muscle, the eye, fibroblasts and keratinocytes and other epithelia. We need to establish tissue culture systems to studying normal cell function and then use transduction methods to alter protein expression and cell function. One part of this project will be the immortalisation of lens epithelial cells taken with informed consent from human patients and donors. This project requires containment level 2 as immortalisation will be achieved by attenuated virus Ad5SVR4 containing SV40 large antigen. Of all the constructs that we plan to use, this one is unique as it is the only one that clearly has the potential to immortalise primary cells. All our other constructs do not have this ability. It is the possibility of opportunistic infection, particularly in the case of the primary human cells when using either Ad5 based transduction methods that require a level 2 containment. Other parts of the project involves the transduction of a wide range of primary cells with the similar constructs for which viral-based vectors offer the most consistency. These cells include primary astrocytes, neurones, fibroblasts, epithelial and muscle cells. These constructs will cause changes in the cytoskeleton, chaperone, cell adhesion, cell architecture or protection properties of the cell. Some constructs will induce protein aggregation or protect cells against stress and other insults. Others will express control proteins such as GFP or beta-galactosidase. We also have access to a wide range of transgenic animals and others expressing mutant proteins and we will be using our transduction strategies to try and reverse the functional deficits in primary cells derived from these animals. Conventional transfection strategies are notoriously inefficient for primary cell cultures, which is the main reason for using these viral transduction approaches. Primary cells are an excellent cell culture system because it is most similar to the tissue situation. These experiments range from clear containment level 1, where structural genes encoding normal proteins will be introduced into primary rodent cells, to the situation where primary CNS, epithelial, muscle and fibroblast cells will be transduced with RNAi and other constructs to modify function and cell responses to the presence of mutant proteins or external insults. Lentiviral systems are the preferred choice and commercial, published and current clinical trials are based on HIV-1 because of the extensive knowledge base that exists for this virus, the unique control methodologies and the existence of drugs to treat infections. We are also planning to transduce some constructs that affect signalling pathways, cell survival, cell polarity and neuroprotection. This project outline is necessarily broad due to the biological questions themselves, but it is also a unique strength as we seek to discover the common pathways that link protein aggregation, cell protection and cell misfunction to disease. By necessity, the project will also use constructs to disrupt normal cell processes in order to test hypotheses concerning cytoskeletal function, epithelial barrier and cell protection mechanisms. The neuroprotection studies will include tracing multi-synaptic neural pathways in rodents with the neurotropic virus, herpes simplex virus type 1 (HSV-1). When injected into a peripheral tissue or brain region, the controlled infection spreads in a sequential manner through the neural network making it possible then to trace how specific genes affect neuroprotective pathways. The HSV-1 utilised for trans-neuronal tracing retains the ability to replicate and as such falls into containment category 2 (Compendium of Guidance 2000, Part 2B, annex 1 & II herpes simplex virus 51-66). The HSV-1 is tagged and these constructs will be introduced into animals in the animal facility by injection using established protocols developed at the University of Birmingham.

Such studies will be very unlikely to alter the tropic properties of the transduced cells or cause immortalisation or transformation of these target cells.

**Recipient or parental organism**

Replication defective Adenoviral, Lentiviral and Baculoviral systems for transduction of animals and human cells in culture. These unmodified GMOs pose no significant health or environmental risk. Tissue culture cells are severely compromised and need highly specialised growth conditions. Exposure to any conditions other than the tissue culture environment will result in their death.

Adenovirus: Replication defective Ad5 will be used. The Ad5 E1E3 or Ad5 E1E3E4 deleted regions deleted so as to prevent replication in human cells and genes will be inserted into the site of the disabling deletion (He et al., 1998, Becker et al, 1994) ensuring that any recombination event that restores replication will remove the expressed gene. The replication deficient adenovirus is infectious to humans by aerosol/droplet but it has no mechanism for long term maintenance in cells. This may be considered to
occurs the resultant virus will not be harmful as the animals are considered to be dead end hosts (Compendium of Guidance 2000, Part 2 Annex 1 & III part 66). There is

or tropism and therefore create a novel virus. In studies where two viruses expressing different coloured markers are introduced into the animal, even if recombination

infects. If left long enough it can kill the infected neurone, but this is not the intended experimental outcome. The individual virus cannot produce variations in pathogenicity

Injection of the virus into the host animal causes a controlled infection to spread through the neural circuit of interest. The virus does not alter the genome of the neurones it

promotors, but the insect genes will not be active in mammalian cells. In addition, no alteration to their genome is envisioned that could lead to a risk to human health. They

infection (m.o.i.). Consequently, Baculovirus is often given Class 1 status. There are also a range of commercial systems designed to generate recombinant virus, and

Gene expression of RNAi constructs (Nicholson et al., 2005). There are important safety features that are attractive to the system. Baculovirus is inherently incapable of

replicating within non-natural host cells because it needs host transcription factors and the transduced cells exhibit no apparent cytotoxicity even at a high multiplicity of

infection (m.o.i.). Consequently, Baculovirus is often given Class 1 status. There are also a range of commercial systems designed to generate recombinant baculovirus, and

Horsep Simplex virus type 1: The HSV-1 (clinical isolate HSV 17) retains the ability to replicate and will be used to produce a controlled infection that spreads in a

Herpes Simplex virus type 1. This eliminates the possibility that pathogenic, replication competent strains arise (Dull et al 1998, Zufferey et al 1998). Retroviruses, including

Herpes Simplex virus type 1. This eliminates the possibility that pathogenic, replication competent strains arise (Dull et al 1998, Zufferey et al 1998). Retroviruses, including

Para A of the Lentinus virus vector reduced the likelihood of activation of endogenous oncogenes upon infection, as has sometimes been observed with Moloney-based

are found in a commercial system produced by Genesys and sold by Invitrogen. Replication-deficient retroviruses have been developed by mutating these genes and inserting complimentary picking into packaging cell lines (Danos and Mulligan 1988). Therefore the disabled recombinant viral vector containing an inserted therapeutic gene can now only replicated in the packaging cell line, but the resulting viruses produced by the packaging cells are still capable of infecting other cells. This limits infection to the initial target population. Elimination of the U3 region in the 3 LTR

region of the Lentivirus vector reduced the likelihood of activation of endogenous oncogenes upon infection, as has sometimes been observed with Moloney-based retrovirus systems. In essence the system comprises the self-inactivating transfer vector (SIN -self-inactivating LTR by a TATA box deletion, expressing no viral gene products (Miyoshi et al 1998) and containing the woodchuck hepatitis virus post regulatory element (W) (Deglon et al 2000). Mouse PGK and CMV are used as internal promotors in this construct. The viral particles are produced by transient clacium phosphate transfection of HEK 293T cells with pCMVDR-8.92 (packaging construct providing Gag and Pol, but lacking both LTRs and has no viral packaging signal, y, as well as Env, Vif, Vpr, Vpu and Nef), pMD.G (Producing VSVG as the envelope component), pRSV-Rev (encoding Rev), and SIN-W-PGK or SIN-W-CMV transfer vectors as previously described (Hottinger et al 2000). The invitrogen system provides a modified cell line 293 (293FT) containing the packaging construct under tetracyline regulation. These systems comply with the HSE recommendation in Part 2B Annex III para 19. Baculovirus (Details of commercial vector given http://www.invitrogen.com/content/sfs/manuals/baculodirect_man.pdf) The insect virus to be used is considered safe with regard to human health. Although it infects human cells it actually requires a very high titre for efficient infection. The inserted genes will be driven by mammalian

The HSV-1 utilised for trans-neuronal tracing retains the ability to replicate and as such falls into containment cat 2 (Compendium of Guidance 2000, Part 2B annex 1). Keratinocytes; rat and mouse hepocytes; myoblasts; myotubes; fibroblasts; neurons and astrocytes. Because they are not of neural origin they pose only a low risk. The recombinant, replication defective viruses will be used to transduce established mammalian cell cultures from such donors. Cells from such donors will be uncharacterised, but will have a very low risk of contamination by blood-borne viral infections (eye lens is avascular). Human cell cultures will be established from donated material taken from the anterior chamber of the eye. (Compendium of guidance 2000, Part A, annex IV). Using table 1, month animals not suspected of carrying BSE and taken from beef cattle will be used for these studies and again pose no significant threat to human health. Primary cultured as unmodified cells. Sometimes bovine cells from the anterior chamber of the eye will be cultivated. Following Compendium guidelines (2000 Part 2A, Annex III), 6 month animals not suspected of carrying BSE and taken from beef cattle will be used for these studies and again pose no significant threat to human health. Primary cells are therefore group 1 when propagated under barrier conditions and health screening already monitors rodent viral infection as a key health status check. These primary cells are therefore group 1 when used for these applications. Vector systems based on the well-established and well-characterised adenovirus, Baculavirus, Lentivirus transduction systems. HSV-1 is a tried and tested virus system used and developed at the University of Birmingham to be used in our neuroprotection studies. The Adenoviral, Baculaviral and Lentiviral vector systems are severely compromised and are replication defective. The inclusion of the genes indicated in this application, which interfere with cytoskeletal, cell adhesion or protection function, will not change infectivity or enable replication of these compromised virus systems. Any recombination events that occur via unintended recombination events or via adventitious viral contamination of cell cultures, will result in simultaneous loss of the gene of interest and therefore remove the risk of generating virus particles with altered host or growth characteristics. The use of a specific cell line for the propagation of the virus particles restricts the potential for altered infection essentially to this stage as both systems involve severely compromised systems where essential components have to be supplied in trans to create infective particles. These particles will infect, but not be able to propagate in their hosts. Unintended adventitious infections can increase the risk as when using primary cell cultures. As a general principle, these primary cells from both animal and human sources will die within a few passages and have no ability to survive outside the laboratory or cell culture dish. Cells from knockout and mutant mouse models will be transduced to either modify gene expression or produce immortalised cell lines. The primary cells pose no significant threat as the animals are not of neural origin they pose only a low risk. The recombinant, replication defective viruses will be used to transduce established mammalian cell lines with a long track record of safe use in which both the adenovirus, baculovirus, lentivirus systems are unable to replicate such as: rat hepatoma cells; mouse keratinocytes; rat and mouse hepatocytes; myoblasts; myotubes; fibroblasts; neurons and astrocytes. The HSV-1 utilised for trans-neuronal tracing retains the ability to replicate and as such falls into containment cat 2 (Compendium of Guidance 2000, Part 2B annex 1). Herpes Simplex Virus 51-66). However, the virus sequence is known (Elliott & O'Hare, 1999; Donnelly & Elliott, 2001). The virus has been used under license to researchers.
at the University of Birmingham since 2000 (HSE ref GM166/99.3). The rodents to be used in these experiments are considered dead end hosts, as they are unable to infect sentinel animals kept in the same cage and therefore pose no additional health or environmental risk than uninfected animals.

**Origin & function**

Origins: The DNA will be derived from human, mouse, rat, bovine, chicken, zebra fish, Arabidopsis, Castania, Jellyfish and e.coli. For cell immortalisation, the large T antigen of SV40 virus will be used in an Ad5-based vector, as a tried and tested method for extending primary cell lifespan.

Intended function: This project aims to use viral vectors to introduce DNA into cells that will result in the expression of proteins that will aid in the identification of the molecular mechanisms by which the cytoskeleton, cell junction, protein chaperone function and cell protection mechanisms operate. Identification of such pathways that are required for sensory cell function will allow the analysis of these pathways and their constituent proteins in specific disease states. Molecules identified will then become potential points for therapeutic intervention. Thus we must express wild type and mutant forms of these proteins. The systems we study are differentiated or isolated cells, as well as ex vivo tissue samples. These are notoriously difficult to transiently transfect, therefore we use an adenoviral or lentiviral vector system to introduce the recombinant DNA into cells. Replication defective adenovirus and lentivirus vector systems offer a number of key advantages over plasmid transfection based systems. The host-vector systems to be used do not generate replication enabled viral particles. The replication deficient viruses are infectious to humans by aerosol/droplet but have no mechanism for long term maintenance of cells. It is the introduction of the SV40 large T antigen that changes the classification of the recombinant Ad5 virus from class I to class III due to its affect on potentially oncogenic signalling pathways. There are no reports, as such, to link any of the other constructs proposed in this study to cell immortalisation or cell transformation, but the pathways concerned do involve cell signalling events that will change cell adhesion, cell motility, intercellular communication and cell survival.

**Evaluation of foreseeable effects**

The research strategies are designed to disrupt cell function by the introduction of mutants with either dominant negative, continuously active or simply inactivate. These reagents are anticipated to disrupt the normal function and process of cell signalling events that will change cell adhesion, cell motility, intercellular communication and cell survival in the sensory cells under investigation. In some situations this could cause the cell lines to die; in others the cells may be more resistant to specific stresses. Alternatively, signal transduction pathways will be disrupted by the expression of these constructs and an output could be altered cell shape, cell motility and increased sensitivity to chemical and physical stresses. The established cell culture cells to be used can be considered as especially disabled hosts and are unlikely to infect humans. The transduction experiments are very unlikely to confer a growth advantage or alter the host tropism as none of the sequences to be transduced except the SV40 large T antigen can be considered oncogenic (Part 2A annex IV).

Human adenoviruses do not naturally infect animals and have only been shown to infect animals (cotton rats) when deliberately administered at high doses of viruses under experimental conditions (see Part 2B - Annex III of the HSE guidelines) and of course the system is highly attenuated as are the lentivirus to be used. Baculavirus only infect mammalian cells if very high titres are used and the system used takes advantaged of an attenuated virus.

The HSV-1 will be used to infect animals in laboratory in a controlled manners and in a manner that positively prevents neuronal cell death as the objective is to map living neural networks. We therefore do not expect any detrimental effects on the experimental animals.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None. Although a class 2 containment activity, the risk of an emergency is effectively zero. In the highly unlikely situation of a release of a virus stock from the facility, the virus cannot replicate therefore propagate outside the helper cell lines. A standard Emergency Procedure code of practice has been prepared for the facility.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Viruses will be applied to target cells via cell culture medium for 2-4 hr, the medium then removed and disposed of, leaving no unctact, inafective particles in the cells being studied. Operations do not involve sharps such as glass pipettes or needles and therefore the major risk of operator contamination is by aerosols.
All solid waste will be autoclaved before disposal. Autoclaves are tested annually for Hse compliance. Annual testing includes thermometric test for small and normal load and safety check, vacuum leak test of automatic controls.

Liquid waste will be either treated by autoclaving or by the addition of the viral and cell killing reagent eg VIRKON to a final concentration of 1% w/v as an accepted and thoroughly tested route for 100% kill.

Treatment with 70% ethanol has been shown to be an effective disinfectant for adenovirus (Rutula 1996), but we will use the Virkon product to disinfect and decontaminate.

Decontaminated solutions will be disposed of to the drain with copious volumes of water.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

What is the source of the HSV-1 material to be used in the project?

This is the same as those used by the group who trained Dr S Pyner at the University of Birmingham.

Non-GMM

Date Project Ceased
Notification is provided here as recommended in communications with HSE since the work will involve use of GM-modified plant pathogen (Pseudomonas syringae) strains.

The objective of this project is to further characterise the molecular, biochemical and cellular events occurring in plant cells infected with virulent and avirulent strains of the pathogen(12,10),(988,977) described in the attached document “Signalling and cell biology of plants responding to psedodmonas infection” and risk assessment.

Recipient or parental organism

Recipient of parental organism: Pseudomonas syringae pv. tomato DC3000 - virulent plant pathogen.

GMM's

* P. syringae pv. tomato DC300 (avr8) - avirulent plant pathogen.
* P. syringae pv. tomato DC300 (avrRPM1) - avirulent plant pathogen.
* P. syringae pv. tomato DC300 (AvrRpt2) - avirulent plant pathogen.
* P. syringae pv. tomato DC300 (luxABCDE) - virulent plant pathogen expressing bacterial luciferase for imaging.
* P. syringae pv. tomato DC300 (AvrRpt2) (luxABCDE) - a virulent plant pathogen expressing bacterial luciferase for imaging.
* P. syringae pv. tomato DC300 (hrpA mutant) - has reduced virulence due to impaired TTSS
* P. syringae pv. Tabaci (hrcV mutant) - has reduced virulence due to impaired TTSS

Relevant genes are described in more detail in the accompanying risk assessment (Appendix 1), Table 1 below and in the accompanying document (Appendix 2) and pathogen profile (Appendix 3).

Host/vector system

* P. syringae strains are plant pathogens as described in the accompanying documents. Some of the strains contain mutations which render them avirulent on the host plant species. Most of the strains to be used are based on P. syringae pv. tomato DC3000. (See attached paper Appendix 4)
* pDSK600 (see diagram opposite) is a broad-host-range cloning and expression vector, (Spr/SMr, IncQ replicon, 3x lac UV5 promoter).

[See attached paper, Appendix 5].

[NB: Appendices / attached papers referred to are available for reference in hardcopy].
[It is on the hardcopy if required for reference].

Origin & function
*avrB, avrRPM1, avrRpt2 are all proteins which are recognised by host plant with appropriate resistance gene, to allow resistance mechanism to occur i.e. makes the pathogen avirulent. See also Appendices 1-3. *luxABCDE encode subunits of the bacterial luciferase enzyme, producing light, used as a reporter gene.

**Evaluation of foreseeable effects**

The consequences of the hazards being manifest are considered to be very low and the likelihood of their manifestation is negligible when the containment proposed above is taken into account. P. syringae strains are plant pathogens that have never been isolated from human hosts; they are unable to grow at 37 deg celsius. Vectors contained in some of the strains harbour antibiotic resistance genes, giving marginal risk of transfer to other strains, however this is highly unlikely and should not affect the risk assessment nor the level of containment required. Taking into account the control measures assigned above, the overall risks to the environment from the genetically modified micro-organisms produced or used in this work are low. Therefore few additional containment or control measures are considered necessary to protect the environment other than those described to protect human health and safety. These include containment of infected plants in growth chambers and measures to prevent insect transmissions from infected plants. Two of the strains we will use contain mutations (P. syringae pv. tomato DC3000 hrpA mutant and P. syringae pv. Tabaci hrcV mutant) which make these bacterial strains contain plasmids which express proteins e.g. AVR proteins which also make these strains more vulnerable i.e. easier for the plant to detect, and hence less pathogenic. Hence if the plasmids were lost, or the mutations reversed, the bacterium would, in a 'worst case scenario', revert to the natural law of pathogenicity of the wild type (DC3000). The assessment presented here and in the risk assessed document (Appendix 1) is thus based on a 'worst case scenario' of the full virulence of the wild type (DC3000) being realised in a genetically modified strain. The only strain to which this applies directly is P. syringae pv. tomato DC3000 (luxABCDE), which expresses harmless bacterial luciferase. Loss of this plasmid or mutation would only lead to loss of luminescence from the luciferase, and hence no change to the risk to the environment or to human health.

Overall it is inconceivable that any of the GM strains to be produced or used could become more pathogenic to plants since there is no intention to manipulate any of the virulence genes - we only intend to work on strains which have already been manipulated and there is a history of safe use of the GM strains to be used.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

No GMO's are associated with this project.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Small samples of infected plant materials for sectioning or biochemical assessment will be taken from CL2 containment to CL1 facilities for processing. Surplus materials will be treated as described in the accompanying schedule prior to disposal. Samples will be leaf explants or tissues taken from treated plants growing under CL2 conditions and mounted on slides for microscopy or placed in sealed eppendorf tubes for extraction and analysis in CL1 laboratories. Residual materials will be processed as described by autoclaving and/or incineration.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

**WASTE MANAGEMENT MEASURES**

All autoclaving is carried out in autoclaves dedicated for GM and CL2 waste processing and equipped with thermal logging system.

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclaved using a 'make safe cycle' as specified in BS 2646, Part 3, 1993 (either 121-125 deg Celsius for at least 15 minutes or 126-130 deg Celsius for at least 10 minutes), any excess liquid discharged to drains, disposal of solids via clinical waste stream for incineration/dispose of solids via the industrial (black bag) waste stream or landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - EITHER autoclaved using a 'make safe cycle' as specified in BS 2646, Part 3, 1993 (either 121-125 deg Celsius for at least 15 minutes or 126-130 deg Celsius for at least 10 minutes), and discharging to drains OR treated with sodium hypochlorite (at 1% available chlorine) OR virkon (at 1% w/v) for at least an hour or overnight and then discharged to drains.

Agar plates - autoclaved using a 'make safe cycle' as specified in BS 2646, Part 3, 1993 (either 121-125 deg Celsius for at least 15 minutes or 126-130 deg Celsius for at least 10 minutes), any excess liquids discharged to drains, solid disposedof via the industrial (black bag) waste stream for landfill.
Sharps (e.g. needles, syringes, scalpels) - disposal as biohazardous sharps waste via clinical waste stream for incineration.

Plants, plant material and soil - autoclaved as specified in DEFRA Plant Health Licence (this in practice involves 50 mins at 121 deg Celsius in the autoclave, and such material is dealt with through a University-approved contractor), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste system for landfill.

DEGREE OF KILL
Autoclaving, effectively 100% kill (annual validation, cycle thermal logger)
Incineration, effectively 100% kill (incinerator by licensed contractor)
Chemical disinfection with Virkon, used according to manufacturers instructions under standard conditions. Hypochlorite used at 1% available chlorine.

Is an emergency plan required according to regulation 20?  
If yes, tick to confirm that it is attached to this form
Tick to confirm that you have attached a risk assessment to this form
Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment
No further questions / suggestions were raised on the Pseudomonas risk assessment so the local risk assessment is approved.

The project aims to understand how plants cope with invading pathogens. By reducing the expression of candidate genes by a disarmed virus based gene-silencing system we can ascertain the role of the candidate genes in plant response to infection. The virus based gene silencing system will not be used outside the containment facility nor will the plants be allowed to flower or release pollen to the outside.

Recipient or parental organism

* BSMV (barley stripe mosaic virus). Jacksons et al., 2009, Annu. Rev. Phytopathol. 47: 385-422,
* TRV (tobacco rattle virus), PVX potato virus X. All these are disarmed viruses and are cloned in pGreen based cloning vector (Bachan et al., 2012, Methods Mol Biol. 894:83-92).
* Wheat barley, rice, maize, N. benthamiana
* Agrobacterium tumifaciens GV3101

Host/vector system

* pTRV (kanamycin resistance)
* pPVX (kanamycin resistance)
* These are pGreen based gene silencing vectors which contain the disarmed viruses (TRV and PVX see references above) fore generating VIGs based siRNA for gene silencing. Plant sequencing will be cloned between viral sequences in these vectors for gene silencing. For details of how silencing works please refer to (Bachan et al., 2012, Methods Mol Biol. 894:83-92).
* pBSMV (kanamycin resistance), see vector details described in attached risk assessment

Origin & function

* Genes affecting the ubiquitin pathway
* Plant cytoskeleton
* Genes involved in general signal transduction
Short portions (22-500bp) of a transcribed sequence from various plants including wheat, barley and related cereal species (the host species identified under "recipient or parental organism" in section 7 above). The intention is to silence endogenous genes rather than express additional ones

Evaluation of foreseeable effects

The basic strategy is to create infectious BSMV in N. benthamiana leaves, which is then used to produce an infectious extract able to secondarily infect host cereals by rub infection with carborundum powder.
After sub-culturing in liquid medium A. tumefaciens strains carrying BSMV alpha, beta and gamma genome components will be combined in 1:1:1 ratio and infiltrated using a needless syringe into leaves of young Nicotiana benthamiana plants. The bacteria transfer Ti plasmids to the plant cells, and the double CaMV 35S constitutive promoter present in the binary plasmids drives synthesis of infectious BSMV transcripts within the cells of the host plant. These transcripts initiate the formation of virus particles that infect the tissue surrounding the inoculation site, and subsequently move systemically to invade upper uninoculated leaves. Infectious BSM viruses are thus only created by a combination of individually non-infectious components within a host Nicotian plant. The viral vector is therefore not transmissible apart from by experimental means.

The cereal hosts include species that are native to the UK and will survive outside containment facility but cannot compete with native forms of the plant as these are not elite cultivars. We are only silencing endogenous genes and not adding new genes so it is unlikely that hazards may arise from this form of research. In the event that the GMO is inadvertently released into the environment via seed or pollen, it is likely that germination will occur. Also, cross-pollination with wild-type relatives may take place. The consequences are unlikely to be severe as the genes being silenced are endogenous to cereals and the virus cannot replicate outside the Agrobacterium transient assays system. There are unlikely to be hazards to human health as cereal leaves are not consumed by humans. The inserted gene is not expected to result in an increase in the hazards posed by handling plant material. Even if the plants were to be accidentally consumed, no harmful effects are known or anticipated. Therefore, the consequences are considered to be negligible.

The basic strategy is to create infectious BSMV in N. benthamiana leaves, which is then used to produce an infectious extract able to secondarily infect host cereals by rubbing infection with carborundum powder. This then allows BSMV based gene silencing in cereals.

TRV is a single stranded RNA virus which is transmitted by a nematode vector. Virus particles are rod shaped and comprise of long (180-197nm) and short rods (46-114nm). Both are required for the production of intact virus particles. The genome is bipartite with RNA1 encoding putative replicase and cell-to-cell movement proteins. The shorter RNA2 encodes the coat protein and an additional protein is required for nematode transmission. The cloned TRV gene silencing vector does not carry the additional protein required for nematode infection in RNA 2 but is replaced by the multiple cloning site for cloning plant genes of interest. The viral vector is therefore not transmissible apart from by experimental means.

Similarly PVX has very wide natural and experimental host ranges. It is reported to occur naturally in at least 62 plant species of 27 families and to be transmissible experimentally to another 348 species in 33 families (Edwardson and Christie, 1997). Transmission of the virus is mechanical e.g. by contact. Both TRV and PVX will be only used to silence or overexpress genes in N. benthamiana. These vectors will be Agroinfiltrated into N. Benthamiana plants for silencing genes of interest. Control measures for BSMV will be similarly employed for TRV and PVX systems.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All the work will be done in a CL2 room and plants will be kept in an approved containment glasshouse and growth room arrangements to contain the micro-organisms (growth room 1 and 2). To eliminate the spread of the virus, infected plants will be discarded before they reach the flowering stage and no other flowering plants would be present in the compartment where the experiment was in progress.

There are 5 people involved in the project. A rota will be drawn up that ensures in any one time at least 1 person will be primarily responsible for the VIGs experiments including plants and viral cultures. While a second person will act as a back up in case the key contact is not available in an emergency. The persons responsible will monitor plant status, i.e. ensure plants do not reach flowering stage, viral cultures are monitored and that standard operating procedures are followed (see comments below).

Standard good practices by adhering to Code of Practice for transgenic glasshouse and growth rooms will be ensured by the PI and the two duty personnel on the rota.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

To eliminate the spread of the virus, infected plants will be discarded before they reach the flowering stage and no other flowering plants would be present in the compartment where the experiment was in progress. Both liquid and solid laboratory waste, waste from glass houses and waste from experiments with infected plants will be double bagged and autoclaved. All viral cultures will be disinfected with bleach. In previous cases these measures have proved to be effective in containing the viral
Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

A key aspect of maintaining containment for this project is that GM plants will not be propagated long enough to flower. The committee requested details about systems to ensure that a single individual is not solely responsible for ensuring that plants do not flower. These are described in section 8.

Project Additional Information

Purposes of the contained use

The project will investigate the underlying mechanisms of resistance to penicillin and meticillin in laboratory-generated strains of S. aureus and determine whether these mutations are important in clinical isolates.

Recipient or parental organism

Staphylococcus aureus Oxford and its derivatives are the main strains to be used in this programme. Expression of penicillin- and meticillin - resistance determinants in this strain would alter the antibiotic resistance profile of the organism, but is very unlikely to alter its ability to invade and establish itself in humans. Any recombinant strains would remain sensitive to a number of other antibiotics (vancomycin, linezolid, trimethoprim-sulfamethoxazole, clindamycin, minocycline).

S. aureus strains Newman, SH1000, NCTC8325, RN4220, RN450 are meticillin-sensitive strains widely used as cloning intermediates (RN4220) and as typical genetic backgrounds in which to study gene expression.

Other strains including COL, BB270, NW2, USA300, EMSRA-15, and EMSRA-16) are meticillin resistant, which means that infections can not be treated with beta-lactam antibiotics can be treated with a number of other antibiotics including vancomycin, linezolid, trimethoprim-sulfamethoxazole, clindamycin, minocycline,

Host/vector system

pUC and derivative vectors for cloning and analysis in E. coli.

pMAD (or similar) is a temperature-sensitive plasmid used for allele replacement in S. aureus (Memmi et al., 2008. Antimicrob. Agents Chemother. 52:955-66).

pLOW (or similar). Stable low copy number E. coli-S. aureus shuttle vector with IPTG-inducible Pspac promoter. (Liew et al., Microbiology-SGM 157:666-676)

pCL%% and derivatives - single site chromosomal integration vector for S. aureus (Lee et al., 1991 Gene 103:101-105)

pGL485 is a E. coli-S. aureus multi-copy shuttle vector carrying the chloramphenicol acetyl transferase gene (cat). (Cooper et al., 2009 BMC Microbiol 9:266)

Transducing phage, such as 80 alpha

Origin & function

The genes involved are resident in S. aureus Oxford, which is a strain that has a long history of use in hospital pathology laboratories and is sensitive to penicillin and meticillin. The genes of interest are those that have changed in laboratory selection of strains that are resistant to these antibiotics, but are presently unknown. Inactivation of these genes is likely to lead to strains that are less fit than the parental strain. Addition of these altered genes to other genetic backgrounds may increase resistance to penicillin/meticillin, but will not alter levels of resistance to other clinically useful antibiotics.

One family of genes identified as targets are the penicillin binding proteins (pbp 1,2,3 and 4). These genes are involved in peptidoglycan biosynthesis and are the target of penicillin and meticillin antibiotics

Evaluation of foreseeable effects

It is likely that one or more genes that we identify will contribute to decreasing the sensitivity of the host organism to penicillin/meticillin. It is unlikely that any (other) gene in isolation will have a dramatic effect on antibiotic resistance or virulence.

S. aureus can infect animals which can act as a reservoir for human infection.

Primary containment measures should be directed towards protecting laboratory workers, but also ensure that these organisms cannot enter the environment.

As the genes that we are pursuing are involved in antibiotic resistance, if they were transferred to related microorganisms, they may have an impact on levels of resistance to penicillin and metacillin. However, it is unlikely that this would cause and added concern to the health of humans or animals as many strains in hospitals and in the
community carry high-level resistance to these antibiotics already.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The disposal of bacterial cultures and other contaminated liquids, e.g. culture supernatants, will be carried out by adding Virkon solution, to 1% final concentration, and incubation for 30 minutes at room temperature prior to disposal via designated sinks. Validated data supplied by the manufacturer indicates that this will result in inactivation of S.aureus strains. Contaminated glassware, centrifuge tubes and work surfaces will be decontaminated by the addition of 1% Virkon solution and incubation for 30 minutes and room temperature.

Solid waste, including plastics and agar plates will be placed in clear autoclave bags for sterilization by autoclaving at 134C for 30 minutes. A printed record of each disposal cycle is checked for time and temperature achieved during the run before disposal of the sterilized waste and annual validation of the waste cycle is carried out using 12 point thermocouple testing.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

The committee noted that the proposal involved a single research worker at times would be working in a restricted access facility. It was noted that there was a departmental policy for lone working that would be adhered to in this situation

Project Ref 40/13.1
The aims of the project are two-fold: Firstly, to exploit a commercially available E. coli based protein expression system to produce proteins and mutant variants of Salmonella enterica serovar Typhimurium. Secondly, to generate Salmonella enterica serovar typhimurium mutants lacking metal homeostasis genes and expression such proteins extra chromosomally, and monitoring gene expression.

Recipient or parental organism

1. Escherichia coli BL21 (DE3), JM109, DH5α and BW25141
2. Salmonella enterica serovar Typhimurium strains (ACDP Hazard Group 2 as they may be pathogenic and able to colonise humans):
   - LB5010a - a restriction deficient, modification proficient strain that is known to be attenuated due to a specific mutation.
   - SL1344 - wildtype that is a derivative of a strain isolated in 1977 which is auxotrophic for histidine and has been safely used in research since this date.

Origin & function

Source of host cells:

E. coli BL21 (DE3) is already a laboratory maintained strain at Durham University.

E. coli JM109 and BW25141 will be supplied by a long standing collaborator, Dr J C from the University of Manchester.

S. Typhimurium LB5010a and SL1344, and bacteriophage P22HT105/1-int will also be supplied by DR J C from the University of Manchester and were originally sourced.
from the Salmonella genetic stock centre.

Source of genetic material
S. Typhimurium genes or genetic regions (e.g. operator-promoter region) will be amplified by PCR using specific primers (no random DNA) from S. Typhimurium cells or purified genomic DNA.

Plasmid vectors - pGEM-T (Promega) and the pET vector system (Novagen) are already laboratory maintained; pUC series, pACYC184, pBR322 series, pKD3, pKD4, pKD46, and pCP20 plasmid vectors will be supplied by Dr J C from the University of Manchester.

Intended use
S. Typhimurium genes encoding metal homeostatic proteins will be cloned into pGEM-T prior to sub-cloning into the pET vector system for protein over-expression, purification and in vitro characterisation. Mutant derivatives will be generated by site-directed mutagenesis in pGEM-T, followed by sub-cloning into the pET vector system.

The lambda red gene disruption method will be used to generate S. Typhimurium strains lacking metal homeostatic genes. Briefly, antibiotic resistant cassettes will be amplified from pKD3 or pKD4 (maintained in E. coli BW25141) with specific primers to allow homologous recombination into the chromosome of S. Typhimurium LB5010a (expressing the lambda Red system from PKD46) and subsequent gene disruption. The gene deletion will be moved into S. Typhimurium SL1344 by bacteriophage P22HT105/1-int and antibiotic resistance removed using the FLP-recombinase encoded by pCP20. Mutations will be complemented using expression of the gene on pACYC184.

Operator-promoter regions of S. Typhimurium metal-responsive genes will be cloned into the pBR322 vector series using E. coli JM109 or DH5a and transformed into S. Typhimurium SL1344 (via LB5010a) to monitor gene expression using the B-galactosidase assay.

S. Typhimurium SL1344 is a derivative of a strain that was isolated in 1977 which has been modified (1981) to be auxotrophic for histidine. SL1344 has been safely used in research since this date without the requirement for microbiology safety cabinets. Laboratory passage means this strain is likely to be more attenuated than the original isolate. LB5010a is a derivative of a strain (S. Typhimurium LT2) that is known to be attenuated due to a specific mutation and therefore the risks associated with this strain are considered to be low. This strain is required to facilitate movement of DNA from E. coli to strain SL1344, as this cannot be done directly.

Evaluation of foreseeable effects
S. Typhimurium SL1344 is a derivative of a strain that was isolated in 1977 which has been modified (1981) to be auxotrophic for histidine. SL1344 has been safely used in research since this date without the requirement for microbiology safety cabinets. Laboratory passage means this strain is likely to be more attenuated than the original isolate. LB5010a is a derivative of a strain (S. Typhimurium LT2) that is known to be attenuated due to a specific mutation and therefore the risks associated with this strain are considered to be low. This strain is required to facilitate movement of DNA from E. coli to strain SL1344, as this cannot be done directly.

The genetic manipulations will be of genes encoding non-toxic products and use well characterised harmless vectors. They will not increase the pathogenicity of the organism. The likelihood of harm to human health in the event of exposure would be no greater than that with non-GM S. Typhimurium and can be considered negligible. The chance of transfer of the vectors to other organisms in the environment can be considered low. It is difficult to envisage how any of the genetic manipulations proposed in this project could confer a harmful phenotype or competitive advantage to the host strains in the environment. The environmental hazards associated with the project are therefore considered no greater than those associated with handling non-GM S. Typhimurium. The project involves small-medium scale work for research purposes and all contaminated material will be completely inactivated by autoclaving prior to disposal. In the highly unlikely event of release into the environment, no risks are envisaged.

Genes subject to characterisation are either characterised or novel homologues of metal homeostasis genes (including metal-responsive transcriptional regulators, chaperones and transporters). Although the inducing metal ions for some of these are unknown, all are predicted to have no deleterious side effects. The gene disruptions of S. Typhimurium will not increase the hazard of the organism. The most likely outcome following removal of metal homeostasis genes will be a hazard no greater than the non-GM S. Typhimurium or even a decrease in pathogenicity towards humans.

No combination of host, vector and insert is considered more hazardous than non-GM S. Typhimurium.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The GMM-contaminated waste will consist of broth/agar cultures, plastic labware and glassware. The bacteria will be viable but can be successfully and rapidly inactivated by a number of disinfectants (for example 70% ethanol, 1% Virkon, Virkon powder and 10% Microsol). Following experimentation, E. coli and S. Typhimurium strains will be decontaminated before disposal either by steam sterilisation or chemical disinfection. They are susceptible (100% kill) to moist heat (121°C for at least 15 minutes). A suitable autoclave will be used which is validated by annual thermocouple mapping (including a probe within a dummy waste run) and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile. All agents are efficiently killed with a 1% Virkon solution (Du Pont™ Rely+On™ Virkon®) which will be used according to manufacturer's instruction. In addition, Gram-negative bacteria are sensitive to 70% ethanol. Any delicate equipment will be cleaned with Microsol 3+ which has a proven efficacy against bacteria (EN1276 for gram negative and gram positive bacteria) yet is non-corrosive. Benches used for S. Typhimurium work will be routinely swabbed with 70% ethanol. All contaminated waste will be completely inactivated (100% kill) before disposal.

Date Project

Page 1850 of 1532
The aim of the project is to characterise the function of genes encoded by Mycobacterium tuberculosis. In order to achieve this in as closely related organism as possible to the virulent M. tuberculosis we will utilise a highly attenuated and genetically validated M. tuberculosis generated by Prof W Jacobs (Albert Einstein College of Medicine, New York). The M. tuberculosis mc(2)7000 strain is an unmarked derivative of the mc(2)6306 M. tuberculosis strain harbouring disabling deletion mutations in RD1 region (associated with the attenuation of bacilli Calmette-Gurin (BCG) vaccine) and panCD (associated with pantothenate synthesis). RD1 mutations limit the ability of M. tuberculosis to grow within animal tissue and have been validated in humans through the use of the BCG vaccine, panCD mutations limit growth in vivo by restricting the availability of essential nutrients to the bacteria. Evidence supporting these statements is to be found in the supporting documents. Additional parallel studies will be performed in Mycobacterium bovis BCG, an avirulent strain of M. bovis, and similar HG2/1 mycobacteria (e.g. Mycobacterium smegmatis, Mycobacterium marinum, Mycobacterium thermoresistibile).

We will exploit these background strains in phenotypic screens. Nulling deletion mutations will introduced in protein coding genes within M. tuberculosis and additionally complement with a mycobacterium specific inducible expression vector. The mutants will enable us to identify the function of these genes using basic phenotypic characterisation studies. Potential foreign genes, which are exploited already within the field as validation markers and reporters, will be cloned into mycobacterium specific vectors to create viable test strains (e.g. luxAB genes from Vibrio harveyi). Antimicrobial testing and mutant generation using these strains will assist our efforts in mode of action studies of novel anti-tuberculosis compounds.

Additionally genes of interest will be expressed at high levels in disabled host bacterium (E. coli) to enable further biochemical and biophysical analysis of the target protein.

**Recipient or parental organism**

The parental Mycobacterium tuberculosis H37Rv strain is a fully sequenced laboratory strain of TB classified as a HG3 organism. The route of transmission is via aerosol but can also infect via oral routes. This strain will not be used in the notified activities. The highly attenuated M. tuberculosis mc(2)7000 strain and its derivatives, classified as hazard group 2, will be used. The GM activities in this notification are grow1h, complementation, and storage of GM mc(2)7000 strains.

Other Mycobacterium related strains with potential opportunistic activities will also be used; Mycobacterium marinum (HG2)
Rhodococcus equi (HG2)
The vaccine strain;  
Mycobacterium bovis BCG  
Non-pathogenic;  
Mycobacterium smegmatis  
Mycobacterium thermoresistibile 
(HG2)  
(HG1)  
Disabled laboratory strains of E. coli including K12/MC1061 or similar/derivatives thereof will be utilised in construction of genetic elements using standard protocols. TOP10, XL-10 Gold (host for routine cloning); BL21, C41, BL21 star (for protein expression).

Host/vector system

The pJV53 and pAL70 series of vectors for generating marked and unmarked mutants in Mycobacterium spp. including M. tuberculosis mc(2)7000 will be used (van Kessel JC, Hatfull GF Nat Methods. 2007. 4(2):147-52, Cascioferro et al., Appl Environ Microbiol. 2010; 76(15): 5312-5316). These vectors carry a hygromycin resistance gene for selection which can be removed by successive passaging of the organism in the absence of the selective marker.

pHAE181 phage is a recombinant phage that contains a derivative of the mariner-based Tn5371. The recombinant phage pHAE181 is derived from a temperature sensitive mutant of the lytic Mycobacteriophage TM4, which can infect many slow and fast growing Mycobacterium species, including M. tuberculosis, M. bovis, M. smegmatis and M. marinum. The phage can replicate inside a mycobacterial host (with a productive lytic cycle) at 30°C, but not at the non-permissive temperature of 37°C. Tn5371, which contains a hygromycin resistance gene (hyg), can thus be delivered by infecting the target Mycobacterium host at 30°C, followed by selection of Tn-mutants on hygromycin-containing plates at 37°C (Kriakov et al., 2003 J Bacteriol 185(16):4983-91).

DNA sequences will be introduced into Mycobacterium spp. including M. tuberculosis mc(2)7000 using well characterised and harmless non-mobilisable (Parsons et al., 1998 Mol. Microbiol. 28: 571-582) shuttle vectors that can replicate in E. coli and mycobacteria (e.g. pJEM15, pMV261, pMV306, pW16, pPR27 and their derivatives). These vectors contain an E. coli origin of replication (from the pUC series of cloning vectors), a mycobacterial origin of replication from plasmid pAL5000 and antibiotic resistance markers (e.g. kanamycin and hygromycin). Additionally pMIND and pMEND derivatives will be used in complementation and overexpression studies (Blokpoel et al. Nucleic Acids Res. 2005 . 33(2):e22. 10.1093/nar/gni023). pNV18 and pNV19 are constructed by inserting a 1.8 kb DNA fragment carrying the pAL5000 origin of replication (Snapper et al. 1990 Mol. Microbiol. 4:1911-1919; Stolt 1997 Nucl. Acids Res.25:3840-3846) into the unique Nhel site of pk18 or pk19 (Pridmore 1987 Gene 56:309-312) for expression in Rhodococcus equi.

E. coli recombinant protein expression for crystallographic and biochemical studies will utilise the non-mobilisable pET expression systems.

Origin & function

Source: M. tuberculosis H37Rv
Genetic material: DNA fragments encoding various well defined genes involved in cell wall metabolism and function, e.g. transferases, fatty acid biosynthesis, polyketide biosynthesis, siderophore biosynthesis, p450 enzymes, core biosynthetic genes, regulatory enzymes and shock response genes. The intention is not to work with any sequences where insertion or deletion could be reasonably foreseen to increase the hazardous characteristics of the organism.
Source: Depending on marker - E. coli for β-galactosidase, luminescent vibrios for luciferase, jellyfish for GFP, Streptomyces for agarases.

The genetic material that are to be expressed are marker protein which are highly unlikely to have any biological effect, eg GFP, luciferase, B-galactosidase, agarase.

Antibiotic resistance genes expressed from their native promoters.

Evaluation of foreseeable effects

1. Hazards to human health:
The parental strain M. tuberculosis H37Rv is capable of causing TB, the deletions of RD1 and panCD are welldocumented in peer-reviewed papers as attenuating the ability of these strains to colonise and cause infection in mammals (see accompanying summary of relevant literature). Furthermore, there is no reduction in the susceptibility of the GMMs to frontline treatments for TB. The likelihood of the 10 disabling gene deletions being overcome is extremely unlikely. The possibility of generating a fully infectious TB strain is therefore effectively zero. Subsequent genetic modifications by over-expression of potential target gene candidates by plasmid expression or through further gene deletions are unlikely to modify the bacteria's virulence or infective route as long as the mutations are not rescuing or reverting the original RD1 and panCD deletion genotype. The majority of GMMs will render the strains less efficient at causing disease. It is not anticipated that any GMMs will show increased virulence.

2. Possible impact on the environment:
The disabling mutations were introduced by multiple gene replacement events in the H37Rv chromosome. The likelihood of mobilisation of the genetic modification from the mc(2)7000 derivatives, or transfer into other species in the environment in the event of a release is diminutive. This is reduced further still when the waste control measures are taken into consideration. All potentially infected material is autoclaved prior to disposal. 100% killing of GMMs is required. Disinfectants such as 2% Trigene and 10% Chloros are available for spills/disinfection of contaminated surfaces. Potential modes of transmission to the environment: Drains, aerosols, faulty autoclaves, and carried on individuals. These risks are reduced to moderated/unlikely, firstly by the disabling mutations within the bacteria, which reduce the likelihood of survival outside the laboratory (panCD) and the control measures used in the contained environment (see BioCOSHH and risk assessment).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not Applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The parental Mycobacterium tuberculosis H37Rv strain is a fully sequences laboratory strain of TB classified as a HG3 organism. This strain will not be used in any part of this notification. The HG2 classified M. tuberculosis mc(2)7000 strain and its derivatives will be used at our premises. The M. tuberculosis mc(2)7000 strain is an unmarked derivative of the mc(2)6306 harbouring disabling deletion mutations in RD1 region (associated with the attenuation of bacilli Calmette-Gurin (BCG) vaccine) and panCD (associated with pantothenate synthesis). RD1 mutations limit the ability of M. tuberculosis to grow within animal tissue and have been validated in humans through the use of the BCG vaccine, panCD mutations limit growth in vivo by restricting the availability of essential nutrients to the bacteria. Therefore we seek a derogation to allow the reclassification of the M. tuberculosis mc(2)7000 strain to HG2. Similar derogations for work with mc(2)7000 and its parental strain have been granted to existing projects in the GM public register, including project Ref 8/15.2 & Ref 552/13.2.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All materials used in the CL2 facility are to be regarded as potentially contaminated and disposed of accordingly to
ensure 100% killing. All solid waste will be autoclaved in a validated autoclave before leaving the laboratory and disposed of in clinical waste bags for clinical waste disposal. Liquid waste is pre-treated with Surfanios at 5% final concentration and left overnight before autoclaving and disposal of as clinical waste. Minimum 126°C degrees for 45 minutes, 10 minutes free-steam. Activities will be separated from those which use Virkon for chemical disinfection, as Virkon is documented as being ineffective against Mycobacteria.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [Y]

Please enter comments on the GM safety committee on the risk assessment

The mc27000 strain is attenuated by two independent means, and letters presented from the safety boards of US institutions indicated that in their opinion this organism could be considered as hazard group 2. One of the attenuating mutations, requiring the organism to scavenge pantothenate, would still permit it to grow in mammalian cells. This is because the organism would be able to obtain some pantothenate from the environment it was infecting. It was agreed that a case for derogation of this organism to hazard group 2 should be made to HSE.

Date Project Ceased

02/03/2022
This project will examine the ability of medically significant pathogens to manage nutrient and toxic metals (copper, zinc, iron, manganese). These metals are essential for the function of nearly half of all bacterial proteins but they are toxic if present in excess or if found in the wrong location. The battle to control metal location and availability is a key component of host-pathogen interactions. Key host immune strategies include starving pathogens of iron and zinc, and harnessing metals (mainly copper) to poison invading pathogens. Consequently, bacterial mechanisms that acquire iron and zinc, and those that expel excess copper are important for pathogenesis. The results from this study will be used to guide development of metal-based strategies for managing infections in a clinical setting.

The activities described herein (activities 1-7 below) form a connected programme of work that involve four mucosal pathogens:

a. uropathogenic Escherichia coli (UPEC)
b. Neisseria gonorrhoeae (GC)
c. Streptococcus pneumoniae (pneumococcus)
d. Streptococcus pyogenes (GAS)

UPEC and GC cause genitourinary infections while the pneumococcus and GAS cause respiratory infections. All four have all been identified as key threats to public health as a result of increased resistance to antibiotics (CDC 2013, WHO 2017).

Specific activities in this programme are:

1. Overexpression and purification of proteins (including artificial site-directed mutants) from the pathogens in an attenuated E. coli host to study protein function and activity ex vivo.
2. Subcloning of DNA fragments from the pathogens in attenuated E. coli cloning strains to aid activities 3-7 below.
3. Generation of pathogen mutants by allelic exchange using DNA fragments or shuttle vectors that carry the intended mutations and antibiotic markers.
4. Restoration of gene function in pathogen mutants by allelic exchange using DNA fragments or shuttle vectors that carry the wild type gene.
5. Restoration of gene function in pathogen mutants by expression of the wild type gene off the native or an inducible promoter (e.g. IPTG) on a shuttle vector.
6. Expression of an artificial reporter gene off native promoters on a shuttle vector to monitor gene expression.

Organisms for Activities 1-2 are attenuated (non-colonising) E. coli K-12 strains and are considered ACDP Hazard
Group 1 organisms. They have a long history of safe use in commercial and research settings.

Activity 1.
Cloning hosts (JM109, DH5a) and overexpression hosts (BL21, BL21(DE3), BL21(DE3) pLySS, BL21(DE3) Rosetta).

Activity 2.
Cloning hosts (JM109, DH5a).

Activities 3-6.
Virulent/pathogenic bacteria a-d as listed in Box 6 above (more details below). All are used widely in research worldwide to understand pathogenicity and antibiotic resistance traits.

a. UPEC (strains UTI89 and EC958).
UPEC causes urinary tract infections (UTI). UPEC can also exist within the human intestinal tract as part of the normal microbiota. Both clinical isolates used here have been sequenced. EC958 is the best characterised ST131 strain that has emerged rapidly and disseminated globally in recent years. It produces Extended Spectrum Beta Lactamases (ESBLs) and causes multidrug-resistant infections.

b. GC (strains 1291, FA19, FA1090).
The gonococcus causes the sexually transmitted infection gonorrhoea. Both of these clinical isolates are likely to be attenuated from decades of laboratory passage but we will assume that they remain virulent. Both have been sequenced.

c. Pneumococcus (strain D39).
The pneumococcus is normally found as a harmless commensal of the human upper respiratory tract but it may lead to invasive infections like pneumonia when the immune system weakens. The D39 strain is likely attenuated in the human host following decades of laboratory passage but this strain remains virulent in mouse models of infection and will be assumed as pathogenic to humans. This strain has been sequenced.

d. GAS (strain SF370, MGAS 5448).
GAS is a common causative agent for scarlet fever and strep throat. MGAS 5448 is an isolate of the hyperinvasive M1T1 strain that has been globally disseminated and is associated with life-threatening conditions.

Host/vector system

Activities 1-2.
Standard commercial non-mobilisable vectors that can be propagated in E. coli:

Activity 1.
cloning vectors (pUC, pT7, pGEM, and pBAD series) and overexpression vectors (pET series).

Activity 2.
cloning vectors (pUC, pT7, pGEM, and pBAD series) and shuttle/helper/complementation vectors described below for Activities 3-6.

Activities 3-6.
All vectors well established in the literature. They are non-mobilisable, ie. they can be propagated in E. coli but they are not stable in non-E. coli host pathogen.

Activity 3.
a. UPEC - helper plasmids encoding components of the lambda-red recombinase system (pKD46, pKD3, pKD4, pCP20).
b. GC - cloning vectors listed in Activity 2 above.
c. Pneumococcus - cloning vectors listed in Activity 2 above.
d. GAS - temperature-sensitive shuttle vector pHY304.

Activity 4.
Origin & function

SOURCES:
All recipient organisms and vectors, including those already carrying genetic modifications described here, will be supplied by Dr Karrera Djoko from the University of Queensland (Australia). Additional genetic modifications will be generated at Durham.

Activity 5.
Full-length genes from the pathogens.
Activity 6.
Common reporter genes that are unlikely to have any biological effect in the recipient organism (eg. betagalactosidase gene, green fluorescent protein gene)

FUNCTION:
Genes of interest in this programme are those involved in metal homeostasis, namely the import, sequestration, and export of iron, copper, zinc, or manganese. These genes encode:
- Transmembrane transporters that allow metal ions to enter or exit the bacterial cytoplasm or periplasm.
- Metal-responsive transcription factors that control the expression of metal homeostasis genes.
- Soluble and membrane-anchored metal carriers that capture metal ions from the solvent and deliver them to target enzymes or transporters.
- Soluble and membrane-anchored proteins that store metal ions.
- Enzymes that require metal ions for activity.
**HUMAN HEALTH:**

For all activities, no combination of vector, host, and insert is considered more hazardous than non-GM host.

Activities 1-2.

No risk to human health. These activities fall into hazard/containment level 1.

Activities 3-6.

The pathogens used in these activities fall into hazard/containment level 2. The activities will not produce a GMO that is any more hazardous than the wild type. The likelihood of harm to human health in the unlikely event of exposure to GM strains will be no worse than exposure to non-GM strains.

Activity 3.

The intended mutations are likely to decrease the fitness of the pathogen and not increase it. Studies have shown that metal homeostasis genes are important for the pathogenesis of all four organisms described here. Disruption of the genes usually leads to attenuation of the pathogen in human or animal model hosts of infections. So far, there is no indication that deletions of metal homeostasis genes will lead to increased fitness of the pathogen in animal model hosts.

The intended genetic modifications will be introduced in the chromosome and not on mobile genetic elements. It is expected that the mutations will be confined in the GMO and not be transferred to other organism.

In the case of an accidental exposure, antibiotic resistance markers will not affect the clinical management of infections caused by the pathogens. Antibiotics used as selection markers (ampicillin, kanamycin, tetracycline, chloramphenicol, erythromycin, spectinomycin, gentamicin) are widely used in research. They are already widely disseminated in the environment, are not clinically relevant to the pathogens, or are obsolete and are no longer in clinical use. Previous studies have not found that the presence of these antibiotic markers in metal homeostasis mutants confer any advantage in the fitness of pathogens in animal model hosts of infections.

Activities 4-5.

These activities will simply reintroduce a gene that was originally present in the wild type pathogen but had been removed by mutagenesis in Activity 3. The resulting GMO will not be any more hazardous than the wild type.

Activity 6.

Insertion of the reporter gene (β-galactosidase, green fluorescent protein) into the recipient organisms described here is common and has not been reported to increase fitness or pathogenicity. The resulting GMO will not be any more hazardous than the wild type.

**ENVIRONMENTAL HEALTH:**

For all activities, no combination of vector, host, and insert is considered more hazardous than non-GM host.

**Evaluation of foreseeable effects**

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

The activities will generate a mixture of solid and liquid waste, including live bacterial cultures, spent media, and contaminated paper towels, gloves, plasticware, and glassware.

All waste will be decontaminated (100% kill) using steam sterilization (autoclaving) at 120°C for at least 30 min. The autoclave will be checked monthly with an accepted biological indicator (e.g., *Geobacillus* or *Bacillus* spores).
commercially available) or more frequently during periods of heavy use. The autoclave will be serviced annually.
Each run will be monitored by a continuous chart or digital recording of the temperature and time. After autoclaving,
solid will be disposed in the clinical waste stream for incineration and landfill using a licenced contractor approved
by the university. Autoclaved liquid waste will be discharged to drains.
Protective clothing (lab coats or gowns) will be autoclaved monthly before laundering using a licenced contractor
approved by the university.
All working surfaces (benches, equipment, tools) will be decontaminated by chemical disinfection using 2% Virkon
(100% kill) or 70% ethanol (100% kill). Accidental spills will be first mopped up with a paper towel and the surface
will be decontaminated with 2% Virkon. The paper towel will be autoclaved before disposal in the clinical waste
stream.

Please enter comments on the GM safety committee on the risk assessment

The Durham GM safety committee noted comments made by the University of Queensland safety committee on
this work regarding the provision of information sheets detailing the antibiotic susceptibility and resistance
characteristics of the organisms involved in this application.
The Durham GM committee commented that clarification was needed regarding one of the proposed methods of
preparing material for autoclaving, as there was a risk that the method described would prevent steam penetration
and hence adequate sterilisation of all parts of the load. A revised procedure that addressed these concerns was
produced.

**Project Additional Information**

### Purposes of the contained use

Project MF02/16: The goal of this research is to isolate, propagate and characterise stem cells from adult human tissues and tumour tissues in order to generate in vitro-ex vivo model systems to study self-renewal differentiation and tumorigenesis.

Project FMW03/2016: The goal of this project is dissect the mechanisms involved in the differentiation of stem cells in the human epidermis.

### Recipient or parental organism

Projects MF02/16 and FMW02/2016:
- E. coli (e.g. DH10B, Stabl2, 4) or derivatives.
- Helper-free retrovirus producer cell line Phoenix-eco.
- Mouse cell line GP + envAm12.

Project MF02/16:
- Human primary cells and primary tumour cells.

Project FMW02/2016:
- Mouse embryonic stem lines (established over 25 years).
- Epithelial tumour cell lines (commercial available with a history of safe usage).
- Human keratinocyte cell lines derived from normal infant skin from screened healthy individuals having a negligible risk of contamination with adventitious human pathogens.
- Primary human keratinocytes purchased from established sources (for instance Lonza; http://www.lonza.com).

### Host/vector system

- E. coli / standard mammalian expression vectors such as pGL, pcDNA or commercially available derivatives
- Human Cell Lines / non-mobilisable viral plasmid vector pBabe (puro) and derivatives, based on Moloney Murine Leukaemia Virus or commercially available lentivirus vectors (such as pRRLSIN_cPPT.PGK-GFP.WPRE).
- Human Cell Lines / pSuperRetro or lentiviral vectors (such as pLKO, pLentiCRISPRv2 and their commercially available derivatives)
Projects MF02/16 and FMW03/2016:
- Genes with autocrine pathogenic effect, some of which are classified as oncogenes or tumour suppressor genes:
  - Dominant negative and activated forms of Myc, β-catenin, Tef/Lef, MEK1, Ras, Raf, Rac, Rho, cdc42, PI3K, Klf4,
  - Oct4, Sox-2, p53, histone methyltransferases, and splice factors.
- Genes with paracrine pathogenic effect, some of which are classified as oncogenes or tumour suppressor genes:
  - Wild-type and mutant constructs of alpha - and [I, integrin subunits, Ephrins, and E-cadherin, components of the
  - Hedgehog signalling pathway (Serrate, Delta, Notch, Sonic Hedgehog, Indian Hedgehog, Patched), TGF-signalling
  - Pathway (Smads), EGF-signalling pathway (LRIG).
- Genes or non-coding RNA genes with poorly characterised pathogenic effects: NSun2, NSun3, NSun6, SRSF2,
  - 7SK, and Vault RNAs.
- Genes with no growth-promoting capacity e.g. GFP, dsRED, tdTomato, confetti, structural genes.
All DNA will be propagated in E coli (e.g. DH10B or derivatives).
The plasmid will first be transfected into an ecotropic packaging cell line, Phoenix-eco, and the retrovirus produced
will be harvested over 1-2 days.
The helper-free retrovirus producer cell line Phoenix-eco, was developed by Dr. G. Nolan at Stanford University,
(http://www.stanford.edu/group/nolan/index.html) and has been used by over 2500 labs. Phoenix-eco cells express
the gag-pol and envelope genes using different non-Moloney promoters to minimize both recombination and intertypic
recombination potential. This cell line has a history of safe usage.
This ecotropic retrovirus will then be used to stably infect a second packaging cell line, GP + envAm12, which
produces disabled amphotropic retrovirus. The mouse cell line GP + envAm12 has been widely used for the
production of amphotropic virus. Tests for the safety of the GP + envAm12 packaging line showed no evidence for the
generation of wild type virus and it has a history of safe usage. Markowitz, Goff and Bank. Virology 167,400-406
(1988). Defective amphotropic virus would then be used for the infection of human keratinocytes. Transduced cells
would be selected and maintained in medium containing an appropriate antibiotic before further use in experiments.
All genes will be inserted downstream of the viral LTR with the intention of achieving a moderate level of expression in
recipient cells. Infection of keratinocytes will be by transfer of supernatant culture fluids without any concentration of
the virus particles.
Lentiviral vectors will be used to deliver transgenes directly into a variety of dividing or nondividing cell types. These
vectors are commercially available and have a history of safe use. The components necessary for virus production
are split across multiple plasmids (3 for 2nd-generation systems, 4 for 3rd-generation systems)
(http://www.addgene.org/viral-vectors/lentivirus/lenti-guide/).
Recipient human cell lines expressing the individual genes under study will be created which are likely to have some
growth advantage or induce increased proliferation in an autocrine or paracrine manner.

Evaluation of foreseeable effects
Recipient human primary cells, human primary tumour cells, human keratinocytes and established cell line
expressing the individual genes under study will be created which are likely to have some growth advantage or
induce increased proliferation in an autocrine or paracrine manner. Alternatively, modified human primary cells,
primary tumour cells and human keratinocytes could be induced to terminally differentiation.
Bacterial strains of E coli such as DH10B and its derivatives are not capable of colonising a healthy individual.
The amphotropic retrovirus is able to infect cells from a broad host range, including humans but can not replicate
unless it recombines with endogenous retrovirus. Exposure of an individual to amphotropic retrovirus, by possibly a
break in the skin, could result in a localised transfer of the pathogenic properties of the particular gene. None of the
cell lines would be expected to remain viable outside the controlled culture conditions and we do not anticipate that
any of the genetic manipulations we are proposing would alter this. It is predicted that over-expression of oncogenes and signalling molecules could lead to an increased rate of cell division although tumour progression and disease in the whole organism is unlikely. The major possible source of hazard to the environment would be accidental escape of high titre virus solutions expressing cDNAs, which could then infect rodents. Retroviruses require close contact for their transmission and their survival in the general environment is poor due to their fragile envelope. The vector is non-mobilisable and the successful infection of a cell would include stable integration of the viral genes into host DNA. Although the amphotropic virus would be able to infect humans it could not replicate unless it recombined with endogenous retrovirus. Even then it is unlikely that expression of a single oncogene or inactivation of a tumour suppressor would cause tumours, as multiple genetic alterations (between 4 and 6) are required for inducing tumours, and safeguard mechanisms exist impeding the accumulation of these alterations in the organisms (i.e. single events like Ras or myc expression instead of unrestrained proliferation, induce growth arrest or apoptosis) (Hanahan&Weinberg, Cell 100, 57-70; 2000).

Lentivirus can infect human dividing and non-dividing cells. The potential for generation of replication-competent lentivirus is minimized by the design of the vectors and by safe laboratory practice. The transfer vector encodes the gene of interest and contains the sequences that will incorporate into the host cell genome, but cannot produce functional viral particles without the genes encoded in the envelope and packaging vectors. Unless recombination occurs between the packaging, envelope, and transfer vectors, and the resulting construct is packaged into a viral particle, it is not possible for viruses normally produced from these systems to replicate and produce more virus after the initial infection. Many of the lentiviral transfer vectors are self-inactivating (SIN) vectors. These vectors have a deletion in the 3'LTR of the viral genome that is transferred into the 5'LTR after one round of reverse transcription. This deletion abolishes transcription of the full-length virus after it has incorporated into a host cell.

The use of sharps will be strictly controlled and avoided wherever possible. Needles and scalpels will not be permitted. Plastic Pasteur pipettes will be used for aspirating culture medium.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable. Generation of larger GMOs (animals/plants) is not proposed.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation requested.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste will be sealed in double autoclave bags and transported to the Departmental autoclave where it will be exposed to steam at 1270°C for 25 minutes. The Departmental autoclave has effectively 100% kill as validated by the annual testing certificates which are held by the Department. Printed readouts from each run will be retained to ensure temperatures within the autoclave were maintained during the cycle. All liquid waste will be inactivated by treatment with Anigene at a final concentration of 10% before disposal via the drains.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
Risk Assessments were reviewed by the Department of Genetics Biological Safety subcommittee including Mark Elsdon (Biological Sciences School Safety Officer) as well as Keff Tibbles (Clinical School Safety Officer) who has a background in virology and a special interest in Lentiviral Vector safety. Comments were returned to Michaela Frye's group who modified the Risk Assessments appropriately. Similar project work has been undertaken with HSE approval by Michaela Frye and her research group at the Wellcome Trust-MRC Cambridge Stem Cell Institute since 2007.

**Project Additional Information**

**Purposes of the contained use**

The obligate intracellular bacterium Chlamydia trachomatis has been considered genetically intractable. However,
there have been multiple recent reports of transformation from different laboratories using recombinant plasmids based on hybridisation of E.coli and the endogenous Chlamydia trachomatis plasmids. We intend to use these vectors to express epitope-tagged or fluorescent fusion proteins in Chlamydia trachomatis to investigate the localization of virulence effectors and components of the type III secretion system biochemically and using imaging techniques.

Recipient or parental organism

The following aspects of this project are assigned to Class 1.
Cloning and manipulation of the vectors and their propagation in E.coli strains
The following aspects of this project are assigned to Class 2.
Transformation and propagation of transformed C.trachomatis within cultured mammalian cells.

Host/vector system

Wild-type Chlamydia trachomatis (this is a Biosafety level 2 organism and not disabled)
E.coli DH5α and XL-1 Blue will be used for plasmid propagation and sub-cloning procedures. These are E.coli K12 derivatives and are classified as ‘disabled and non-colonising’ by the ACGM.
X11-Blue recA1 endA1 gyrA96 thi-1 hsdR17 supE44 relA1 lac [F ’ proAB lacIqZΔM15 Tn10 (TetR)]
DHSalpha F- phi80lacZ::M15 delta(lacZYA-argF)U169 deoR recA1 endA1 hsdR17 (r- m+) phoA supE44 thi-1
 gyrA96 relA1 lamdA pASKGFPL2
 pTRL2-GFP
 pCDSSKO
 placZ-CD55KO

Origin & function

We plan to study the localisation and function of C.trachomatis proteins encoding components of the type III secretion system (inner and outer membrane protein, ATPase, translocon and needle) and the substrates, which are delivered into the boundary membrane of the replicative vacuole (hydrophobic inclusion proteins), host cytosol or nucleus.
These genes will be amplified by PCR from chromosomal DNA of C-trachomatis held in our laboratory or by gene synthesis (as some genes are exceptionally difficult to amplify by PCR). Epitope tags will be added to the sequence as part of the PCR primer or synthesised product (e.g. FLAG, Myc) when required. In the case of fusion proteins to MBP, GFP, mKate2 these will be amplified from existing commercial vectors (e.g. pEGFP-C2; Clontech) or obtained from collaborating laboratories where necessary.

Evaluation of foreseeable effects

E.coli. will be used to make the expression constructs. The Chlamydia trachomatis will be used to express the various components of the epitope-tagged or fluorescent fusion proteins to investigate the localization of virulence effectors and components of the type III secretion system biochemically and using imaging techniques. The GMOs themselves will not, in our assessment, cause any additional harm to human health above the virulence of the wild-type organism. Chlamydia elementary bodies survive for only a very short time outside their host cells (30 minutes to 1 hour), so risks from environmental release do not significantly exceed those of the wild-type organisms.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
The control systems in place are designed to ensure that any contaminated waste is efficiently sterilised and any GMOs killed. There are two main routes for the sterilisation of laboratory waste to be used in this notification. All liquid and solid laboratory waste will either be incubated with 1% Virkon for at least 30 minutes or will be autoclaved on the same day using validated conditions. Each autoclave cycle is validated with the inclusion of a thermolog S strip to monitor that the target temperature for killing the GMOs has been successfully achieved. The sterile, solid autoclaved material can then be disposed of via our normal waste route. The 1% Virkon treated sterile liquid waste would go down the sink route.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The risk assessment entitled "Transformation of Chlamydia trachomatis" was considered at the College GM safety committee on Wednesday 29th October 2014. The committee approved the risk assessment level at GM category 2 and agreed that it should be forwarded to the HSE for notification and consideration with the appropriate fee.

Project Ref 43/01.1

Date Ackn'd 05/01/2001  CU2 Project Title IDENTIFICATION OF NATURAL KILLER CELL ACTIVATING LIGANDS  Class: Class 2  CultureVolClass2: < 1 litre  CultureVolumeClass3-4:
Natural killer cells are a population of peripheral blood lymphocytes able to lyse certain virus-infected and tumor cells in a non-MHC restricted fashion. Normal human fibroblasts are not lysed by human NK cells, but the same fibroblasts infected with e.g. HSV are attacked and killed by NK cells. The aim of this project is to directly test the hypothesis that the expression of incorrectly folded MHC Class I molecules at the cell surface is one of the mechanisms by which a given target cell can become susceptible to attack and lysis by human Natural Killer cells.

Recipient or parental organism

The recombinant organism to be used in the course of this work include mutants of Herpes Simplex Virus (HSV)-1 (all of which are at least gH and thus unable to produce infectious virions) and some recombinant vaccina viruses (derived from strain WR, but thymidine Kinase deficient).

Host/vector system

The mutant and recombinant viruses will be used to infect in vitro maintained cultures of human foreskin fibroblasts and the human B cell line 721.221 and various Class I MHC transfectants of the parental cell line.

Origin & function

The mutant HSV strains were provided by Dept. of Pathology, University of Cambridge and MRC Virology Unit, Glasgow. The recombinant vaccina viruses were gifts of NIH and University of Cambridge Vet School.

The aim of this work is to directly test the hypothesis that the expression of incorrectly folded MHC Class I molecules at the cell surface is one of the mechanisms by which a given target cell can become susceptible to attack and lysis by human Natural Killer cells. Expression of incorrectly folded MHC Class I molecules at the cell surface is one of the effects of the protein product of the HSV gene ICP-47, thus the hypothesis can be tested by examining:

1. Does infection with mutant HSV strains lacking ICP-47 still result in enhanced susceptibility to NK cell lysis?
2. Is the introduction of solely the ICP-47 gene, via the recombinant vaccina, sufficient to cause enhanced susceptibility to NK cell lysis?
The work proposed would not include the use of experimental animals and would be carried out in the ACGM category 2 tissue culture suite in the department under the guidelines for good practice laid out in the ACGM compendium of guidance. Accidental ingestion, inoculation or aerosol exposure represent possible routes of laboratory worker contamination and thus these viruses will only be used in category 2 (operator safety) microbiological cabinets by experienced workers wearing gloves and labcoats. No sharps should need to be used during these experiments.

The HSVs to be used in these experiments can be considered replication defective, by virtue of lacking the gH protein and the probability of this mutation being complimented in vivo by a wild-type virus can be estimated as being very low. The experiments with HSV are extremely likely to pose any risk to the environment. Humans are the only natural host for HSV and the virus is extremely labile thus the overall risk can be considered to be effectively zero.

The recombinant vaccina viruses have been attenuated by loss of the TK locus and the likelihood of recombination in vivo is low. Moreover although the recombinant vaccina expressing ICP-47 might be considered to have an increased ability to evade recognition by cytotoxic T cells (CTL), it is worth pointing out that even when ICP47 isexpressed as an immediate early gene product in HSV infection a substantial CTL response to HSV can still be generated. Further, a neutralising antibody response, which ICP47 expression would not be expected to affect, is a significant component of the immune response to vaccina virus. Finally, all evidence that is isolated down-regulation of MHC Class I glycoproteins increases immune rejection of tumor cells through the action of NK cells. The other recombinant vaccina expresses the p25 gag gene of maedi-visna virus, a virus infection of sheep. The protein product of this gene forms the core of the visna-virus particle. Expression of this gene product would not be expected to alter any of the pathogenic characteristics of the vaccina.

Vaccina has been extremely widely used as a vaccine vector for both man and animals and the accumulated experience indicates that although the virus can survive long periods for example in dried scabs, the virus is unlikely to become established in the wild. However to minimise the risk of escape the virus will only be used in the ACGM category 2 tissue suite in the department under the guidelines for good practice laid out in the ACGM compendium of guidance. This should minimise any risk to the environment and thus the overall risk is low.

### Evaluation of foreseeable effects

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

| None |

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All liquid and solid waste will be autoclaved, this should result in effectively 100% kill of all microorganisms. As a precautionary measure before autoclaving, liquid waste will be treated with 1% vircon. Validation of kill via autoclaving will depend on regular testing of the autoclave installed in the ACGM category 2 tissue culture suite in the department.

Project Additional Information

Purposes of the contained use

There are two objectives:

1. to design cellular immune assays using recombinant adenoviruses to determine cytotoxic T cell responses to papillomavirus antigens.
2. to investigate the effect of papillomavirus proteins on the eukaryotic cell cycle in vitro.

Recipient or parental organism

The parental organisms are the canine oral papillomavirus COPV and human papillomavirus types 6, 16, 18. The recipient organism is a replication defective adenovirus.
**Host/vector system**

Vector amE1 deleted replicator defective adenovirus (Ad-5).

**Origin & function**

COPV early genes. - The E6, E7, E2, E1 and E4 genes of COPV are cloned from COPV DNA. The COPV isolate was derived from a clinical case of oral warts in a retriever. The virus has not been passaged in vitro, generates warts in beagle dogs, does not transform cells in culture. The early genes will be expressed via a replication defective adenovirus to generate peptide fragments for recognition by T cells.

HPV 16, 6, 18 - The E2, E1, E6 and E7 genes are cloned from reference DNAs originally isolated from clinical samples. These genes will be expressed in replication defective adenoviruses. The viruses will be used to infect cells in tissue culture to determine the effects of the HPV genes on the eukaryotic cell cycle.

**Evaluation of foreseeable effects**

Vector - an E1 deleted replication defective adenovirus (Ad-5). This modified virus cannot initiate a full replication cycle and there is no survival value. Recombinant viruses expressing COPV proteins - COPV is not an oncogenic papillomavirus, there is no evidence that any COPV protein delivered via an oxogenous vector can immortalise human cells. COPV does not induce carcinoma in the natural host. Recombinant viruses expressing HPV proteins - HPV 16 and 18 are oncogenic viruses, encoding the oncogenes E6 and E7. Co-expression of both proteins is required for immortalisation of human cells in vitro. Expression of E6 or E7 alone in primary cells results in apoptosis. Experiments will involve the use of adenoviruses expressing either E6 or E7 or E1 or E2. The recombinant adenoviruses cannot initiate a full replication cycle and there is no survival value. All work is small scale using standard laboratory procedures. Replication defective adenoviruses are Class I GMOs. The insertion of the HPV genes with the properties detailed above raises these GMOs to Class 2. Containment is therefore at level 2. The identifiable risk is infection of the laboratory worker by aerosol; therefore all work is done in a laminar flow class II hood. Full containment level 2 requirements will be applied and the risk to human health and the environment is minimal.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

The identifiable risk is infection of the laboratory worker by aerosol, therefore all manipulations with recombinant viruses are conducted in a Class II laminar flow hood in a restricted culture facility under negative pressure. Air is exhausted to the exterior through HEPA filters. The restricted culture facility is for work at Class 2 level containment only.

Gloves, face masks and protective clothing are worn within the facility. Soiled and used protective clothing is double bagged and autoclaved within the facility before disposal. Glassware is avoided wherever possible and disposable pipettes, tubes, culture flasks etc are employed. Used disposables are double bagged in autoclave bags and autoclaved within the facility before disposal. Sharps are disposed in sharps bins that are autoclaved within the facility before disposal.

Infected media is collected in aspirator traps containing available chlorine at 2000 ppm [100ml chloros/litre or 5 klorsept 7 (Jencons) tablets/litre]. Any glassware is immersed fully in a solution containing available chlorine at 2000 ppm for 2 hours.

Spillages are disinfected with Klorsept granules which contain and absorb the spill.
All the work involves standard laboratory procedures on a small scale (maximum culture volume/flask 150 ml). The level 2 containment and control measures in place make it improbable that the GMOs will reach the environment and cause harm to humans or animals outside the laboratory.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

### Project Additional Information

**Purposes of the contained use**

To investigate the functions of influenza virus gene products in virus replication and pathogenesis.

**Recipient or parental organism**

Vaccina virus - coding sequences derived from influenza viruses.
Influenza virus - 'reporter genes' (e.g. LacZ, firefly luciferase, green fluorescent protein) coding sequences derived from influenza virus genes

**Host/vector system**

Eukaryotic viruses (ACDP group 2)/mammalian and avian (established, commercially available).

**Origin & function**

**Origins:** Sequences will be sub-cloned from pre-existing plasmid clones. In some instances influenza virus sequences will be isolated from purified viral RNA.

**Functions:** The biological properties of influenza virus genes are considered in the detailed risk assessment. These genes will be expressed in eukaryotic tissue culture cell lines (via eukaryotic vectors) to examine the location, trafficking and function of influenza virus proteins, or to provide helper functions for disabled influenza viruses.

'Reporter genes' will be inserted into influenza virus genomes to enable tracking of the tagged viruses.

**Evaluation of foreseeable effects**

Influenza virus genes act in concert to achieve virus replication. Some of the gene products are known to be cytotoxic but these are not secreted and only the expressing cell is expected to be affected. Influenza viruses are not oncogenic and transforming genes have not been identified in these viruses. Influenza virus gene function is, however not fully understood and some influenza virus genes are known to modify host immune responses. The eukaryotic vectors used are either heavily attenuated or replication incompetent in mammalian hosts. No change in tissue tropism or host range of the vectors expressing influenza virus genes is foreseen (see detailed risk assessment). The assessment to human health indicated no greater hazard from those of the wild type unmodified virus.

The insertion of 'reporter genes' into the influenza virus genome is likely to either reduce the replication capacity and virulence of the recipient virus or to leave it unchanged. No increase in virulence, alteration of tissue tropism or modification of host range is predicated.

The creation of replication competent reassortant influenza viruses might conceivably result in increased virulence or host-range properties. However, the recipient and donor viruses are all of low pathogenicity for humans. In addition, reassortant influenza viruses arise continually in nature and there is also a long history of their safe creation in the laboratory. As discussed in the detailed risk assessment (attached), the risk of creating a virus with increased pathogenicity is extremely low.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

02/03/2022
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Standard validated methods will be used:

Liquids: made 2000ppm available chlorine (5% chloros) and disposed via drains after a minimum of 12 hours.

Mixed disposable waste: Validated autoclave, 121 degrees/30 min, then disposed as domestic waste.

Disposable pipettes: Either a) as for mixed disposable waste or b) immerse in solution of 2000ppm available chlorine (5% chloros) for minimum 12 hours, followed by incineration.

Re-usable materials: Autoclave, 121 degrees/30 min.

I had forgotten to inform you that the local ACGM committee had reviewed and approved the 6 applications.

**Project Additional Information**

**Purposes of the contained use**

To investigate the functions of herpesvirus gene products in virus replication and pathogenesis.

**Recipient or parental organism**

- Adenovirus 5, Amphotropic retrovirus, Vaccinia virus: coding sequences derived from mammalian alpha or beta herpesviruses.
- Herpes simplex virus, Human cytomegalovirus: 'reporter genes' (eg LacZ, firefly luciferase, green fluorescent protein).

**Host/vector system**

Eukaryotic viruses (ACDP group 2)/mammalian cell lines (established, commercially available).

**Origin & function**

- Origins: Sequences will be sub-cloned from pre-existing plasmid clones. In some instances herpes virus sequences will be isolated from purified viral DNA.
- Functions: The biological properties of herpes virus genes are considered in the detailed risk assessment. These genes will be expressed in mammalian cell lines (via eukaryotic vectors) to examine the location and trafficking of herpes virus proteins, or to provide helper functions for disabled herpesviruses. 'Reporter genes' will be inserted into herpesvirus genomes to inactivate specific virus genes and to identify the resulting disabled or attenuated viruses.

**Evaluation of foreseeable effects**

The insertion of 'reporter genes' into viral genomes is expected to reduce the replication capacity of the recipient virus or to reduce its virulence. No increase in virulence, alteration of tissue tropism or modification of host range is predicted.

Herpesvirus genes act in concert to achieve virus replication. Some of the gene products are known to be cytotoxic but these are not secreted and only the expressing cell is expected to be affected. Mammalian alpha and beta herpes viruses are not oncogenic and transforming genes have not been identified in these viruses. Herpesvirus gene function is, however not fully understood and some herpesvirus genes are known to evade or modify host immune responses. The eukaryotic vectors used are either fully disabled or heavily attenuated. No change in tissue tropism or host range of the vectors expressing herpesvirus genes is foreseen (see detailed risk assessment). The assessment to human health indicates no greater hazard than those of the wild type unmodified virus.
**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**Project Additional Information**

**Purposes of the contained use**

To investigate the functions of herpesvirus gene products in virus replication and pathogenesis.

**Recipient or parental organism**

- Adenovirus 5, Amphotropic retrovirus, Vaccinia virus: coding sequences derived from mammalian alpha, beta or gamma herpesviruses, murine cellular genes.
- Murine gamma-herpesvirus 68 (MHV-68): 'reporter genes' (e.g., LacZ, firefly luciferase, green fluorescent protein) coding sequences derived from MHV-68.

**Host/vector system**

Eukaryotic viruses (ACDP group 2)/mammalian cell lines (established, commercially available).

**Origin & function**

**Origins**: Sequences will be sub-cloned from pre-existing plasmid clones. In some instances, herpes virus sequences will be isolated from purified viral DNA or amplified from genomic DNA/cDNA by PCR.

**Functions**: The biological properties of herpes virus genes are considered in the detailed risk assessment. These genes will be expressed in mammalian cell lines (via eukaryotic vectors) to examine the localisation and function of herpesvirus proteins, or to provide helper functions for disabled herpesviruses. 'Reporter genes' will be inserted into herpesvirus genomes to inactivate specific virus genes and to identify the resulting disabled or attenuated viruses. MHV-68 coding sequences will be re-inserted back into the MHV-68 genome in order to rescue disabled knockout viruses.
The insertion of 'reporter genes' into viral genomes is expected to reduce the replication capacity of the recipient virus or to reduce its virulence. No increase in virulence, alteration of tissue tropism or modification of host range is predicted.

Herpesvirus genes act in concert to achieve virus replication. Some of the gene products are known to be cytotoxic but these are not secreted and only the expressing cell is expected to be affected. We have not found MHV-68 to be an oncogenic virus in vivo or in vitro, and the equivalents of other gamma-herpesvirus transforming genes have not been reliably identified. Herpesvirus gene function is not fully understood and some herpesvirus genes are known to evade or modify host immune responses. The eukaryotic vectors used are either fully disabled or heavily attenuated. No change in tissue tropism or host range of the vectors expressing herpesvirus genes is foreseen (see detailed risk assessment). The assessment to human health indicates no greater hazard than those of the wild type unmodified virus.

02/03/2022
CLONING AND EXPRESSION OF GENES OF VIRAL, HUMAN, MOUSE OR PARASITE ORIGIN AND OTHER RELATED ACTIVITIES (TRANSFERRED TO GM353)

Purposes of the contained use

1. Identification of viral proteins that block various aspects of the host immune response.
2. Characterisation of the activity of viral and parasite proteins in vitro, in binding assays to several ligands and functional analysis, and comparison with the properties of the human or mouse counterparts.
3. Understanding the role of viral proteins and their cellular counterparts in viral pathogenesis and immune modulation in a mouse model of infection.

Recipient or parental organism

Vaccinia virus and amphotropic retroviruses expressing reporter genes (eg LacZ, firefly lucerase, green florescent protein), selectable genes that confer resistance to specific compounds (EcoGpt, puromicin resistance gene) or the ability to grow in a rabbit cell line (vaccinia virus K1L gene), or coding sequences derived from viruses (poxviruses, herpesviruses), parasites (leishmania, schistosoma), humans or mice.

Ectromelia viruses expressing (i) reporter genes (eg LacZ, firefly lucerase, green florescent protein), (ii) selectable genes that confer resistance to specific compounds (EcoGpt, puromicin resistance gene), (iii) gene from proxviruses or herpesviruses or (iv) mouse or human genes.
Host/vector system

Eukaryotic viruses (ACDP group 2).

Ectromelia virus (ACDP group 1).

Mammalian cell lines (established, commercially available) (ACDP group 1).

Origin & function

Origins: Sequences will be amplified by polymerase chain reaction using viral, parasitic or cellular DNA as a template, or will be subcloned from pre-existing plasmid clones.

Function: The biological properties of the genes are considered in the detailed risk assessment. These genes will be expressed in mammalian cell lines (via eukaryotic vectors) to examine the location and function of proteins. Reporter and selectable genes will be inserted into viral genomes to inactivate specific viral genes and to identify the resulting recombinant virus.

The biological effects derived from inactivation of genes in proxviruses (vaccinia or ectromelia viruses) or from the replacement of ectromelia virus genes by homologous genes will be determined in vivo in a mouse model of infection.

Evaluation of foreseeable effects

The insertion or reporter or selectable genes into viral genomes is expected to reduce the replication capacity of the recipient virus or to reduce its virulence. No increase in virulence, alteration of tissue tropism or modification of host range is predicted.

The eukaryotic vectors used (vaccinia, retrovirus) are either fully disabled or heavily attenuated. No change in tissue tropism or host range of the vectors expressing foreign genes is foreseen (see detailed risk assessment). The assessment to human health indicated no greater hazard than those of the wild type unmodified virus.

Whereas vaccinia virus and cowpox virus can replicate in a number of mammalian species, ectromelia virus is restricted to mice. Recombinant poxviruses lacking specific genes are expected to be attenuated and to transmit poorly between individuals. No change in tissue tropism or host range of the vectors expressing foreign genes is foreseen (see detailed risk assessment). The assessment to human health indicates no greater hazard than those of the wild type unmodified virus.

The ectromelia virus mutants lacking immunomodulatory genes are expected to be attenuated. Insertion into ectromelia virus mutants of related genes from other proxviruses or herpesviruses, or mouse/human genes, with similar functions, is unlikely to increase ectromelia virus virulence to levels higher than wild type. However, if an increased virulence is observed, it is unlikely to change the tissue and host tropism of ectromelia virus (highly restricted to mice), and therefore to represent a greater hazard to human health than wild type ectromelia virus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Standard validated methods will be used:

Liquids: made 2000ppm available chlorine (5% chloros) and disposed via drains after a minimum of 12 hours.
Mixed disposable waste: Validated autoclave, 121 degrees/30 min, then disposed as domestic waste.

Disposable pipettes: Either a) as for mixed disposable waste or b) immerse in solution of 2000ppm available chlorine (5% chloros) for minimum 12 hours, followed by incineration.

Re-usable materials: Autoclave, 121 degrees/30 min.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

not applicable

Project notified under transitional arrangements [N]
### Purposes of the contained use

To investigate the functions of herpesvirus gene products in virus replication and pathogenesis.

### Recipient or parental organism

- **Adenovirus 5, coding sequences derived from mammalian alpha or gamma herpesviruses.**
- **Adeno associated virus**
- **Amphotropic retrovirus**
- **Herpes simplex virus, 'reporter genes' (eg LacZ, firefly luciferase, green fluorescent protein)**
- **Murine gammaherpes virus 68, coding sequences derived from Gammaherpesviruses.**

### Host/vector system

- **Eukaryotic viruses (ACDP group 2)/mammalian cell lines (established, commercially available).**

### Origin & function

**Origins:** Sequences will be sub-cloned from pre-existing plasmid clones. In some instances herpes virus sequences will be isolated from purified viral DNA.

**Functions:** The biological properties of herpesvirus genes are considered in the detailed risk assessment. These genes will be expressed in mammalian cell lines (via eukaryotic vectors) to examine the location and trafficking of herpesvirus proteins, or to provide helper functions for disabled herpesviruses. 'Reporter genes' will be inserted into herpesvirus genomes to inactivate specific virus genes and to identify the resulting disabled or attenuated viruses.

### Evaluation of foreseeable effects

The insertion of 'reporter genes' into viral genomes is expected to reduce the replication capacity of the recipient virus or to reduce its virulence. No increase in virulence, alteration of tissue tropism or modification of host range is predicted.

Herpes simplex virus genes act in concert to achieve virus replication. Some of the gene products are known to be cytotoxic but these are not secreted and only the expressing cell is expected to be affected. Mammalian alpha herpes viruses are not oncogenic and transforming genes have not been identified in these viruses. Herpes simplex virus gene function is, however not fully understood and some herpesvirus genes are known to evade or modify host immune responses. The eukaryotic vectors used are either fully disabled or heavily attenuated. No change in tissue tropism or host range of the vectors expressing herpes simplex virus genes is foreseen (see detailed risk assessment). The assessment to human health indicates no greater hazard than those of the wild type unmodified virus.

Murine gammaherpes virus 68 is a naturally occurring herpesvirus of rodents and has been isolated from a number of rodent species in Europe. There is no direct evidence that this virus infects man although the virus is known to replicate in human cells. Inactivation of virus gene products and the insertion of reporter genes into viral genomes
is expected to reduce the replication capacity of the recipient virus or to reduce its virulence. In common with other well characterised gammaherpesviruses MHV-68 is likely to encode gene products with transformation potential thus expression of virus genes with unknown function or known transformation potential in will be restricted to fully disabled vectors. No change in tissue tropism or host range of the vectors expressing MHV-68 gene is expected (see detailed risk assessment). The assessment to human health indicates no greater hazard than those of the wild type unmodified virus.

### Project Additional Information

**Purposes of the contained use**

To analyse papillomavirus gene functions in eukaryotic cells and innate and adaptive immune responses to these proteins.

**Recipient or parental organism**

Recipient/Vector: Inserted Material.

Adenovirus 5 Vaccinia virus: coding sequences from human papillomaviruses and canine oral papillomavirus.

**Host/vector system**

Eukaryotic viruses (ACDP group 2).

Eukaryotic cells.

**Origin & function**

Origins

papillomavirus genes - sequences will be sub cloned from pre-existing plasmid clones (HPV and COPV). The COPV isolate was derived from a clinical case of oral warts
In a retriever. The virus has not been passenged in vitro, generates oral warts in beagle dogs and does not transform human or canine cells in future.

Functions

The biological functions are considered in the detailed risk assessment. The genes are expressed in tissue culture cells via recombinant viruses to:

1. general peptide fragments for recognition by immune cells
2. generate viral proteins
3. analyse biological functions of viral proteins in eukaryotic cells in vitro.

Evaluation of foreseeable effects

Vectors

An E1 deleted replication defective adenovirus (Ad-5). This modified virus cannot initiate a full replication cycle and there is no survival value.

Vaccina virus. Insertion of papilloma sequences in the thymidine kinase (TK) site resulting in a TK negative Phenotype. The recombinant virus is attenuated by several orders of magnitude compared to the wild type. The inserted genes are expressed under the control of promoters operational only in the vaccinia lytic cycle, the expression of the inserted gene is therefore always accompanied by cell lysis.

Recombinant genes expressing COPV proteins.

COPV is not an oncogenic virus and there is no evidence that expression of COPV protein delivered via an exogenous vector can immortalise human cells. COPV does not induce carcinoma in the natural host.

Recombinant viruses expressing HPV proteins

The HPV E6 and E7 proteins must be expressed co-ordinately for immortalisation of human cells in vitro, expression of these genes singly results in cell death by apoptosis.

All work is small scale using standard laboratory procedures. The identifiable risks to workers are by aerosol and therefore all work is done in a laminar Class II hood and full containment level 2 requirements are applied.

The risk to human health and the environment is minimal.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Cloning and expression in prokaryotic transfer vectors is a Class I activity and is covered under "Papillomavirus protein expression" Project Number 21 ACGM Centre 43.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The identifiable risk is infection of the laboratory worker by aerosol, therefore all manipulations with recombinant viruses are conducted in a Class II laminar flow hood in a restricted culture facility under negative pressure. Air is exhausted to the exterior through HEPA filters. The restricted culture facility is for work at Class II level containment only.
Gloves, face masks and protective clothing are worn within the facility. Soiled and used protective clothing is double bagged and autoclaved within the facility before disposal. Glassware is avoided wherever possible and disposable pipettes, tubes, culture flasks etc are employed. Used disposables are double bagged in autoclave bags and autoclaved within the facility before disposal. Sharps are disposed in sharps bins that are autoclaved within the facility before disposal. Mixed disposable waste: validated autoclave 121 degrees/30 mins then disposed as disposable waste.

Infected media is collected in aspirator traps containing available chlorine at 2000 ppm [100ml chloros/litre 5 Klorsept 7 (Jencons) tablets/litre]. After a minimum chlorine treatment of 12 hours liquids are disposed via drains. Any glassware is immersed fully in a solution containing available chlorine at 2000ppm for 2 hours, rinsed within the facility and autoclaved. Validated autoclave 121 degrees/30 mins.

Please enter comments on the GM safety committee on the risk assessment

Project Additional Information

Purposes of the contained use

We aim to express mammalian genes that putatively regulate apoptosis pathways into mouse mammary epithelial cells. Changes in the rate of cell death, cell cycle, cell motility and/or cell adhesions will be monitored in these cells. cDNA will be cloned into a commercially available prokaryotic vector (pAdTrack or pShuttle), recombined with a replication defective disabled adenoviral backbone (pAdEasy) in a bacterial host, BJ5183, then linearised and transfected into cultured 293 cells to produce replication defective Ad. 293 cells will be passaged through 1-5 rounds of infection and high titre virus then purified on a CsCl gradient. Established mouse mammary epithelial cells lines will be infected with diluted purified virus and subsequently monitored for cellular changes in situ and by harvesting cell lysates for molecular analysis.

Recipient or parental organism

Attenuated E. coli strain BJ5183 (recipient micro-organism), if accidentally ingested in large quantities may produce mild temporary gastrointestinal symptoms. Wild-type Ad5 (not used here) is common in the population (>50% children carry antibodies to Ad5) and manifests a mild respiratory disease on initial infection or in immunocompromised hosts. Persistence of infection is dependent on replication competence and infected epithelial cells are eliminated and replaced by the host apoptosis mechanisms. Replication deficient adenovirus (used here) can only be propagated in 293 cells, due to the absence of the essential E1 gene in the viral genome. In addition the replication deficient vector has a deletion of the E3 immune evasion gene which, although non-essential in vitro, is likely to be an important virulence determinant. Adenovirus has a short lifetime outside the host and is inactivated immediately on contact with virkon. Adenovirus can be transmitted by aerosol.

Host/vector system

Hosts: E. coli BJ5183
Transformed and semi-transformed mouse mammary epithelial cells lines (KIM-2, NMuMG, EP-H4).
Transformed human embryonic kidney cells (AD-293) carrying E1 gene.

Vector system: Replication defective human adenovirus (serotype 5) derivative: pAdEasy, pAdTrack-CMV, pShuttle (Commercially available as AdEasy Adenoviral Vector System, Stratagene)

Origin & function

Apoptosis regulators may suppress or promote cell survival. However, as apoptosis is a cell autonomous process, this will not affect the survival of neighbouring cells and will not be propagated to cell progeny. Promotion of survival may prolong the life of damaged, excess or unwanted cells and therefore may increase the risk of cells accumulating genetic damage. However, apoptosis pathways in the cell are redundant and the regulators proposed to be used here are extremely unlikely to block all apoptosis pathways.

Evaluation of foreseeable effects

Cells infected by recombinant virus will express high levels of inserted gene within 24 hours (in culture), which may persist for the life of the cell, however transduced genes will not integrate into the host genome and therefore will not be propagated by the infected cell. Only cells that come into direct contact with the packaged virus will become infected. The routes of transmission to deliver the virus or its products to tissues are airways and eyes. So, the identifiable risk is infection of the laboratory worker by...
aerosol, or through needle stick injury during the purification procedure. The training of staff on the standard operating procedure for CsCl purification will be given particular attention in order to minimise the risk of needle stick injury. Adenoviruses used in this set of experiment are deficient in the E1 gene. Viral vector and recombinant vectors are stable in propagating bacterial and mammalian cells. The probability of reversion to the wild type is low as recombination in absence of E1 is performed in bacterial host prior to propagation in 293s. Consecutive rounds of amplification in 293 cells have the potential to increase titres of recombined replication-competent adenovirus, so amplification passages will be restricted to a maximum of 4 rounds. Dependent on the regulatory gene expressed, infected cells may either become susceptible to or resistant to cell death by specific apoptosis pathways but alternative mechanisms of cell death (eg. Other apoptosis pathways, necrosis, immune mediated lysis, senescence) will be unaffected.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All media/supernatants will be pipetted into Virkon. All cultures performed in sealed flasks and handled in Class II laminar flow hood in a restricted culture facility under negative pressure. Air is exhausted to the exterior through HEPA filters. Gloves, facemasks and laboratory coat are worn within the facility. Any disposable flasks, pipettes, filtered tips, plastic tubes etc. are fully immersed into Virkon for 24h and disposed by an approved decontamination method following autoclaving. Work surfaces and spillages are decontaminated by spreading Virkon. Liquids: transfer by filtered pipettes to Virkon. Soak for 24 hrs and disposed by sink. All the work involves standard laboratory procedures on a small scale. The level 2 containment and control measures in place make it highly improbable that the GMOs will reach the environment and cause harm to humans or animals outside the laboratory.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The Department of Pathology GM safety committee identified two issues:
1. The generation of replication competent adenovirus containing the genes involved in apoptosis.
2. The handling of highly concentrated replication incompetent viruses.

The Committee is now satisfied that both issues were specifically addressed by:
1. Screening for replication competent viruses and limiting passage.
2. Identification of needlestick injury during CsCl virus purification with the implementation of specific training to minimise the risk.

Project Containment
The use of lentiviral and retroviral expression vectors to influence gene expression and cell signalling in myelinating oligodendrocytes.

**Purposes of the contained use**

The study of oligodendrocyte differentiation, and the oligo-axonal interactions involved in myelination, so as to develop new strategies to enhance repair in Multiple Sclerosis. This project aims to induce the expression of adhesion molecules involved in multiple phases of oligodendrocyte development in myelinating oligodendrocytes. A second objective is to inhibit the expression of candidate genes hypothesized to regulate axo-glial adhesion and myelination using short hairpin RNA’s. The use of viral expression is necessary for these investigations, because myelination occurs over multiple weeks, and the duration of gene expression or repression required is greater than what can be attained using conventional transfection methods.

**Recipient or parental organism**

DH5alpha E.coli (disabled) and other common disabled E.coli K12 strains. LinX or equivalent packaging cell line for retrovirus, and HEK293 FT or equivalent for lentivirus. Cells to be infected are rodent oligodendrocyte and other precursors, neurons, neurospheres or oligospheres.

**Host/vector system**

D7alpha E.coli (disabled) and other common disabled E.coli K12 strains. LinX or equivalent packaging cell line for retrovirus, and HEK293 FT or equivalent for lentivirus. Cells to be infected are rodent oligodendrocyte and other precursors, neurons, neurospheres or oligospheres.
Bacterial cloning vectors (e.g. pUC based vectors). Retroviruses including pSM2 and LMP (Open Biosystems), lentiviruses including pLenti6.2v5 and ViralPower Packaging mix (a mixture of pLP1, pLP2 and pLP/VSVG plasmids; Invitrogen).

**Origin & function**

The objective of our studies is the knock-down of gene expression by the use of virally expressed small interfering RNA's, and/or disruption of protein function by virally expressed dominant negative isoforms, resulting in the inhibition of adhesion signalling pathways implicated in myelination, leading to alterations of myelin-forming capacity or the generation of myelin-forming cells.

DNA clones for expression (encoding wild-type or dominant negative forms of adhesion and related signalling molecules) will be obtained from collaborators, or generated by standard molecular biology techniques from DNA libraries held within the laboratory. Short-hairpin RNA sequences will be obtained from Open Biosystems Inc. Or will be designed using software such as "shRNA Retriever" from RNAi Central and then synthesised commercially and inserted into the vectors described above.

**Evaluation of foreseeable effects**

It will cause serious harm to the researcher is very low as the decrease in gene expression could not spread beyond the small number of cells directly exposed to the virus, either within the individual or to other individuals. Similarly, the ectopic expression of wild-type or inactive forms of oligodendrocyte proteins such as integrins may likewise alter the function of cells that are infected. The risk this poses will be minimised in two ways. First, the great majority of proteins expressed or knock-down to study myelination will have no effect on cell proliferation - an entirely different cellular process. In those cases were proteins implicated in myelination have been shown to have secondary effects on proliferation, the constructs used will be designed to express proteins that inhibit or prevent cell proliferation. Second, the very small number of cells affected by any contact of a researcher with the (replication-incompetent) viruses would limit the consequences of such an accident.

c) The vector (LMP) is derived from a mouse stem cell retrovirus (MSCV) vector, and while replication competent, cannot be packaged without viral gag, pol, and env genes, which it does not contain. pLenti contains a deletion in the 3’ long terminal repeat (LTR) that results in self-inactivation of lentivirus after transduction of the target cell, resulting in the virus being replication-incompetent. In both cases, once integrated into the transduced cell, the virus can no longer be packaged. The potentially harmful effects to the environment are effectively zero because

a) Genetic material will not have any outside target mammalian cells, and in the case of the small interfering RNA's will be species-specific.

b) The donor micro-organisms are disabled and will therefore not cause environmental harm by transfer to other organisms.

c) The vectors are replication-incompetence that will prevent dissemination or transfer to other organisms.

d) The resulting genetically modified micro-organism are extremely susceptible to dessication and will only survive a few hours at room temperature. Taken with the non-oncogenic nature of the genetic sequences to be used, the specificity of the vectors for mammalian hosts and their replication incompetence the resulting GMM poses no effective risk to the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

### Host/vector system

**Eukaryotic viruses (ACDP group 2)/ mammalian cell lines (established, commercially available) mammalian primary cells**

### Origin & function

**Origins:** sequences will be subcloned from existing plasmid clones. In some instances, herpesvirus sequences will be amplified from cDNA or genomic DNA by PCR.

**Functions:** the biological properties of herpesvirus and mammalian genes are considered in the detailed risk assessment (appended). These genes will be expressed in mammalian primary and cultured cell lines (via eukaryotic vectors) to examine their function.

### Evaluation of foreseeable effects

The insertion of reporter genes into viral genomes is not expected to alter the tropism of the virus/

Pseudo-typed, replication defective retroviruses will be capable of infecting a wide range of cell types. The modified lentivirus is replication-defective, i.e., is capable of only single round of virus production, and viral particles are labile. Infected primary cells can only survive in tissue culture.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Standard validated methods will be used.

- Liquids will be made 2000ppm available chlorine (5% chloros) and disposed of via cdrains after a minimum of 12 hours.
- Mixed disposable water: validated autoclave, 121°C for 30 minutes, then disposed of as domestic waste.
- Disposable pipettes: either (a) as for mixed disposable waster or (b) immerse in solution of 2000ppm available chlorine (5% chloros) for a minimum 12 hours; followed by incineration.

Project Additional Information
### Purposes of the contained use
To investigate the role of protein products generated as a result of genomic abnormalities in tumour development.

### Recipient or parental organism
The ultimate recipients for the inserts will be well characterised mouse and human cell lines.

### Host/vector system
The third generation retroviral vector systems employed will ensure that replication-competent viruses are not produced and thus that replication cannot occur in workers in the unlikely event that they are exposed to infectious virus.

The mouse ecotropic viruses will not infect humans. Amphotropic viruses could infect individual cells in exposed individuals, but without subsequent spread; infection is most likely via percutaneous introduction therefore the use of sharps will be minimised. The effects of operator infection with viruses generated without expressed inserts would likely be due to insertional mutagenesis. This risk is real, but of low probability. The infection risk itself is minimised by physical containment coupled with relatively low stability and ease of inactivation. Biologically the probability of an untoward event must be proportional to the number of infected cells and their ability to proliferate following infection.

The experience from the French SCID-X1 gene therapy is not fully informative in this context but it is clear that insertional mutagenesis leading to premalignant proliferation only occurred in two of nine patients and that the efficient ex vivo infection of a stem cell population must have been crucial to the outcome. It is highly unlikely that any conceivable laboratory accident would fulfil these preconditions.

### Origin & function
The genetic material will be derived and isolated from human and mouse genomic DNA generated from primary human tissue samples, bacterial artificial chromosomes and/or well characterised cell lines.

The inserted genetic material will encode oncogenes with potentially deleterious effects if inserted into, amongst others, lymphoid cells. The candidate oncogenes are from human tumours with therefore some expectation that their introduction into appropriate cells will result in transformation/oncogenesis. This is indeed the basis for the proposed assays. The in vitro assays will use cell lines that have already accumulated a background of mutations such that the further addition of a candidate oncogene will produce an altered growth phenotype. It is likely that oncogenic effects in humans or experimental animals would depend on the sequential accumulation of multiple changes in proto-oncogenes against the background of high level expression of the candidate oncogene. The time taken for tumours to develop in rodents infected with high doses of oncogene-expressing retroviruses reflects the need for this accumulation of additional genetic changes. It is thus unlikely that any single oncogene candidate would be able to "transform" a normal cell in the unlikely event of exposure to DNA by inoculation or inhalation. The exposure risk to the oncogene is presented by high concentrations of plasmid DNA containing oncogene inserts as well as the viral vectors; therefore care must be taken when handling these DNA preparations. Sharps will not be used and aerosol exposure prevented by handling concentrated solutions of oncogene containing DNA in a class 2 cabinet. Any gene-specific adverse effect of insertion will probably be dependent on transcription. While retroviral insertion occurs preferentially in transcriptionally active regions the majority of insertions will not lead to transcription and subsequent translation.

### Evaluation of foreseeable effects
The recombinant retroviruses capable of expressing a human oncogene combine the risks associated with inappropriate expression of the inserted gene and the insertional mutagenesis risk associated with the vector alone. The risk of infection even following a puncture wound is likely to be low. These risks are only associated to any significant extent with the amphotropic, not the ecotropic, constructs. Again the control of exposure coupled with inability to replicate in the unlikely event of operator infection are crucial.
exposure provide the major controls on risk. The possibility that any given insertion event might lead to adverse effects is itself of low probability. These adverse effects could however be severe, but are further mitigated by a requirement for the accumulation of multiple genetic changes in the target cell (or its progeny) before tumour formation. These changes would only occur following sustained proliferation.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

GM animals are housed in a barrier facility. All staff entering the facility change into clean clothes inside the unit and remove this clothing on exiting. All staff wear the necessary safety equipment including gloves, hats, overshoes and safety spectacles as required. The GM animals are kept in isolator cages (IVCs) and do not leave the facility. Containment measures in place include physical barriers and deposition of rodent poisons on the floor around the facility.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Producing retroviruses will be housed in a category II facility in a marked incubator. Waste liquid will be inactivated following overnight incubation in a 1% solution of Virkon. Solid waste will be autoclaved and incinerated before disposal.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The committee has considered the risk assessment for the project entitled “An investigation into mechanisms of tumorigenesis” and believes that it is consistent with the guidance provided by the SACGM compendium and with our knowledge of the facilities available in the laboratory in which the work would be carried out. We therefore approve the risk assessment subject to comment from the HSE.

Investigation into the mechanisms of tumorigenesis in human tumours

To investigate the biological functions of the candidate oncogenes and tumour suppressor genes as well as their associated mechanisms in tumorigenesis

Recipient or parental organism
Human and murine established cell lines, primary human cancer-derived cells

Host/vector system
The use of third-generation retroviral systems will ensure that replication-competent viruses are not produced in the laboratory environment and thus replication cannot occur in the unlikely event that a laboratory worker was exposed to infectious virus. The same replication-deficient criteria also apply to the AAV system and the recombinant adenovirus. The mouse ecotropic viruses will not infect humans. Amphotropic viruses could infect cells in exposed individuals, but without subsequent spread. The most likely route of infection is through percutaneous introduction which can be avoided by banning the use of sharps. The outcome of an infection with viral vectors devoid of any inserts would likely be insertional mutagenesis. Although real, this risk is of low probability. The infection risk itself is minimised by physical containment coupled with relatively low stability and ease of inactivation. Biologically the probability of an untoward event must be proportional to the number of infected cells and their ability to proliferate following infection. An insertional mutagenesis leading to premalignant proliferation occurs very rarely. It is highly unlikely that any conceivable laboratory accident would fulfil these preconditions.

The adeno-associated virus AAV-2 is a naturally defective virus not known to cause any human disease. Production of nild-type recombinant virus is prevented by the lack of homology between the required individual plasmids. Furthermore the helper-free system serves to eliminate the requirement for wild-type adenovirus co-infection. The AAV-2 virus replicates epichromosomally, viral integration into the genome can occur but is a rare event, limited to chromosome 19 reducing the probability of intact viruses to disrupt an endogenous gene still further.

No host genome integration for recombinant adenoviruses
the genetic material will be derived and isolated from human genomic DNA extracted from human tumours and corresponding normal tissues and also well-characterized cell lines currently used for in vitro experiments. The genetic material we wish to insert into eukaryotic vectors represents a number of novel candidate oncogenes or TSGs initially identified by genome-wide CGH array screening in our laboratory. In order to investigate the role of these genes in tumourigenesis in vitro, we need to produce tagged molecules and transflect them into an appropriate cell line. The tagged molecule will aid in the detection and purification of the corresponding recombinant proteins for further functional-protein interaction studies. The low efficiency of transient transfections in some cell lines represents a major barrier to observe cell behavioural phenotypes. For example, a routine cell proliferation assay requires a high proportion of transfected cells representing a homogenous population expressing a particular oncogene or TSG to clearly identify a growth promoting/reducing effect as compared to untransfected cells. In order to circumvent this problem, we aim to produce recombinant stable cell lines derived from single cell clones expressing the transgene after integration into the host genome hence the need for retroviral vectors. Finally tagging of the endogenous gene will bring yet another level of control in those studies by keeping the gene under tight physiological regulation. This approach requires the use of the AAV system which allows for targeted homologous recombination. In summary, insertion of the genetic material under investigation into a wide range of vectors will allow for a greater understanding the biological function of these important genes and the multiple roles that they play in tumourigenesis.

The inserted genetic material may encode an oncogene with potentially deleterious effects if incorporated into, amongst others, neuronal cells. Our candidate genes have been initially cloned from human tumour DNA. Their introduction into appropriate cells could therefore lead to transformation or tumorigenesis. Our current understanding the transformation process requires a well-ordered series of genetic changes. Ourestablished cell lines have already accumulated a background of mutations (some of them identified by our own studies) in which the addition of a candidate oncogene/TSG will produce an altered growth phenotype detectable through standard in vitro assays. It is thus unlikely that overexpression of any single gene would be able to replicate the effect of the accumulation of multiple changes in specific genes to “transform” a normal cell in the unlikely event of exposure to DNA by inoculation.

Inhalation. The exposure risk inherent in the use of an oncogene is presented by high concentrations of plasmid DNA as well as the viral vectors. These DNA preparations will be handled carefully avoiding the use of sharp instruments and aerosol exposure by working in a class II safety cabinet. Any gene-specific adverse effect of gene insertion will also probably be highly dependent on active transcription. While retroviral insertion occurs preferentially transcriptionally active regions the majority of insertions will not lead to active transcription and subsequent protein translation. For epitope tagging of endogenous proteins, the inserted genetic material will be a combination of an epitope tag such as Flag or HA and an antibiotic resistance gene, neither of which are likely to possess a deleterious effect in host cells.

### Evaluation of foreseeable effects

The recombinant retroviruses expressing a suspected human oncogene combine the risks associated with the expression of the inserted genetic material and the inherent mutagenesis risk of the inserted vector alone. The risk of percutaneous infection is likely to be low and is only associated to any significant extent with the amphotropic, not the ecotropic, constructs. The minimal exposure to the genetic material coupled with the replicative deficiency of the recombinant viruses constitute strong safeguards in the unlikely event of operator exposure. Again as above, the possibility that any given insertional event might lead to adverse effects is itself of low probability. These adverse effects could however be severe, but are further mitigated by a requirement for the accumulation of multiple genetic changes in the target cell (or its progeny) before tumour formation. These changes would only occur following sustained proliferation. The AAV-2 recombinant vector will only carry a small carboxy-terminal tagged sequence of the target gene together with an antibiotics-resistance gene and therefore present the same risks as the constructed retroviral recombinant vectors but at a reduced probability of adverse effects. The recombinant adenovirus will only be transiently expressed in host cells.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Host cells producing viruses will be housed in a category II facility in a marked incubator. Liquid waste will be inactivated through overnight incubation in a freshly made
solution of 1% Virkon. Solid waste will be autoclaved and incinerated before disposal. The degree of kill is 100% and no viable GM organisms remain after treatment.

The committee has considered the risk assessment for the project entitled “Investigation into mechanisms of tumorigenesis in human tumours” and believes that it is consistent with the guidance provided by the SACGM compendium and with our knowledge of the facilities available in the laboratory in which the work would be carried out. We therefore approve the risk assessment subject to comment from the HSE.

**Project Additional Information**

**Purposes of the contained use**

2. Introduction of mouse and human cellular genes, including oncogenes, into mammary cells and transplantation of these cells into mouse mammary fat pads

**Recipient or parental organism**

1) Retroviruses-lentiviral (3rd generation) vectors - All vector systems have been described in the literature and are self inactivating. The lentiviral packaging and envelope components (gag,pol, rev) are separated from the vector containing the DNA sequences of interest that will be incorporated into target cells. The packaging plasmids share no significant homology to any of the expression lentiviral vectors, expression vector or any other vector to prevent generation of a recombinant replication-competent virus. The packaging plasmids lack any packaging signals so are not present in the packaged viral genome and therefore the lentiviral particles are replication incompetent. A deletion in the enhancer of the U3 region of 3' LTR ensures self-inactivation of the lentiviral construct after transduction and integration into genomic-DNA of target cells. Therefore no new HIV-1 virons can be produced from infected cells. Retroviruses are rapidly inactivated outside the host therefore spread into the environment is unlikely. There is very small theoretical risk that the attenuated HIV-1 vector can recombine with wild type (thus replicative) HIV-1 virus. To prevent this we shall not use tissue known to be infected with the wild type HIV-1 virus. Because the HIV-1 envelope, which usually binds CD4 and chemokine receptors, has been replaced by the vesicular stomatitis virus envelope (VSV-G), this virus can infect many different cell types in vitro and possibly in vivo. This introduces a potential aerosol/contact transmission threat in addition to percutaneous hazard. Particles are more physically stable but are sensitive to complement. The virus will carry the WPRE cassette, increasing vector titre and transgene expression and therefore risk. The vector integrates into host cell's DNA so there is some risk of long term expression or of insertional mutagenesis. Vector is considered ACDP HG1.

2) All mammalian cells used (primary or cell lines, mouse or human) are especially disabled and cannot survive outside laboratory culture. They are unable to colonize humans and survive in the environment. Any human cell lines used will be thoroughly characterised with a history of safe use. In such cells adventitious pathogens are unlikely to be present, therefore the risk of colonization is low. In primary cells there is a slightly elevated risk owing to the increased risk of adventitious pathogens being present, although the likelihood of colonization remains low. Human cells will not be used from patients known to be HIV+ or hepatitis+. Mouse cells give negligible risk because of the phylogenetic difference means adventitious pathogens and colonization both become very low probability.

3) Bacteria are disabled E. coli K12-derived strains and cannot survive outside of laboratory culture. They are unable to colonise humans or survive in the environment.
**Origin & function**

Origins: Sequences will be sub-cloned from existing plasmid clones or from cellular genes. In some instances, cellular sequences will be amplified from cDNA or genomic DNA by PCR.

Functions:
1) LacZ, green fluorescent protein, mCherry fluorescent protein, tdTomato fluorescent protein, EY fluorescent protein or some other fluorescent protein or firefly luciferase will be inserted into mammalian cells and expressed as reporter molecules.

2) Coding sequences for mammalian cellular genes and reporter genes (e.g. LacZ, green fluorescent protein, mCherry fluorescent protein, tdTomato fluorescent protein, EY fluorescent protein or some other fluorescent protein or firefly luciferase) will be inserted into retroviral or lentiviral vectors for long-term expression in mammalian cells. These cells may be introduced into animals by injection at various sites or by transplantation into mammary fat pads.

3) Coding sequences of mammalian cellular genes and reporter genes will be introduced into mammalian cells using the viral vectors for long term expression in mammalian cells to facilitate the study of their functions in cell death, growth and differentiation processes. These cells may be injected into mouse mammary fat pad and allowed to grow to assess the functions of specific genes in regulating stem cell activity and progenitor potential or in controlling cell death.

4) Coding sequences from mammalian cellular genes will be inserted into lentiviral vectors for expression in mammalian cells. These cells will then be transplanted at various sites or injected into mammary fat pads. We will study their role in directing the phenotype of cancer after targeting to various cell types. The oncogenes we will use include, but are not restricted to, ErbB2, Ras, Wnt, Notch and Jak2V617F.

6) Sequences designed to interfere with specific endogenous mammalian cellular genes (for example shRNA) will also be inserted into lentiviral vectors in order to study the role of the cellular gene. The target genes will be associated with normal mammary cell growth, differentiation and death and may also be tumour suppressors.

**Evaluation of foreseeable effects**

1) The insertion of reporter genes into vector genomes is not expected to alter their potentially harmful properties.

2) Lentiviral vectors bearing reporter genes and/or cellular genes of interest are capable of introducing these genes into cells of the body. While the number of cells affected will be small and limited to the initial round of infection, the expression may be long term and involve potentially transforming events. However, the genes are unlikely to enable full oncogenic transformation in isolation and long term expression has been difficult to achieve in practice even in instances of deliberate optimisation for gene therapy trials. Cells expressing viral protein will be targeted by the immune system.

3) The properties of mammalian cells with respect to hazards to human health and the environment will remain unaffected by any of the non-oncogenic genes introduced. Should a vector with an oncogene be inoculated into human cells in situ, the oncogene could potentially stimulate division of the cell, but will not be able to propagate or infect other cells. The risk of inoculation will be minimal as work will be carried out in a tissue culture hood with no glass or sharps present. Also should the mouse cells be inoculated directly into a human they should be recognised by the immune surveillance system and removed. No toxic proteins will be produced.

4) The genes mainly encode eukaryotic functions that are unlikely to affect the properties of bacteria. The proteins produced are not known to be toxic.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Animals infected with retroviruses and lentiviruses will be killed within the animal facility, tissues fixed in formaldehyde or frozen, and carcasses disposed of by incineration.
Virkon (a peroxygen compound) used at a concentration of 1% is known to have a wide range of anti-microbial activity and is bacteriocidal against many human viruses, including HIV. All tissue culture material and disposable plastic ware will be soaked for a minimum of 18-24hrs in a freshly prepared 1% Virkon solution. The fluid is then disposed of down a laboratory sink with excess water. Solid waste is then double bagged in biohazard bags and autoclaved at 134°C for 20 minutes at 3.2 bar pressure.

Validation of this method will be by independent thermocouples placed in the centre of the load. Verification that the correct conditions have been reached will be obtained by checking the chart recorder printout. The autoclave undergoes a planned preventive maintenance inspection every 3 months. All inactivated waste is then treated as "clinical waste" and removed from site by a contractor.

Is an emergency plan required according to regulation 20?

## Project Additional Information

### Purposes of the contained use

Work in our lab involves comparative computational analysis of virus sequence data in order to identify new functional elements, followed by experimental analysis to verify computational predictions and to characterize the function of the elements identified. Recent examples include the discovery of an essential overlapping 'hidden' gene in the Potyviridae (the largest and most economically important family of plant viruses), short overlapping coding sequences in the alphaviruses and the Japanese encephalitis serogroup of flaviviruses, both of which are translated via ribosomal framshifting, and a short overlapping gene in equine arteritis virus and other arteriviruses. Experimental work for these projects took place outside of the UK. However, we continue to identify new functional elements in new viruses and the purpose of this GMO form is to cover the GM work required to investigate such cases. Work typically involves the generation of mutant viruses in which the predicted functional element is mutated, and comparison of wild-type and mutant virus phenotypes via standard virological assays. It is expected that mutant viruses will most likely be either similar to wild-type virus or attenuated.

Currently we intend to start work on a project involving cardioviruses but we envisage the possibility of amending this form at a later date, if necessary, to include other viruses.

### Recipient or parental organism

We will use infectious cDNA clones of two cardioviruses (family Picornaviridae, genus Cardiovirus): the mengovirus strain of Encephalomyocarditis virus (EMCV), and Theiler's murine encephalomyelitis virus (TMEV).

Infection with wildtype EMCV is associated with sporadic cases and outbreaks of myocarditis and encephalitis in domestic pigs, in numerous species of nonhuman primates, and in other mammalian species. Transmission is generally via ingestion of contaminated water or feed or dead animals, but transplacental, contamination of wounds and other close-contact mechanisms of transmission may also occur. In susceptible animals disease is often fatal. Virus isolation aand serologic studies indicate EMCV is distributed worldwide. Serologic studies indicate that humans have been infected by EMCV or immunologically related viruses but clinical disease in humans is relatively infrequent and, when observed, generally occurs as a self-limiting febrile illness. However, our EMCV work will be limited to the mengovirus construct vMCO - a mutant that grows like wild-type virus in cell culture but is severely attenuated in mice (10^6 to 10^9) and other mammals via removal of a 50-115 nucleotide poly-C tract in the 5'UTR (Martin et al, 1996, J Virol 70:2027-2031, PMID 8627731).

MEV is not known to be a human pathogen despite being used extensively in the scientific community. TMEV infects mice and is transmitted faecal-orally and transplacentally. Most infections are subclinical; however susceptible mice may develop severe neurological disease. We will use strain GDVII.

Both EMCV and vMCO and TMEV may be considered to be ACDP hazard group1. Handling of these virus under BSL2 conditions is sufficient to control any slight risk of infection.

### Host/vector system

02/03/2022
Plasmids will be grown in disabled strains of E. coli which have a long history of use without harm to human health or the environment and lack reasonably conceivable means to cause such harm.

Origin & function

RNA viruses have very compact genomes that are subject to intense selection pressure. As a result, the identity of most nucleotides have been highly optimized and mutation most often either have no effect or attenuate the virus. Using computational analyses of virus sequences data we have identified a number of highly conserved elements. Such high evolutionary conservation suggest functional importance and we now wish to verify and explore the functionality of these elements via targeted mutations and comparison of the phenotypes of mutant viruses with wildtype viruses in cell culture. Mutations are most likely to have either no affect or attenuate the virus.

Evaluation of foreseeable effects

Genetically modified disabled E. coli would be no more hazardous than the unmodified host. Little or no expression of virus sequence should occur in E. coli and this is unlikely to provide a suitable environment for virus production. No adverse effects are expected for low level expression of any of the viral genes in E. coli.

Both EMCV vMCO and TMEV may be considerd to be ACDP hazard group 1. TMEV is not known to be a human pathogen despite being extensively in the scientific community. EMCV vMCO is very highly attenuated and not observed to revert to wild-type. Handling of these virus under BSL2 conditions is sufficient to control any sight risk of infection. In the wild, TMEV (strain GDVII) causes acute encephalomyelitis in susceptible mice (most infections are subclinical) but there is very low risk of the virus coming into contact with potential hosts.

It is unlikely that the genetically modified cardioviruses would be any more hazardous than the unmodified host: mutations in RNA viruses most often either have no effect or attenuate the virus. None of the mutations involve the introduction of any known toxins or oncogenic sequences. No changes are proposed that would be predicted to alter the host range or tissue tropism of the virus, or alter its susceptibility to host defence mechanisms except in so far as the virus may be attenuated.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste- autoclaved (run shown to reach and hold temperature ).

Liquid waste - autoclaved as above or treated with appropriate disinfectant, Lifeguard (2.5%) for bacterial cultures, Chloros for virus-containing fluids.

Surface decontamination - Lifeguard for bacterial work, chloros for virus work (2% virkon for metal surfaces such as the surfaces of class II cabinets or incubators but work should be performed in plastic trays to avoid the need for this).

Pipettes soaked overnight in 2% virkon (bacterial work at level 1), plastic pipettes soaked overnight in chlorine-based disinfectant, >2500 ppm available chlorine (virus work at level 2).

All procedures expected to give 100% kill.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

02/03/2022
The GM committee has approved your project "Analysis of Functional elements of RNA virus genomes" as a CL2 project. The project involves the mutagenesis of two cardioviruses endemic in mice (TMEV and ECMV) and although the risk to human health is low, in the case of ECMV human infections have been documented. For this reason it was considered that the work should be carried out at CL2.

### Purposes of the contained use

To study gene expression and proteomics in *Toxoplasma gondii* and in mammalian host cells infected with *Toxoplasma gondii*.

### Recipient or parental organism

| A. E. coli | Attenuated K-12 derivatives of *E. coli* will be used. The standard intermediate recipients *E. coli* (XL-1 Blue, DH-10 etc) are highly disabled strains. |
| B. *T. gondii* | *Toxoplasma gondii* is an obligate intracellular parasite and neither the tachyzoite nor bradyzoite can survive outside the host. *Toxoplasma gondii* is an ACDP Hazard Group 2 organism and thus requires Level 2 Containment. Wild type, haploid, tachyzoite forms of *T. gondii* (eg Types I, II and III strains), as well as their mutant derivatives: hxgprt gene knockout mutants, ku80 gene knockout mutants (lack nonhomologous end-joining DNA repair mechanisms), lac Z+, TATi-1 strain (contains a functional tetracycline transactivator to regulate reversible gene expression). See Appendix to the Risk Assessment for further technical details. |
| C. Mammalian Cells | Well-characterised mammalian cells in culture, eg NIH/3T3, HeLa, BHK, 293T, HFF, RAW264. |

### Host/vector system

| A. E. coli | Standard cloning plasmids including puC series, BACs, cosmids and Lambda ZAP II. |
| B. *T. gondii* expression vectors | Expression vectors, engineered with *T. gondii* protein promoters, loxP flanking regions, and selectable markers such as CAT or HXGPRT, and fluorescent protein genes. See Appendix to the Risk Assessment for further technical details. |
| C. Mammalian expression vectors used are pcDNA 5/FRT/TO plasmids (and similar variants; Invitrogen) that can be used in both transient assays and integration into host cells modified with a chromosomal FRT site. For transient assays, tetracycline induction of the hybrid CMV/TetO2 promoter drives gene expression. Hygromycin resistance is selected upon integration into the FRT site via co-transfection with the pOG44 plasmid that expresses the FLP recombinase. Hygromycin can only be expressed upon FRT site integration as the recombination event is required to place the hygromycin gene next to the SV40 promoter. |

### Origin & function

**Origins of genetic material involved:**
The origin of the genetic material involved is from *Toxoplasma gondii* and related apicomplexan species, cloned in *E. coli*. DNA encoding *Toxoplasma gondii* genes (and mutant versions) and in some instances orthologous genes from other relevant apicomplexans may be expressed in the parasite.

**Expected biological action of genetic material involved:**
(i) knock out endogenous gene products,  
(ii) express genes from conditional promoters,  
(iii) generate mutant gene replacement products (eg inter-strain).
(iv) label *T. gondii* proteins with standard fluorescent proteins and allow localisation and monitoring of expression,
(v) express *T. gondii* proteins directly in host cells.

**Evaluation of foreseeable effects**

While these manipulations may alter parasite and host cell transcriptional and proteomic processes, they are not expected to increase parasite virulence nor are they likely to expand the host cell range.

(i) The presence of fluorescent proteins will not affect the parasite's virulence
(ii) Construction of knockouts will either not change or might even decrease the parasite’s virulence.
(iii) In cases where gene constructs will be interchanged between parasite strains, no resultant parasite will be more virulent than the wild type Type I, which itself is only virulent in mice.
(iv) Variant/altered gene products would not be expected to change either the host range or host cell type, which already extends to all nucleated cells in warm-blooded animals.

None of the vectors used for these manipulations is able to persist in mammalian host cells. Thus, the possibility of adverse effects due to accidental exposure is severely reduced. Moreover, mammalian cells expressing *T. gondii* genes are not able to infect humans or other animals.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All experiments will be performed in a Containment Level 2 suite. In accordance with the waste management procedures of the suite, no material or equipment can be removed without first having been decontaminated or autoclaved.

Liquid waste (cell culture medium containing live GMOs) is treated overnight with Distel (v/v 5%) as recommended by the manufacturer's validated instructions.

Solid waste which may have come into contact with live GMOs (such as empty culture vessels) is autoclaved in the Containment Level 2 Suite, before being incinerated as clinical waste.

Each autoclave run is logged with the operator's name, the date and contents of the run, as well as the conditions of the run (1 hour at 125°C in a Boxer Petite). At the end of each autoclave run, the name of the operator emptying the load is also recorded.

The use of sharps is limited to those operations where it is essential. Sharps that may have come into contact with live GMOs are disposed of in a dedicated labelled sharps bin which, once full, is sealed, autoclaved and then incinerated (as with other solid waste above).

Is an emergency plan required according to regulation 20?

### Project Additional Information

#### Purposes of the contained use

The work in this project has been devised by and will be carried out under the supervision of Professor Ian Goodfellow.

The project aims to understand the basic mechanism of RNA virus biology, including the identification of cellular and viral proteins involved in the life cycle of a number of
RNA viruses.

The work can be broken down into various subsections as detailed below:

1) Expression of virus products for functional, structural and immunological studies:
Viral genes from members of the Caliciviridae, Astroviridae and Hepeviridae will be expressed in E.coli and mammalian cells to study their function. Plasmid expression systems and retroviruses will be used as delivery systems to examine the effect of viral gene expression on host cell pathways and virus replication.

2) Expression and inhibition of cellular pathways involved in RNA virus life cycles:
Cellular proteins or inhibitors of cellular proteins involved in various aspects of the virus life cycle will be expressed in cells by either plasmid transfection or retrovirus-mediated delivery and their effect on virus replication monitored. Examples include translation initiation factors, transcription factors, RNA binding proteins and proteins involved in the innate immune response.

3) Immortalization of mammalian and avian cells:
In order to develop new cell lines for the study of RNA virus replication we aim to generate a number of lentiviral vectors expressing proteins known to prolong cell survival and facilitate immortalization. These include: SV40 Large T antigen, telomerase, vRel and vRas.

4) Generation of modified viruses for studies of virus replication/attenuation:

(a) Caliciviridae
The overall aim of the project is to further our understanding of the molecular mechanisms caliciviruses use for replication and translation. Specifically we aim to address the role various RNA structures, viral proteins and host cell proteins play in the calicivirus life cycle as well as their relative contribution to viral virulence. The project will involve the use of human caliciviruses, including human norovirus and sapovirus as well as cellular factors thought to play a role in the viral life cycle (e.g. RNA binding proteins, translation initiation factors).

Development of a cell culture system for human caliciviruses. In order to fully understand the roles that RNA structures as well as viral and cellular proteins play in the various aspects of the virus life cycle we need to introduce mutations into the viral genome and study their effects on virus replication. A reverse genetics system already exists for feline calicivirus, however the efficiency of this system is poor. No systems are currently available for human noro and sapoviruses. We will attempt to develop such systems.

In addition, we wish to produce genetically tagged viruses containing innocuous biochemical markers such as green fluorescent protein (GFP) and luciferase to monitor virus replication.

(b) Hepeviridae
The aims of this project are to identify viral and cellular components required for efficient virus replication in cell culture. Initially the project will exclusively use non-infectious hepatitis E virus replicons that lack the capsid sequences and are therefore unable to produce infectious virus. We will use proteomics to identify host factors that interact with viral RNA structures and viral proteins. We then aim to use viral replicons to characterise the role of these interactions on virus replication in cell culture. In some instances we may wish to express the viral capsid proteins in trans to examine the ability of capsid proteins to encapsidate viral RNA. The particles produced by such an approach will remain unable to go through muli-cycle replication and are considered defective. Due to the replicon construction, co-transfection of cells with replicon and plasmids expressing viral proteins cannot result in recombination that would restore the capsid open reading frame. The replicon carries only the first 3 nucleotides of the capsid coding region therefore homologous recombination cannot occur.

(c) Astrovirus
The aims of this project are to identify and characterise viral and cellular factors required for viral replication. Human astrovirus infectious cDNA clones will be used to generate mutant and WT viruses as well as viruses carrying reporter proteins such as luciferase, GFP etc. Human astrovirus infects >90% of individuals prior to the age of 5 and results in acute gastroenteritis only. Other astroviruses (e.g. murine) have yet to be replicated in cell culture but this is one of the aims of this project.
Recipient or parental organism

1) Human Caliciviridae members - all human caliciviruses are ACDP hazard group 2 pathogens and cause acute gastroenteritis. These are common pathogens with >80% of the UK population being seropositive. Their genomes are positive sense single stranded RNA. We foresee that all the modifications to the viral genome will have little to no appreciable affect on viral virulence and in most cases is likely to debilitae replication.

2) Hepatitis E virus (non-infectious replicons only) - This work is currently limited to non-infectious replicons that lack the capsid sequences only. Hepatitis E virus causes acute hepatitis and is currently classified as ACDP hazard group 3 pathogen, however as replicons do not possess capsid sequences they are unable to form infectious particles and infect cells. Their genomes are positive sense single stranded RNA. We foresee that all the modifications to the viral genome will have little to no appreciable affect on viral virulence and in most cases is likely to debilitae replication.

3) Astroviruses, including animal and human members. Human members are classified as hazard group 2 pathogens and cause acute gastroenteritis. As with caliciviruses, these are common with >90% seropositivity reported in some instances. Their genomes are positive sense single stranded RNA. We foresee that all the modifications to the viral genome will have little to no appreciable affect on viral virulence and in most cases is likely to debilitae replication.

4) E.coli (lab strains only). These are lab adapted and highly attenuated strains of E.coli, widely used around the world. No pathogenic potential. We do not foresee any of the modifications to increase pathogenic potential.

5) Mammalian and avian cell lines. We will use numerous widely available immortalised human and avian cell lines e.g. (293, HeLa, Caco, DF1) as well as cell lines that will be generated in house from primary tissues. Part of the aim of this project will be to produce novel immortalised cell lines from primary tissue.

6) Disabled/replication defective retroviruses. These are non-replicating and require the transfection of cells with components that are expressed on separate plasmids. Self inactivating LTRs are employed. In a small number of cases, we intend to generate retroviruses carrying known oncogenes (telomerase, SV40 large T antigen, vRAS and vREL). These will possess oncogenic potential but will not be used with sharps and strictly used under BSL containment level 2 conditions.

Host/vector system

Plasmids will be grown in disabled strains of E. coli which have a long history of use without harm to human health or the environment. pUC-based vectors have a long history of use without harm to human health or the environment and lack reasonably conceivable means to cause such harm.

Mammalian and avian cells. Include currently available immortalised human and avian cell lines. In addition a number of novel cell lines will be produced during the course of the project.

Retrovirus vectors. These are non-replicating and require the transfection of cells with components that are expressed on separate plasmids. Self inactivating LTRs are employed. In a small number of cases, we intend to generate retroviruses carrying known oncogenes (telomerase, SV40 large T antigen, vRAS and vREL). These will possess oncogenic potential but will not be used with sharps and strictly used under BSL containment level 2 conditions.

Origin & function

1) Plasmid vectors in E. coli:
   a) Positive strand virus sequences even if expressed will have no toxic or oncogenic potential. These will include viral gene products encompassing both structural and non-structural genes of Hepeviridae, Caliciviridae and astroviridae members.
   b) Cellular proteins involved in the RNA virus life cycle even if expressed will have no toxic or oncogenic potential. These include cellular RNA binding proteins, translation initiation factors, molecular chaperones etc.

2. Retrovirus vectors: All vectors will be replication defective
a) Viral gene products will again not have toxic or oncogenic potential.
b) Cellular factors involved in the life cycle of RNA viruses: examples include RNA binding proteins, translation initiation factors, transcription factors. No toxic or oncogenic potential.
c) Cellular cytokine or interferon stimulated genes – expression may result in increased local inflammation.
d) Oncogenes and proteins required for cellular transformation: These are limited to the following: telomerase, SV40 large T antigen, vRAS and vREL. They function in various ways to enable cell immortalization including the inactivation of cellular tumour suppressors including p53 and pRb.

Evaluation of foreseeable effects

1) Plasmid vectors in E. coli:

   d) Oncogenes and proteins required for cellular transformation: These are limited to the following: telomerase, SV40 large T antigen, vRAS and vREL. They function in various ways to enable cell immortalization including the inactivation of cellular tumour suppressors including p53 and pRb.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste - autoclaved (run shown to reach and hold temperature).
Liquid waste - autoclaved as above or treated with appropriate disinfectant, Lifeguard (2.5%) for bacterial cultures, Chloros, Virkon or Perasafe for virus-containing fluids.
Surface decontamination - Lifeguard for bacterial work, chloros for virus work (2% virkon or Perasafe for metal surfaces such as the surfaces of class II cabinets or incubators).
Pipettes soaked overnight in 2% virkon, plastic pipettes soaked overnight in chlorine-based disinfectant, >2500 ppm available chlorine (virus work at level 2).
All procedures known to give 100% kill.

- **Withdrawn**: N
- **Tick if notifying a connected programme of work**: N

**Historical Significant Changes**

- **Historical Date of Additional Info**

**Project Additional Information**

**Purposes of the contained use**

Production and/or use of replication-defective lentivirus, adenovirus, retrovirus and vaccinia virus particles to enable:

1. The expression of individual human papillomavirus proteins in human keratinocytes and other cell types.
2. The expression of mediators of signaling pathways (cellular proteins) relevant to HPV-mediated disease.
Recipient Organism

Viruses:
1. Defective retroviruses and lentivirus – viral vector systems in which all the viral genes have been removed and which contain self-inactivating mutations/deletions.
2. Defective Adenoviruses deleted in E1 and E3.
3. Thymidine Kinase negative Vaccinia Viruses.

Bacteria:
1. Disabled E.Coli strains, including DH5a, DH10b, Top10, 2 T1R

Cells and cell lines:
1. Hela, W12, S12, SiHa, CaSki, C33A, which are derived from human cervix.
2. U2OS, Saps-2, which are derived from human bone.
3. FSK, NEK, HaCat, NIKS, EF1F, which are derived from human skin.
4. COS, CV-1, which are derived from monkey epithelium.
5. CHO, HEK-293, which are derived from hamster epithelium.
6. 293, 293T, 293TT, phoenix cells, which are derived from human epithelium.
7. J2 3T3, NIH 3T3, TK143, which are of mouse fibroblast origin.
8. Primary keratinocytes and other cell types derived from normal human or mouse tissue (skin, tonsil).

Host/vector system

Genetic Material and Vectors

Plasmids containing Viral and Cellular Sequences

Genetic material for use in these experiments will be derived from papillomavirus or cellular DNA sequences cloned into standard bacterial vectors. The laboratory cloning vectors used in this study will generally consist of pUC series plasmids (or related plasmids) containing human or mouse genes, or viral genes encoded by mouse or human papillomaviruses. Included amongst these are commercially-available bacterial plasmids such as pENTR, pShuttle and pDONR (all non-mobilisable).

In addition, we will also use standard mammalian expression vectors containing papillomavirus or cellular DNA sequences. Amongst these will be pBabeNeo, pBabepuro, pBabehygro, pLXSN, pQCXlH, pQCXlPuro, pQCXZeo, pQCXIbsd, CSII-CMV, CSII-TRE-Tight, pCAG-HIVgp, pCMV-VSV-G-RSV-Rev, pCL-Gag-pol, pHCMV-VSV-G, pAdEasy-1.

Plasmids containing Complete Papillomavirus Genomes.

The complete double-stranded DNA genomes of HPV and MusPV have been cloned into bacterial vectors. These genomes contain endogenous viral promoters, and in some instances additional mammalian promoters (e.g. CMV, EF1F or TRE-Tight) positioned to drive the expression of reporter genes (such as GFP), or drug-resistance markers (such as blasticidin). There is no expected biological action of papillomavirus genes in bacteria and no modifications will be made to increase the level of expression of viral gene products or reporter genes in bacterial hosts.
Retrovirus and Lentivirus vector systems.

These are defective, unable to propagate themselves after infection, and contain self-inactivating deletions. Lentivirus vectors (CSII) contain a deletion in the 3' long terminal repeat (LTR) that results in self-inactivation, and lack the pol, tat, rev, env and gag genes. They cannot produce packaged virions unless co-transfected with pCAG-HIVgp and pCMV-VSV-G-RSV-Rev. Retrovirus vectors lack gag, pol and env cannot be packaged without pCL-Gag-pol, and pHCMV-VSV-G. In both cases, once integrated into the transduced target cells, the virus can no longer be packaged. Cell lines used for packaging contain genes required for virus replication on a separate cassette in order to prevent autonomous virus production. The cell lines used to receive genes of interest are not hazardous and are unable to infect people or animal. Genes will be expressed in mammalian cells from CMV, TRE-tight, EF1F, CAG or TGK promoters, or from the retro/lenti virus promoter contained in the viral LTR. While the cell lines that receive the genes of interest are not expected to be hazardous, some of the genes under investigation have well described oncogenic effects (e.g. HPV 16 E6 and E7). The standard code of practice for virus-handling will be followed and work will be carried out under category 2 containment.

Adenovirus and Vaccinia virus vector systems.

Recombinant Adenoviruses will be prepared using the pAdEasy (Ad 5) backbone, which is deleted in the E1 and E3 genes. The E1 deletion renders the viruses defective for replication and incapable of producing infectious viral particles in target cells. The E3 region encodes proteins involved in evading host immunity and is dispensable. The deletion of both genes creates room for up to 7.5 kb of foreign DNA that can be inserted into the Ad5 genome. The E1 gene, which is necessary for the production of viral particles, is provided in trans by AD-293 cells. pAdEasy-1 carries the ampicillin resistance gene, which is lost after recombination with a shuttle vector. Recombinant vaccinia viruses expressing papillomavirus proteins have a thymidine kinase –ve phenotype (TK-). TK- vaccinia are typically 1000 to 10,000 fold less virulent than parental TK+ viruses. Recombinant Adeno and Vaccinia viruses expressing HPV proteins will be used at category 2 containment level. The standard code of practice for virus handling will be followed.

Origin & function

Inserted Genetic Material

The human papillomavirus type 16 E6 and E7 proteins are expected to provide cells with an increased ability to progress through the cell cycle and to proliferate, when compared to parental cells. The HPV E4 protein functions to inhibit cell cycle progression, and mediates cell cycle arrest in the G2 phase of the cell cycle. The other viral genes that may be expressed in these systems include E1, E2 and E5, which will be subcloned from the full length papillomavirus genome. E1 is a replication protein with helicase activity. E2 is a transcription factor and is involved in viral replication. E5 is a membrane protein that can affect cell receptor density and responsiveness to growth factors, and which can increase cell growth rate.

In the first instance, the cellular genes studied will include components of the Hippo, Wingless (Wnt), NF-kb and Notch pathways. Our analysis will focus on the Yap and Taz transcriptional co-activators, which control cell proliferation (Hippo pathway), β-catenin and for the Notch and NF-kb pathways we will focus on the Notch Intracellular Domain (NICD) and on IkB. All are transcriptional regulators or co-activators. The following constructs will be typical of those used in this study …

Retroviral and Lentiviral Vectors.

i) pQCXIH-YAP 5SA (encodes a constitutively active form of human YAP carrying 5 serine to alanine mutations [Addgene Plasmid #33093])
ii) pQCXIH-YAP ΔCT (Dominant negative form of human YAP lacking the C-terminal trans-activation domain [Addgene Plasmid #33095])
iii) pQCXIH-TAZ (Wild type human TAZ [Addgene Plasmid #32841])
iv) pQCXIH-TAZ 5SA (Constitutively active form of human TAZ carrying 5 serine to alanine mutations [obtained by site-directed mutagenesis of the wild type protein])
v) pQCXII-TAZ ΔCT (Dominant negative form of human TAZ lacking the C-terminal trans-activation domain [obtained by site-directed mutagenesis of the wild type protein])
vi) pLXSN-β-catenin ΔN90 (Constitutively active form of human β-catenin lacking the N-terminal phosphorylation sites for GSK3-3β [Obtained through the recombination of pENTR-N90-beta-catenin [Addgene Plasmid #31787] with the empty pLXSN vector using the Gateway Technology])
vii) pLXSN-β-catenin ΔN90 ΔCT (Dominant negative mutant of human β-catenin lacking the C-terminal trans-activation domain [obtained by site-directed mutagenesis of the wild type protein ΔN90 β-catenin protein])
viii) pBabe-ixBalpa-mut (super-repressor) (mutant form of IκBα with two serine to alanine mutations which increase its repressive activity to NF-κB [Addgene Plasmid #15291])
ix) pLXSN-HPV-16 E6 (Encoding for the wild type E6 protein of HPV-16 [the sequence was subcloned from pre-existing plasmid clones])
x) pLXSN-HPV-16 E7 (Encoding for the wild type E7 protein of HPV-16 [the sequence was subcloned from pre-existing plasmid clones])
xii) pLXSN-HPV-16 E6 SAT (Encoding for a HPV-16 E6 mutant form defective in the p53 binding activity [obtained by mutagenesis of the wild type HPV-16 E6 coding sequence])
xiii) pCSII-HPV-16 E1 (Encoding for the human papillomavirus E1 wild type protein)
xiv) pCSII-HPV-16 E1mut (Dominant negative form of E1 obtained by site-directed mutagenesis of the wild type protein)

Adenovirus and Vaccinia virus vectors.

pAd-HPV-16 E4 (which encodes the human papillomavirus type 16 E4 proteins), pAd-LacZ (which encodes the E.coli β-galactosidase protein) and rVacc-E4 (recombinant Vaccinia virus encoding the papillomavirus E4 protein) have been described previously (Davy,C.E. et al 2002 J Virol 76:9806-9818. ; Doorbar,J. et al (1991) Nature 352:824-7). The papillomavirus E4 protein expressed from these vector systems was obtained from cloned HPV DNA. The E4 protein is an inhibitor of cell cycle progression.

Evaluation of foreseeable effects

Retrovirus and Lentivirus for the generation of stable cell lines.

Although recombinant Retro and Lentiviruses can infect humans, both are defective and unable to be propagated after infection because of the presence of self-inactivating deletions. Cell lines used for lenti/retrovirus packaging require the expression of replication genes from a separate cassette, which eliminates the possibility of autonomous virus production. The cell lines used as recipients of foreign genes are not hazardous, as they are unable to infect people or animals. Foreign genes will be expressed in mammalian cells from either the CMV, TRE-tight, EF1F, CAG or TGK promoters, or from the Retro/Lenti virus promoter contained within the viral LTR. While the cell lines that receive the genes of interest are not expected to be hazardous, some of the genes under investigation have well described oncogenic effects (e.g. HPV 16 E6 and E7). Retro/Lentivirus production and infection will be carried out under category 2 containment, and we will follow the standard code of practice for virus-handling.

Recombinant Adenovirus and Vaccinia virus vector systems.

Recombinant Adenoviruses will be prepared using the pAdEasy (Ad 5) backbone, which is deleted in genes E1 and E3. The E1 deletion renders the viruses defective for replication and incapable of producing infectious viral particles in target cells. The E3 region encodes proteins involved in evading host immunity and is dispensable. The deletion of both genes creates room for up to 7.5 kb of foreign DNA that can be inserted into the Ad5 genome. The E1 gene, which is necessary for the production of viral particles, is provided in trans by AD-293 cells. pAdEasy-1 carries the ampicillin resistance gene, which is lost after recombination with a shuttle vector. The viral and cellular sequences expressed from the recombinant Adenovirus vectors will not affect the vector characteristics. As the HPV E6 and E7 genes have well described oncogenic function, the work will be carried out under category 2 containment as described for Lentil/Retroviruses above.

We do not anticipate a need to produce new recombinant Vaccinia viruses able to express foreign genes, but will use recombinant Vaccinia viruses that we have prepared previously. Recombinant vaccinia viruses expressing papillomavirus proteins have a thymidine kinase –ve phenotype (TK-). TK- vaccinia viruses are typically 1000 to
10,000 fold less virulent than parental TK+ viruses. Recombinant Adeno and Vaccinia viruses will be used at category 2 containment level with adherence to the standard code of practice for virus handling.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The primary identifiable risk is infection of the laboratory worker by aerosol. As a result, all manipulations with recombinant viruses will be conducted in a class II laminar flow hood in a restricted cell culture facility under negative pressure (Class 2 level containment). Gloves, protective masks and protective clothing will be worn within the facility. Soiled and used protective clothing will be sealed in bags and autoclaved before disposal. Glassware is avoided wherever possible and disposable pipettes, tubes, culture flasks etc will be employed. Used disposables will be sealed in bags and autoclaved before disposal. The use of sharps is discouraged when working with recombinant viral vectors because of the risk of contamination through needle-stick injury. When required, sharps will be disposed of in sharps bins that will autoclave prior to final disposal disposal. Liquid waste will be decontaminated using Virkon Tablets (Du Pont), and solid waste will be treated by autoclaving according to standard protocols for the category 2 containment facility.

Please enter comments on the GM safety committee on the risk assessment

A requirement to attach the Code of Practice for working with recombinant viral vectors was made. This is now attached. A standard operating procedure to the disposal of recombinant viral vectors was also made. Again, this is now attached.
The project aims to understand the role of viral proteins in the papillomavirus life cycle using an organotypic raft culture approach. Part of this work will look at the process by which HPV causes new lesions, which will be carried out using infectious papillomavirus particles isolated from organotypic rafts. Differences in infectivity between HPV virions prepared from wild type and mutant papillomavirus genomes (e.g. papillomavirus gene knock-outs and point mutants) will allow us to establish the role of individual viral proteins during infection and during the full productive life-cycle. An initial interest centres around our working hypothesis that the viral E4 protein can associate with virus particles to influence infectivity, virulence and virion survival outside the cell. In the first instance, we will focus on the assembly and release of infectious virions, and on the role of viral proteins such as E4 that may have a putative role in virus survival and resistance to desiccation in the environment.

A second aim of our work is to establish how viral genomes from high and low-risk groups are maintained in the infected cell, and to understand how virus infected cells respond to the presence of viral episomes. This work is expected to provide new insight into the initial stages of disease development, and will involve the use of papillomavirus reporter genomes in which a region from the L1 and L2 genes has been replaced with the coding sequence for Green Fluorescent Protein. Such mutant genomes will be made in the context of the wild type papillomavirus background, or in the context of specific mutants that may affect genome replication success. It is hoped that such studies will provide key insight into the different mechanisms that high and low-risk HPV types use to cause disease in humans.

Work on polyomaviruses will investigate the replication of these viruses, with a primary focus on virus host interactions. Recombinant viruses will be constructed that lack the entire genes or certain domains of viral proteins that are thought to be important for interaction with host cell processes. These recombinant viruses will be used to investigate the role of viral protein – host protein interactions for virus replication. In addition, reporter viruses expressing markers such as GFP or luciferase, either as soluble proteins or as fusions with viral proteins, will be constructed. These will be used to aid the identification of infected cells and the expression and localisation of specific viral proteins.
Recipient Organism

Human Papillomaviruses and Polyomavirus genomes of different type, including:

1. HPV 1 (V01116), HPV 2 (X55964), HPV 4 (X70827), HPV 5 (M17463), HPV 6 (X00203), HPV 7 (X74463), HPV 8 (M17463), HPV 11 (M14119), HPV 16 (K02718),
   HPV 18 (X05015), HPV 31 (J04353), HPV 33 (M12732), HPV 45 (X74479), HPV 52 (X74481), HPV 57 (X55965), HPV 58 (D90400), HPV 60 (U31792), HPV 65 (X70829),
   HPV 88 (NC_010329), HPV 95 (AJ620210), HPV 126 (AB646346), Mouse Papillomavirus type 1 genome (GU808564), BKPyV (NC_001538.1), JCPyV (NC_001699.1),
   Murine PyV (NC_001515.1)
Genbank Accession numbers are indicated in brackets

Bacteria:

1. Disabled E.coli strains, including DH5a, DH10b, Top10, 2 T1R

Cells and cell lines:

1. Hela, W12, S12, SiHa, CaSki, C33A, which are derived from human cervix.
2. U2OS, Saos-2, which are derived from human bone.
3. FSK, NEK, HaCaT, NIKS, EF-1F, which are derived from human skin.
4. COS, CV-1, Vero, which are derived from monkey epithelium.
6. 293, 293T, 293TT, phoenix cells, which are derived from human epithelium.
7. RPTEC, which are a commercially available primary human renal epithelial cells
8. U87-MG, which are derived from human glioblastoma
9. J2 3T3, NIH 3T3, TK143, which are of mouse fibroblast origin.
10. Primary keratinocytes and other cell types derived from normal human or mouse tissue (skin, tonsil), or from mice with different genetic backgrounds

Host/vector system

Genetic Material and Vectors:

1. Plasmids containing Viral and Cellular Sequences.

Genetic material for use in these experiments will be derived from papillomavirus or cellular DNA sequences cloned into standard bacterial vectors. The laboratory cloning vectors used in this study will generally consist of pUC series plasmids (or related plasmids) containing human or mouse genes, or viral genes encoded by mouse or human papillomaviruses.

2. Plasmids containing Complete Papillomavirus or Polyomavirus Genomes:

The complete double-stranded DNA genomes of various HPV types and of MusPV and human polyomaviruses have been or will be cloned into bacterial vectors. These genomes contain endogenous viral promoters, and in some instances additional mammalian promoters (e.g. CMV, EF1F or TRE-Tight) positioned to drive the expression of reporter genes (such as GFP), or drug-resistance markers (such as blasticidin) will be inserted. In some instances, mutant viral genomes will be used that are defective
in normal virus protein function. There is no expected biological action of papillomavirus genes in bacteria and no modifications will be made to increase the level of expression of viral gene products or reporter genes in bacterial hosts.

3. Cells and Cell lines:

Papillomavirus or polyomavirus genomes will be excised from their parental vector, before being re-ligated and transfected into the cell systems outlined above. Propagation of whole papillomaviruses genomes will generally be carried out in the NIKS keratinocyte cell line or in primary keratinocytes. Some level of viral gene expression will occur in monolayer cell culture, with life-cycle completion and virus synthesis being limited to cells stimulated to differentiate. Assembled virus particles will be harvested from differentiating cells, either in organotypic raft culture or following differentiation with high-calcium or methyl cellulose. For propagation of polyomaviruses RPTE cells (for BKPyV) or U87-MG cells (for JCPyV) will be used.

Origin & function

Inserted sequences will be either reporter genes such as GFP or Luciferase, or components of recombination systems that allow expression.

1. Cre recombinase (P1-phage); A Type I topoisomerase that catalyzes the site-specific recombination of DNA between loxP sites.
2. LoxP sequence (P1-phage); Target sequence for Cre recombinase which mediates the site-specific recombination of DNA.
3. FRT sequence (Saccharomyces cerevisiae); Target sequence for Flp (flippase) catalyzes the site-specific recombination of DNA between FRT sites.
4. CreERT2; Cre recombinase - estrogen receptor T2 fusion gene. Tamoxifen- inducible Cre recombinase.
5. GFP and its derivatives (Aequorea victoria); Green fluorescent proteins.
6. Gaussia Luciferase (Gaussia princeps); A secreted reporter luciferase.
7. Blastcidin resistance (Bacillus cereus); Blasticidin-S deaminase.
8. LacZ (Escherichia coli); β-galactosidase.

The expression of reporter genes will be directed by several promoter sequences including

1. Human cytomegalovirus promoter (human cytomegalovirus)
2. P tight promoter (synthetic Tetracycline responsible promoter, Clontech, USA)
3. EF-1α and HTLV fusion promoter (rat and HTLV-1, respectively)

Evaluation of foreseeable effects

Wild-type human papillomaviruses typically cause benign epithelial tumors in humans. The HPV types used in this study are typical of those found in the general population, and have the same virulence and epithelial tropisms. In some individuals, HPV-induced lesions can persist and can cause neoplasia. HPV-types (e.g. HPV 11) that are not associated with neoplasia comprise the majority of HPV types, and these types are classified as low-risk. HPV16 and 18 are high-risk HPV types are considered as high-risk, and can be associated with the development of neoplasias and cancers at particular epithelial sites.

The mutated human papillomaviruses produced in this study include knock-out mutants that cannot express particular virus proteins, as well as less severe mutations that express modified viral proteins. Some of the modified viral genomes will have their late genes replaced with a reporter gene such as GFP or luciferase. Such mutant genomes are expected to decrease genome virulence when compared to their wild type counterparts. Gene substitutions that lead to the loss of the virus late genes necessary for virion production will not be able to complete their productive cycle.

MusPV, like all papillomavirus is host and tissue specific, does not infect humans. MusPV is prevalent in wild European mice but is associated only with inapparent infections that are controlled by the animals immune system. Mutations in MusPV are not expected to increase genome virulence, or to change its host range.

Polyomaviruses are small non-enveloped DNA viruses that are ubiquitous pathogens of humans. These viruses establish long-term persistent infections in humans and the majority of the population are infected by these viruses early in childhood. Polyomaviruses cause relatively benign or asymptomatic infections in immunocompetent hosts and appear to cause pathology only in immunocompromised patients. Given that the majority of the population is seropositive for these viruses and they do not appear to
cause disease in healthy individuals, handling these viruses would only conceivably pose a risk to immunocompromised, seronegative people. Polyomaviruses have theoretical oncogenic potential; they all express large-T and small-t antigens and these proteins from some polyomaviruses have the capacity to transform cells in culture. However only one human polyomavirus (MCPyV) has a well-documented association with human cancer, a rare form of skin cancer known as Merkel Cell Carcinoma, in immuno-compromised patients. However the other human polyomaviruses have not been associated with any neoplastic conditions, despite long-term or even life-long persistent infection by these viruses. The recombinant viruses that will be constructed will either contain reporter genes (such as GFP or luciferase) and/or mutations that are expected to be deleterious (such as gene deletions and point mutations designed to inhibit function). No alterations that could be expected to alter virus tropism will be introduced into polyomavirus genomes.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The primary identifiable risk is contamination of the laboratory worker either by aerosol or needle stick inoculation. As a result, all manipulations with recombinant viruses will be conducted in a class II laminar flow hood in a restricted cell culture facility under negative pressure (Class2 level containment). Gloves, protective masks and protective clothing will be worn within the facility. Soiled and used protective clothing will be sealed in bags and autoclaved before disposal. Glass ware will be avoided wherever possible and disposable pipettes, tubes, culture flasks etc will be employed. Used disposables will be sealed in bags and autoclaved before disposal. The use of sharps will be discouraged when working with recombinant viral vectors because of the risk of contamination through needle-stick injury. When required, sharps will be disposed of in sharps bins that will be autoclaved prior to final disposal. Liquid waste will be decontaminated using Virkon Tablets (Du Pont) or hypochlorite (e.g. Chloros at 10% v/v), and solid waste will treated by autoclaving according to standard protocols for the category 2 containment facility. Work areas will be disinfected with 1% Virkon (or equivalent) treatment after use.

Is an emergency plan required according to regulation 20?  

N

If yes, tick to confirm that it is attached to this form

N

Tick to confirm that you have attached a risk assessment to this form

Y

Tick if you are claiming exemption from disclosure for section of the risk assessment

N

Please enter comments on the GM safety committee on the risk assessment

A requirement to attach the Code of Practice for working with recombinant viral vectors was made. This is now attached. A standard operating procedure to the disposal of recombinant viral vectors was also made. Again, this is now attached.

### Project Additional Information

**Purposes of the contained use**

We study host-parasite interactions within the context of blood-stage malaria infection and Trichinella spiralis muscle stage infection. This involves looking at the host cellular responses to the parasite as well as studying parasite pathways important to maintaining homeostasis. Trichinella parasites will not be maintained on site, we will be working with specific parasite proteins that we will individually express in mammalian myoblasts to study their effects on the host. For the malaria work we will be genetically modifying parasite lines either by knock-in or knock-out techniques to study the function of individual genes in the parasite itself and in its interaction with host antigen presenting cells (either cell lines or primary cells).

The aim of this work is to gain insights into mammalian cell biology by first understanding how parasites manipulate host pathways to their advantage.

**Recipient or parental organism**

Organisms that will be genetically modified as part of this project:

- A. Mammalian Cells
- Well-characterized mammalian tissue culture cell lines including THP-1, RAW264.7, DC2.4, HeLa, 293T, C2C12 as well as primary human macrophages
B. E. coli
Standard laboratory strains such as XL-10, XL-1 Blue, DH-10, BL21, Rosetta2 which are all highly disabled strains.

C. Plasmodium falciparum parasites
Parasite lines to be modified include laboratory-conditioned strains 3D7, NF54, Dd2.

Host/vector system

A. pGEMT, pcDNA3.1+, pLVX, pLPCX, pPRETO, lentiviral and retroviral accessory plasmids gag/pol, vsvg, tat, rev.
Viral vectors are under the CMV or the UBC promoters. Retroviral and lentiviral vectors are 3rd and 4th generation, commercially available, and replication defective, therefore unable to propagate themselves after infection.

B. pGEMT, pet28, pet29, pGEX, pUC series plasmids

C. pUML, pCAM-BSD, pCC1, pDC2-AttP, Plasmodium expression vectors containing a drug selection marker to either WR 33063 or blasticidin antimicrobials and the hsp86 promoter.

Origin & function

Plasmid vectors in E. coli: DNA plasmids will be propagated in E. coli.
Protein expression in E. coli: E. coli will be transformed to express recombinant proteins.
Lentiviral and retroviral production/infection in mammalian cells: we will be using viral transduction to create transgenic primary cells and cell lines. We will be focusing mammalian proteins involved in antigen capture, processing and presentation. These include cell-surface receptors on antigen presenting cells and components of the endosomal pathway. We plan to fluorescently or biochemically tag these proteins and to express them in relevant mammalian cells. In addition, we plan to express genes of unknown function of Trichinella spiralis in mammalian cells to understand what they do.
Knock-out and knock-in mutants in Plasmodium falciparum: We will be knocking out specific genes and observing parasite viability to assess whether they are essential to Plasmodium survival. For knock-in mutants, we will be replacing endogenous genes with tagged version to allow for biochemical and imaging analyses. The resulting parasite lines will be used to query gene product behaviour and function.

Evaluation of foreseeable effects

Plasmid vectors in E. coli: This approach will not have any toxic or oncogenic effects.
Protein expression in E. coli: None of the proteins to be expressed are toxic or oncogenic.
Lentiviral and retroviral production/infection in mammalian cells: We will be using the commercially available 3rd generation lentiviral systems from Clontech where all essential replication genes have been removed. Lentivector and packaging functions (gag/pol, tat, rev, vsv-g) have been separated into 4 vectors and the envelope protein has been replaced with the G protein of vesicular stomatitis virus. Viral plasmids will be co-transfected into mammalian packing cell lines (293T cells) with accessory plasmids gag/pol, tat, rev and vsv-g. Cell supernatants will contain live viruses that are replication defective and are, therefore, unable to propagate themselves after infection.
Recombination events giving rise to viruses competent of reproduction have not been observed and are highly unlikely given that at least 4 recombinations in non-homologous regions would need to occur. The cell lines that will be subsequently transduced by these viruses are not infectious or hazardous to humans. The specific genes of interest that will be expressed in cells are also non-hazardous and have no known deleterious effects. We will not be using any known oncogenes or genes with high oncogenic potential, but we will rather be focusing on mammalian proteins involved in antigen capture, processing and presentation. These include cell-surface receptors on antigen presenting cells and components of the endosomal pathway.
We plan to characterize the function of individual Trichinella spiralis proteins by expressing them in mammalian cell lines and assessing changes in phenotype. Most of these proteins have known orthologs in other organisms and
others are unknown and T. spiralis-specific. The constitutive expression of a parasite protein in a mammalian cell is a very artificial system and aims to specifically characterize the function of the individual proteins. Therefore, the risk of creating a more infectious organism is entirely non-existent. The minimal clinical symptoms associated with Trichinellosis on a whole organism level underscore the implausibility of T. spiralis proteins posing a higher risk on an individual level, particularly when expressed in well-defined, commercially available cell lines. The standard code of practice for virus-handling will be adhered to for lentivirus production and infection.

Knock-out and knock-in mutants in Plasmodium falciparum: Although these manipulations may alter parasite transcriptional and proteomic processes, they are not expected to alter parasite virulence. Plasmodium falciparum is a very well-studied organism and there is no evidence, either published, anecdotal or in our own experience, that eliminating a gene results in a parasite with increased infectivity or virulence. Tagged genes will be targeted to the endogenous locus via homologous recombination and will effectively replace the wild-type version of the gene. Therefore, the resulting parasite line will be phenotypically no different than wild-type.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

DEROGATED CONTAINMENT LEVEL 3 FOR PLASMODIUM FALCIPARUM:
Blood-stage infection is not transmitted by aerosols. However, the wild type strains themselves are infective to humans at the erythrocytic stage with which we will be working. To avoid infection, parasites will be handled within a microbiological safety cabinet, using a labcoat gloves and safety glasses (standard laboratory PPE) and use of sharps will be avoided. In case of suspected exposure to infected erythrocytes by needlestick, standard protocols for Plasmodium-exposure that are in place will be followed, including treatment with chloroquine. Plasmodium falciparum is a human pathogen that is treatable but that can cause significant symptoms. It is, therefore, classed as a Hazard Group 3 pathogen and needs to be handled with care to minimize the risk of self-inflicted infection. Given that it does not aerosolize, needs a mosquito vector to be naturally transmitted, and exposure to it can be minimized with standard laboratory PPE, it can be handled in a derogated Containment Level 3 setting. Specifically:
- the laboratory does not need to be maintained at an air pressure negative to atmosphere because the agents are not transmissible by the airborne route
- the laboratory does not need to have exhaust air extracted using HEPA filtration, although any work that could give rise to an aerosol of infectious material will be carried out in a microbiological safety cabinet,
- the laboratory does not need to be sealable to permit fumigation because these agents are extremely easily broken down and cannot survive and/or multiply in the environment

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste pertaining to bacterial work including liquid cultures, contaminated glassware and all solid waste will be autoclaved using validated temperatures and recorded temperature cycles. Likewise, Any equipment used during viral production and cellular transduction will be decontaminated with Virkon, Perasafe or Chloros (hypochlorite) under manufacturers’ validated conditions and all solid waste will be autoclaved using validated and recorded temperature cycles.
Plasmodium falciparum work and handling of human red blood cells will be done under derogated CL3 conditions and all waste will be autoclaved before exiting the CL3 area.
Autoclaving is expected to kill all organisms.
The project was reviewed by our internal Biological Safety Committee, and amended as follows:

- More detail added regarding the genes to be propagated and expressed in E. coli
- More detail added regarding the genes to be modified in Plasmodium falciparum; specifying that gene knock-ins are repairs of knock-outs
- A statement that all staff working with P. falciparum were to be notified to Occupational Health.

Historical Significant Changes

Historical Date of Additional Info 02/03/2022
Project Additional Information

Purposes of the contained use

The Aim of this project is to identify new cancer pathways and to discover clinically significant marker or target genes. We have and continue to identify genes which are amplified or deleted as well as genes which transcription is deregulated in cancers of interest (in particular cervical cancer or other HPV induced cancers, SCC in general as well as childhood cancers, including malignant germ cell tumours). We also have and will continue to identify novel fusion genes which are the results of translocation events in cancers of interest. Depending on the characteristics of the genes/fusion genes identified, a variety of experimental work is carried out. Identified genes as well as other genes associated in relevant pathways are investigated to study the effects of neoplastic changes and evaluate their potential as clinical marker or target genes. When appropriate, the effects of overexpression of genes of interest or of genes involved in the regulation of the genes of interest are studied in details in appropriate cell models through the establishment of stable cell lines. Conversely, we may want to study the effects of temporary or permanent suppression of genes associated in relevant pathways on neoplastic changes and evaluate their potential as clinical marker or target genes. This will be achieved by stably expressing shRNAs or by genome editing of the genes of interest.

We are also interested in identifying specific effects that LR and HR-HPV may have on cellular gene functions including expression of genes modulating innate immune responses, cell growth, neoplastic changes, as well as in regulating the expression of their own genes. We already use cell lines containing all of the listed genes either as episomal viral genomes, or as integrated virus, but these studies will help dissecting out the contribution of each individual gene to effects we have already identified in cell lines containing the whole viral genome. In some cases we will modify by genome editing genes or regulatory regions in the already existing cell lines to study the effects of these changes, in particular with reference to the regulation in cis or trans of specific regions due to chromatin remodelling following viral integration.

Recipient or parental organism

Replication defective Lentiviruses/retroviruses (generally considered ACDP1 if not containing exogenous material) are produced following co-transfection of 293T or similar cells with two or three plasmids independently providing packaging and replication. Although they are replication-incompetent, they may have a broad tissue tropism due to
the presence of a VSV-G envelope. The ultimate goal is to use the GM viruses to transduce cells so that we can alter expression of genes of interest. The obtained cell lines will then be used for further investigations.

**Host/vector system**

Viral vectors: The second/third generation of lentivirus has been significantly modified for biosafety, including some or all of the following: 1. Packaging vector lacks both LTRs and has no viral packaging signal (y); 2. The viral genes (env, tat, vpr, vpu, vif and nef) have been deleted from the packaging vector; 3. Rev is supplied in trans on a different vector (3rd generation only); 4. The vector expressing the packaged viral genome has a self-inactivating LTR (TATA box deletion) and expresses no viral gene products; 5. Envelope is expressed from a separate vector. In some cases, mutations to the woodchuck hepatitis virus posttranscriptional regulatory element (WPRE) sequence may be also present. The presence of WPRE significantly increases transgene expression in target cells: however the WPRE sequence contains a truncated form of the WHV X gene, which has been implicated in animal liver cancer. Similarly retroviruses vectors lack gag, pol and env cannot be packaged without provision in trans. Although they are replication-incompetent, they may have a broad tissue tropism due to the presence of a VSV-G envelope.

**Origin & function**

Lentivirus/Retrovirus for the generation of stable cell lines: We will produce viruses to ultimately produce cell lines of interest. Viruses will be produced using second generation or later packaging systems which have improved safety. As a minimum, the cell lines that are used for virus packaging contain, either transiently or stably, the genes required for virus replication on separate cassettes in order to eliminate the possibility of autonomous virus production and no viral accessory proteins (Vif, Vpu, Vpr or Nef). Additionally, the viruses contain self-inactivation deletions, such as deletion in the U3 region of the 3’ –LTR. Moreover, mutations to the woodchuck hepatitis virus posttranscriptional regulatory element (WPRE) sequence may be also present. The presence of WPRE significantly increases transgene expression in target cells: however the WPRE sequence contains a truncated form of the WHV X gene, which has been implicated in animal liver cancer. The GM viruses will contain genes that will be expressed from promoters that are active in mammalian cells such as CMV, TRE3GV, TRE-tight, EF1F, CAG or PGK promoters, or from the retro/lenti virus promoter contained in the viral LTR. We may use constitutive or induced expression systems. The use of inducible system of expression will allow the study of particular pathways without the added effects that long-term expression of these genes may have on cellular processes. The use of inducible systems provides an extra layer of safety allowing the expression of the genes of interest in a controlled fashion. In some cases the inserted genes will have well described oncogenic effects (e.g. HPV 16 E6 and E7). We will also generate viruses expressing sh-RNAs to silence genes of interest. Finally, crRNA, tracrRNA, sgRNA and/or Cas9 expressing viruses will be produced to carry out gene editing of genes of interest or other genomic areas of interest using the CRISPR/Cas9 system. Although these viruses can infect humans, they are defective and unable to propagate themselves after infection.

**Evaluation of foreseeable effects**

Genes/miRNA/molecules of interest:

There are many genes/molecules of interest we have identified in the course of our studies. Current work primarily focusses on the ones listed below, but new ones are identified continuously. We study the genes/molecules of interest themselves as well as other genes/molecules of interest that may be part of downstream or upstream pathways e.g. the signalling pathways that the genes/molecules of interest activate. This is not an exclusive list, but gives an idea of the direction of our studies. The genes described are typical of the type of genes that will be genetically manipulated and the phenotypes of genes not explicitly listed here are not expected to be more severe than for the listed genes.

1. Cytokines, cytokine receptors and their downstream pathways.

We are interested in how cytokines influence cancer cells and in particular we focus on cytokines which receptor is
overexpressed in cervical and other cancers. In particular we are currently interested in: OSMR and its ligand OSM: OSMR is a member of the type I cytokine receptor family. OSMR hetero-dimerizes with interleukin 6 signal transducer to form the type II oncostatin M receptor and with interleukin 31 receptor A to form the interleukin 31 receptor, and thus transduces oncostatin M and interleukin 31 induced signalling events. Oncostatin M is a member of a cytokine family that includes leukemia-inhibitory factor, granulocyte colony-stimulating factor, and interleukin 6. This gene encodes a growth regulator which inhibits the proliferation of a number of tumour cell lines. It regulates cytokine production, including IL-6, G-CSF and GM-CSF from endothelial cells.

STATs: In response to cytokines and growth factors, STAT family members are phosphorylated by the receptor associated kinases, and then form homo- or heterodimers that translocate to the cell nucleus where they act as transcription activators. Various cytokines and growth factors including IFNs, EGF, IL5, IL6, HGF, LIF and BMP2 induce such phosphorylation. STAT family members mediate the expression of a variety of genes in response to cell stimuli, and thus play a key role in many cellular processes such as cell growth and apoptosis.

HIFs: These genes encode transcription factors involved in the induction of genes regulated by oxygen, which is induced as oxygen levels fall. They are regulated by and in turn regulate STATs.

2. microRNAs and the genes/pathways they regulate:
There are numerous microRNAs expressed in human cells. We are particularly interested in a subset of microRNAs which are either overexpressed or under-expressed in Germ Cell Tumours. These include miR-371–373, and the clusters miR-302/367, as well as miR-9, the miR-30 family, miR-125 and miR-181. Not all functions of microRNA have been elucidated to date, some of the identified roles include regulation of cell proliferation (miR371–373, miR125, miR-9), alternative splicing (miR-30), metastasis (miR371–373, miR-9) and cell metabolism (miR-181).

DROSHA: A members of the ribonuclease III superfamily of double-stranded (ds) RNA-specific endoribonucleases which participate in diverse RNA maturation and decay pathways in eukaryotic and prokaryotic cells. The RNase III Drosha is the core nuclease that executes the initiation step of microRNA (miRNA) processing in the nucleus.

3. Chromatin modellers and Transcription regulators:
Changes in chromatin structure and regulation of gene expression by epigenetic mechanisms, such as histone posttranslational modification, are involved in most cellular biological processes. Abnormal regulation of epigenetics is implicated in the occurrence of various diseases, including cancer. We are interested in modulating complexes which have a role in chromatin structure, as we have found that chromatin epiregulation at HPV16 integration site has a role in determining the levels of viral genes transcription. We would like to study the effects of silencing by shRNA and/or genome editing of cellular genes involved in these processes on the transcription levels of the viral genes. In some cases genome editing will be used to constitutively upregulate the expression of some genes of interest. We will also want to target for genome editing binding sites for the genes of interest, including on the HPV genome integrated in cells. Genes we will be targeting include for example CDK9, HATs such as TIP60 and p300, HDACs, lysine methylases and generally enzymes involved in regulating the presence of epigenetic marks on histones. We are also interested in dissecting the roles of transcription regulators such as transcription factors and hormone receptors on the level of viral gene transcription, as the HPV16 URR contains numerous binding sites for a variety of transcription factors (AP-1, YY1, GR, etc). We may also want to target other structural regulatory proteins such as CTCF and their binding sites, which also have a role in regulating gene transcription. Finally we are also interested in genes adjacent or distal to the viral integrations sites which are deregulated by novel chromatin interactions following HPV integration, to assess if the viral induced modification of chromatin structure has an effect on transcription of genes that may promote carcinogenesis.

4. Human Papilloma Virus genes:
There are two classes of HPV: high risk and low risk – the classification reflecting their capacity to promote cancer. Most of our work will use high risk HPV16 type but we may use low risk viral genes as well for comparison. Although
the functions of the viral proteins are somewhat similar in high and low risk viruses, high risk viruses genes tend to have more functions and potentially have a higher risk associated with them. We have used plasmid to make stable cell lines, but this has not always been successful. We are proposing the use of retroviruses to increase the efficiency of delivery. Three HPV genes have known oncogenic effects.

E7 protein of HPV16 has both transforming and trans-activating activities. Disrupts the function of host retinoblastoma protein RB1/pRb, which is a key regulator of the cell cycle. Induces the disassembly of the E2F1 transcription factors from RB1, with subsequent transcriptional activation of E2F1-regulated S-phase genes. Inactivation of the ability of RB1 to arrest the cell cycle is critical for cellular transformation, uncontrolled cellular growth and proliferation induced by viral infection. Stimulation of progression from G1 to S phase allows the virus to efficiently use the cellular DNA replicating machinery to achieve viral genome replication. Interferes with histone deacetylation mediated by HDAC1 and HDAC2, leading to activation of transcription. More biological actions are expected in the transfected cells as E7 has also roles in immune modulation and new interactions are still being described for this protein.

E6 protein of HPV16 plays a major role in the induction and maintenance of cellular transformation. Acts mainly as an oncoprotein by stimulating the destruction of many host cell key regulatory proteins. E6 associates with host E6-AP ubiquitin-protein ligase, and inactivates tumour suppressors TP53 and TP73 by targeting them to the 26S proteasome for degradation. In turn, DNA damage and chromosomal instabilities increase and lead to cell proliferation and cancer development. The complex E6/E6P targets several other substrates to degradation via the proteasome including host NFX1-91, a repressor of human telomerase reverse transcriptase (hTERT). The resulting increased expression of hTERT prevents the shortening of telomere length leading to cell immortalization. Other cellular targets including Bak, Fas-associated death domain-containing protein (FADD) and procaspase 8, are degraded by E6/E6AP causing inhibition of apoptosis. E6 also inhibits immune response by interacting with host IRF3 and TYK2. These interactions prevent IRF3 transcriptional activities and inhibit TYK2-mediated JAK-STAT activation by interferon alpha resulting in inhibition of the interferon signalling pathway. More biological actions are expected as the list of proteins E6 interacts with is continuously increasing.

E5 of HPV16 acts to keep host cells in a proliferation-competent state upon differentiation. Enhances host epidermal growth factor receptor (EGFR) activation after stimulation by EGF by inhibiting EGFR internalization. Induces a redistribution of host caveolin-1 and glycosphingolipid (ganglioside GM1) components of lipid rafts to the plasma membrane. Since GM1s inhibit cytotoxic T-lymphocytes, block immune synapse formation, and enhance proliferative signalling by the EGFR, E5 may enhance immune evasion and cell proliferation via a common mechanism. E5 also alters endosomal pH by interacting with the vacuolar H+-ATPase, which is a proton pump responsible for acidifying cellular organelles. Additionally, E5 prevents transport of the major histocompatibility class I to the cell surface and retains the complex in the Golgi apparatus. More biological actions are expected as not all E5 interactions are fully understood.

No significant hazard is anticipated with regard to the expression of the other viral genes and their mutants in mammalian cells.

The E1 protein is a replication protein with helicase activity.

The E2 protein is a transcription factor and is involved in viral replication and viral genome segregation during cell division.

The E4 protein inhibits cell proliferation and interferes with the normal structure of the cytoskeleton.

5. CRISPR/Cas9 system:

We will use the CRISPR/Cas9 system for genome editing using lentiviruses to deliver Cas9 and crRNA/tracrRNA/sgRNA. CRISPR/Cas9 systems use the ability of Cas9 to be recruited by crRNA/tracrRNA to specific genomic sites and in turn create DNA double strand breaks which can be then repaired in an altered manner. In genome editing systems, Cas9 is directed to the site of interest via a synthetic guide RNA (sgRNA), which can be
provided in cis or trans. Catalytically inactive or "dead" Cas9 can also be recruited by gRNAs to specific target DNA sites and used as a platform for recruitment of heterologous effector domains to specific genomic loci. For example, dCas9 fusions to a transcriptional activation domain (VP64 or the p65 subunit of nuclear factor kappa B; NF-kB) or a transcriptional repression domain (the Krüppel-associated box (KRAB) domain) have been shown to regulate the expression of endogenous genes in human and mouse cells. This technology has become widely used but is still being further developed. Currently there are two main systems in use. One delivers Cas9 separately from the crRNA/tracrRNA/sgRNA and when this system is used Cas9 expression is generally (but not exclusively) inducible under the control of the TET repressor, and only after treatment of transduced cell with doxycycline or similar compounds there is expression of Cas9. The alternative system will deliver Cas9 and crRNA/tracrRNA/sgRNA via the same lentivirus, and in this case Cas9 expression is always constitutive. Constitutive expression of Cas9 can result in non-specific ds breaks, which in turn could lead to mis-repairing and potential mutagenesis. The chosen system has implications for the safety of the GM lentivirus with inducible Cas9 expression introducing a further level of safety. Both systems will be used in this project, although preference will be given whenever possible to Cas9 inducible systems.

<tbody>
<tr>
<td>Transduced cell lines: Lentiviral transduction will be used to make new stable cell lines expressing naive, as well as mutated active or inactive forms of genes of interest. This will include both human, mouse and viral (i.e. Human Papillomavirus) genes. In other cases, we will make cell lines in which a gene or set of genes will have been silenced by either the use of shRNA or by CRISP-R/Cas9 based genome editing. In some case genome editing will be used to express constitutively genes of interest. All of the established cell lines utilised are well characterised or authenticated with a low risk of endogenous infection with a biological agent and which have been tested for the most serious pathogens. As such they will pose minimal risk to both human health and the environment. In primary cells there is a slightly elevated risk owing to the increased risk of adventitious pathogens being present, in particular for human primary cells, although the likelihood of colonization remains low. Mouse cells give negligible risk because of the phylogenetic difference means adventitious pathogens and colonization both become very low probability. This risk is not going to be greatly increased by the addition of the genes of interest. The expectation is that there will be an effect from the transduction of these cells, which will be the subject of investigation; we are expecting a variety of effects which will vary depending on the gene of choice. Some of the genes under investigation have well described oncogenic effects (e.g. HPV 16 E6 and E7), or are tumour suppressor genes, however, the cell lines that receive the genes of interest are not expected to be more hazardous as a result of the genetic manipulation, as they do not produce infectious material and are unable to infect people or animals.</td>

Page 1937 of 1532
A patient has a germline mutation in Fbxo7. Our aim is to study the effects of the loss of Fbxo7 expression for this patient, and to determine the cellular pathways that are defective in his cells. To do this our aim is to complement his mutation, introducing back in WT expression and also to use his cells to create fibroblasts that contain mutations in Fbxo7 that have been associated with cases of PD.

Recipient or parental organism
Cultured patient fibroblasts

Host/vector system
Retroviruses-lentiviruses (3rd generation)

Origin & function
Cells are obtained from a skin biopsy from the patient, and they will be cultured in vitro for biochemical and cellular assays.

Evaluation of foreseeable effects
Patient fibroblasts have a limited lifespan in culture, typically between 1-3 months before undergoing senescence. The introduction of a wild-type copy of the gene may allow the cells to grow for longer in culture. Fbxo7/PARK15 gene expression can transform already immortalized cells. The recipient patient cells are primary fibroblasts, and will likely undergo senescence as normal fibroblasts do. It is extremely unlikely that introducing this single gene back into the patient's fibroblasts will do more than complement the known mutation.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Standard validated methods will be used:
- Liquids will disposed of in Virkon (1% solution) and disposed of via drains after a minimum of 12 hours. Effectively 100% kill.
- Mixed disposable plastic waste: validated autoclave, 121°C for 30 minutes, then disposed of to incinerator. 100% kill.
- Disposable pipettes: either (a) as for mixed disposable waste or (b) immersion in solution of Virkon (1% solution) for a minimum of 12 hours; the Virkon drained off, followed by autoclaving and incineration. 100% kill.

The Department's Biological Safety Committee reviewed the attached risk assessment and approved it once the waste disposal policy had been made consistent, and the requirement for appropriate vaccination of workers had been added.

Project Ref 43/19.1

Date Ackn'd 21/11/2019

CU2 Project Title The p53 protein family: Tp53, Tp63 and Tp73 gene silencing or over-expression to investigate their biological functions

Date Project Ceased

Class 2 CultureVolClass2 < 1 Litre

Consent Granted
During the initial experimental phase, we will generate knock-out cell lines for p53, p63 or p73 by different strategies. On the counterpart, over-expression of the proteins will be obtained through simple plasmid DNA transfection for episomal transient expression. Knock-out of either of the three genes will be obtained through small interfering RNA transfection or through the CRISPR/Cas9 technology.

CRISPR/Cas9 is a gene editing technique that exploits a DNA sequence-specific guide RNA (gRNA) to target a bacterial nuclease Cas9 on a selected nucleotide sequence. In our case, the designed gRNAs, specific to either of the p53 family genes, recognise its target being partially complementary to its nucleotide sequence, hybridise with it and recruit the Cas9 enzyme. Cas9 cleaves DNA inducing a double strand-break shortly downstream of the gRNA recognition sequence. The DNA double strand break is then repaired by the DNA repair machinery, usually resulting in frameshift mutation of the target gene and therefore its knock-out.

Concurrent expression of the gRNA and the Cas9 nuclease, essential for gene knock-out, could be obtained through simple transfection methods, using standard transfection agents, or by lentiviral or retroviral infection of the target cells.

Cells will be screened for the gene deletion through Sanger sequencing of the gene locus to prove the efficiency of the knock-out.

Finally, genetically modified cells will be used in various cellular biology assay such as proliferation, citotoxicity, migration assays, etc.

The host micro-organism used during the cloning phase of the gRNA or the gene of interest in each vector, is the bacterial E. coli TOP10 strain (which is a K12 derivative strain). This is not a mammalian expression strain. Expression can happen but there is a very low risk potential.

Defective lentivirus or retrovirus produced from packaging mammalian cell lines, in which the helper genes are located in two separate plasm ids, thus eliminating the possibility of a reversion to replication competence by a single recombination event.

**Origin & function**
The host micro-organism used during the cloning phase of the gRNA or the gene of interest in each vector, is the bacterial E. coli TOP10 strain (which is a K12 derivative strain).

**Evaluation of foreseeable effects**
The knock-out of each of the mentioned genes might have oncogenic potential. Lentivirus are able to infect human cells. However, GM viruses are replication deficient. Any exposure to the virus may carry some hazard, but the separation between the Cas9 and the gRNA delivering viral particles will minimise the possibility of an accidental gene knock-out in the case of exposure of a worker. In case the knock-out might be obtained through classical transfection techniques, instead, the risk for exposure is effectively zero.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
No GM animals or plants will be used, but only micro-organisms

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
GMMs will be stored in a dedicated -80°C freezer located in the containment level 2 designated tissue culture room. The containers will be clearly labelled with the name of the operator, the date, and a concise description of its content. In case GMMs will need to be stored outside the CL2 rooms, the freezer will be clearly labelled to specify that it contains hazard group 2 organisms.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
Solid waste: solid waste will be autoclaved before disposal. Plasticware will be pre-treated with Prespekt overnight before autoclaving. Prespekt (which contains sodium dychloroisocyanurate) will be used at a final free chlorine.

02/03/2022
concentration of 10,000 ppm. Before autoclaving, the excess detergent will be drained off. Tissues and gloves should be also placed in the autoclave bin. Liquid waste: liquid waste will be treated with Presept for 24 hours and then discarded. In case of spillages surfaces and instruments can be treated with 10% Chloros (10,000 ppm available chlorine).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The Biological Safety Committee assessed the risk assessment and gave its approval after the author had provided clarification of the appropriate level of PPE and disinfectants to be used, as well as further detail on the levels of risk attributed to the procedures involved.

Project Ref 43/19.2

Date Ackn'd 04/12/2019

CU2 Project Title

Investigating the effects of evolutionary divergent intracellular pathogens on host cell gene expression and immune response.

Date Project Ceased

Withdrawn N

Tick if notifying a connected programme of work N

Class Culture Vol Class 2 Culture Volume Class 3-4

Class 2 < 1 Litre

Non-GMM Consent Granted

Project notified under transitional arrangements N
To investigate gene expression of intracellular pathogens and host cells during infection. In particular, this study addresses how the pathogens manipulate host cell immune response and gene expression.

Recipient or parental organism

- Listeria monocytogenes

Wild-type Listeria monocytogenes (strains 10403S and EGO, both of which are serotype 1/2a) and derivatives where genes of interest are deleted through means of homologous recombination. For example, genes encoding the protein virulence factors listeriolysin 0 (LLO), internalin A (InIA), InIB and actin assembly-inducing protein (ActA). Knock-in L. monocytogenes mutants, expressing reporter proteins (e.g. YFP or GFP) will also be utilised. 10403S is a streptomycin-resistant derivative of the clinical isolate 10403 and is the predominant laboratory strain of L. monocytogenes used for research in the United States of America (USA). It was originally isolated from a human skin lesion in 1968. Infected individual by streptomycin-resistant strains will declare they have been exposed to a streptomycin-resistant strain when presented at the hospital.

EGO is a strain derived from the original L. monocytogenes strain that was isolated from rabbits in 1926. It's original supplier was the Trudeau Institute, who have since distributed the strain to laboratory's across the globe. Deletions in each of the virulence factors are expected to reduce the virulence of L. monocytogenes due to the role of these genes in the infection and colonisation process. Virulence for reporter knock-in mutants are expected to be reduced compared to wild-type.

A recent overview of these strains can be found at 001: 10.1128/mBio.00969-14.

- Salmonella typhimurium

Wild-type Salmonella typhimurium (SL 1344 and SJW11 03, both derivatives of the original lab adopted parental strain L T2) and derivatives where genes of interest are deleted through means of homologous recombination. The parental strains SL 1344 and SJW11 03 are auxotrophic for histidine with reduced fitness, and has been used safely in research labs since 1977. Both strains are able to cause localised gastroenteritis in humans if ingested but resolves itself with 3-7 days or can be managed with antibiotics. Although laboratory passage means both SL 1344 and SJW11 03 are likely attenuated.
- **Listeria monocytogene**
  pMTL20, pMTL23, pE194ts for allelic exchange to generate in-frame deletion of virulence factors.

- **Salmonella typhimurium**
  Well characterised vector systems with a history of safe use will be used, for example, commercially available nonmobilisable/mobilisation defective plasmids, pUC series, pACYC184, pWSK29, pBR322 series vectors, and pKD3, pKD4, pKD46, pCP20, pET, pGEX, pTrc99, pBAD, pLG339, pOU71, pMRS101, pWRG730 plasmid vectors.
  Mutations of Salmonella Typhimurium will be created by means of homologous recombination by using lambda red recombinase expression plasmids (e.g. pWRG730, pKD46) to facilitate introduction/removal of genes of interest.

**Origin & function**

- **Salmonella typhimurium**
  Source of genetic material- pACYC184 (NEB), and pUC series (e.g. NEB), pBR322 series (e.g. NEB) vectors, and pKD3, pKD4, pKD46, pCP20 (Datsenko and Wanner 2000), pET, pGEX, pTrc99, pBAD, pLG339 pOU71, pMRS1 01, pWRG730, all plasmid vectors are already laboratory maintained. These vectors carry antibiotic resistance markers of no or limited clinical value such as ampicillin, kanamycin or chloramphenicol. Bacterial virulence genes will by amplified by PCR from parent.

  Intended function
  High-copy pUC vectors will be used to express GFP or RFP that will act as a reporter to allow direct visualisation of the pathogen during cell infection.
  Low-copy pBR322/pACYC184 vectors encoding tagged virulence effectors (e.g. GFP-tagged prgJ) will be used to complement parental null mutant strains and investigate virulence factors inside the target host cell.
  Mutations of Salmonella Typhimurium will be created by means of homologous recombination by using lambda red recombinase expression plasmids (e.g. pWRG730, pKD46) to facilitate introduction/removal of genes of interest.

**Evaluation of foreseeable effects**

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Containment protocols that minimise aerosols and spillages during bacteria culture via use of airtight sealed tubes, i.e. falcon tubes, in as small a volume as possible, typically 1 ml.

Autoclaving of waste material at 121°C for 60 minutes provides 100% inactivation. The autoclave used for waste is located in the building; all waste to be transported is double bagged in autoclave bags and then sealed in a plastic container. Annual validation of the autoclave by independent means will be performed.

For spillages, ethanol is an effective surface disinfectant in an aqueous solution of 70% (v/v), and ready-to-use proprietary disinfectant, such as Distel spray (formerly known as Trigene) which is proven to kill bacteria. Virkon
powder can be used directly for larger spillages.
- Liquid waste will be aspirated into liquid vessels containing proprietary Distel or Virkon proven to disable bacteria/viruses, incubated for at least 30 minutes before disposal of the deactivated waste down the sink.

The Biological Safety Committee was happy to give approval for the risk assessments once a number of details had been clarified regarding disinfection procedures. Clarification was also sought on safe working procedures, both for the laboratory and animal facility staff.

### Project Ref 43/20.1

- **Date Ackn’d**: 03/04/2020
- **CU2 Project Title**: Using CRISPR/Cas9 genome editing on 2D and 3D cultures of primary cells from the human placenta and uterus to study placental development and the influence of the uterine microenvironment
- **Class**: Class 2
- **CultureVolClass2**: < 1 Litre
- **Non-GMM**: Consent Granted
- **CultureVolumeClass3-4**: 
- **Project notified under transitional arrangements**: N

02/03/2022
How does the human placenta develop and how is this influenced by the maternal uterine microenvironment? This is the central question we are trying to address in lab. Normal growth and development of the fetus depends on the placenta, the extra-embryonic organ derived from trophectoderm and the establishment of interactions between the placenta and the decidua, the pregnant lining of the uterus. Defective placental development and interactions at the maternal/fetal interface results in miscarriage, pre-eclampsia, fetal growth restriction and stillbirth.

Understanding the molecular and cellular mechanisms underlying these maternal/fetal interactions has been challenging due both to practical and ethical limitations and lack of reliable in vitro models. I have recently derived 3D culture systems (organoids) from human decidua and placenta that will provide the essential tools. We will use these organoids combined with co-culture methods with other cell types, single cell genomics and Crispr/Cas9 genome editing to study: (i) the molecular mechanisms that drive the development of the placenta and (ii) the role of the signalling from the maternal uterus in regulating placental development.

Primary human cells from the placenta and uterus grown as 2D and 3D cultures (organoids) will be used for gene targeting using CRISPR/Cas9 gene editing.

No vectors will be used. Synthetic crRNA/tracrRNA molecules will be combined with recombinant purified Cas9 protein to generate a ribonucleoprotein (RNP) complex. The crRNA will be homologous to the targeting region of interest, so its sequence will be specific to the gene we will target. The RNP complex will be directly transduced into cells by electroporation.

Genes of interest in placental and uterine cells will be edited by inducing double-stranded breaks in target sequence, to achieve knockout/knockin at the locus of interest. The expected outcome of the gene targeting is disruption/correction in these cellular processes. We will also introduce fluorescent tags to create placental and uterine cell lines that will be fluorescently labelled to allow co-culture studies with other cell types.

The RNP complex presents very low risk of activity in humans if exposed. For RNP delivery, sgRNA and Cas9 protein will be mixed only immediately prior to delivery into the cells and are inactive beforehand. In the unlikely event of direct contact, RNP delivery in the absence of electroporation is extremely inefficient. In addition, the RNP has a short half-life in the cell. It is only active for up to 12 hours before being degraded. Furthermore, no sharps will be used in the process of preparing the RNP complex. Thus the process of gene targeting of human cells will not have any additional risks to the research staff. The cultures will also bear no
additional harmful properties compared to the starting biological material. As cells are isolated from unscreened human tissue is used, thus the potential harmful properties regard pathogens. However, these samples are obtained from women from the Cambridge area thus are considered low risk. In the event that a potentially hazardous pathogen is later revealed in any samples, the procedure will be to remove the sample from the study and destroy all stocks by incineration. We will notify relevant workers of the finding and to have them followed up with Occupational Health. The possibility that this issue might arise will need to be explained to workers at the outset so they can make an informed choice about whether they are comfortable with handling the samples. Also, the workers will be following risk assessments and SOPs, and handling specimens as if they DO harbour potentially hazardous pathogens therefore the overall risk is very 'low'.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All genetically-modified human cells and any other liquid reagents used in experiments, will be inactivated using 1% Virkon solution (which is virucidal/bactericidal/fungicidal), and will be incubated with solution for 24 hrs after which is safe to discard down the sink. Any plastic waste produced will be collected as biological hazard waste for autoclave and then send to landfill.

Project Additional Information

Purposes of the contained use
To help us understand how cytomegalovirus crosses the placental barrier

Recipient or parental organism
Pathogenic clinical strain (TB40E) of HCMV.
Health and Safety
Executive
Activity Notification
Organism is already genetically modified and provided by Prof. Joh Sinclair, Department of Medicine, University of Cambridge.
In vitro assays will be used to infect human placental cells and blood monocyte derived macrophages with HCMV.

Host/vector system
Plasmid encoding yellow flourescent protein, fused with the viral protein IE-2

Origin & function
Gene product is expressed during early stages of viral infection of cells, and acts as a flourescent marker, localised to the nucleus. This will allow us to identify cells in which the virus is replicating. In particular, we plan to use in vitro systems to develop our understanding of the interactions of CMV with human placental cells. Lab procedures involved include infecting human placental macrophages and other blood monocyte derived cells with CMV (TB40E). Viral
spread is monitored by light and UV microscopy. Assays are harvested by treating virus infected cells with trypsin to detach cells, these are inactivated with 2% paraformaldehyde prior to analysis on a flow cytometer. Supernatants are harvested to determine productive viral infection. Supernatants are added to human fibroblast cultures and infection is quantified. Supernatants are harvested to test for cellular cytokine production upon infection.

Viral spread assays are also carried with human fibroblasts that are infected with HCMV. Viral spread is monitored as stated above. Human fibroblasts will be seeded with infected human Hofbauer cells or blood monocyte-derived cells, to determine the extent of cell-to-cell spread of virus. Viral spread is monitored as stated above.

Immunofluorescence of HCMV infected cells: HCMV infected cells in 96 well plates, on slides or in slide chambers are fixed in 70% EtOH at -20C. Fixed cells are washed in PBS and stained with antibodies. Slides are sealed with a coverslip and analysed on the confocal microscope.

Flow cytometry sorting of live HMCV infected cells: Cells are infected as stated above. Cells will be transported from the containment level 2 laboratory to the containment level 2 Department of Pathology flow facility. Tubes will be sealed and within a secondary box lined with absorbent material.

**Evaluation of foreseeable effects**

This Gene product is expressed during early stages of viral infection of cells, and acts as a flourescent marker, localised to the nucleus.

HCMV is in the ACDP human pathogen hazard group 2.

Primary infection can cause an acute infectious mononucleosis like illness with high temperatures; this is self-limiting and very rarely requires medical attention. Infection of HMCV seronegative women during pregnancy can lead to infection of the developing foetus and serious morbidity.

The gene product expressed by CMV does not alter the morbidity or risk associated with CMV infection.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Access to containment level 2 laboratory is limited to laboratory personnel and other specified persons.

All work takes place in a class II microbiological safety cabinet (MSC) with a UV light source.

All solid and liquid waste is inactivated by immersion in 5% virkon for 1 hour prior to disposal. Virkon kills 99.999% of organisms, that is it kills organisms to an extent where they no longer pose a threat to health. All waste is then placed in doubled sealed bags before autoclaving followed by incineration.

Remaining inactivated liquid waste is poured down the appropriate lab sink and water is then run down the sink for 5 minutes.

Work surfaces are cleaned down with disinfectant 5% viron, then 70% ethanol. The safety cabinet is the irradiated with UV for 15minutes to deactivate any potential aerosols.

All items that were in MSC with the virus and need to be reused, such as pipettes will be irradiated with UV light for 15 minutes and sprayed with 70% ethanol before removal from the MSC.

Any accidents and spillages that occur will be dealt with immediately. Minor spills in the MSC will be cleaned up with 5% virkon and paper towels. These towels will be inactivated in 5% virkon for 1 hour and double bagged in autoclave bags, and autoclaved prior to incineration. If spills occurs in sealed centrifuge buckets and sealed containers, the buckets and containers will only be opened once placed in MSC. Again 5% virkon and 70% ethanol and paper towels.
will be used to clear spillage. If spills occur outside of MSC, work will be stopped. Other people in the area will be informed and asked to evaluate the immediate until the spill is cleared. The spillage will be isolated and immediately cleaned up. The spillage will be cleaned up with 5% virkon and 70% ethanol and paper towels. The papers towels will be inactivated as described above.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The Biological Safety Committee approved this risk assessment after a few small amendments were made as requested.

Characterisation of MHC class I and class II antigen presentation pathway components controlling peptide selection for immune recognition

Class 2
Culture Vol Class 2 < 1 Litre
Consent Granted

Project notified under transitional arrangements N
Withdrawn N
Tick if notifying a connected programme of work Y
Peptide presentation on major histocompatibility complex (MHC) molecules is central to mounting effective antiviral and antitumoural immune responses. Our overreaching aim is to identify and characterise components of the antigen presentation pathway, including the peptide editor TAPBPR, MHC-I and MHC-II and their interaction partners. Several aspects of this work require the use of class 2 GM material:

1. Generation of mammalian cell lines with modified expression of antigen presentation pathway components
   Through lentivirus transduction, components of the MHC antigen presentation pathway (e.g., MHC-I, MHC-II, TAPBPR, tapasin) and their potential ligands/interaction partners will be knocked out or introduced and overexpressed. This may include natural variants and mutated versions of these proteins. Furthermore, the expression of proteins that are identified as antigen in either T cell responses or recognised by specific antibodies will be modified using knockout techniques or overexpressed. This may include the expression of variants and mutated forms of these proteins.

2. Characterisation of the immunopeptidome in hepatitis B and hepatocellular carcinoma
   Potential hepatitis B virus (HBV) peptides presented on MHC molecules will be defined. This work requires the use of a panel of mammalian cell lines expressing selected MHC class I and class II molecules and stably transduced with individual HBV proteins or all HBV proteins except the viral polymerase (HBpol). These cell lines are generated using lentiviral vectors.

3. Functional characterisation of TAPBPR, and other known or novel antigen presentation pathway components, in the context of virus infections
   Virus-mediated manipulation of the antigen presentation components will be assessed. This project requires the use of hazard group 2 biological agents such as human cytomegalovirus (HCMV), vaccinia virus (VACV), herpes simplex virus (HSV)-1, Zika virus, influenza A virus and human respiratory syncytial virus (RSV). These viruses may be modified to knockout gene function or to express a tag (e.g., HA-tag or green fluorescent protein [GFP]). Additionally, mammalian cell lines transduced with viral proteins will be generated. Phenotypes of the mutant viruses and cell lines expressing viral proteins will be assessed using standard virological and immunological assays.

E. coli disabled strains (ACDP hazard group 1) have a long history of use without observation of harmful effects.

All mammalian cells that will be used are widely available (e.g. ATCC, ECACC), well established and have a long history of safe use, e.g. HeLa, HEK293T, A549, Jurkats, HFFF-TERTs, Hep G2.

Lentiviruses (produced following co-transfection of 293T or similar cells with two or three plasmids independently providing packaging and replication) are replication-incompetent but have a broad tissue tropism due to the presence of a VSV-G envelope. The third generation of lentivirus has been significantly modified for biosafety, including 1) Packaging vector lacks both LTRs and has no viral packaging signal; 2) The viral genes (env, tat, rev, vpr, vpu, vif and nef) have been deleted from the packaging vector; 3) Rev is supplied in trans on a different vector; 4) The vector expressing the packaged viral genome has a self-inactivating LTR (TATA box deletion) and expresses no viral gene products; 5) Envelope is expressed from a separate vector.

Other viruses used are categorized by ACDP as hazard group 2 biological agents and can cause disease in healthy adults:

- Vaccinia virus (VACV) has been widely used as a vaccine in the smallpox eradication campaigns. The virus may cause particularly severe disease during pregnancy, in
people with active skin disorders such as eczema or psoriasis, or in immunocompromised individuals such as those infected with HIV.

- Human Cytomegalovirus (HCMV) causes a life-long infection and has a prevalence of 55-100% within the human population. Primary HCMV infection is generally asymptomatic in healthy hosts but it can cause severe and sometimes fatal disease in immunocompromised individuals and neonates. HCMV infection is often controlled by early treatment with antivirals.

- Herpes Simplex Virus (HSV)-1 is a highly contagious infection, that is common and endemic throughout the world. Most HSV-1 infections are acquired during childhood, and infection is lifelong.

- Influenza A virus. Naturally occurring and/or vaccine-induced immunity exists against the PR8, WSN, and Eng glycoproteins, as well as their variants, and should provide a large measure of protection against infection and spread of the proposed mutant viruses.

- Zika viruses are transmitted via a vector (mosquito) and thus pose an extremely low risk for contamination through the described work.

- Human respiratory syncytial virus (RSV). Natural immunity against RSV exists. RSV causes a mild-respiratory disease in adults and children, but it can be severe in infants who are at increased risk of acute lower respiratory tract infection.

**Host/vector system**

Lentiviral expression vectors are used to generate second or third generation self-inactivating and replication disabled lentiviruses. This system is used to knockout (KO) or introduce components of the MHC class I and class II antigen presentation pathway in mammalian cells or to transduce mammalian cells to stably express a viral protein. Furthermore, it may be used to KO or introduce a protein which is the target of a T cell or antibody response. Promoters used will be either constitutively expressed or under the control of a repressor (inducible systems).

Small expression plasmids (standard commercially available cloning plasmids) and in vitro transcribed RNA are used for reverse genetics to generate virus particles (incl. lentivirus), as well as bacterial artificial chromosome (BAC) and BAC helper plasmids required to produce virus particles. Overall, these vectors are of no human or environmental risk.

**Origin & function**

Lentiviral vectors

Lentiviral expression vectors are used to modify expression of known or novel components of the MHC class I and class II antigen presentation pathway including their ligands/interaction partners, to modify expression of identified or potential targets of T cells and antibodies, and/or to introduce a viral protein of interest into mammalian cell lines. Lentivirus particles will be produced using second generation or later packaging systems which show improved safety. As a minimum, the cell lines that are used for virus packaging contain, either transiently or stably, the genes required for virus replication on separate cassettes in order to eliminate the possibility of autonomous virus production. Additionally, the viruses may contain self-inactivation deletions. The GM lentiviruses will contain genes that will be expressed from promoters that are active in mammalian cells (e.g. CMV promoter) or from the lentivirus promoter contained in the viral LTR. We may use constitutive or induced expression systems.

Mammalian cell lines

Resultant modified cell lines are not expected to be more hazardous as a result of the genetic manipulation, as they do not produce infectious material and are unable to infect people or animals. CL2 will be necessary for the transduction of the cell lines with the lentivirus vectors. All established cell lines will be utilised in CL1 laboratories. Although expression of certain viral genes may be expected to be toxic to the expressing cells, there is no expectation that neighbouring cells or the environment will be affected. Of the viral proteins of interest, only HBV protein x (HBx) has been postulated to have oncogenic effects in human hepatocytes. Overexpression of HBx in non-dividing cells does not have deleterious effects, which is consistent with the lack of a cellular stress response to HBV-infected hepatocytes. Introduction of any of the other viral proteins of interest in mammalian cells is not expected to result in proliferation of the cell. Some of the mammalian cell proteins that are recognised by specific T cell and antibodies whose expression will be manipulated through knockout techniques or via overexpression may potentially be oncogenic. Although there is a risk if accidental gene transfer occurs, the absence of a promotor region mean there would be a negligible impact on human health. The use of inducible systems provides an extra layer of safety allowing the expression of the genes of interest in a controlled fashion.

Viruses

Hazard group 2 viruses will be grown in mammalian cells. GM viruses are expected to behave the same as WT virus. KO of viral genes or inserting tags poses no risk to human health and is highly unlikely to increase virulence or fitness of the virus above that of the parental wild-type virus. These viruses are by no means expected to display enhanced replication as gene products of genes altered/deleted from viruses are not expected to be involved in replication.
Evaluation of foreseeable effects

The packaged lentiviruses with the gene of interest inserted will be able to potentially infect humans. Depending on the gene inserted, the effects will be different. Accidental exposure to this material without a promoter region will have negligible impact on human health. Accidental exposure when already cloned in a plasmid, with a constitutive promoter before it, may potentially have a localised effect. However, there will be no spread to other cells as the virus cannot replicate or infect other cells. The risk of inoculation will be minimised, as work will be carried out under CL2 conditions.

Virus will be produced in mammalian cells when deliberately introduced in genomic form, but there is a negligible chance of this being introduced to susceptible hosts. It is unlikely that the GM viruses with tagged/modified/deleted genes would be any more hazardous than the unmodified viruses as our experiments are not designed to enhance function. None of these manipulations can increase virulence or stability and CL2 is therefore appropriate.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All of the cell lines to be utilised are well characterised or authenticated with a low risk of endogenous infection with a biological agent presenting no apparent harm to laboratory workers and which have been tested for the most serious pathogens and as such will pose minimal risk to both human health and the environment. This risk is not going to be greatly increased by the addition of the genes of interest. Although expression of certain genes may be expected to be toxic to the expressing cells, there is no expectation that neighbouring cells or the environment will be affected or that proliferation of the cell will result. The use of inducible systems provides an extra layer of safety allowing the expression of the genes of interest in a controlled fashion.

Activity

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

E. coli strains are especially disabled and have a negligible chance of surviving in the environment as well as a negligible risk of such release occurring. Disinfection using solutions of phenolic compounds (e.g. Virkon) will achieve 100% kill, preventing these GMOs from reaching the environment beyond the lab. Solid contaminated waste is disposed of through autoclaving and landfill disposal. There are multiple autoclaves available in the department, thus there are alternatives available if the regular autoclave is out of service. If disinfection/autoclaving were to fail for any reason, the E. coli strains used are highly attenuated and will not survive in the environment. The inserts contained within the plasmids pose no hazard to the environment.

Mammalian cells used are well characterised or authenticated and as such will pose minimal risk to both human health and the environment. Liquid waste is inactivated using solutions of phenolic compounds (e.g., Virkon), which will achieve 100% kill, preventing these GM cells from reaching the environment beyond the lab. Solid contaminated waste is disposed of through autoclaving and landfill disposal.

Viruses used in this study (lentivirus vector and other viruses) do not pose a hazard to the environment. Handling of these viruses under CL2 conditions as described above is sufficient to control any risk of infection.

All liquid waste is inactivated using either chemical treatment Virkon, Perasafe or Chloros (hypochlorite) under the manufacturers’ validated conditions. Liquid waste will be treated for at least 30min before discarding. - Effectively 100% kill.

Solid wased is autoclaved using validated and recorded temperature cycles. Disposable plasticware is double bagged and stored in a container in a CL2 location until autoclaved. The department has multiple autoclaves available, thus there are alternative available if the regular autoclave is out of service. As a contingency, solid waste will be soaked in Virkon if the autoclaves have broken down. - Effectively 100% kill.

Surface contamination in safety cabinets is cleaned using 70% ethanol & UV irradiation. - Effectively 100% kill.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
The Department Biological Safety Committee approved the related risk assessments for this work with corrections from the research group.

**Project Ref** 43/21.3

- **Regulation of innate immune responses by host cell intrinsic signalling**

- **Class**: 2
- **Culture Volume**: < 1 L
- **Non-GMM Consent Granted**: Yes

**Historical Significant Changes**

- **Historical Date of Additional Info**: 23/05/2021

**Project Additional Information**

**Purposes of the contained use**

The aim of the project is to understand how pathogens interact with pattern recognition receptors (PRRs) of the innate immune system. PRRs initiate immune responses by binding to conserved pathogen associated molecular patterns (PAMPs) and damage associated molecular patterns (DAMPs). These ligation events drive the production of...
interferons, cytokines and chemokines from the PRR-expressing cells to initiate the immune response to pathogens or damaged tissues. We are specifically interested in the detection of foreign and self nucleic acids by intracellular PRRs. The sensing of DNA and RNA by these receptors is essential for the type-I interferon response to virus infection and is implicated in the pathogenesis of multiple auto-inflammatory and auto-immune diseases. To study the interactions between host cells and pathogens we will use mammalian and avian cell lines and infect them with DNA or RNA viruses. These viruses will activate DNA or RNA sensing PRRs and initiate the downstream signalling pathways that we are studying. PRR signalling, downstream of the receptors, relies on a combination of adaptor proteins and kinases that propagate the signal, resulting in the activation of specific transcription factors that drive the expression of interferons and pro-inflammatory mediators. Examples of specific pathways we are studying include, but are not limited to, the sensing of DNA viruses by the cytoplasmic DNA PRRs DNA-PK and cGAS, which operate via the adaptor protein STING, leading directly to activation of TBK1 kinase and the type-1 interferon-inducing transcription factors IFR-3/7 and NF-kB. We are also studying the RNA sensing PRRs RIG-I and MDA5 and how they activate the same transcription factors via the adaptor protein MAVS. These signalling pathways are regulated by several fine tuning mechanisms, particularly using the ubiquitin machinery to positively and negatively regulate PRR signalling outputs. By studying the PRRs themselves and the proteins that propagate the downstream signalling pathways we can understand how our cells and bodies sense the presence of infection. In turn, viruses make proteins that inhibit these signalling pathways in order to suppress the innate immune response and promote their survival in tissues. To study these pathways in the host and the viral inhibitors we use genetically modified viruses in which one or more of these immunomodulatory genes has been deleted or modified by genetic recombination. These techniques allow for the deletion, mutation or epitope tagging viral genes to generate viruses to be used in experiments that will explore the mechanisms and functions of these genes in inhibiting immune responses.

**Recipient or parental organism**

1. Vaccinia virus (VACV, strains WR, Copenhagen, MVA, SKV, Lister)
2. Fowlpox virus (FPV, strain FP9)
3. Herpes simplex virus 1 (HSV-1, strains 16 and 17)
4. Marek’s disease virus (MDV, low virulence strains)
5. Influenza A virus (IAV, strain A/PR/8/1934)

**Host/vector system**

pUC, pCDNA based plasmid vectors

**Origin & function**

We will use sections of genetic material (not containing open reading frames) cloned from the viruses into the plasmid transfer vectors. These vectors will be used to generate modified viruses by homologous recombination in mammalian cells that are infected with the target WT viruses.

**Evaluation of foreseeable effects**

We will generate attenuated viruses by deleting or mutating viral genes that interact (or are predicted to interact) with the host innate immune system. The deletion or mutation of such viral genes will most likely result in pathogens with equal or lower virulence than the wild-type viruses and will not alter the tropism or transmissibility.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

n/a

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

n/a

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Disposing of the viral supernatant will be done within a tissue culture hood while wearing appropriate PPE (lab coat and nitrile gloves). Virus will be inactivated in 1% Virkon before being removed from the hood. Expected 100% kill efficiency for all viruses. Solid waste is double-bagged, sealed and autoclaved. Surface contamination in safety cabinets – Virkon 1% solution will be used for 10 minutes (100% kill for all viruses), followed by wiping with 70% ethanol. Non-proteinaceous virus-containing liquid waste –
Virkon added to 1%, left >30 minutes and then disposed of - effectively 100% kill for all viruses. For virus-containing tissue culture supernatants (or other proteinaceous solutions) – Virkon 5% solution – effectively 100% kill for all viruses. Disposable plastic ware is double bagged and autoclaved - effectively 100% kill for all viruses.

The Biological Safety Committee approved these risk assessments.

Date Ackn'd 16/05/2013

CU2 Project Title T-cell signalling mechanisms. Over-expression or down-regulation of the target genes in cell lines and primary cells using transfection

Class 2

Culture Volume < 1 Litre

Non-GMM Consent Granted

Project notified under transitional arrangements N

Historical Significant Changes transferred from GM678 16/05/2013

Project Additional Information

Purposes of the contained use

The nature of T-cell surface receptors (TcR, costimulators CD28, CTLA-4, ICOS) signalling pathways responsible for regulation of T-cell activation and adhesion and motility. Our objective is to study the role of costimulators CD28, CTLA-4, ICOS, PD-1 as well as adaptor proteins SLP-76, ADAP and SKAP-55 and the kinases including ZAP70, LCK FYN and GSK3. Over-expression or down regulation of the target genes in cell lines and primary cells using transfection. T-cell function in vitro including activation, proliferation, and adhesion will be examined

Recipient or parental organism

Mammalian cells: Mammalian primary cells or cell lines are especially disabled and unable to survive or propagate outside of laboratory culture.

Host/vector system
Host Human or murine cell lines, such as Jurkat DC27, T8.1, A20, 3A9 or primary cells and other cell lines such as 3T3, 293T, phoenix cells.

Retroviral vectors (pinco, MigR1, pMX, pMDG, pMLV-GP, p8.91, pGIPZ)
Lenti-viral vector (HIV-1 self-inactivating vector SIN, pFIP)
pLKO.1 vector (lentiviral (HIV)-based plasmid)
plasmid encoding the envelope plasmid derived from vesicular stomatitis virus (VSV) G protein

Cells will be transfected with retroviral or lentiviral plasmids and viral supernatant harvested (max vol 30ml/vector/transfection) and used to infect target T-cell lines or primary T-cells. After infection twice target cells are harvested and used for functional assessments. Max culture vol of target cells in 100ml/cell type, if viral supernatant is frozen for stock, viral supernatant is aliquot in small vial (~2ml/vials) and stored in allocated areas or boxes in -80 degree freezer. 200 µl will contain approximately 1 x 10^6 TU/ml

For example, shRNAs will be cloned into the pLKO.1 transfer vector which is compatible with standard two plasmid (packaging vector with rev gene and envelope vector) or a three plasmid (packaging vector without rev gene, envelope vector, and rev expression vector) packaging systems. In the case of MISSION shRNA, the viral particles cannot be propagated and are replication incompetent.

A three plasmid transient transfection system will be used to generate recombinant replication-defective retroviruses 293T cells, a human cell line carrying SV40 T cell antigen will be transfected with (a) An HIV-1 self inactivating vector (SIN) cDNAs encoding the genes of interest will be cloned into the HIV-1 derived SIN vectors, which have a deletion in the U3 region of the 3’ long terminal repeat (LTR) of the DNA used to produce the vector RNA. During reverse transcription this deletion is transferred to the 5’ LTR and abolishes the transcriptional activity of the LTR and as a result the production of full-length vector RNA in transduced cells is abolished (b) An HIV-1 derived retroviral sequence encoding viral gag/pol tat and rev genes, from which the virulence genes vif, vpr, vpu and nef have been deleted and (c) a plasmid encoding the envelope plasmid derived from vesicular stomatitis virus (VSV) G protein. This is a well defined lentivirus system that is in use under our GM centre No 678.

Origin & function
The genes targeted are involved in aspects of cell signalling, activation and proliferation and are not expected to be toxic.
None of the proteins are known oncogenes and are therefore highly unlikely to foster tumour progression.

Evaluation of foreseeable effects
Mammalian primary cells or cell lines are unable to survive or propagate outside of laboratory culture.

The genes targeted are involved in aspects of cell signalling, activation and proliferation and are not expected to be toxic
None of the proteins are known oncogenes and are therefore highly unlikely to foster tumour progression.

The vectors used will be self inactivating (SIN). A deletion inactivates transcription from the proviral LTR, so reducing the potential for transcriptional activation of cellular genes and also prevents mobilization of any RCL. However as the virus integrates into the host cell DNA there is still a potential for insertional mutagenesis to occur.

A plasmid encoding the envelope protein from vesicular stomatitis virus envelope protein G (VSV-G) increases the host cell range/tissue tropism and makes it permissive for human cells, including quiescent cells. This feature means that there is a risk of infection through contact/aerosol transmission in addition to the normal HIV percutaneous route. Such particles are also physically more stable.

The genes or other sequences of interest will be delivered by an integrative process leading to potential long-term expression for the life of the target cell. The results of such expression for most of the sequences will not be severe and will be limited to the cells targeted and no further.

VSV-G enables the vector virus to infect a wide variety of mammalian cells. There may also be enhanced environmental stability. However, the viruses are replication disabled, they cannot produce progeny virus and so cannot spread to the wider human population or other animals. The possibility of RCL being generated and released is negligible.
The MISSION TRC lentiviral particles are replication incompetent. Non of the modifications will alter the broad properties of the vectors. They will remain replication disabled and so are biologically contained.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Project Ref 77/01.2
GENETIC MANIPULATION OF VACCINIA VIRUS AND OTHER CLASS 2 POXVIRUSES

Fundamental research in virology and vaccine development.

Recipient or parental organism

The genetically modified viruses will have characteristics either similar to the parent virus, or of reduced virulence.

The expression of foreign genes by vaccinia virus will not increase the hazard posed by the virus and often the insertion of these recombinant viruses is associated with a reduction in virulence because the gene is inserted into a site in the virus genome that affects virulence. The foreign proteins pose no toxic hazard and are designed to promote appropriate immune responses that will be beneficial in preventing or reducing disease caused by infectious disease and cancer.

The deletion of existing vaccinia virus genes will either be neutral or, more often, decrease virus virulence. Removal or genes affecting the ability of the virus to be released from infected cells and spread to other cells is accompanied by a dramatic reduction in virulence. Removal of genes encoding proteins that aid virus escape from the immune system also reduces virus virulence since the virus infection is better recognised and cleared by the host immune response.

Other poxviruses to be used include the orthopoxviruses cowpox and camelpox virus and the yata poxviruses tanapox and yaba-like disease virus. Cowpox virus is similar to, and often confused with, vaccinia virus and poses a similar hazard. Camelpox virus is a less well characterised orthopoxvirus that causes a severe disease in camels but does not cause disease in man. Tanapox virus and yaba-like disease virus are simian viruses that have caused rare zoonoses in man. Such zoonoses usually produce a single lesion that heals without adverse consequence.

Host/vector system

Vaccinia virus is the live vaccine used to eradicate smallpox and has been used widely as an expression vector since 1982. For cowpox virus, yaba-like disease virus and tanapox virus see comments above under section 7. All these viruses will be treated as for vaccinia virus and pose similar or reduced risk to man. All viruses will be housed in our category 2 containment laboratory and will not be released from that laboratory. The genetic manipulation of all these viruses requires construction of plasmids in bacterial vectors (level 1 GM work).
### Origin & function

Each genes to be deleted from or inserted into vaccinia virus or other class 2 poxviruses are described in detail in the accompanying document.

In summary, the genes to be deleted from these viruses encode proteins that either enable the virus to be released better from infected cells, or affect interactions with the host immune system. The latter group of proteins interfere with the host response to infection, and the deletion of these genes therefore may reduce virulence and enhance immunogenicity.

Foreign genes to be expressed in these viruses are either marker proteins that enable the virus to be detected in cell culture, such as β-galactosidase or green fluorescent protein, or antigens from other micro-organisms against which an immune response is sought. These latter proteins are not toxic but are important targets for immune responses that help prevent or reduce disease.

### Evaluation of foreseeable effects

The foreseeable effects of deleting genes from vaccinia virus and other class 2 poxviruses are to make the virus less fit, less virulent and less able to cause disease and survive in nature. These virus genes selected encode proteins that aid virus dissemination from infected cells or to aid virus escape from the immune system. It follows that deletion of such genes, will reduce virus virulence and fitness. The foreseeable effects of expressing foreign genes in vaccinia virus are to make the virus a candidate vaccine for different infectious diseases or cancers. The foreign proteins to be expressed pose no toxic hazard and the immune responses to them are likely to be beneficial.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All material from our virus containment room will be autoclaved, or incubated in 1% (weight/volume) virkon overnight to ensure no infectious virus remains.

---

The local safety committee reviewed and approved the proposed work at category 2 containment in October 2000.
This programme of work will use lentivirus vectors to aid analyses of the functions of viral proteins involved in poxvirus entry, morphogenesis and immune modulation as well as human orthologues of these proteins. The lentivirus vector system will enable the efficient infection of cells grown in tissue culture with lentiviruses expressing cellular and viral proteins.

Recipient or parental organism

Lentiviruses will be produced by transfection of the SV40 transformed human embryonic kidney cell line HEK 293T. Human and rodent cells grown in tissue culture will be the recipients of the lentivirus GMOs. These cells will include (but are not restricted to) BSC-i, HeLa, and TK-143 cells and other human or rodent (e.g. NIH 3T3) cell lines supplied by ATCC. In addition, some primary cells will be used including rat embryo fibroblasts. After trypsinisation these cells will express the transgene but will not produce or contain any lentiviruses and so are non-infectious.

Host/vector system

The vectors are based on mutated lentivirus genomes, pseudotyped with a vesicular stomatitis virus (VSV) envelope glycoprotein (VSV-G) allowing infection of a broad
range of cell types and containing a gene for puromycin resistance to allow the selection of expressing cells. The vectors are pCMVR8.91 (encodes the lentivirus genes), pMD (encodes VSV-G), pdlNotI’MCS’R’Pk and pdlNotI’nPk’MCSR, (each contain a multiple cloning site to allow cloning of gene of interest fused to a N- or C-terminal V5 epitope tag respectively, and a puromycin resistance gene).

Origin & function

1. Poxvirus proteins involved in entry or morphogenesis
A33, A34, A36, A56, A56, B, D, E2 and K2 each have a role in the entry or exit of vaccinia virus. Each will be cloned into the lentiviral vector.

2. Poxvirus immunomodulators
K7, B14, Ni, A46, A52, A49, C6, A41, A44, B15, B18, and v-GAAP are all non-essential for virus replication in vitro but have roles in altering the host response to infection in vivo. Each of these will be cloned separately into the lentivirus vector. In addition, uncharacterised poxvirus proteins, which have a putative immunomodulatory role, may be expressed in this way in the future.

3. Cellular orthologues of poxvirus proteins
Many poxvirus proteins have cellular orthologues, the function of some of which is not yet fully understood, and each of these may be cloned into the lentivirus vector. This includes the newly characterised human Golgi anti-apoptotic protein (h-GAAP), which shows 73% amino acid identity to the vaccinia virus v-GAAP (Gubser et al., 2007. PLoS Pathogens 3:ei7).

Evaluation of foreseeable effects

Each lentivirus vector produced will be able to infect cells, but is not able to replicate in those cells and so cannot spread to new cells. These vectors are therefore classified as replication-defective. The nature of the foreign proteins expressed by these vectors is not likely to affect the hazard group of the parent vector and will only be expressed from the infected cell. Lentivirus vectors provide an efficient means to transduce genes into human cells. In theory, these genes can be transduced into laboratory personnel working with the packaged viruses, however, the virus is replication-defective, and so an ongoing infection with these viruses is not possible. The ability of h-GAAP to block apoptosis means that any cells transduced with h-GAP? would be resistant to cell death, which would in theory increase the chance of those cells becoming cancerous. Because the lentivirus is replication-defective, there is a very low probability that infection will occur in stem cells with the potential to become cancerous. This programme of work will not include viral oncogenes which have multiple oncogenic activities such as the SV40 T antigen, nor will it include clusters of genes such as HPV16 E6-E7. Genes encoding toxins will not be included in this work.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid Waste
Treated with 1% final concentration of Virkon disinfectant for a minimum of 30 minutes at room temperature. 100% effective kill rate as specified by manufacturer (http://www.antechn.com/virkongd.html) Treated waste will then be disposed of via the sink.

Solid Waste
Waste will be autoclaved using a cycle of 121 deg C, 20 minutes. Treatment is monitored via a chart recorder attached to the autoclave and validated by an annual 12 point thermocouple test. Once autoclaved the waste will join the hospital clinical waste.
Following the discussion of your proposal the following amendments are requested prior to approval:

1-25: Remove the sentence; "Any other viral gene subsequently implicated in morphogenesis may also be included.” The Committee recommend that further genes be considered on a case by case basis in new (Form C, if appropriate) submissions.

1.3: The sentence; The ability of h-GMP to block apoptosis indicates that it may be a proto-oncogene and contribute to cancer” is too broad and needs clarification.

3.8: Tick declaration box.

Agreed: Class 2, Containment Level I IC reference number: GMIC-01698.1

Please enter comments on the GM safety committee on the risk assessment

Please enter comments of the GM safety committee on the risk assessment
The aims of the study are to investigate the mechanisms of replication of RNA viruses and how they subvert the cellular machinery to achieve this goal. Recombinant viruses will allow us to analyse this process in greater detail and is fundamental to this research strategy and its aims. The long term aims are the improvement of fundamental knowledge in the area of RNA virus replication and the future development of vaccines and antivirals.

The GMOs are viruses derived from DNA plasmid copies of RNA viruses, specifically non-segmented RNA viruses from the Mononegavirales order such as Measles virus. The target viruses are all classed as ACDP2 or lower and will not include ACDP3+ or SAPO restricted pathogens from this Order. The GMOs will also include pseudotyped replication defective lentiviruses that are capable of transducing mammalian cells to overexpress viral or host genes e.g. to over-express genes relevant in studying pathogenesis. The recipient hosts for these GMOs are mammalian cells (primary derived or immortalised cell lines) and/or mice (lab-strains or transgenic derivatives). Bacteria (commercial non-pathogenic strains) will also be used to replicate the DNA clones prior to manipulation.

The vector system for these studies is based on the use of full length DNA clones of RNA virus genomes. The non-segmented RNA virus genomes of ACDP2 (and lower) pathogens are cloned downstream of promoters that can drive transcription of a genome like RNA. This RNA, in the correct context, and with the correct support, is capable of producing infectious virus. The plasmid backbones used for this system are based on standard commercially available versions. The lentiviral system for over-expression of chosen genes is based on the commercially available ViraPower based system. A replication defective and truncated HIV1 genome is used as a vector to generate pseudotyped particles capable of infecting (non-productively) target cells. Integration and selection is anti-biotic mediated however, no nascent virus can be produced.

Origin & function

Recipient or parental organism

The GMOs are viruses derived from DNA plasmid copies of RNA viruses, specifically non-segmented RNA viruses from the Mononegavirales order such as Measles virus. The target viruses are all classed as ACDP2 or lower and will not include ACDP3+ or SAPO restricted pathogens from this Order. The GMOs will also include pseudotyped replication defective lentiviruses that are capable of transducing mammalian cells to overexpress viral or host genes e.g. to over-express genes relevant in studying pathogenesis. The recipient hosts for these GMOs are mammalian cells (primary derived or immortalised cell lines) and/or mice (lab-strains or transgenic derivatives). Bacteria (commercial non-pathogenic strains) will also be used to replicate the DNA clones prior to manipulation.

Host/vector system

The vector system for these studies is based on the use of full length DNA clones of RNA virus genomes. The non-segmented RNA virus genomes of ACDP2 (and lower) pathogens are cloned downstream of promoters that can drive transcription of a genome like RNA. This RNA, in the correct context, and with the correct support, is capable of producing infectious virus. The plasmid backbones used for this system are based on standard commercially available versions. The lentiviral system for over-expression of chosen genes is based on the commercially available ViraPower based system. A replication defective and truncated HIV1 genome is used as a vector to generate pseudotyped particles capable of infecting (non-productively) target cells. Integration and selection is anti-biotic mediated however, no nascent virus can be produced.
The genetic material (viral or cellular) will be sourced from biological isolates of these RNA viruses (Mononegavirales of ACDP2 and lower classification only), from mammalian cell-lines, from primary cell cultures or through in vitro commercial genetic synthesis. All ethical approval for the receipt of the relevant clinically associated samples will be in place prior to the commencement of work. Importantly, the genetic material will be used to generate recombinant RNA viruses with equivalent or reduced pathogenesis relative to the parental strain. Also, the pseudotyped lentiviruses are incapable of producing productive progeny virus. Recombinant tagged/mutant viruses will be used to determine the molecular basis for pathogenesis both in vitro and in vivo (in mice only).

Evaluation of foreseeable effects

Recombinant viruses: Only ACDP2 class 1 and 2 pathogens from the Mononegavirales order will be 'rescued'. Work with ACDP3+ and SAPO restricted pathogens will not be carried out. The viruses rescued will be designed in such a way as to not increase pathogenesis, relative to the parental strain. This will obviously be confirmed using in vitro tests under ACDP2 conditions in the lab. The foreseeable effects to the organism of such mutations and/or addition of tags (fluorescent etc) are therefore to either maintain its virulence or attenuate it. The risks to the environment and public are therefore effectively zero. This bears true for the recombinant lentiviruses as well as these are replication competent and incapable of producing nascent virus after the primary infection step.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Transgenic mice will be used for some of the proposed work, where virus is used to infect mice or transgenic mice. These will be held in a secure Animal facility, with the use of isolators to house the infected mice. Agreed procedures will be in place for the removal of carcasses.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation - full CL2 applied

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GM MeV in waste will be inactivated with 1% Distel (formerly Trigene) or 1% Virkon, which has been shown to be an effective agent for inactivation of a wide range of enveloped viruses including Measles. Measles is also susceptible to 70% Ethanol.

All biological waste generated in the IBR is then autoclaved at 135°C for 15 mins under pressure before removal as clinical waste by licensed contractors. Nothing is released to the environment. All autoclave runs are monitored and recorded by trained staff - any failed runs are treated as infectious and re run.

Is an emergency plan required according to regulation 20? [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [Y]

Please enter comments on the GM safety committee on the risk assessment

Generation of recombinant Measles virus from cloned cDNA: The assessment stated that "At no-point" will gain of function viruses be intentionally generated i.e. those with increased scope for pathogenesis, replication, broader host-range*. A reviewer queried this, and asked how would the researcher identify what changes might potentially increase the scope for pathogenesis: "Although in general, certainly, one would generally expect mutations to reduce 'fitness' of the virus, might there be instances where this is not the case? I would suggest you include a bit more discussion around this issue; presumably, faster replication/spread, greater infectious yield of a novel GM derivative would become apparent in your initial in vitro experiments with the virus - so you could get an early indication of whether 'fitness' were unexpectedly increased."

This was addressed within the assessment.

02/03/2022
The objective of this project is to enhance fundamental understanding of the neuropathogenesis of RNA viruses by determining genetic loci in viral genomes which determine phenotypic properties of neurotropic viruses.

Recipient or parental organism:
Semliki Forest Virus, Bunyamwera Virus and Theiler's Virus.

Host/vector system:

cDNA derived, Semliki Forest Virus, Bunyamwera Virus, Theiler's Virus.

Origin & function

Specific gene loci will be targeted in Semliki Forest Virus, Bunyamwera Virus, Theiler's Virus. These sequences may be swapped between different natural isolates that have varying phenotypes or may be mutated or deleted. Any transfer of genetic material will only be between different strains of each virus, there will be no gene transfer between the different species.

Evaluation of foreseeable effects

Most of the genetic changes that will be introduced into the viruses can be expected to attenuate fitness. However in some cases changes in the sequences of avirulence virus cDNAs which change the sequence to that of a virulent virus cDNA would be expected to increase virulence but the changes are such that it would be only to a level seen in wild type isolates. These engineered recombinant viruses would only have sequences found in natural virus isolates, they are therefore considered highly unlikely to have increased virulence compared to that of wild type isolates. The viral envelope glycoproteins and capsid proteins which are the major determinants of host range and cell tropism will not be changed in these studies; host range and cell tropism are therefore unlikely to be altered. The changes are not expected to significantly alter susceptibility to host defence mechanisms. There are no vaccines or treatments available for these viruses and so effects of the modifications on these aspects are not applicable.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

**Project Additional Information**
Purposes of the contained use

To investigate how Vaccinia virus (VACV) and Cowpox virus (CPXV) replicate and interact with the host’s immune system, leading to a better understanding of VACV genes that affect virulence. This work requires genetic manipulation of VACV and CPXV including the deletion and modification of genes to investigate their role in viral virulence.

Recipient or parental organism

Vaccinia virus
Cowpox virus

Host/vector system

Viral host with plasmid vector

Origin & function

Genes likely to affect the host’s response to viral infection will be deleted or mutated. In particular, genes that may be involved in cytoskeletal rearrangement or the modulation of the ubiquitin / proteasome system. Mutations involve minor alterations to amino acid sequence to identify functional domains. Standard non-harmful marker genes (such as E. coli gpt, β-gal, luc or enhanced fluorescent proteins) and epitope tags (such as Flag, c-myc, His or HA) will also be inserted.

Evaluation of foreseeable effects

The genetically modified viruses produced in this work are not expected to have increased virulence, pathogenicity, extended tissue tropism or host range or altered susceptibility to host defence mechanisms when compared to wild type strains and in many cases viruses will be attenuated.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids (eg plasticware such as pipettes, flasks, tubes etc and agar plates) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or heat treatment or via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge to drains.

Sharps (in sharps bin, eg needles, syringes, scalpels) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), dispose via clinical waste stream for heat treatment.

Animal bedding and carcasses – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), dispose of carcasses via clinical waste stream for incineration and bedding via clinical waste stream for heat treatment or via the industrial (black bag) waste stream for landfill.
Degree of kill:
Autoclaving - effectively 100% kill (annual validation using 12 point thermocouple of worst case loads)
Heat treatment or Incineration – not applicable, all waste is autoclaved prior to disposal by heat treatment or incineration.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form  

Tick to confirm that you have attached a risk assessment to this form  

Tick if you are claiming exemption from disclosure for section of the risk assessment  

Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM to control the risks to human health and safety and to the environment.

**Project Additional Information**

**Purposes of the contained use**

Ticks carry a number of infections of importance in medicine and veterinary medicine. Little is known about how tick cells and ticks respond to microbial infections, how microbes persist in ticks for long periods of time and whether responses to one microbe affect responses or the outcome of infection to another microbe. This project will use a genetically modified tick-borne virus, Langat virus (LGTV) and a genetically modified tick-borne bacterium, Borrelia burgdorferi to investigate the responses of tick cells and ticks to infection, how one infection affects another and how and where these infections persist within ticks.

**Recipient or parental organism**

For LGTV: Disabled, commercially available E. coli strains and eukaryotic cell lines.

**Host/vector system**

LGTV sequence with changes in the replicase genes or insertion of reporter gene sequences in standard bacterial plasmids containing antibiotic resistance genes.

Non-human eukaryotic cells infected with LGTV, LGTV mutants or LGTV containing inserted reporter genes.

Plasmid JAH2 derived from the pBLS590 B. burgdorferi - E. coli shuttle vector. pJAH2 contains the gene for kanamycin resistance and a reporter gene driven by a bacterial ‘erp’ promoter.

**Origin & function**

LGTV containing a reporter gene and B. burgdorferi containing a reporter gene will be used to monitor infection or co-infection of eukaryotic cells, arthropods and rodents.

**Evaluation of foreseeable effects**

The LGTV structural proteins will not be changed; there should thus be no change to the tropism or host range of this virus. LGTV is not associated with human disease and has been used as a vaccine for other tick-borne encephalitis viruses. LGTV is not known to be present in the UK environment. It is not known whether it could be naturally sustained here if released, however release from our laboratories would be very unlikely to result in infection of ticks (naturally infected by blood meal) or vertebrates (naturally infected by bite). LGTV is not on the SAPO list. Borrelia causes borreliosis (Lyme disease) in humans. Laboratory acquired human infections have not been reported.

Infection can be treated with antibiotics. This bacterium is present in the UK environment. The GM bacterium would have no selective advantage for survival and establishment in the environment and if released from our laboratories would be very unlikely to infect ticks or vertebrates (natural route of infection is by bite). No harmful properties have been attributed to the inserted reporter genes.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste disposal procedures and protocols for biological material are in place in the Virology Towerblock, Summerhall Square. All biological material is inactivated by autoclaving or incubation with chlorine (as appropriate) before being disposed of through established waste disposal channels.

**Project Additional Information**

**Purposes of the contained use**

The aim of the experiment is to analyse the effects of an inhibitor of the transcription factor NF-kB encoded by an African swine fever virus (ORF A238L) on Sindbis.
virus-induced apoptosis. The inhibitor is encoded by ORF A238L from BA71V and ORF 5EL from Malawi isolates of ASFV. It is cloned into a replicon of Sindbis virus designated SinRep5 (Invitrogen). The replicon encodes Sindbis non-structural proteins and an SP6 promoter that allows transcription of the Sindbis genes and the gene of interest. Recombinant RNA produced from the replicon is transfected into BHK cells for high level expression of protein. The RNA from this replicon can be transfected together with a defective helper, DH26S or DHBB, which provides the structural proteins in trans. The transfected cells produce pseudovirions, which can be used to infect a second cell type, such as primary vascular endothelial cells. The pseudovirions only undergo one round of infection, because they should not contain RNA for the helper virus encoding the structural proteins. Infection with pseudovirions enables primary cells which are difficult or impossible to transfect to produce high levels of protein from the gene of interest. This is useful for investigating co-associating proteins, biological activity and localisation of the protein in the cell and to study mutated protein. Vascular endothelial cells are easily infected by both Sindbis virus and ASFV, and undergo NF-κB activation and apoptosis. Phenotypic characterisation of these highly differentiated cells will determine the mechanism of action of the IkB homologue without the influence of other ASFV genes.

Recipient or parental organism

Sindbis virus naturally infects mosquitos and other animal species such as birds. The risk to humans is low if the virus is handled in appropriate safety cabinet. The risk of spread is minimal in the absence of available competent mosquito vector. There should be no risk of altered infectivity with our recombinant vector.

There is a risk that fully infectious virus will be generated by recombination events during RNA replication. Recently, it has been shown that there is a low level of infectious virus produced where both structural and non-structural RNAs are packaged. The titre of this type of virus increases with subsequent passaging (Lu and Silver 2001) Transmission of replication-defective sindbis helper vectors encoding caspid and envelope proteins J. Virol. Methods 91: 59-65) Moreover, a report has appeared in the literature that recombination of the two RNAs can take place resulting in a replicon coding for the non-structural and structural proteins as well as the gene of interest (Herrmann et al, 1998 BiocheM Biophys Res Comm 253: 524-531). The risk of a recombinant replication competent Sindbis virus containing the ASFV IkB homologue is still considered to be of low risk to humans and the environment.

Host/vector system

RNA from SinRep5 plasmid (Invitrogen) or the recombinant SinRepA238L plasmid are cotransfected in BHK cells or primary cultures of porcine aortic endothelial cells (PAECs). The plasmid SinRep5 contains the SP6 promoter, non-structural proteins 1-4 and a subgenomic promoter. The DH26S helper virus is derived from a naturally occurring defective RNA and the sequence upstream of the subgenomic promoter is rearranged with no open reading frame. DHBB is a helper that gets packaged very, very poorly.

Origin & function

The ORF A238L is from the BA71V isolate of African swine fever virus (ASFV) and the ORF 5EL is from the Malawi isolate of ASFV. The intended fuction of the gene is unknown, but it may delay apoptosis and prevent inflammation in host cells. It has been shown to bind to the transcription factor NF-κB and to protein phosphatase 2B, also called calcineurin. It inhibits expression of genes controlled by NF-kB and by the transcription factor NF-AT.

Evaluation of foreseeable effects

The effects of A238L/5EL expression by Sindbis virus in vascular endothelial cells will be assessed by FACs analysis, RT-PCR, Western blotting and co-immunoprecipitation. It is expected that A238L will bind to NF-κBp65 and prevent expression of NF-kB dependent genes. This will result in inhibition of secretion of cytokines, surface expression of adhesion molecules and alter expression of apoptotic factors.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No animals or plans will be used. Animal cells in culture will be destroyed after the experiment with Stericol and autoclaving.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None for Class 2.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Waste plastics and glassware is autoclaved. The plastics are then incinerated and glassware washed and sterilised. Waste liquids are treated with Stericol before sterilisation with alkali in our sewage treatment.

The safety committee considered that a Class 2 risk assessment was appropriate.

Historical Significant Changes

Historical Date of Additional Info
### Purposes of the contained use

The objective of the study is to induce early immunity for the protection against FMDV through the enhancement of innate and passive immunity using defective (E1 and E3 sites deleted) human recombinant adenoviruses type 5 expressing various interferons, heavy and light chains of FMDV neutralising Mabs, FMDV structural or non-structural proteins or Sh RNAs (short hairpin RNAs) directed against the highly conserved sequences of structural and non-structural proteins of FMDV virus. A) Interferons are required for production of innate immunity, b) Mabs are required for humoral antibody, c) Structural and non-structural proteins are required to generate adaptive immunity and d) Sh RNA will provide the anti virals for the protection against FMDV infection.

### Recipient or parental organism

- The recipient is human adenovirus 5. It produced from the pAd/CMV/V5/ΔE1/ΔE3-DEST or pAd/PL/ΔE1/ΔE3-DEST expression vectors, is replication-incompetent in any mammalian cells that do not express the E1a and E1b proteins. The recombinant viruses could grow only in 293 A human embryonic kidney cells in tissue culture where E1 has been supplied.

### Host/vector system

- Adenovirus vectors produced from a) the pAd/CMV/V5-DEST and Block iT™ Adenoviral expression system, Invitrogen, USE, b) pAd/PL-DEST is obtained from Adeno Quest system, Q Biogen, Canada.

### Origin & function

- The genetic material involved is the recombinant adenovirus, interferon genes, heavy and light chains of FMDV neutralising Mabs, FMDV structural or non-structural proteins or Sh RNAs (short hairpin RNAs) directed against the highly conserved sequences of structural and non-structural proteins of FMDV virus.

- Interferons are required for production of innate immunity, b) Mabs are required for humoral antibody, c) Structural and non-structural proteins are required to generate adaptive immunity and d) Sh RNA directed against the highly conserved sequences of structural and non-structural proteins of FMDV virus will provide the anti virals for the protection against FMDV infection.

The recombinant adenoviruses will be amplified in 293 A HEK cells allowing (by supplement of E1) for the propagation of these recombinant constructs and titrated. Titrated viruses will be transduced in to the (bovine thyroid) BTY/IBRS-2 cells (no viral replication) and then challenged with various serotypes of FMDV 24 hours later. These recombinant adenoviruses will also be used to immunise cattle by an appropriate route (parenteral/nasal) and challenged with one of the seven sterotypes virulent FMDV 24 hours later. Different clinical samples like blood, nasal and ocular secretions will be collected prior to immunisation and at a regular interval during the period of study. The anti-viral activity of the various constructs will be studied by different virological and immunological assays.

### Evaluation of foreseeable effects

- The ability of the GMMs to extend the tissue tropism or host range of the AD5 vector is not expected to be increased by manipulation(s) to be carried out in this study. No toxicity is expected to recipient. There is no risk at all in case of this replication deficient adenovirus containing different FMS, FMD Mab constructs and ShRNAs and may be considered as class 1 containment level. However, the vector expressing the interferon (cytokines) may represent a risk to human health. In the extremely unlikely event of accidental inoculation there is possibility of accumulation of cytokines locally, mainly in the upper respiratory tract and the eye where they might have inflammatory or other immunological consequences. Therefore, this may be considered as class 2 containment levels.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Decontamination of all liquid and solid waste in the class II hood should be done in 2% FAM. Persons handling the interferon - expressing viruses to wear gloves; eye protection to be worn when administering virus to animals.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

The local ACGM safety committee agreed that the only potentially hazardous constructs were the interferon-expressing recombinant viruses, and the potentially harmful nature of the expressed proteins from these constructs are the reason for this project being raised from the normal class 1 for helper cell-dependent human adenovirus 5 to class 2.

Project Ref 53/08.1

Date Ackn’d CU2 Project Title

10/09/2008 Use of Lentivirus-based vectors to study the function of proteins from animal virus

Class Culture Vol Class 2 Culture Volume Class 3-4

Class 2 < 1 Litre
For all the animal pathogens that are the focus of research at the institute, there is a common need to be able to study the roles of viral protein in isolation, to identify the host proteins with which the viral proteins interact, if any, and to characterise the role that interaction plays in the viral life cycle. This program of work involves the production of lentivirus-based pseudovirions to define the functions of proteins expressed by African swine fever virus, rinderpest virus, peste des petits ruminants virus, classical swine fever virus or other virus causing disease in livestock. The work proposed will use these vectors in several different approaches. These are: firstly to use the vectors to transduce cells and thereby construct cell lines expressing the virus gene of interest. These cell lines will then be used in various functional assays as appropriate, including the affinity purification of viral proteins and the characterisation of co-purifying host or viral proteins by proteomic systems. Secondly, the vectors will be used to express interfering RNAs targeted against either specific virus or host cell genes in cell lines. These cell lines will be used to study the effect of knocking down expression of either virus or host genes on the replication of the respective virus or the modulation of host cell functions caused by virus infection. Thirdly, the vectors will be used to construct cell lines overexpressing individual host genes which are identified as being targeted by virus infection.

Recipient or parental organism

The recipient vector is a replication deficient lentivirus-based vector. This is comprised of a transfer vector consisting of proviral cDNA from which virus coding sequences have been deleted or replaced with a genetic insert. The packaging system consists of three helper constructs that express viral genes needed to generate infectious virus particles (two plasmids for the retroviral genes and a third to express vesicular stomatitis virus surface glycoprotein G (VSV-G); VSV-G is required to replace the viral env protein and enables the resulting pseudovirions to enter most mammalian cells including non-dividing cells. The generation of replication competent virus (RCV) and insertional mutagenesis as a result of provirus integration pose the major safety issues when handling retrovirus vectors. Although transformation with lentivirus-based vectors has not been seen when using lentivirus-based systems in a broad range of in vitro and animal studies, some reports indicate that tumours can arise following administration of some lentivirus-based vectors. The woodchuck hepatitis post-transcriptional regulatory element included in some vectors is thought to be associated with these tumours. The lentivirus-based vectors are replication incompetent. Generation of replication competent lentiviruses through recombination is a very unlikely event since it would require simultaneous recombination between three plasmids during the intial transfection. Further safety is provided by the modification of the insertional elements (deletion of most of U3 region of 3’ LTR) to prevent reversal of the process, creating a so-called self-inactivating vector.

The animal virus coding sequences to be inserted in the lentivirus-based vectors include those for proteins involved in replication and in modulating host functions, including immunomodulatory genes. If individuals were accidentally infected by such constructs, and inserted genes integrated into stem cells, there is a possibility that the function of these cells may be affected. For example, the host immune system may be suppressed in the affected cells. A more likely event is the local entry of the GMOs into cells in exposed tissue (e.g. eyes, subdermal tissues exposed by cuts or abrasions). As discussed above, integration of DNA from some lentivirus-based vectors into
host genomes may cause tumours. These risks are managed appropriately by preventing contact of personnel with large amounts of the GMOs through the work being
carried out at ACGM
level 2. The interfering RNAs expressed will be specific for individual virus genes or non-human mammalian host genes. The
sequence specificity of interfering RNAs makes it very unlikely that these would be active against human genes.

Host/vector system
The lentivirus-based vector systems that will be used include those marketed under the name ‘ViraPower’ by Invitrogen, or similar commercial and non-commercial
systems (e.g. the Stanford University Helix system or the derivatives ofpHR-SIN
CSGW(Demaison C et al. (2002) 13, 803) based on HIV-I LTR sequences that have been modified to prevent reforming of live
virus, and also to prevent deintegration of DNA sequences after integration into the target cell genome. The interfering RNAs
will be expressed using the BLOCK-IT lentiviral RNAi system from Invitrogen, or similar. This expresses sbRNAs under
control of a pol II dependent promoter.
These constructs will be used to establish a range of different mammalian cell lines.

Origin & function
The genetic material involved is the lentivirus-based vector, protein coding sequences from animal virus pathogens and individual mammalian host genes. The function of
the animal virus pathogen coding sequences is either in replication of the virus or in modulation of host cell function. In particular, animal virus pathogen genes involved in
interfering with host defence systems will be investigated. Host genes from non-human mammalian sources will also be used. These will include genes from host pathways
targeted by virus infections. shRNAs will be targeted against individual animal virus genes or non-human mammalian genes. The genes to be used do not have known oncogenic
properties. Separate risk assessments will be prepared for each category of use of lentiviruses that is for each animal virus pathogen as well as for different types of host
gene or interfering RNA.

Evaluation of foreseeable effects
The individual animal virus pathogen genes to be expressed have a variety of functions in replication and in manipulation of host cell functions, particularly in inhibition of
host defence pathways such as the interferon pathway. Some of the genes to be expressed have no known function. The genes are from animal virus pathogens which are
not oncogenic and non of the genes to be studied have known oncogenic activity. They are therefore considered not to pose a risk significantly above that of the
lentivirus-based vector alone. The interfering RNAs to be expressed are specific for individual animal virus pathogen genes or non-human host genes and there is therefore
a negligible risk that they would pose a risk to human health. There is therefore a negligible risk of an adverse effect on human health associated with the described work
when handled at class 2 containment level.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Decontamination of all liquid and solid waste will be carried out in Class II MBSC using FAM at 1 in 200 dilution.
Individuals will wear protective clothing including a back fastening gown and gloves when handling non-sealed vessels
containing lentivirus-based vectors.
There were no additional comments from the committee.

Project Additional Information

Purposes of the contained use

The vaccinia virus (VV) Copenhagen strain, VC-2, will be used as the recipient virus. Using homologous recombination, open reading frames encoding selected viral proteins will be inserted into non essential loci of the vaccinia genome. Target viruses include dsRNA viruses and other ssRNA viruses, particularly flaviviruses, alphaviruses and phleboviruses. The recombinant organism would retain its interferon resistant phenotype. In the case of dsRNA viruses, some of the proteins are supposedly acting as anti-interferon (anti-PKR) proteins and therefore will be used to rescue the replication a VC-2 E3L defective strain (vp1080, that is sensitive to interferon). Therefore, some of the proteins that will be tested would not alter the interferon resistant phenotype of VC-2, while other proteins would rescue the interferon resistant phenotype of a VC-2 E3L defective strain: hence the contained activity is regarded as class 2.

Recipient or parental organism

The vaccinia virus that would be used is the VC-2 copenhagen strain. A VC-2 derivative vp1080, which is an E3L defective virus will be used to test the anti-PKR anti-interferon activity of some of the dsRNA binding proteins of dsRNA viruses. The wild type VC-2 strain would replicate in a wide range of cell lines and can infect humans. A vaccinia virus infection is very mild and is typically asymptomatic in healthy individuals, but it may cause a mild rash and fever. The characteristics of the vp1080 strain were published earlier by Beattie et al., Journal of Virology, 1995,69: 499-505. The deletion of the E3L was found to block the replication in Vero (Monkey Kidney), HeLa (Human), and L929 (Murine) cells, but not in chick embryo fibroblasts. The blocking of the replication is attributed to the loss of the anti-PKR/interferon phenotype.

Host/vector system

The virus will be used to study protein functions in cell culture models and there would be no involvment of any animal models.

Origin & function

A Vaccinia virus infection is very mild and is typically asymptomatic in healthy individuals, but it may cause a mild rash and fever. However, skin lesions and lesions to the eyes could occur in some individuals. Infection could occur if there is exposure of mucous membranes (eye conjunctiva, lips, mouth) to virus aerosols or exposure of skin cuts or by inhalation of large quantities of aerosolized virus. This is unlikely as material will be used within a class II microbiological safety cabinet.

Evaluation of foreseeable effects

A Vaccinia virus replication is inhibited by an authorised antiviral, cidofovir (an acyclic nucleoside phosphonate). Infection can be controlled through the administration of antivaccinal immunoglobulin.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Contaminated plasticware will be soaked in a disinfectant such as Activanios® with an appropriate dilution (0.2% glutaraldehyde + quaternary ammonium salt) for 45 minutes inside the safety cabinet. The material is then transferred into an autoclave where it will be further decontaminated at 134°C for 30 minutes. The surface of the container is decontaminated with a Virkon (1%) spray. Any work surfaces will be contaminated with Virkon spray and wiped with paper towels, which will be autoclaved at 134°C for 30 minutes. All autoclaved solid waste will be placed in heavy duty waste bags and incinerated.

Any liquid waste will be decontaminated with an appropriate disinfectant (0.2% glutaraldehyde + quaternary ammonium salt) contained in autoclavable polypropylene jars that can be closed hermetically. The jars are kept for 45 minutes under the hood, surface decontaminated then autoclaved at 134°C for 30 minutes. The liquid waste can then be disposed down the drains.

The dilution of Activanios that are used, kill the virus within 30 minutes of contact. Testing virus viability after treatment is done by removal of the disinfectant using ultrafiltration and washing any residual material with cell culture media. The recovery of any residual material and inoculation of permissive cell cultures such as Vero, HeLa or L-929 cells indicate that the virus has been inactivated irreversibly.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Please enter comments on the GM safety committee on the risk assessment

This is a connected programme of work for which a first risk assessment was provided and authorisation is granted for this particular activity. The risk assessment covers the usage of the E3L defective vaccinia virus (vp1080 to identify dsRNA binding proteins with an anti-PKR/interferon activity. Further risk assessments will be submitted in due course to the BAGMSC before a different activity is to be started, particularly before using the non modified VC-2 strain.

The risk assessment 07/08 was originally approved by the ACGM in 2007. Due to the delay in starting this work the RA was reviewed again at the local BAGSMC and approved on 24/03/2010

Project Additional Information

**Purposes of the contained use**

**Research Question:**
What are the basic virological properties of emerging H7N9 viruses infecting poultry and what is their zoonotic transmission potential?

**Objectives**
1) To generate viable recombinant influenza viruses based on H7N9 with variable combinations of internal genes derived from prevalent H7N9 and H9N2 viruses,
2) To determine the virological properties of the recombinant viruses in vitro using cultured avian and mammalian cells and ex vivo organ cultures.
3) To determine the virological properties of the recombinant viruses in embryonated eggs

**Recipient or parental organism**

This project focuses on LPAI strains of H7N9 and H9N2 viruses. The novel H7N9 virus emerged through complex genetic reassortment events involving HA and NA genes from H7N3 and H7N9 viruses, which are prevalent in duck and wild aquatic birds respectively, and the six internal gene segments from H9N2 viruses, which are enzootic in chickens in China (1). Infection of chickens with H7N9 produces no clinical disease or mortality in infected chickens (2), therefore they are not HPAI. However, due to its ability to cause zoonotic infections and in some cases severe and fatal disease in humans with case fatality rate of 39% (3), it must be handled as a ACDP HG 3 agent (4). All reported human infections have been linked to direct contact with live poultry or potentially contaminated environments, particularly markets trading live birds. The virus does not appear able to transmit from human-to-human (5).

Recent evidence suggests that as H7N9 spreads in China it is undergoing further genetic reassortment and acquiring internal genes from distinct strains of H9N2 endemic in local regions (6-7). The H9N2 viruses are the most prevalent subtype in bird population worldwide and are also undergoing rapid genetic diversification by acquiring internal genes from other AlVs subtypes infecting poultry, including HPAI H7 and H5 viruses (8-9). Epidemiological and phylogenetic models suggest that highly diversified and distinct clades of H9N2 are enzootic in poultry in different countries (10). Modelling studies also predict that there is high likelihood that the H7N9 virus will potentially spread to other countries where distant clades of H9N2 are endemic (11). The likely co-circulation of both H7N9 and novel genotypes of H9N2 viruses containing diversified internal genes therefore could result in the emergence of novel reassortant H7N9 virus.
strains with unknown pathobiological features. This raises a number of important basic scientific and control policy-related questions that we aim to tackle through this research. Part of this project was recently funded by the BBSRC.

To determine the virological properties and in vitro host tropism of H7N9 Influenza virus strains infecting poultry and humans, we will use influenza virus Reverse Genetics (RG) approach to generate Genetically modified microorganisms (GMMs) H7N9 RG viruses (12). These GMMs will mimic the potential natural evolution of H7N9 and contain internal genes from diversified strains of H9N2 or H7N9 viruses currently prevalent in poultry in different regions of the world (6-7).

The GMMs will contain HA and NA genes of currently circulating H7N9 viruses and single or multiple internal genes from different strains of H7N9 or H9N2 viruses isolated from birds. These GMMs will be produced from known sequences in public databases of influenza viruses. The GMMs will have single or multiple internal genes identical to natural H7N9 or H9N2 virus isolates derived from infected birds or humans. Internal genes sequences of representative H7N9 or H9N2 strains (prevalent at different geographical regions) will be used for generation of H7N9 PG viruses. The representative internal genes of H7N9 or H9N2 viruses will be produced from known sequences using either synthetic gene synthesis approach (produced commercially) or through site-directed mutagenesis approach. All gene products to be used for generation of H7N9 AG viruses will be subjected to sequence analysis and integrity of gene sequences of rescued PG viruses will also be verified by complete sequencing of virus genome.

The activities that will be undertaken with these viruses are detailed below:
- Generation by reverse genetics methodology in cell culture.
- Propagation in embryonated hen eggs.
- Characterisation of growth and fitness in cells and ex-vivo organ cultures.
- Inactivation and extraction of PNA for sequencing.

**Host/vector system**

**Bacteria**

cDNA clones will be generated in E.coli and plasmids containing the influenza genes will be transfected into cells of eukaryotic origin (avian or mammalian) to rescue infectious virus.

**Origin & function**

DNA plasmids containing influenza virus gene segments (HA, NA) of H7N9 and internal genes (PB2, PB1 and PA, NP, M and NS) of H7N9 or H9N2 viruses will be generated from sequence data on the NCBI database by de novo synthesis by a commercial gene synthesis company. All sequences will be analysed by Sanger sequencing prior to use in viral rescue.

Point mutations in the nucleotide sequences representative of natural field isolates will be generated by us through site-directed mutagenesis and confirmed by sequencing the genetic segment prior to virus generation.

Once generated these viruses will be used to test their replication fitness such as infectivity and plaque forming morphology in permissive cell line such as MDCK cells, chicken embryo fibroblast (CEF), or replication in ex vivo chicken or ferret tracheal organ cultures or replication in embryonated eggs.

**Evaluation of foreseeable effects**

**Bacteria:**

No potential hazards to human health are envisaged with the manipulation of MV derived sequences in bacteria. The standard laboratory strains, disabled E. coli K12, will be used in this project. These strains pose no harm to human health. The inserted influenza genes are under the control of viral or eukaryotic promoters, so viral genes will not be expressed in the bacteria.

**H7N9 RG viruses:**
All the H7N9 RD viruses detailed in this assessment should be considered as capable of infecting humans, but the control measures in place in the Containment Level 3 laboratory (AWW-COP-i rev 2) are such that the virus will be contained appropriately.

Human infection with H7N9 viruses can cause severe and, on occasion, fatal disease (13). The widespread circulation of these viruses in birds and infection in humans is resulting in novel strains of R7N9 (14). Currently, limited data is available describing the impact of natural evolutionary changes in the internal genes on virus pathogenicity or host tropism compared to the wild-type H7N9 strains isolated from birds and humans. The proposed changes in internal genes of H7N9 that will contain single or multiple internal genes from diverse range of circulating H7N9 or H9N2 viruses may alter (increase or decrease) virus infectivity and replication characteristics. Any of these anticipated phenotypic characteristics will be monitored through our routine in vitro characterisation of novel influenza viruses. The routine in vitro characterisation of all isolates engineered in this study will provide evidence as to whether they possess any changes in virus infectivity or replication or plaque forming morphology in permissive cells such as MDCK and chicken embryo fibroblast (CEF) cells, ex vivo chicken or ferret tracheal organ cultures or replication in embryonated eggs. Work on viable recombinant viruses that show marked in vitro phenotypic changes (such as significant increase in virus titres and for plaque formation) compared with the wild type virus will be analysed by performing full genomic sequence analysis. This will allow identification of any molecular changes that the viruses might acquire during generation and replication in cells or eggs. Particular emphasis will be to identify unintended changes that potentially alter virulence such as insertion of polybasic residues at the HA cleavage site [conversion of low pathogenicity to high pathogenicity phenotype] or any known changes in NA (such as amino acid substitution H274Y, N294S, R292K and Eli 9V) that potentially increase resistance to antiviral drugs. Any viruses with identified mutations in HA or NA will be destroyed, the Pirbright Institute biosafety team will be informed.

All viruses generated by RD will be handled at Containment Level 3 in a dedicated suite of laboratories for avian influenza viruses. No changes in the HA gene will be made that may alter virus Phenotype from low pathogenicity to high pathogenicity. No change in the NA gene will be made therefore all GMM’s will remain sensitive to existing antiviral drugs.

In any potential cases of viral exposure diagnostics and antiviral treatment procedures will be implemented as detailed in The Pirbright Institute Q-Pulse document (H&S-GUIDE-29).

H7N9 viruses have been circulating in China for 3 years and there is no evidence of human-to-human transmission (15). Therefore, in the event of human infection any spread in the community is highly unlikely. All the RG viruses produced in this assessment will be handled separately in a class III microbiological safety cabinets or a flexible-film isolator with dedicated or clean (via a validated means including chemical disinfection or fumigation) equipment (pipettes etc). This procedural control will help to prevent potential mixing of influenza genetic segments via reassortment in vitro.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

| N/A |

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

| No derogations required, these GMMs will be worked with under full ACGM conditions. |

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

| All work with these GMMs will be undertaken in a suite of high containment laboratories for working on avian viral disease pathogens up to and including Advisory Committee on Dangerous Pathogens (ACDP) hazard group (HG) 3 pathogens and pathogens up to and including group 4 of the Specified Animal Pathogen Order (SAPO). The Avian suite (Avian west wing, AWW), is a self-contained suite of laboratories within The BBSRC National Virology Centre: The Plowright Building at The Pirbright Institute, herein alter called The Plowright Building. All work involving these GMMs will be undertaken within primary containment, microbiological safety cabinets (MBSC) class I/III in class III mode or flexible film biosisolators within the AWW. Disposable equipment will be used where possible. All waste will be decontaminated by disinfection with one of the validated methods below; Virkon 1% 10 minutes Distel 10% 10 minutes Formaldehyde 40% 12 hours FAM 30 1:100 dilution 30 minutes Validation: Tests have been carried out by the Harbin Veterinary research Institute in China confirming the efficacy of Distel and Virkon against H5N1 virus. See Distel Medical test summary for validated data against influenza viruses. (DISTEL-1) FAM 30 is a DEFRA approved disinfectant again notifiable avian influenza viruses. http://evansvanodine.co.uk/asset/2-FAM-30-PROFILE-ISSUE-7.pdf Following disinfection the waste will be placed within a autoclave bag and removed from the primary containment before being sealed within an autoclave container. These containers have a PTFE seal to prevent the transfer of |
unfiltered air and a space for a plastic tag to secure the lid and indicate that the container is full. The containers are made from aluminium or specialised plastic containers to reduce weight. These are then transported to the dedicated within suite autoclave, where validated autoclave cycles for various types of waste including, solid, liquid and eggs are used by trained individuals. Autoclaved waste is removed from the clean side of the autoclave outside of the ADCP level 3 SAPO 4 suite and taken for incineration via The Pirbright Insitute clinical waste stream or if non-disposable taken to wash-up for reuse.

All users of the AWW suite will be trained in the correct disposal and operation of the within suite autoclave prior to becoming an authorised user of the suite. All training is documented by The Pirbright Institute training management systems. A risk assessment by the biosecurity team will be undertaken should the autoclave fail and robust procedures are in place to manage such an event. The autoclave within the suite is serviced and validated every six months as part of the planned preventative maintenance schedule and after any unscheduled maintenance work.

Date Project

02/03/2022
To study the phenotypic effects and biological functions of defined host cellular and viral proteins in mammalian and avian cells; to silence expression of target genes; and to genetically program primary cells. For example:

1. We will use a 3rd generation replication deficient recombinant lentivirus vector to express GFP-fused to Npro from classical swine fever virus in order to study Npro’s localisation in relation to subcellular organelles/compartments and apoptotic proteins in porcine cell lines and primary cells.
2. We will use a 2nd generation replication deficient recombinant retrovirus vector expressing Bcl-6 and Bcl-xL to prevent the terminal differentiation of porcine memory B cells and enable their continuous proliferation with secretion of monoclonal antibodies.

The generation of recombinant retroviruses and lentiviruses will involve initial amplification of transfer, packaging and envelope plasmids using bacteria and commercial plasmid purification kits. All bacteria used for such amplification will be standard commercially-available ACGM class 1 strains of Escherichia coli (E.coli) such as JM109 and TOP10. Genes encoded by the plasmids are unlikely to be expressed in such strains of E. coli and pose no risk to the environment. Persistence is unlikely as all transformed E. coli will be lysed during plasmid preparation and all waste discarded into 1% Virkon (Gasparini, 1995). In addition, bacteria will never be transformed with more than one type of plasmid.

Only standard packaging cells, such as the human HEK 293T cell line, will be used to generate retrovirus stocks. Retroviral mediated expression of the host and viral proteins or silencing RNAs will be carried out in transduced cell lines or primary cells of mammalian or avian origin.

No infection of animals with recombinant retroviruses and lentiviruses will be conducted.

This project will utilise the retrovirus delivery and expression system, comprised of either the Moloney murine leukemia retrovirus or lentiviral (e.g. HIV-1-based) transfer, packaging and envelop plasmids. Recombinant retrovirus encoding mammalian, avian or viral genes will be prepared and transduced into mammalian or avian cells. These vectors may be pseudotyped with other envelope proteins such as gibbon ape leukemia virus envelope (GALV-env) or Vesicular stomatitis (VSV)-G protein to produce amphotropic viral particles.

Only 2nd or 3rd generation retrovirus systems designed to be replication incompetent will be used. The 2nd
generation system requires co-transfection of 3 plasmids encoding transfer, packaging and envelop proteins to generate replication incompetent retrovirus. The 3rd generation system requires an additional plasmid because the packaging proteins are split between two plasmids; in addition the 3rd generation system does not express the Tat protein.

Only retroviral transfer vectors such as pLJM1, that do not contain the post-transcriptional regulatory element from woodchuck hepatitis virus (WPRE), will be used.

**Origin & function**

The genetic materials involved will be cDNA encoding host cellular proteins involved in a range of processes including immune responses, growth factors (such as cytokines) and oncogenes (such as Bcl-6 and Bcl-xL) and viral proteins (such as classical swine fever virus Npro), which are known or suspected to interact with host cellular processes/pathways.

Genetic materials may encode interfering RNA molecules designed to silence specific genes of interest. In addition, the genetic material may contain or be solely cDNA encoding epitope tags (such as Myc, His, Strep, V5) or marker proteins (such as GFP, GST and luciferase) for the purposes of purification and detection of the above mentioned mammalian and viral proteins.

Genetic material may also contain a selectable drug marker e.g. the pac gene encoding a puromycin N-acetyl transferase, which confers puromycin resistance and enables selection of transduced cells.

**Evaluation of foreseeable effects**

The expectation is that cells transduced with recombinant retro and lentiviral vectors will have the proviral DNA inserted into the genome resulting in constitutive expression of the transgene(s). There is the potential for this to disrupt the normal pattern of gene expression within the infected cell, including the possibility of cellular transformation. Since the vectors to be used are replication incompetent no infectious progeny would be produced and disseminated.

Only second and third generation packaging systems will be used to propagate pseudotyped viral particles and thus the risk of generating replication competent virus is negligible.

The amphotropic virus particles are capable of infecting cells of both human and non-human animal species, but will not replicate. In the extremely improbable event that the vector acquires replicative potential by recombining with endogenous retroviral sequences, this single agent is unlikely to cause deleterious consequences in an accidental host. It is estimated that between 4 and 6 separate alterations are necessary to generate a tumorigenic cell.

Retroviruses are also inherently unstable and very high titres would be required to produce a persistent infection in an immunologically competent individual. The primary dangers in working practice are expected to be the formation of aerosols and use of sharps. We propose to carry out all manipulations in a Class II microbiological safety cabinet and any additional local safety guidelines appropriate to this work. Work involving glassware and sharps will be avoided where possible to mitigate the risk of exposure through non-intact skin. Where essential, work involving glassware and sharps will only be conducted by fully trained personnel and after risk assessment. The sonication of solutions, which may contain virus, will only be conducted by indirect sonication which prevents aerosols or cross-contamination.

None of the cell lines would be expected to be capable of remaining viable outside of the controlled culture conditions used and we do not anticipate that any of the manipulations we are proposing would alter this.

The risk of exposure to retro and lentiviral vectors in transduced cells subsequently used for other activities e.g. non-

CU 22015 (rev 11/15) Page 3 of 10
HSE Health and Safety
Executive

fixed flow cytometric cell sorting is negligible since the cells do not incorporate any helper function and residual
infectious virus particles are reduced by replacing the potentially infectious cell supernatant medium. In these circumstances, no additional containment measures beyond those needed for the non-transduced cells are required. Please refer to the overarching risk assessment CM 16/08, which users may work under as part of this connected program, although they must also complete a separate, project specific risk assessment, which will be assessed and approved by BAGMSC (see attached examples CM 16/05 and CM 16/07) prior to work commencing, however, should BAGMSC feel that there is an increased risk or the work falls outwith the scope of this notification, the work will be notified to HSE. Initially, this connected program will commence using the attached risk assessment GM16/07, although similar work will follow.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The proposed work consists of small-scale in vitro experiments to produce recombinant pseudotyped retroviral and lentiviral vectors and to transduce cells with these vectors. The following measures will be implemented to safely manage waste and safeguard human health and the environment:

1. A lab coat and gloves will protect the operator from skin contact with the pseudotyped viral particles.
2. A validated disinfectant e.g. 1% Virkon S or 70% ethanol will be used to disinfect any exposed surfaces. Both are effective at inactivating retroviruses and lentiviruses.
3. Accidental spillages of liquid waste will be deactivated with a validated disinfectant e.g. 2% Virkon S; the use of double strength disinfectant will ensure that it is not diluted past the effective concentration.
4. All liquid waste will be inactivated by a validated disinfectant for the contact time (e.g. 1% Virkon S for 10 minutes) and then disposed.
5. All solid waste will be autoclaved at 121 oC or 134oC dependent on the autoclave for 30 minutes prior to incineration by validated means.
6. Work involving glassware and sharps will be avoided where possible to mitigate the risk of exposure though non intact skin. Where essential, work involving glassware and sharps will only be conducted by fully trained personnel and after risk assessment.
7. All ACGM Class 2 work will be carried out in a class II microbiological safety cabinet (MBSC).
8. Centrifugation must be carried out in closed containers with sealed rotors or safety cups. Safety cups are to be loaded and unloaded inside the MBSC. After use safety rotors/cups are disinfected using a validated disinfectant.
9. Work will only be conducted in laboratories with restricted access to unauthorised personnel.
10. Flow cytometric analysis of transduced cells will be conducted following fixation of cells e.g. 4% paraformaldehyde for 20 minutes at 4oC.
11. Flow cytometric sorting of transduced cells will be conducted in a cell sorter fitted with an aerosol evacuation system and housed within a MBSC unless the risk assessment deems the risk of residual infectious virus to be negligible, whereby, no additional containment measures beyond those needed for the non-transduced cells are required.
Reviewed by BAG MSC on the 12/07/16 and approved at ACGM2 with the following amendments included:
Expand the scope of the risk assessment to include expression of interfering RNAs and selectable drug markers.
Include flow cytometric cell sorting of live cells on the bench provided that the risk of residual infectious virus had been reduced to negligible by washing the cells to replace the potentially infectious cell supernatant medium.

Project Ref 53/17.1

Date Ackn'd: 08/05/2017
CU2 Project Title: In vitro and in vivo studies with recombinant porcine reproductive and respiratory syndrome viruses

Consent Granted

Non-GMM

Consent Granted: Yes

Project notified under transitional arrangements

Historical Significant Changes

Historical Date of Additional Info
Porcine reproductive and respiratory syndrome (PRRS) is one of the most important pig diseases worldwide with a huge economic impact, estimated in the USA and Europe to exceed US$600 million and 1.5 billion Euros p.a., respectively. The PRRS virus (PRRSV) is an arterivirus, which exists in two distinct genotypes: PRRSV-l (formerly European) and -2 (formerly North American). Both genotypes are widely distributed although PRRSV-l remains the predominant genotype in Europe and PRRSV-2 predominates in North America and Asia. PRRSV-l is endemic in the UK whilst PRRSV-2 has never been reported. Common to most RNA viruses, the PRRSV replication cycle is prone to mutation and recombination events resulting in rapid evolution. This characteristic is most dramatically illustrated by the emergence of highly pathogenic variants in Southeast Asia and Eastern Europe. Vaccination is considered a key element to PRRS control but existing vaccines are evidently failing to control the PRRS panzootic. An improved understanding of PRRSV and its interactions with the porcine immune system is urgently required to support the development of improved vaccines and disease control intervention strategies. The purpose of the contained use is to create and manipulate cDNA copies of the genomes of PRRS viruses in plasmids and use these to recover live viruses with specific modifications. Viruses will be modified for example to:

1. Prevent expression of specific viral proteins to examine their effect on viral replication and on the host cell response.
2. Introduce specific modifications/mutations to individual viral proteins to study the effects of those mutations on viral replication and/or interaction with host proteins, or to create epitope tags on the viral proteins allowing these proteins to be recognised by specific antibodies.
3. Exchanging genomic regions, untranslated regions or open-reading frames with equivalent genetic material from other strains of PRRSV with different pathogenicity, to identify virulence factors.
4. Introduction of extra genes to express heterologous proteins which act as infection markers (e.g. GFP) or to express non-PRRSV proteins so that the virus may act as a polyvalent vaccine.

Recombinant PRRS viruses will be studied both in vitro in primary cells and cell lines, and, in vivo in the natural porcine host.

The generation of recombinant PRRS viruses will involve initial amplification and modification of plasmids carrying cDNA copies of the PRRSV genomes using bacteria and commercial plasmid purification kits. All bacteria used for such amplification will be standard commercially-available ACGM class 1 strains of Escherichia coli (E.coli) such as JM109 and TOP10. Genes encoded by the plasmids are unlikely to be expressed in such strains of E. coli and pose no risk to the environment. Persistence is unlikely as all transformed E. coli will be lysed during plasmid preparation and all waste discarded into 1% Virkon (Gasparini, 1995). In addition, bacteria will never be transformed with more than one type of plasmid.

Recombinant PRRSV will be rescued following transient transfection of cell lines, e.g. BHK-21 or MARC-145 cells, or primary porcine cells, e.g. porCine alveolar macrophages with infectious copy plasmids or RNA derived from in vitro transcription of infectious copy plasmids. Recombinant PRRSV will be propagated in vitro using MARC-145 cells or porcine alveolar macrophages. The phenotype of recombinant PRRSV will be studied in vitro using MARC-145 cells or primary porcine cells, and, in vivo, in experimentally infected pigs. Recombinant PRRSV are expected to retain the
phenotype of the parental wild type strain from which the infectious cDNA clone was derived. Genetically modified PRRSV may display an attenuated phenotype due to the introduction of modifications/mutations affecting the expression or function of individual viral proteins. Introduction of a specific viral gene or genomic region from a highly virulent strain to a low virulence strain may result in an increase in the virulence but this is not expected to exceed that of the virulent parental wild type strain.

Host/vector system

This project will utilise mammalian expression plasmid vectors e.g. pCMV to manipulate and express full-length infectious cDNA clones of the PRRSV genome. Cell lines e.g. BHK-21 cells will be used for initial transfection of plasmids or RNA derived from in vitro transcription of infectious copy plasmids. MARC-145 cells and porcine macrophages and related myeloid cells will be used for virus rescue and subsequent in vitro experiments. In vivo experiments will be conducted in pigs, the only species susceptible to PRRSV infection.

Origin & function

The genetic materials involved will be cDNA encoding genotype 1 and 2 PRRSV. These may be derived from viral strains of defined virulence (e.g. attenuated, low virulence, high virulence). Alternatively, these materials may be chemically synthesised based on PRRSV genome sequence data. Genetic materials may have specific modifications/mutations introduced into individual PRRSV open-reading frames (ORFs) or 5' and/or 3' untranslated regions (UTR). Alternatively genomic regions or ORFs may be replaced with those from heterologous PRRSV strains. In addition, the genetic material may contain cDNA encoding epitope tags (such as Myc, His, Strep, V5) or marker proteins (such as GFP, GST and luciferase) for the purposes of purification and detection of the recombinant PRRSV or defined PRRSV proteins. These materials will allow the production of recombinant PRRS viruses which will be used to study basic aspects of viral biology, to study the interaction of the virus and individual viral proteins with the innate and adaptive immune systems and to develop novel vaccines.

Evaluation of foreseeable effects

Recombinant PRRS viruses derived from infectious cDNA clones are expected to display the same phenotype as the parental wild type strain from which they are derived. None of the novel genes which might be inserted will encode toxic or immunomodulatory proteins, nor will any oncogenes be added. No gene will be inserted which would alter the host cell tropism or extend the host-range of the recombinant virus. The majority of the manipulations to the PRRSV genome including the introduction of mutations to disrupt the interactions of viral proteins with host ligands or the disruption of the expression of specific viral proteins are expected to reduce the virulence and fitness of the virus. An increase in the virulence and fitness of the virus may be achieved by the introduction of genetic material from a virulent strain into the genome of an attenuated/low virulence strain, however, the resultant virulence of the chimeric strain is not expected to exceed that of the virulent parental strain. Therefore, all proposed mutations/modifications will leave the GMM with the same or lessened hazard than the parental virus. There is no evidence that recombinant (or wild-type) PRRSV could infect humans or cause harm to human health. However, recombinant (and wild-type) PRRSV will infect domestic and wild pigs and thus they pose an environmental hazard which would be controlled by the control measures detailed below.

Please refer to the overarching Connected Programme of Work (CPW 17IXX), which provides further details of the context and scope of the proposed work. Users will complete project specific risk assessments, which will be assessed and approved by The Pirbright Institute Biological Agents and Genetic Modification Safety Committee (TPI...
BAGMSC) (see attached example GM 17/ZZ) prior to work commencing, however, should BAGMSC feel that there is
an increased risk or the work falls outwith the scope of this notification, the work will be notified to HSE. Initially, this
connected program will commence using the attached risk assessment GM17IXX, although similar work will foNow.
Since TPI carries out work on highly contagious pathogens of livestock, all animals on-site have to be housed in high
containment (SAP04) facilities. In vivo work with recombinant PRRSV-1 (ACGM class 2 GMM) may be conducted in
lower containment using CL2 animal facilities of the Animal and Plant Health Agency (APHA), Weybridge. Project
specific risk assessments covering such in vivo work will be assessed and approved by both the TPI and APHA
BAGMSCs.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogations required, these GMMs will be worked with under full ACGM conditions.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The proposed work consists of small-scale in vitro experiments to produce recombinant PRRSV-1 and -2 viruses.
These viruses will subsequently be used in in vitro and in vivo studies. In vitro and in vitro work with recombinant
PRRSV-1 (ACGM class 2) will be conducted in CL-2 laboratories and animal facilities whereas work with recombinant
PRRSV-2 (SAP03 ACGM class 3) will be conducted in laboratories and animal facilities under SAPO level 4
containment. The following measures will be implemented to safely manage waste and safeguard human health and the
environment:

In vitro ACGM class 2 work with PRRSV-1 (handled within CL-2 Jenner Laboratory, The Pirbright Institute (TPI»
1. A lab coat and gloves will protect the operator from skin contact with GMM.
2. A validated disinfectant e.g. 1 % Virkon S or 0.5% FAM 30 will be used to disinfect any exposed surfaces. Both are
effective at inactivating PRRSV.
3. Accidental spillages of liquid waste will be deactivated with a validated disinfectant e.g. 2% Virkon S or 1 % FAM
30; the use of double strength disinfectant will ensure that it is not diluted past the effective concentration.
4. All liquid waste will be inactivated by a validated disinfectant for the required contact time (e.g. 1 % Virkon S for 10
minutes) and then disposed to drains.
5. All solid waste will be autoclaved at 121 oC or 134oC dependent on the autoclave for 30 minutes prior to
incineration by validated means.
6. All work with live virus will be carried out in a class II MBSC.
7. Centrifugation must be carried out in closed containers with sealed rotors or safety cups. Safety cups are to be
loaded and unloaded inside the MBSC. After use safety rotors/cups are disinfected using a validated disinfectant.
8. In vitro work with PRRSV-1 will only be conducted in CL-2 virus handling laboratories with restricted access to
unauthorised personnel.

In vitro ACGM class 3 work with PRRSV-2 (handled within SAP04 Plowright Laboratory. TPI)
1. A lab coat and gloves will protect the operator from skin contact with GMM.
2. A validated disinfectant e.g. 1 % Virkon S or 0.5% FAM 30 will be used to disinfect any exposed surfaces. Both are
effective at inactivating PRRSV.
3. Accidental spillages of liquid waste will be deactivated with a validated disinfectant e.g. 2% Virkon S or 1% FAM
20; the use of double strength disinfectant will ensure that it is not diluted past the effective concentration.
4. All liquid waste will be inactivated by a validated disinfectant for the required contact time (e.g. 1 % Virkon S for 10
minutes) and then disposed to the heat effluent treatment plant.
5. All solid waste will be autoclaved at 121°C or 134°C dependent on the autoclave for 30 minutes prior to
incineration by validated means.
6. All work with live virus will be carried out in a class II MBSC, in sealable rooms, with room air having a single
supply and double extract HEPA filter, with the room operating under negative pressure.
7. Centrifugation must be carried out in closed containers with sealed rotors or safety cups. Safety cups are to be
loaded and unloaded inside the MBSC. After use safety rotors/cups are disinfected using a validated disinfectant.
8. In vitro work with PRRSV-2 will only be conducted in SAP04 virus handling laboratories with restricted access to
unauthorised personnel.

In vivo ACGM class 2 work with PRRSV-1 (handled within Animal and Plant Health Agency (APHA) CL2 Animal Units.
samples processed in CL2 Jenner Laboratory. TPI)
1. In vivo work with recombinant PRRSV-1 may be conducted in a CL-2 animal facility at APHA. Weybridge.
2. Recombinant PRRSV-1 will be prepared for inoculation within CL2 virus handling laboratories at TPI and
packaged within a secure secondary container for transport to APHA.
3. PPE (disposable overall, boots, gloves) will be worn whilst working with infected animals. Gloves and overalls to
be disposed after use, bagged up. bags disinfected with 2% Virkon S or 1% FAM 30. left for 1 h and incinerated.
Boots will be cleaned with 2% Virkon S or 1 % FAM 30.
4. All solid waste including bedding will be bagged and incinerated. No liquid or solid waste will be allowed to enter
the normal drainage system and all drains in the relevant area will be blocked. In effect liquid waste will soak into
bedding and be disposed of as solid waste.
5. Samples will be packaged in the animal facility with the outer packaging disinfected with a validated disinfectant
e.g. 1% Virkon S or 0.5% FAM 30, and then packaged within a secure secondary container for transport to CL2 virus
handling rooms in the Jenner Laboratory. TPI. Unpacking of samples is carried out in a class II MBSC.

In vivo ACGM class 3 work with PRRSV-1 and -2, respectively (handled within TPI SAP04 animal isolation
facility, samples processed in SAP04 Plowright Laboratory. TPI)
1. In vivo work with recombinant PRRSV-1 may be conducted in TPI isolation units, which operate under SAPO level 4 containment.
2. In vivo work with recombinant PRRSV-2 will be conducted in TPI isolation units, which operate under SAPO level
4 containment.
3. Staff will remove clothing, access via an airlock and put on scrubs. Staff will don waterproof clothing prior to
entering animal rooms, which are disinfected on exit from animal rooms. Staff remove clothing and shower on exit
from the facility.
4. Liquid waste is disposed to drains and heat-treated to 94°C for 1 hour in the effluent treatment plant. All solid
waste will be autoclaved at 1210°C or 134°C dependent on the autoclave for 30 minutes or incinerated in the barrier
incinerator. Removal of items or equipment that cannot be autoclaved or incinerated are surface disinfected prior to
fumigation with formalin vapour.
5. Animal rooms are sealable and have single HEPA on supply air and double HEPA on extract air, with the room
operating under negative pressure.
6. Samples will be packaged in the animal isolation rooms with the outer packaging disinfected with a validated
disinfectant e.g. 1 % Virkon S or 0.5% FAM 3D, and then packaged within two secure containers resulting in 4 layers of
containment. Samples are then moved directly to virus handling rooms within the SAP04 Plowright Laboratory.
Unpacking of samples will be carried out in a class II MBSC.

Project Additional Information

Purposes of the contained use

The purpose of our projects is to increase our understanding of the viral determinants for host range, transmission and pathogenesis of influenza A viruses (IAV) and to develop tools that could enhance control of influenza viruses in poultry, humans and swine.

Recipient or parental organism

We intend to generate several different groups of IAVs, all which are assessed as ACDP HG 2. None of the IAV we generate will be categorised as highly pathogenic as defined by HSE (in possession of a multiple basic cleavage site in the HA gene or having an intravenous pathogenicity index score in chickens of over 1.2). We will also not generate viruses with altered characteristics that enhance the replication and transmission in humans or surrogate human animal models (e.g. the ferret).

Group 1: Wild-type IAV strains. Human IAV strain (Pre 2009 H1N1, pandemic 2009 H1N1, H3N2 but not H2). Swine influenza viruses (H1N1, H3N2, H3N1 but not H2 viruses). All subtypes of low pathogenicity avian influenza virus where the natural HA sequence does not contain a multiple basic cleavage site (defined as greater than 2 basic amino acids). Will not generate any highly pathogenic virus (HPAI) as defined in the HSE guidance. We will also not generate viruses known to cause severe disease in humans as these are categorised as ACDP HG3 (e.g. H7N9 and H10N8).

Group 2a: Segment swaps in whole viral strains: Segment swaps between IAVs isolated from the same species. For example any of the genetic segments could be swapped individually or in combination between the chicken LPAI viruses H9N2 and H6N1. Segments from highly pathogenic viruses will not be swapped into LPAI viruses. We will not swap segments between different species for example between the human H1N1 and the chicken H9N2 virus.

Group 2b: Segment swaps between IAVs isolated from different avian species (e.g. ducks and chickens). The only exception to the previous boundary regarding segment swaps between different species is within the avian genus since the ability of all avian species isolated viruses to replicate in mammalian hosts is limited and reassortment between these viruses is not likely to generate strains with enhanced ability to replicate or transmit in mammals. Segments may be swapped individually or in combination. Segments from highly pathogenic viruses will not be swapped into LPAI viruses only swaps between LPAIs will be made.

Group 3a: Sequence mutations in viral proteins: Mutations in IAVs that occur in other IAV strains isolated from the same species in nature. Mutation of single or multiple residues will be made in the genetic material of IAVs in coding or non-coding regions of the genome that are reflective of sequences deposited on the database from viruses isolated in the field from the same species. For example where there is a chicken H9N2 virus sequence on the
NCBI influenza database containing a Leucine residue at position 226 in the
HA protein we may alter the HA of a chicken H6N1 virus or chicken H9N2
virus at position 226 to a Leucine residue. Mutations only observed in
sequences from highly pathogenic viruses will not be engineered into LPAI
viruses. Mutations only observed in isolates from one species will not be
engineered into IAV isolated from different species, (e.g. sequences only
observed in human IAV isolates and not identified in natural chicken isolated
IAVs will not be engineered).

Group 3b: Point mutations in IAVs that occur in other IAV strains isolated
from different avian species in nature. The only exception to the previous
boundary regarding engineering mutations into IAVs only seen in different
species is within the avian genus since the ability of all avian species
isolated viruses to replicate in mammalian hosts is limited and mutational
switches between these groups of viruses are not likely to generate strains
with enhanced ability to replicate or transmit in mammals. Mutations only
observed in sequences from highly pathogenic viruses will not be engineered
into LPAI viruses.

Group 4a: Deletion: The deletion of coding or non-coding portions of the IAV
genome. The deletion may be achieved by generating IAV segments that
have portions removed or by introducing stop codons in protein coding
regions to prevent expression of the region. Genes may be deleted partially,
fully or in combination with others.

Group 4b: Insertion: The insertion of tags or reporters into the genetic coding
capacity of IAVs. Tags such as small epitope tags for the purpose of gene
identification using ubiquitous antibodies may be added to the N or C
terminus of IAV proteins in the viral genome (e.g. V5, FLAG, (His)6).
Reporter genes such as fluorescent proteins (GFP, mCherry etc) or
luminescent proteins (luciferase) may be inserted into the viral genome,
either as fusions with IAV proteins or as standalone proteins released by
proteases (such as self-cleaving proteases like 2A from porcine teschovirus-
1 or endogenous proteases). Insertion of such tags and reporters may occur
in a number of sites individually or in combination (such as in the NS, PB2 or
PA segments (3-9)). Group 5a: PR8 backbone IAVs: IAVs with vaccine
strain (A/PR/8/34) internal segments (M, NS, NP, PA, PB1, PB2) and the HA
and NA of any other HA (H1-H18) or NA (N1-N11) seen in nature. H5 and
H7 HAs that do not possess a multiple basic site only will be produced (i.e.
from low pathogenic H5 and H7 IAV isolates only). If the HA from a highly
pathogenic H5 or H7 is to be used in such a virus then the multiple basic cleavage site must be engineered out of the HA as has been exemplified by
the NIBSC vaccine strain candidates for avian influenza viruses such as
RG14 (HA from HPAI H5N1 A/Vietnam/1194/04 virus with an excised
multiple basic cleavage site) or RG23 (HA from HPAI H5N1
A/turkey/Turkey/1/05 virus with an excised multiple basic cleavage site).

Group 5b: PR8 backbone IAVs that include mutation from the natural
sequence in HA or NA proteins. Similar to the above group 5a PR8 backbone IAVs these viruses will contain the internal genetic segments (M, NS, NP, PB1, PB2, PA) from the vaccine strain A/PR/8/34 and HA from any of the H1-H18 and NA N1-N11 segments. Mutation of the HA segment may occur with such purpose to alter the antigenic profile of the viruses, to remove glycosylation sites, alter the receptor binding preference, HA stability or ability to facilitate membrane fusion. Mutation of the NA segment may occur with such purpose as to modify the NA stalk length, glycosylation, antigenic profile, sialidase activity.

Group 6a: PR8 pseudotyped IAVs: IAVs with the internal genetics segments from any influenza virus (M, NS, NP, PB1, PB2, PA) and the HA and NA (as a minimum) from the A/PR/8/34 (PR8) IAV strain. The internal genetic components may come from any natural IAV isolate including HPAI virus. More PR8 genetic segments other than the minimal HA and NA can be included up to 7 from the vaccine strain PR8.

Group 6b: PR8 pseudotyped IAVs that include mutation from the natural sequence in the internal genetic segments. Mutation of the PR8 HA and NA will not occur when mutation of internal genetic components occurs.

Host/vector system

cDNA clones will be generated in E.coli and plasmids containing the above mentioned influenza genes will be transfected into cells of eukaryotic origin (avian or mammalian) to rescue infectious virus.

Origin & function

cDNA constructs for the rescue of IAVs will be generated by de novo synthesis according to our sequences or obtained from collaborators where they will be fully Sanger sequenced prior to use in IAV rescue. Point mutations may be introduced via site-directed mutagenesis using the guidelines set out above. Once generated these viruses will be used in vitro to assess fitness in avian and mammalian cell lines by measuring replication characteristics, innate response antagonism and the ability to interact with host derived partners. The viruses may be used to inoculated avian species (e.g. chickens, turkeys or ducks) to assess fitness in a whole animal model and look at transmission. Insertion of influenza A virus genes or reporter or tags and the associated gene products to K-12 derived E.coli will not alter the pathogenic traits of the bacterial host since none of these have known harmful characteristics.

Group 1 – Wild type influenza viruses will not be altered in sequence from the natural isolate and the use of reverse genetics will not alter the characteristics of the virus from the parental isolate.

Group 2 & 3 – Segment swapped viruses and sequence mutation viruses in the whole are not likely to alter existing pathogenic traits in humans since segment swaps or point mutations will only occur amongst viruses isolated
from the same species host (e.g. human virus segment swaps or identified point mutations into other human viruses) or between avian species only (e.g. duck virus segment swaps or point mutations into isolates from chickens). The swapping of avian influenza segments into other avian influenza virus isolates may result in the introduction of a mammalian adaptation motif into a strain that previously did not have that motif. For example the swapping of the PB2 (viral polymerase) segment for one that contains a mutation at amino acid position 627 to a Lysine, many avian strains in nature do possess this mutation. Mutation at 627K in PB2 is known to enhance the ability of the influenza viral polymerase complex to replicate genomic RNA in mammalian cells. However since avian virus mammalian adaptation is multi-factorial including receptor preference changes, virion stability enhancement as well as viral polymerase activity an increased ability in one characteristic as a result of a segment swap or cluster of point mutations in a segment will not lead to greatly enhanced replication of an avian virus in mammalian hosts (10-12). We will not generate avian viruses that might be predicted to have more than one of these characteristics enhanced in mammal. Low pathogenicity avian viruses that contain a single mammalian virus motif may infect a human after exposure to a high aerosolised dose and replicate in lung cells but this will not be efficient replication, the virus would be susceptible to anti-viral drugs and no onward transmission would occur.

Group 4 – Insertions and deletions to influenza viruses. The deletion of viral genetic segments or non-coding portions of the viral genome are on the whole likely to reduce pathogenicity of influenza virus strains in humans. Many of the viral proteins are essential for efficient replication in a cellular environment. In addition many of the accessory proteins have also been demonstrated to be important in conferring pathogenicity in vivo (13). The majority of the influenza genomic segments encode for one or two proteins so deletion of proteins does not alter or may only alter the level of protein expression of one other viral protein. There are no known toxic or oncogenic characteristics known for any of the viral proteins. Insertion of tags or reporters into the genome of influenza viruses will not increase the pathogenic traits of the virus, tags and reporters are notoriously unstable in influenza viruses and their fusion to viral proteins will not change the function of viral proteins in an adverse way. If anything the insertion of tags or reporters will disrupt virus replication or protein function leading to an attenuation of virus pathogenesis.

Evaluation of foreseeable effects

Group 5 - PR8 backbone IAVs. These viruses contain the internal genetic segments (M, NS, NP, PA, PB1 and PB2) from the well characterised lab adapted vaccine strain A/PR/8/34 (PR8) and the HA from any low pathogenic HA subtype (H1, H2, H3, H4, H5 (without multi-basic site only), H6, H7 (without multi-basic site only), H8, H9, H10, H11, H12, H13, H14, H15, H16) coupled with any NA subtype (N1, N2, N3, N4, N5, N6, N7, N8, N9). These viruses will be lowered in their pathogenic potential compared to the parental virus from which the HA and/or NA originate from. PR8 is a highly laboratory adapted influenza strain that has been passaged in cell culture, mice and ferrets over 1000
times and as a consequence has become highly attenuated in humans (14). The exact mutations that have led to this attenuation in humans has not been documented but human volunteer trials of recombinant influenza viruses possessing the six internal genes (PB1, PB2, PA, NP, M, NS) of the highly lab adapted vaccine strain A/PR/8/24 and the 2 surface proteins (HA & NA) from other human virulent influenza strains demonstrates that the attenuation is conferred by the presence of the six PR8 genes and that the HA & NA genes of PR8 are not required for attenuation in humans (14, 15). Viruses with the same genetic constellations as described above are generated by many laboratories all over the world and are generated in huge quantities worldwide at ADCP HG 2 during part of human influenza vaccine manufacture, including in the UK at NIBSC. Alteration of the natural HA and/or NA in sequence to change receptor preference, HA stability, antigenicity or NA activity will not increase the pathogenicity of the PR8 backbone IAVs. We will not generate PR8 backbone viruses that are altered in the NA segment to be resistant to neuraminidase inhibitor drugs.

Group 6 – PR8 pseudotyped IAVs. These viruses contain the HA and NA (as a minimum) from the well characterised lab adapted vaccine strain PR8 and the remaining segments from any other IAV, including those categorised as highly pathogenic in their parental form. The pathogenic traits of these viruses will be lower or equivalent to the parental viruses from which the other genetic segments originate. The hazards directly associated with recombinant influenza viruses bearing the surface antigens of the attenuated vaccine strain PR8 virus is low since the PR8 HA has a receptor preference for α2-3 linked sialic acid which is not found abundantly in the upper respiratory tract of mammals and thus are highly unlikely to infect an individual or transmit (Roberts et al 2011). The host range is not predicted to be extended for any of these viruses. In the extremely unlikely scenario these viruses do infect a human the PR8 HA & NA, which have a preference for α2-3 linked sialic acid, may allow replication deeper in the respiratory tract where these sialic acids are found in humans rather than the typical upper respiratory tract infection usually experienced by human influenza infections and this may cause increased respiratory symptoms. These viruses remain susceptible to neuraminidase inhibitors that are routinely used for treatment in humans against influenza infection. Moreover, there is considerable cross-reactivity between the pdmH1N1 2009 human virus and PR8, so people infected in 2009 or subsequently vaccinated will have protection against infection with the PR8 based viruses (16). For highly pathogenic viruses it has been shown that removal of the multiple basic cleavage site is sufficient to reduce the pathogenicity of the virus genetic constellation (17). The multiple basic cleavage site in the HA of highly pathogenic viruses is responsible for viral spread beyond the respiratory tract and the cause for the extreme pathogenicity observed by these viruses. The substitution of highly pathogenic HA and NA genes with those from the restricted PR8 virus will substantially lower the pathogenicity of these viruses in mammals.
in vivo work will be performed in the Poultry BSU both in containment level 2 laboratories on The Pirbright Institute site.

1. A lab coat and gloves will be worn to protect from contamination
2. All work with infectious influenza virus will be performed in primary containment (a class II MBSC, negative pressure poultry isolator or on a down-table with a face-fitted FFP3 face mask). All primary containment is serviced annually by an outside contractor and records maintained.
3. Influenza virus work is carried out in restricted access containment level 2 laboratories.
4. Training is given to all workers prior to unsupervised work on identification of influenza viruses that can be used concurrently, the need for separated equipment for different IAV groups and disposable consumables including filtered tips, and the segregated storage of plasmids carrying IAV genetic information, how to respond to an uncontained spill of IAV (exit the laboratory and inform the duty biological safety officer).
5. All IAVs will be stored appropriately in screw-capped tubes with O-rings and labelled.
6. All contaminated waste will be chemically decontaminated by a validated disinfectant (5% Distel for 5 minutes or 1% Virkon for 10 minutes) before being disposed down the sink or autoclaved before leaving the building. The only exception is infected eggs or avian carcasses which are disposed of in double bags in sealed and labelled burn bins and disposed of via a clinical waste route.
7. Accidental spillages inside primary containment dealt with double concentration disinfectant (e.g. 10% distel for 5 minutes or 2% Virkon).
8. Occupational Health screening and policy in place to identify those at greater risk from influenza virus infection, (immune-suppressed, pregnancy etc) (H&S-GUIDE-29).
9. Vaccination with human seasonal influenza vaccine offered to all workers and confidence of workers to report influenza like illness to line managers to prevent community influenza being brought into the laboratories.
10. All new HA and/or NA segments will be sanger sequenced prior to reverse genetics rescue to determine that the expected sequence is correct following cloning or synthesis of plasmids. This is of particular importance when using plasmids encoding for the influenza sequences of H7 or H5 HAs where the multiple basic cleavage site has been engineered to be single basic and therefore of low pathogenicity.
11. All PR8 backbone viruses will be attenuated for replication in humans due to the six internal genetic segments from the PR8 strain which has been shown be limited in human hosts (7, 8).
12. No known mutations to alter the susceptibility of the NA gene for the anti-influenza neuraminidase inhibitor class of drugs (e.g. Oseltamivir, Zanamivir and derivatives) will be introduced.

Validation of disinfectants
1% Virkon with a contact time of 10 minutes and 5% Distel for 5 minutes have been validated against various strains of influenza virus or are approved by DEFRA as a method of disinfection for avian influenza viruses (a) (b) (c).

Project Additional Information

02/03/2022
Purposes of the contained use

The purpose of this document is to describe projects involving genetically modified animal herpesviruses at The Pirbright Institute. The projects will involve: 1) use of animal herpes viruses as vaccine vectors to control animal viral disease, and 2) understanding pathogenesis of animal herpesviruses in their natural hosts. A list of the herpesviruses is provided in section 7 of this document.

Recipient or parental organism

Among the members of the subfamily Alphaherpesvirinae of Herpesviridae, at The Pirbright Institute, genetic modification of viruses is being conducted on Marek's disease virus (MDV; also known as gallid herpes virus 2, GaHV-2), MDV-2 (also known as MDV strain 2, MDV strain SB-I, MDV strain HPRS24 or gallid herpesvirus 3, GaHV-3), infectious laryngotracheitis virus (ILTV, also known as gallid herpesvirus 1, GaHV-1), herpesvirus of turkey (HVT, also known as Meleagrid herpesvirus 1), duck enteritis virus (DEV), psittacid herpesvirus 1 (PsHV-1, also known as Pacheco's parrot disease virus), perdicid herpesvirus 1, pheasant herpesvirus, stork herpesvirus, quail herpesvirus, bovine herpesvirus 1 (BHV-1) and equid herpesvirus 1 (EHV-1).

The only Betaherpesvirinae member which will used in GM related projects at the Pirbright Insitute is porcine cytomegalovirus (PCMV).

The only Gammaherpesvirinae member which will be used in GM related projects at the Pirbright Institute is bovine herpesvirus 4 (BHV-4).

The viruses mentioned above will be refered to as the parental organisms throughout this document.

Host/vector system

BHV-1 and BHV-4 mainly affect cattle. PCMV is only known to infect pigs. The host system for EHV-1 is horse. No positive serological results have been shown in samples from humans working with horses infected with EHV-1.

Domestic chicken (Gallus gallus domesticus) is considered as the host organism for GaHV-1, GaHV-2 and GaHV-3. Domesticated turkey (Meleagris gallopavo) is considered the host for MeHV. Anatidae species (ducks) are hosts for DEV. MDV is isolated from species other than domestic chicken such as partridges, european quails, ducks or geese.

There is no confirmed report indicating infection of MDV or other avian herpesviruses listed above in human. Stork herpesvirus was isolated from black storks (Ciconia nigra) and it has shown no serological cross reactivity with other avian herpesviruses. Pheasant herpesviruses affect pheasants, as their name implies.

E.coli strains (mainly strain DH10Beta, its derivatives and in some cases strain DH5alpha or B strain derivates) will be used for cloning and/or genetic manipulation of the parental viruses. These strains are avaliable commercially and are considered as non-pathogenic strains widely. In addition, E.coli Strains EL250, EL350 and SW102 are derivatives of E.coli strain DH1 OB. These strains contain a defective " prophage with recombination proteins exo, bet and gam.

Origin & function

Bacterial artificial chromosome (BAC) technology and/or CRISPR/Cas9 method will be employed to generate genetically modified microorganisms (GMMs) from the parental organisms (listed above). The inserted gene products will be heterologous antigens, such as a surface or internal viral protein. We will also consider insertion of cytokines such as IL 18 that may result in a better immune response to the vaccine. Individual risk assesments will be required in such occasions. Genetic materials for the vaccines will be chosen from a wide range of sources and for different purpouses (explained below):

1- For vaccine studies and expression of heterologous antigens of other viral origins: parental organisms will be used to deliver antigens selected from pathogen of the hosts which are listed in the section 7. For example, GaHV-2 will be
used to deliver antigens from sources such as avian influenza viruses (e.g. HA and/or NA glycoproteins of AIV), infectious bursal disease virus (e.g. VP2 protein), ILTV (e.g. glycoproteins 0, I or B), infectious bronchitis virus (e.g. spike protein), MDV (e.g. glycoprotein B), Newcastle disease virus (e.g. F glycoprotein). Similarly, BHV-4 will be employed as a multispecies vaccine to deliver heterologous antigens from sources such as Nipah virus (NiV). PCMV will be used as a porcine vaccine vector to deliver heterologous antigens from sources such as porcine reproductive and respiratory syndrome viruses.

2- Vaccine studies and expression of immunomodulatory genes to boost the immune response to the vaccines. More specifically, studying the effect of IL18 in enhancing immune response in GaHV-2 or GaHV-3 origin vaccines delivering gO, gI or gB antigens from ILTV. In such cases, individual risk assessments will be performed to ascertain the safety of the vaccines.

3- Mutagenesis techniques or deletions of specific genes (such as gB, Meq’ or pp38 of MDV, or Bc12 of HVT) to study the effect of the genes on the parental viruses entry, replication, egress, pathogenesis and/or oncogenicity.

4- Exchange of genes from two related viruses (such as exchange of HVT origin gE, gI and/or gM with their counterpart from MDV) to study the effect of the glycoproteins in cell free virus production.

Evaluation of foreseeable effects

Evaluation of any foreseeable effects on human health:
MDV, GaHV-2, GaHV-3, DEV, PsHV-1, perdicid herpesvirus 1, pheasant herpesvirus, quail herpesvirus and stork herpesvirus are not pathogenic in human. It is not expected genetic manipulation of the viruses would expand the tropism of the viruses to humans.

There is no evidence that BHV-1, BHV-4 or PCMV can infect humans. Sera from naïve humans contain natural antibodies that efficiently neutralize BHV-4, which may provide an innate immune mechanism preventing crossspecies transmission of BHV-4 to humans. No positive serological results have been shown in samples from humans working with horses infected with EHV-1. It is not expected to see a higher level of pathogenicity in BHV-1, BHV-4, PCMV and EHV in their host or in human.

Any mutation or gene expression in the context of the viruses which may result in a change in viral tropism is outside of the scope of this document. In such cases, a separate risk assessment will be required.

Evaluation of any foreseeable effect on the environment:
Avian herpesviruses such as MDV and HVT do not infect and replicate in mammals, as a result the only potential hazard is to poultry. HVT and GaHV-3 are widely used as vaccines against MDV and as vaccine vectors to deliver antigens from other viral pathogens to chicken safely. It is not expected to see a higher level of pathogenicity in HVT or GaHV-3 delivering a heterologous antigen, as the fitness of the recombinant viruses are usually lower than that of their parental virus. It is also not expect to see a change in tropism of the viruses due to insertion of heterologous antigens. Majority of the heterologous antigens are usually localised across the cytoplasmic membrane and herpesviruses have a nuclear maturation cycle. As a result, the risk of changing the parental virus tropism due to inclusion of the antigens in the mature herpesvirus particles is very minimal. The only concern is with expression of ILTV gO/1 or gB in the context of GaHV-2 or other avian herpesviruses. It is likely that the recombinant GaHV-2 would carry IL TV gO/1 or gB in its viral particle. However, considering that both viruses are viruses of poultry with a tropism to the respiratory system, it is unlikely to see a change in the virus pathogenicity, tropism and/or widening its host range. In addition, gB from ILTV are used safely in a fowlpox system (001: 10.1080/03079450120044542) to vaccinate chickens against ILTV. As it was noted earlier, it has been reported widely that alterations to MOV, HVT or GaHV-3 genome to insert antigens from other viruses usually is associated with a reduction in the fitness 01 the parental virus which results in further attenuation 01 the recombinant virus vectors. Delivery 01 antigens with GaHV-3, HVT or attenuated vaccine strain of MOV is shown to be safe, it is used commercially worldwide. It is expected that delivery of gB or gOlgl using GaHV-3 will be safe too.

The vaccine vectors will not be used to express any oncogenes or toxins. However, usage 01 cytokine genes such as
IL-18 that may result in an enhanced immune response to the vaccines will be considered. IL-18 cytokine has been used safely in fowlpox virus vector vaccines (00110. 1016~ .vaccine .2006.03 .006 and 10.1111/j.1574-695X.2011 .00850.x). Chicken immunised with FPV expressing IU8 and heterologous antigens, have shown a superior immune response to the vaccine compared to the control group. It is also thought the expression of IL-18 helps chicken to overcome the toxico-side effects 01 FPV (10.1 016/j.vaccine.2006.03.006). Although, there is no report indicating expressing IL8 using an avian herpesvirus, there are records reporting safe usage 01 HVT in chicken delivering different cytokines including IFN-gamma. Considering the relation between IU8 and IFN-gamma and based on the previous reports, we are not expecting to see any adverse effects in GaHV-3 vaccines delivering chicken IU8 and ILTV gB or gOli.

Usage 01 OEV, PsHV-l, perdicid herpesvirus 1, pheasant herpesvirus and stork herpesviruses will be limited to deliver heterologous antigens to their natural hosts. Unfortunatley, there has been a lack 01 information regarding the above viruses. However, based on our experience with them, we are not expecting to see a higher level 01 infectivity in their recombinant compared to that 01 their parental strains. Work involving GMO derived MOV, GaHV-2, GaHV-3, MeHV, ILTV, OEV, PsHV-l, perdicid herpesvirus s 1, pheasant herpesvirus, quail herpesvirus and stock herpesvirus will be performed in ACGM containment level 2 facilities.

BHV-l, BHV-4, EHV-I and PCMV:

BHV-I causes infectious bovine rhinotracheitis (IBR) and infectious pustular vulvovaginitis in cattle. BHV-I can infect sheep, goats and pigs, but without causing disease. BHV-4, in contrast, causes no illness in cattle. BHV-4 can infect goats, but not sheep or pigs. BHV-I and BHV-4 are found in cattle all over the world and are not mentioned in animal health orders, except in Oenmark and Switzerland that have eradicated BHV-I. Cattle can become latently infected with BHV-I and BHV-4. However, BHV-I gE and gI deletion mutants are not pathogenic in their natural host, cattle, do not appear to establish latent infections and are being considered as live vaccines. The same considerations 01 the effects of foreign viral or cytokine genes on the pathogenicity 01 BHV-I lor animals other than cattle, apply as lor humans. BHV-I is a labile virus and is spread by direct contact rather than airborne transmission. Virus is therefore unlikely to survive lor any length 01 time in the environment. Insertion of foreign viral or cytokine genes into attenuated BHV-I may confer a selective advantage in infected animals in the wild, therefore all infected material, including animals, have to be properly contained and disposed 01. Recombination between modified BHV-I and another bovine herpesvirus is low as the homology between the two viruses would be too low to support a recombination event. Although expression olloiregional viral genes may increase the virulence 01 gE or gl-deleted mutants 01 BHV-I for cattle, the virulence 01 the recombinants is unlikely to be greater than that 01 wild-type BHV-I. Since expression 01 certain bovine cytokine genes may increase the virulence 01 the recombinant virus lor cattle, all animal experiments will be done under high containment so that the potential 01 infection from experimental animals should be negligible. The hazard 01 recombinant BHV-4 vectors to humans and to the environment is extremely low and the risk is no more than that 01 the wild type virus. The safety 01 BHV-4 viral vectors has been demonstrated in a range 01 mammalian species. BHV-4 viral vectors are highly attenuated in species other than cattle. In non-bovine species, BHV-4 does not establish a viraemia or result in virus shedding. Rather BHV-4 vectors show a highly attenuated, transient replication localized to the site 01 inOCUlation and are incapable 01 spreading to other animals. As a member 01 the enveloped Herpesviridae family, BHV-4 and other viruses listed in this document are expected to possess low environmental stability and direct contact between cattle is typically necessary for spread. The hazard of BHV-4 viral vectors to the environment is extremely low and the risk is no more than that 01 the wild type virus.

EHV-I is a pathogen of equine species and BHV-I is known to cause several disease worldwide in cattle including respiratory disease, abortion, genital disease, or occasionally encephalitis. Glycoprotein E and I deleted EHV-I recombinant viruses has been used as vaccine candidates. Oeletion 01 gE in BHV-I was associated with attenuation
01 the virus. Glycoprotein I or glycoproteins II deleted BHV-I was used as candidate vaccines. It can be concluded both gE and/or gl deleted EHV-I and BHV-I are associated with the viruses pathogenicity. Hence, the risk of gE/gl deleted viruses to the environment will be minimal.

PCMV is highly species-specific and is ubiquitous within its pig host, where infection is generally subclinical. PCMV infects the nasopharyngeal region of the upper respiratory tract and similar to all herpesviruses establishes a latent/persistent life-long infection. Recombinant PCMV are expected to possess low environmental stability and direct contact between pigs is typically necessary for spread. The hazard of recombinant PCMV viral vectors to the environment is extremely low and the risk is no more than that of the wild type virus.

Any work related to genetically modified organisms related to BHV-I, BHV-4, PCMV and EHV discussed in this section will be assigned to ACGM containment level 2. No specific containment under SAPO is required.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

In vitro and in vivo work with recombinant organisms listed in this document (ACGM class II) will be performed in the containment level II facilities. The following measures will be implemented for safely management of waste:

In vitro ACGM class 2 work with GMs listed in this document will be performed in compliance with the SACGM compendium of guidance:

1. A lab coat and gloves will protect the operator from skin contact with GMMs.
2. All in vitro work with live virus will be carried out in a class II microbiological safety cabinet (MBSC).
3. A validated disinfectant such as 1 % Virkon S [Dupont], Trigene or 0.5% FAM 30 [Evans Vanodine] will be used to disinfect any exposed surfaces. Both are highly effective virucidal disinfectants.
4. Any solid waste, culture vessels or exposed disposable equipment needs to be autoclaved at 120°C for 30 minutes.
5. Any liquid waste will be disinfected appropriately using a validated disinfectant (1 % Virkon for 15-30 minutes).
6. Only authorised personnel will have access to the GMMs.
7. Accidental spillages of liquid waste will be deactivated with 2% Virkon S or 1 % FAM 30; the use of double strength disinfectant will ensure that it is not diluted past the effective concentration.

All agreed and accepted by BAGMSC Committee with final approval 08/01/19.
Project Additional Information

Purposes of the contained use

The Pirbright Institute is a research institute focusing on preventing and controlling viral diseases, especially of livestock but also zoonotic and human pathogens. Much of this work can be conducted in various types of cultured cells, in keeping with our commitment to replace, reduce and refine the use of animals in research. Contained use in this respect relates to addition/modification of genetic material to cultured cells of animal origin.

Recipient or parental organism

The cultured cells covered by this application are not viable except in cell culture. In some very special cases, e.g.
mouse embryonic stem cells, the cells could be recovered into a whole-animal in vivo form (mouse); such recovery and its products are not included. Human pluripotent stem cells (human embryonic stem cells (hESC) or human induced pluripotent stem cells (human iPSCs) are also excluded.

**Host/vector system**

The exogenous nucleic acid may be inserted into the cell using chemical or physical means, e.g. chemical transfection agents (calcium phosphate, Lipofectin or other proprietary systems) or physical methods such as electroporation. Viral vectors are not covered by this risk assessment.

**Origin & function**

Genetic inserts/genes - Expressed genes under this RA must not encode known toxins, e.g. Schedule 5 toxins such as ricin. Genetic material inserted into cells must not be infectious (i.e. capable of reproducing a whole pathogen), this is particularly relevant when cloning the genome of positive sense RNA viruses. When transfection of genetic material representing viral genomes is undertaken (including DNA or RNA versions) no more than 80% of the genome can be encoded in aggregate between the DNA/RNA molecules used in a single transfection and care should be taken that no overlap of concurrent work where the whole genome might be in contact occurs (recombination). Examples of nucleic acids considered within this Risk Assessment include protein-coding genes from other organisms, plasmids, non-coding RNAs such as guide RNAs, hairpin RNAs, synthetic DNA, non-coding RNA (all with the exclusions noted above and below, e.g. non-infectious).

Gene editing - it is not entirely clear under current legislation (as of Jan 2019) whether products of gene editing that do not incorporate exogenous nucleic acid are to be considered GM under UK legislation (“mutagenesis” exemption, Part 3(a) of Schedule 2 of The Genetically Modified Organisms (Contained Use) Regulations 2014, Guidance on Regulations, Schedule 2, Part 3(a)) or, for genetic material derived from the same or similar species “self-cloning” exemption at Part 3(b)). Conservatively, animal cells that are such products are included in this risk assessment as their risk profile is considered similar to other animal cells with modified genetic material; this does not imply a position as to whether any such cell or cell line is or is not a GMO under relevant legislation.

**Evaluation of foreseeable effects**

GMOs are cultured cells with additional/modified genetic material. Cultured animal cells are unable to survive or replicate outside an artificially-maintained tissue culture environment and pose negligible risk to the environment. In some cases, e.g. mouse embryonic stem cells, the cells can be recovered into a whole-animal form (mouse); such recovery and its products are not included in this risk assessment. Animal cells, including human cancer-derived cells ex vivo, are not known to pose significant hazards to human health. Cells may harbour animal pathogens or other environmental hazards and may therefore need to be handled at higher containment levels or with cell-type specific mitigations (but cells known or likely to harbour group 3 or group 4 agents are excluded from this Risk Assessment).

Genetic material used under this risk assessment must not encode for known toxins, e.g. Schedule 5 toxins, or infectious material. For genetic material encoding other potentially hazardous molecules, such as immune modulators, growth factors, allergens, hormones or oncogenes, consideration must be given as to whether exposure could be sufficient to cause harm to human health or the environment - this is a priori considered unlikely for the cells but may affect assessment of downstream processes, e.g. purification of such molecules from the cells or tissue culture supernatant.

The genetic inserts will not be known toxins. The genetic inserts will also not be capable of producing an infectious pathogen. The genetic inserts will be unable to be passed to bacteria as the vectors are non-mobile or mobilisation defective. The GM cells/organisms are considered to be no more harmful to human health or the environment than the unmodified form. Exposure to large quantities of cells, tissue culture media or gene products, e.g. by ingestion,
could conceivably cause harm to human health, this is appropriately mitigated by good laboratory practice, e.g. as per applicable building and laboratory codes of practice, appropriate to the unmodified form.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

| not applicable (no larger GMOs included) |

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

| N/A |

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

The GMOs - cultured animal cells - are not viable outside special culture conditions, e.g. tissue cell culture media, controlled temperature, etc. For disposal, all viable material will be rendered inviable by physical or chemical means, e.g. autoclaving 134°C 30 minutes or using 2% Virkon for the required contact time. Where possible disposable consumables will be used. Contaminated disposables are placed in waste bags which are sealed, placed in labelled metal tins and transferred to Central Services Unit for autoclaving and disposal. Spillages and contaminated surfaces will be treated with a validated disinfectant, e.g. 2% Virkon, and wiped with absorbant tissue until dry; said tissue disposed as disposable consumables. Non-disposable items will be soaked in 1% Virkon for the required contact time and autoclaved.

### Purposes of the contained use

In order to investigate the relative contribution of RSV proteins to the host range phenotype of RS viruses, the replication of recombinant BRSV, in which the surface glycoproteins or the non-structural genes have been replaced either alone or in combination by those from HRSV, will be investigated in different bovine and human primary cell cultures and cell lines. In addition, the replication of these chimeric viruses in cattle and mice will be investigated.

Characterisation of the role of different RSV proteins in determining the host range phenotype of RS viruses may lead to the development of a small animal model of BRSV and/or the development of attenuated RSV vaccines for man and cattle.

### Recipient or parental organism

Bovine respiratory syncytial virus.

### Host/vector system

Bovine RSV in which the F, G, SH, NS1 and/or NS2 genes have been replaced with those from human RSV.

### Origin & function

Bovine RSV in which the F, G, SH, NS1 and/or NS2 genes have been replaced with those from human RSV have been made by collaborators.

The F protein mediates virus attachment and penetration of cells.

The G protein mediates virus attachment and may also have other, as yet unidentified, functions.

The function of the SH protein is not known.

The NS proteins are involved in aspects of virus replication, in resistance to the antiviral effects of type I interferons, in regulating the induction of type I interferons and may also have other, as yet unidentified, functions.

### Evaluation of foreseeable effects

HRSV is a major cause of respiratory disease in young children and BRSV causes a similar disease in young calves. Although closely related, with greater than 80% amino acid identity for 8 of the 11 proteins, BRSV and HRSV display a restricted host range in vivo. However, HRSV and BRSV have an overlapping host range in cell culture, in vitro. Replacement of BRSV genes by genes from HRSV may alter the host range phenotype of the virus. Thus the chimeric BRSV may be able to infect humans, chimpanzees, cotton rats and/or mice and may replicate more efficiently in primate cells than the parental BRSV. It is possible that some of the chimeric BRSV may replicate less efficiently than the parental virus in some cells or animals. If replication is poor the chimeric virus may adapt and evolve giving rise to virus with altered pathogenicity.

HRSV is ubiquitous in the human population, the majority of whom have experienced one or more HRSV infections and therefore have some pre-existing immunity. HRSV infection in adults is usually restricted to the upper respiratory tract. However, HRSV infection in young infants, the elderly or in immunosuppressed individuals can be severe. Similarly infection with BRSV is widespread in the cattle population and reinfection is usually restricted to the upper respiratory tract. If chimeric rBRS viruses were to infect an adult, pre-existing immunity to the F protein of HRSV, which is the major protective antigen of the virus, is likely to limit the replication of the chimeric virus. Thus there is only 19% amino acid difference between the BRSV and HRSV F proteins and neutralising monoclonal antibodies specific for the F protein recognise both the HRSV and the BRSV F proteins. These anti-F mAbs protect against experimental HRSV infection in mice, HRSV in children and BRSV infection in calves. Bovine sera will neutralise HRSV and human convalescent sera neutralise BRSV. However, the neutralisation titres are higher against homologous viruses. Intramuscular injection of cattle with HRSV will protect against BRSV infection and infection of cotton rats with BRSV will protect against HRSV infection. Infection of adults with the GMM is therefore unlikely to produce disease any more severe than a cold. In contrast, infants and immunosuppressed individuals are at risk of developing bronchiolitis and pneumonia if they became infected.

The chimeric viruses may be more hazardous to humans than wild-type BRSV, but are unlikely to be as hazardous to humans as wild-type HRSV.
Since the organisms will be handled as ACDP category 2 pathogens for all experiments, the likelihood of environmental exposure is small. Furthermore, RS viruses do not replicate in the environment outside of the host animal and would not be expected to survive for long in the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

RS viruses are labile viruses and are readily inactivated. All contaminated or potentially contaminated category 2 laboratory waste is autoclaved or incinerated (100% kill).

Pipettes and similar objects are disinfected, and surfaces are wiped, with hypochlorite solution or 70% ethanol (100% kill). Waste animal bedding and small animal boxes will be autoclaved (100% kill). Large animal rooms will be fumigated with formaldehyde (100% kill). Animal carcasses will be incinerated (100% kill).

Please enter comments on the GM safety committee on the risk assessment

Initially, the proposed genetic modification work was brought to the attention of the Genetic Modification Safety Committee in the form of an amendment to be considered as part of a previously notified CU2 project in 2000 (re-notified under transitional arrangements in 2001) but the Committee felt this was inappropriate and had requested to the project proposer that a new full risk assessment must be carried out and suggested some amendments. This was reviewed by the Committee and is the risk assessment attached here.

As part of the current programme on immunity to TB in cattle, we will evaluate immune responses and protective efficacy of recombinant adenovirus expressing antigen (Ag) 85 of Mycobacterium bovis. The objectives of the project are:

1. To evaluate the immune responses elicited in cattle by the recombinant human adenovirus type 5 expressing Ag85A (Ad85A) of M. bovis.

2. To evaluate the use of recombinant the Ad85A for in vitro stimulation of T-cells.

No construction of vector will take place at IAH as the GMO will be supplied by our colleagues at Veterinary Laboratory Agency. E.coli DH5alpha or equivalent.

Recipient or parental organism

Recombinant, replication deficient human type 5 adenovirus.

The vector is pACCMV or equivalent, such as pjW24. This is a widely used shuttle vector for producing recombinant adenoviruses.

Host/vector system

Recombinant DNA will be placed between the cytomegalovirus promoter and the SV40 poly(A) sequence.

Origin & function
Mycobacterial DNA encoding Antigen 85A (Ag85A). The gene encoding Ag85A will be inserted into the adenovirus vector mentioned above for expression in mammalian hosts for expression and immunization.

Evaluation of foreseeable effects

Recombinant Ag85A expressed in adenovirus vectors will induce Ag85A specific immune responses in immunised hosts. This construct has been shown to elicit immune responses in cattle (Vordermeier, H.M. Infect Immun 74:1416-1418).

Due to its attenuation, no new virus particles will be produced in the host. Ag85A has no known toxic effects, it is not a known virulence gene and it is not expected to confer replication competency to the adenovirus vector.

The adenovirus to be used in these experiments is human type 5, which is a double-stranded DNA virus. Wild-type, unattenuated adenovirus most commonly causes self-limited infections in the respiratory tract, causing the "common cold" and the gastrointestinal tract, causing diarrhoea.

Wild type adenovirus have been safely used as oral vaccines to prevent adenoviral infections to more than 10 million people and is also being given to military personnel in the USA and Canada (Rubin B.A. and Rorke, L. B. Adenoviral vaccines. In: Plotkin & Mortimer (Eds). Vaccines. (1988) W.B. Saunders. Philadelphia, pp 492).

The vector to be used in these experiments will have deletions in the E1 and E3 regions of the adenoviral genome and has been described by Wang, J. et al. J Immunol 173:6357-6365. In brief, the Ag85 sequence is in frame downstream of human tissue plasminogen activator signal peptide, which in turn is downstream of the murine cytomegalovirus promoter. 3' of the Ag85 sequence will be the SV40 poly (A) signal. The E1 region is essential for replication and propagation and its removal renders the virus replication deficient. Deletion of the E3 region is not essential for viral growth, but its removal allows the insertion of guest genes in this region. (Trappe, B. Adenoviral vectors for gene transfer. Advance Drug Delivery Rev. (1993). 12:185.; Bramson, J.L. et al. The use of adenoviral vectors for gene therapy and gene transfer in vivo. Curr. Opin. Biotech. (1995). 6:590).

The recombinant adenoviral vector has been evaluated in a number of clinical trials and found to be safe. The safety and efficacy data from both clinical and pre-clinical studies using recombinant adenoviral gene transfer vectors have widely been reported (Zhang, W. W. Development and application of adenoviral vectors for gene therapy of cancer. Cancer Gene Ther. (1999). 6:113).

The main hazard with adenovirus would be infections of humans and other animals, but no detrimental effects are expected on either. Exposure monitoring by eg. Serological testing of animal carers, etc. is not necessary. These tests would be unable to distinguish between wild type viruses and the attenuated virus used in this study. Wild type adenovirus is a common cause of mild upper respiratory infections worldwide and many of us will already have seroconverted. The hazard is also minimal given the replication deficiency of the construct. We intend to reduce even this minimal risk by working with the construct at ACGM level 2.

Given the replication deficiency and the containment level at which we intend to work, the likelihood of release of the recombinant vector to the environment is effectively zero. There is no production of new viral particles in vaccinated hosts.

All work under this proposal will be carried out at HG 2 containment. No additional hazards over those of wild type adenovirus are foreseen. Cattle inoculated with recombinant adenovirus will be housed in appropriate category 2 containment facilities at all times during the experiment.

Accordingly this proposal seeks approval for a confirmed containment level 2 for work to be carried out under this proposal.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Waste materials generated by these experiments will be inactivated mainly by autoclaving at 121°C for 30 min and/or by incineration. Where necessary, materials will be soaked with 1% solution of Virkon for a minimum of 20 minutes.

# Project Additional Information

## Purposes of the contained use

The aim is to assess the potential of new vaccination strategies in protection against bovine TB. Prime-boost strategies utilising MVA expressing mycobacterial antigens have been used in human studies and show enhanced immunogenicity compared to conventional vaccines (McShane et al, Nature Med 2004)

Cattle will be vaccinated with BCG (prime) and boosted at defined intervals with MVA expressing immunodominant antigens from Mycobacteria. Immune responses will be assessed in vaccinated cattle to assess vaccine efficacy. This vaccination strategy is expected to induce broad protective immunity.

## Recipient or parental organism

Modified vaccinia virus ankara (MVA) expressing M. tuberculosis antigens will be produced by infection of permissive chick embryo fibroblast cell and transfection with a shuttle vector containing the recombinant genes plus a marker gene (green fluorescent protein). The shuttle vector recombines with the viral genome inside cytoplasm of the cell. The MVA viruses will be manufactured at Jenner Institute Vector Core facility at Oxford University.

## Host/vector system

Modified Virus Ankara (MVA) is an attenuated vaccinia strain that, by extensive passage in chick embryo fibroblasts, has had multiple regions of the genome deleted. This strain has been demonstrated not to replicate in a range of primary human cells and mammalian cells, but has recently been shown to replicate in a baby hamster kidney cells. Genes from M. tuberculosis will be expressed in a shuttle vector under the control of the MVA 7.5 promoter.

## Origin & function

Mycobacterial DNA encoding Ag85A, TB9.8, TB10.4 and Acr2. The genes have been cloned at the Jenner Institute, Oxford.

The proteins to be expressed (Ag85A, TB9.8, TB10.4 and Acr2) are immunodominant proteins produced by Mycobacteria species during in vivo infection, these are major targets for T cell recognition.

The aim is to test the recombinant MVA expressing these proteins as part of vaccination strategies in cattle: by incorporating immunodominant proteins into the vaccine the protective T cell response should be enhanced leading to immunity from infection
Evaluation of foreseeable effects

MVA is highly attenuated and can only form infectious particles in permissive avian cells.

MVA expressing mycobacterial antigen 85A has been used in phase II human vaccine trials and has an excellent safety record (Hawksridge et al, J Infect Dis 2008).

No infectious particles can be generated in human or animal cells and therefore MVA cannot cause infection or disease.

MVA cannot disseminate in the environment due to its replication deficiency.

None of the expressed genes are oncogenic or toxic and are not expected to increase virulence of MVA

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Laboratory procedures: blood samples from MVA immunised cattle will be handled at containment level 2 within class II microbiological safety cabinets according to IAH vaccinia virus rules. Liquid waste will be treated overnight with 2% virkon prior to disposal into drains. Solid waste (plasticware) will be autoclaved (121°C, 30 min) prior to incineration. The safety cabinets will be disinfected with 2% Virkon wipe down at the end of any experimental procedure.

Animal housing procedures: animals will be housed at containment level 2 in locked accommodation with restricted access. All personnel handling MVA immunised animals will be required to wear protective accommodation with restricted access. All personnel handling MVA immunised animals will be required to wear protective clothing and gloves, which will be disinfected by wash down with 2% virkon following contact with animals. Walls and floors within the animal accommodation will be scrubbed with 2% virkon solution (minimum 10 minutes); wash down will be into drains with traps which contain 2% virkon (held for minimum of 10 minutes). Solid waste will be covered with 2% virkon for > 30 minutes prior to removal for incineration. All animals will be culled at the end of the experimental period and the carcasses incinerated.

This assessment has been reviewed and passed by the IAH Compton BAGMSC

Project Containment
The determinants of replication, transmission and pathogenicity of avian influenza viruses

The purpose of these experiments is to increase our understanding of the viral determinants for host adaptation, increased transmissibility and virulence of influenza viruses (AI) of poultry and mammalian species. This may lead to improved vaccines and better control measures against avian influenza infections in poultry and hence reduction of the viral load in the environment. We will use the reverse genetics system to produce recombinant influenza viruses derived from wild-type animal viruses to define which polypeptides, combination of polypeptides or particular amino acid residues are responsible for increases in either virus-host interactions, increased virus attachment and replication of viruses in different avian or mammalian cells and in animal models.

Recombinant low pathogenicity influenza viruses will be generated by transfecting eukaryotic cells (avian or mammalian) with the plasmids pHW 2000 or pHWScdB containing PB2, PB1, PA, HA, NP, NA, M and NS genes from low pathogenicity influenza A viruses, specifically:
(1) A/chicken/Italy1279/00 (H7N1)
(2) A/chicken/Pakistan/UDL-1/08 (H9N2)
(3) A/turkey/Turkey/1/05 (H5N1). The HA gene derived from this virus will be modified to delete polybasic amino acids at the cleavage site. The GMP construct will have a
mono basic HA cleavage site identical to that present in the low pathogenicity phenotype of H5N1 avian influenza viruses. (4) A/PR/8/34. This virus will be used as recipient of HA, NA and PB2 genes derived from the H7N1 and H9N2 and H5N1 viruses described above (number 1-3).

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

| Liquid waste containing infectious virus will be treated with 1% Virkon for a minimum of 30 minutes inside the Class II Microbiological Safety Cabinet (Class II-MSU), then a 50-100 ml maximum volume (in plastic flasks) will be placed into double autoclave bags (double autoclave bags will be made by inserting one autoclave bag inside the other one, this will create two protective plastic layers of the autoclave bags which further reduce the chances of any potential leakage of the contaminating material inside the autoclave bags) and into the designated metal tins, transferred to Microbiological Services (within the same building) and autoclaved at 135° C for 30 minutes prior to disposal by incineration. |
| Solid waste: Solid waste contaminated with infectious virus (plastic tips, flasks) will be immersed in 1% virkon for minimum of 30 minutes inside the Class II-MSU, then placed in double autoclave bags, put in a secure metal tin and autoclaved as described above and disposed by incineration. |
| Other solid waste such as eggs will also be disposed of by bagging in double autoclave bags within the ClassII-MSU, put in a secure metal tin and autoclaved as described above and disposed of by incineration. |
The autoclave is serviced quarterly and annually validated; records are kept and examined.

The Class II-MSU are tested and validated every six months during a scheduled maintenance period.

Animal waste in the animal facility (EAH corridor D) will be placed in the autoclave bags and sprayed with 1% virkon before being removed for autoclaving. They will then be autoclaved within EAH corridor D building before disposal by incineration.

The proposal has been extensively reviewed by the local Biological Agents and Genetic Modification Safety Committee and is now considered to be acceptable for notification.

Project Ref 97/11.1

Date Ackn’d 17/10/2011

Date Project Ceased

CU2 Project Title Vaccine efficacy of recombinant Newcastle disease virus expressing respiratory syncytial virus fusion (F) glycoprotein

Class 2

CultureVolClass2 < 1 Litre

Consent Granted

Project notified under transitional arrangements N
**Project Additional Information**

**Purposes of the contained use**

The aim of the project is to evaluate immune responses and protective efficacy induced by recombinant Newcastle disease virus (rNDV) expressing either bovine (B) or human (H) respiratory syncytial virus (RSV) fusion (F) glycoprotein (rNDV-F) in calves. The rNDV has been produced by Dr*, Mt Sinai School of Medicine, New York, USA. The RSV F gene has been inserted between the P and M genes of the Hitchner B1 strain of NDV. Calves will be inoculated intranasally (i.n.) or i.n. and intratracheally (i.t.) with rNDV-F and analysed at intervals for excretion of NDV, induction of RSV-specific immune responses, and clinical signs of disease. Vaccinated calves will be challenged with BRSV to determine the effect of vaccination on BRSV replication in the nasopharynx and lungs, and the development of pulmonary pathology.

**Recipient or parental organism**

The Newcastle disease virus (NDV) to be used is the lentogenic, avirulent Hitchner B1 strain, which is a licensed live vaccine virus, available for use in the UK.

**Host/vector system**

NDV is an avian paramyxovirus serotype 1 (APMV-1), and belongs to the Avulavirus genus within the Paramyxoviridae family. NDV is classified as ACDP CL2 and has been reported to cause short-lived conjunctivitis and 'flu-like symptoms in man. Many of the reported instances of NDV infection in humans have been the result of direct inoculation into the eye, either by laboratory workers or those handling vaccines. Reports of 'flu-like illnesses associated with NDV are rare. Both virulent (mesogenic) and avirulent (lentogenic) strains of NDV appear to be equally able to cause conjunctivitis in humans. However, both mesogenic and lentogenic strains of NDV have been tested in man as oncolytic viruses and cancer vaccines with no adverse effects, signs of evolution towards human pathogenicity, recombination or transmission from human to human. Furthermore, virus could not be recovered from either the nose or tracheal lavage of African green monkeys that had been inoculated intranasally and intratracheally with a lentogenic strain of NDV expressing the HN protein of human parainfluenza virus-3 (HPIV3).

Lentogenic strains of NDV are used as live vaccines in poultry. The Hitchner B1 strain is not classified as a specified animal pathogen by Defra (see page 133 of [http://www.hse.gov.uk/biosafety/gmo/acgm/acgmcomp/part2.pdf](http://www.hse.gov.uk/biosafety/gmo/acgm/acgmcomp/part2.pdf)) and is licensed for use in the U.K. Statutory action to control NDV is taken only for strains which are classified as "virulent" ([http://archive.defra.gov.uk/foodfarm/farmanimal/diseases/vetsurveillance/profiles/documents/sp-newcastle-disease.pdf](http://archive.defra.gov.uk/foodfarm/farmanimal/diseases/vetsurveillance/profiles/documents/sp-newcastle-disease.pdf)). NDV does not appear to infect cattle and vaccine strains of NDV are highly attenuated in experimentally infected calves. Although, NDV has been isolated from pigs with an influenza-like illness, experimental inoculation of piglets with a strain of NDV that resembles the B1 strain did not produce any clinical signs of disease.

**Origin & function**

The RSV F protein mediates fusion of the virus envelope with the cell membrane and fusion of infected cells with adjacent uninfected cells. The F protein is the major protective antigen of RSV and does not contain any potentially toxic or oncogenic sequences. Inoculation of mice or cattle with eukaryotic expression plasmids expressing the RSV F gene under the control of the HCMV promoter does not result in any harmful effects. There is no evidence that the RSV F protein activates TLR4 and induces the production of pro-inflammatory cytokines. However, no adverse effects have been seen following vaccination of small laboratory animals or cattle with recombinant virus vectors expressing the F protein.
RSV and NDV are related viruses of the Paramyxovidae family and cause respiratory disease in their respective host. rNDV-F expresses the native NDV F and HN proteins, which are involved in viral attachment and invasion of cells, and does not incorporate the RSV F protein into the virion. Therefore, expression of the HRSV or BRSV F protein will not be expected to alter the host range or tissue tropism of NDV. Furthermore, a lentogenic strain of NDV expressing the HN protein of HPIV3, which is more closely related to NDV than RSV, was highly attenuated in the nose and lungs of African green monkeys that had been inoculated intranasally and intratracheally with high titres of the recombinant virus.

If accidentally released into the environment, rNDV-F could infect susceptible individuals, but is unlikely to cause disease in livestock or poultry. Thus, following i.n. and i.t. inoculation of calves with high doses of a lentogenic strain of NDV expressing the bovine herpesvirus-1 (BHV-1) gD protein, NDV was not isolated from nasal swabs of any of the animals and none of the animals developed clinical signs of disease, even when the gD protein was incorporated into the NDV virion. Furthermore, there is evidence that insertion of a foreign gene between the P and M genes of lentogenic strains of NDV attenuates the virus further for poultry. Thus, rNDV (Hitchner B1 strain) expressing an influenza virus HA gene is attenuated in embryonated chicken eggs, in contrast to the parent wild-type. Similarly following ocularnasal inoculation of 1-week-old SPF chickens with 10^6 EID50 of a lentogenic vaccine strain of NDV expressing influenza virus H5 HA gene, replication of rNDV-H5 was attenuated in the lungs and oropharynx compared with the control rNDV, rNDV-H5 was not detected in cloacal swabs, and there were no clinical signs of disease.

Recombination between single-stranded, negative-sense RNA (ssRNA(-) viruses such as NDV is rare. The ssRNA(-) genome of NDV is found exclusively in a RNAse-resistant nuclecapsid that also contains the viral polymerase. Based on studies with other ssRNA(-) viruses, the potential for intermolecular recombination during mixed infection with closely related parainfluenzaviruses appears to be very rare. However, analysis of the genome of NDV isolates became infected with the GMM and a closely related virus and recombination occurred, transfer of the RSV F gene is unlikely to alter the tropism or virulence of the related micro-organism as virulence of paramyxoviruses is multigenic with the GMM and a related virus, it may be possible that pseudotype viruses could be produced in which the genome of one may be packaged in a virion which includes the surface glycoproteins expressed by the GMM. Such virus particles are unlikely to have an altered cell tropism as they infect similar pulmonary epithelial cells, and their progeny would be that encoded by the viral genome.
This assessment was reviewed and approved by the Biological Agents and Genetic Modification Committee, who agreed it should not be notified as a stand-alone activity.

**Historical Significant Changes**

- Transferred from GM97 28/07/2015

**Project Additional Information**

**Purposes of the contained use**

The purpose of these experiments is to determine if the PB1-F2 protein which is extensively conserved in avian influenza strains is a virulence factor in the infection of poultry by influenza viruses. This will help understand this protein's interactions with the host and elucidate whether the PB1-F2 protein is a valid target for anti-viral strategies. We will use reverse genetics to generate avian influenza strains that express the PB1-F2 protein and isogenic viruses that do not and assess their fitness and probe their interactions in vitro and in vivo using poultry lines.
We will generate recombinant avian influenza viruses which possess:
- The surface proteins (HA & NA) of the attenuated vaccine strain A/PR/8/34 (H1N1) and the internal genes (M, NS, PB2, PA & NP) of either:
  1) A/Turkey/Turkey/01/05 (H5N1)
  2) A/Turkey/England/50-92/91 (H5N1), or
  3) A/Chicken/Pakistan/UDL-1/08 (H9N2).

This will generate 2:6 recombinant influenza viruses safe to use at containment level 2.

These viruses will then have various mutations made to them in the PB1 segment to truncate or abolish the expression of the PB1-F2 protein which is in a +1 frame on the PB1 gene.

At no time with the HA & NA if H5N1 influenza viruses (either LPAI or HPAI) be rescued in conjunction with these genes. Therefore no complete H5N1 viruses will be generated in this process.

These viruses will be assessed for replication, innate immune response induction, pathogenicity and transmission in vitro in cell lines and ex vivo tissue sections as well as in vivo in poultry species.

Recipient or parental organism

Origin & function

The hazards directly associated with this class of GM influenza virus are small because they bear the surface antigens of the attenuated vaccine strain PR8 virus and thus are highly unlikely to infect a human or transmit. The main hazard would be from inadvertent co-infection of a cell culture with these viruses and other viruses that bear human or avian influenza surface antigens. This will be minimized by either working with these viruses in a separate MSC and incubator than used for other routine work with influenza viruses or fumigation of the MSC prior to use.

Clear signage on the outside of the hood will be used to indicate the last time the hood was used and which virus was used. We eliminate the possibility that workers are 'mixing vessels' by our OH policy of seasonal influenza vaccination. These viruses remain susceptible to both neuramidase inhibitor used routinely as anti-viral treatment for human influenza infection. Mutation of the PB1 gene segment to remove the expression of PB1-F2 or truncate it should reduce any risk from these viruses as PB1-F2 is thought to be a virulence factor.
The hazards to the environment are small from these GM influenza viruses due to the HA & NA from the vaccine strain PR8. This HA & NA combination should be capable of infecting avian species but the control measures in place in both the CL2 in vitro lab (G1B) and EAH are such that the virus will be contained appropriately. This HA & NA combination will render these viruses low pathogenic in nature in avian species. Manipulation in G1B will be carried out exclusively inside a class II MSC, transportaion will be under double containment, liquid waste will be decontaminated via contact with 1% Virkon for at least 10 minutes and all associated waste directed to autoclave. Poultry infected with these viruses inside the EAH will be done so in containment level 2 rooms and housed inside isolators. Every room in EAH has rodent barriers the input and output air is filtered and all waste and drainage liquid is autoclaved. Poultry to be infected will be screened for pre-infection by Influenza virus by looking for the presence of Influenza antigens or antibodies. Experiments will not be performed in animals previously infected with Influenza virus preventing the chance of a natural reassortment event in poultry. It is highly unlikely that the animals would be exposed to Influenza prior to the experiment as all poultry are reared on site at IAH under good biosecurity. Mutation of the PB1 gene segment to remove the expression of PB1-F2 or truncate it should reduce any risk from these viruses as PB1-F2 is thought to be a virulence factor.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Stewart building lab G1B - in vitro assays

In vitro assays with live virus will be carried out exclusively in a class II MSC cabinet. Cabinets are routinely serviced and tested on an annual basis by an outside contractor and service records are maintained. The risk to laboratory workers can be virtually eliminated by carrying out all work with potentially infectious samples, virus or infected material, in a class II microbiological safety cabinet (MSCII).

- All workers will wear appropriate protective clothing.
- All work in the MSCII will be carried out in benchcote.
- All items will also be sprayed with 70% Ethanol before removal from the MSCII. Items which cannot be directly sprayed with ethanol before being removed from the MSCII will be placed in plastic storage containers prior to removal, the containers will be sprayed before removing from the MSCII.
- Disposable equipment should be used where possible and filtered tips should be used on pipettes.
- Contaminated waste from the hoods will either be;
  (a) soaked in 1% Virkon for at least 10 minutes and then disposed of through the incineration route for laboratory waste or
  (b) disposed of directly into a double bagged autoclave bag which will be sealed with tape inside the hood and placed directly into an autoclave tin. The autoclave tin will be marked with G18 and INFLUENZA VIRUS before being taken to microbiological services for autoclave.

Infected material will be transported from the MSCII to the destination within a sealed container. e.g. plastic storage containers to incubator, sealed rotors to centrifuges. All items will be sprayed with 70% Ethanol before removal from the MSCII.

Infected tissue culture will be incubated in a designated CO2 incubator. Cells will be transferred to the incubator in a sealed container, once in the incubator the lid will be unsealed and removed to allow circulation of CO2. This will prevent spills and drips whilst inside the incubator also.

Influenza viruses are routinely grown in 10-day old embryonated hen's eggs

- Allantoic fluid will be harvested within the MSCII by cracking the top of the egg shell (placing a disposable pipette tip in the hole made previously by the egg gun) and removing the disc of shell with blunt forceps. The embryo is pushed to one side with disposable equipment (pipetter or wooden spatula), the allantoic fluid is removed using a jumbo pastette or disposable pipette and placed into 50ml falcon tubes.
- Eggs are discarded into a double autoclave bag within the MSCII which is sealed then placed into a metal tin for autoclaving. The tin should then be marked with contents (EMBRYONATED EGG WASTE) and taken immediately to microbiological services for processing.

02/03/2022
- Any non-disposable instruments (e.g. metal forceps) will be left in 70% Ethanol for 30 minutes and then sent for autoclaving.

All infective material will be autoclaved, incinerated or otherwise rendered sterile, unless being transported to another CL2 facility or being put to storage. Infective material will not be voided through the drain system, but inactivated with either by autoclaving or using 1% Virkon. Where possible disposable consumables will be used. Non-disposable items will be soaked in 1% Virkon for the required contact time, any attached labels removed and transferred to the Microbiological Services Department (in the same building) in labelled lidded metal tins for autoclaving and disposal.

This assessment was reviewed by BAGMSC on 14/02/2012 and the committee approved this RA as a GM2 project

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

The aim of the project is to understand the biology of recombinant Newcastle disease virus (NDV) vaccine strain (LaSota) expressing either fusion 9F) or haemagglutination-neuraminidase (HN) genes, single or jointly, closer to the promoter-proximal region of the genome. Growth kinetics of these construct will be evaluated in the chicken and duck cell culture systems. Having an improved NDV vaccine candidate in hand, genes of viruses will be introduced into this recombinant La Sota strain. The V protein, which is a non-structural protein of NDV, will be knocked out from vaccine strain of NDV to investigate the effect on the pathogenesis of the virus. The NDV infectious clone used in this work is tagged with GFP marker and has been produced by Dr Ben Peeter at central veterinary laboratory, The Netherlands. The modified viruses along with vaccine strain of NDV (La Sota) will be used to infect chicken and duck cell-lines to understand the role of these proteins playing in the replication and expression of the surface glycoproteins. The rescued viruses will be inoculated in 9-days old embryonated eggs to propagate and to make a stock. The same stocks will be used for quantification and titration purposes.

**Recipient or parental organism**

The vaccine strain of NDV to be used in this proposal is the lentogenic, avirulent (non-pathogenic) La Sota strain, which is a licensed live vaccine virus and is being used in Major endemic countries. NDV has extensively been used as vaccine vector for both veterinary and medical viruses with satisfactory results without change in the pathogenicity of the vaccine strain of NDV (Bukreyev, et al. 2005) Moreover, the genomic rearrangement presented in this work has already been made in other paramyxoviruses of medical origin such as vesicular stomatis Virus and Respiratory Syncytial Virus (Krempl At Al 2002). Such genetic rearrangements did not affect the pathogenicity of these medical viruses (Wertz, Et al 1998). It is therefore plausible to expect that such rearrangement in NDV, a similar virus but of veterinary importance, Will not affect its pathogenicity.

**Host/vector system**

The NDV is an avian paramyxovirus serotype 1 (APMV-1), and belongs to the Avulavirus genus within the Paramyxoviridae family. Vaccine strains of NDV are classified as ACDP CL2 and has been reported to cause short-lived conjunctivitis symptoms in man (Capua and alexander, 2004). Many of the reported instances of NDV infection in humans have been the result of direct inoculation into the eye, either by laboratory workers or those handling vaccines. However, reports of illnesses associated with NDV are rare. Both virulent (mesogenic) and avirulent (lentogenic) strains of NDV appear to be equally able to cause conjunctivitis in humans. However, both mesogenic and lentogenic strains of NDV have been tested in man as oncolytic viruses and cancer vaccines with no adverse and effects (Zamarin and Palese, 2012) Signs of evolution towards human pathogenicity , and recombination or transmission from human to human. Furthermore, virus could not be recovered from either the nose or tracheal lavage of African green monkeys that had been inoculated intratracheally with a lentogenic strain of NDV expressing the HN protein of human parainfluenza virus-3 (HPIV3) (Bukreyev, et al 2005)

Lentogenic strains of NDV are used as live vaccines in poultry. The hitchner B1 strain, which is very similar to LaSota strain in terms of pathogenicity and genome characteristics, is not classified as a specified animal pathogen by Defra and is licensed for use in the uk. NDV does not appear to naturally infect cattle, and vaccine strains
of NDV are highly attenuated in experimentally infected calves. Although, NDV has been isolated from pigs with an influenza-like illness, experimental inoculation of piglets with a strain of NDV did not produce any clinical signs of disease. Genomic rearrangements will likely to attenuate the vaccine strain of NDV as it did in medical viruses such as vesicular stomatitis Virus and Respiratory Syncytial Virus (Krempl et al 2002; Wertz et al 1998).

**Origin & function**

Three Genes, Presented in this proposal, will be modified. Briefly (i) the HN protein determines the host tropism by binding to sialic acid receptor of the host. (ii) the F protein mediates fusion of the NDV envelope with the cell membrane and fusion of infected cells with adjacent uninfected cells. Both HN and F protein are the major protective antigens of NDV and do not contain any potentially toxic or oncogenic sequences. (ii) the V protein is a non-structural protein which is known to involve interferon regulations activities.

**Evaluation of foreseeable effects**

Genomic rearrangement may lead to attenuation of the LaSota vaccine strain of NDV as it has been experienced with viruses of same family. Since the same gene of La Sota vaccine strain will be moved to promoter proximal region, it is unlikely that the resultant virus will change any tropism. Moreover, all the modifications, presented in this protocol, will be made only in the vaccine strains of NDV. Based on the reported studies, it is very likely that these recombinant NDV vaccine viruses will have increased virulence (Wertz et al 1998; Krempl et al 2002). Examples are available indicating the expression of any foreign gene in NDV can lead to attenuation in the animals that had been inoculated intranasally and intratracheally with high titres of the recombinant virus (Bukreyev, A et al 2005).

Recombination between single-stranded, negative-sense RNA (ssRNA(-)) viruses such as NDV is rare. The ss RNA9(-) genome of RDV is found exclusively in a RNAse-resistant nucleocapsid that also contains the viral polymerase. Based on studies with other ssRNA(-) viruses, the potential for intermolecular recombination during mixed infections appears to be very rare. However, analysis of the genome of NDV isolates from China suggests that homologous recombination of NDV can occur naturally, which is a rare event.

In the unlikely event that this genomic rearrangement will alter the tropism of the NDV since gene of the same vaccine will be moved to promoter region, virulence is unlikely to increase because pathogenicity in NDV is determined by the cleavage site in the F protein and we are not intended to mutate cleavage site in this proposal. Moreover, such rearrangements in other paramyxoviruses including vesicular stomatitis virus and respiratory syncytia virus have not increased the virulence of the recombinant viruses but has induced the protective immune responses, collectively, indicating least possible hazard associated.

The V protein of NDV is associated with interferon antagonism. Generation of LaSota NDV, Not expressing V Protein, is very much likely to be attenuated due to immune responses produced against NDV in infected cells. Therefore, there appears to be no adverse foreseeable effects with this modification.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Contaminated laboratory plastics will be decontaminated by 1% Virkon for 30 minutes prior to disposal by incineration and contaminated glassware will be autoclaved. Any tips, flasks, or other plastic wear that has been exposed to virus will also be decontaminated prior to disposal by incineration. Spillages and contaminated surfaces will be decontaminated with 2% Virkon for a minimum of 30 minutes.

Date of Significant Change

Reviewed by the BAGMSC and Dr M B (a paromyxovirus research group leader) on 26/11/13 and approved at GM2.
## Project Additional Information

### Purposes of the contained use

To develop the use of MCMV as vaccine vectors against human and livestock diseases.

### Recipient or parental organism

Mice

### Host/vector system

Murine cytomegalovirus

### Origin & function

- **Nucleoprotein (NP) and matrix (M1) proteins of X31 Influenza Virus.**
- The intended function is to induce a durable immune protective immune response against Influenza viruses.

### Evaluation of foreseeable effects

MCMV does not pose any harm to human health. MCMV has been shown to infect human cells in vitro, but infection leads to an abortive replication cycle. Accidental infection could induce immune response to MCMV and inserted transgenes, which would not be harmful.

Release of rMCMV into the environment is very unlikely due to the standard procedures employed in the lab or animal house. However even if such an event occurred, although rMCMV could infect wild mice (prevalence of wild type MCMV infection in wild mice is 65-90%) this is unlikely to occur because rMCMVs are attenuated and naturally infected wild mice should be cross protected against rMCMV. Furthermore even if infection did occur, attenuated rMCMVs are very unlikely to cause any pathology. The risk of infection of any other species is extremely low.

MCMV is an enveloped virus and therefore has poor survival in the environment. MCMV transmission is thought to require direct contact with contaminated excreta/secretions and cross-contamination between cages has so far not been reported.

The inserted genes are internal proteins from Influenza viruses to which humans are frequently exposed and which are known to induce immune responses. As stated above, because the risk of rMCMV infecting humans is minimal the risk of recombination between the transgene and human Influenza Virus is extremely low. Modified vaccinia Ankara or Adenovirus expressing NPM1 has been administered already to mice, pigs, chicken and humans without ill effects and these genes are present in the influenza vaccines, administered to humans.

In the case of the MCMV infected animals being challenged with Influenza virus there is no increased risk of these animals excreting a virus that could be transmissible to people compared to any other mouse strain. We shall use either A/PR/8/34 or PR8 based viruses. These challenge viruses pose very little risk for humans since PR8 is poorly infectious in people. The animals will be handled in isolators so that the risk is minimal.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Contaminated laboratory plastics will be incinerated and contaminated glassware will be autoclaved. Spillages and contaminated surfaces will be decontaminated with 2% Virkon for a minimum of 10 minutes. All waste will be disposed following MSD-113.

All waste and rubbish from the animal house should be placed in an autoclave bag. This should then be double bagged and sprayed with 1% Distel before it is removed from the room. The waste should then be autoclaved before being placed in yellow clinical waste bags. These yellow bags should then be placed in the yellow bins for incineration. Staff handling the mice will shower out on exit of the unit.

The purpose of this work is to generate reverse genomics systems for endemic avian viruses (Chicken Astroviruses (including Avian Nephritis virus), and Chicken Anaemia virus) and uses these systems to investigate the mechanisms of genome packaging employed by these viruses. Improving understanding of the mechanisms used by these viruses to encapsidate viral genomic nucleic acids as a key step in virion formation may contribute to efforts to develop new antiviral strategies. Such new strategies are required to provide new control measures to improve and maintain the sustainability of global poultry production and improve animal health and welfare.

Chicken Astrovirus (CAstV including Avian Nephritis virus (ANV)): cDNA genome clones will be generated from strains of virus that are circulating within the UK. Selected strains are considered clinically mild by comparison with Asian strains of this group. Strains used will be: CAstV 11672 and 612, ANV G4260. Astroviruses are +ve sense ssRNA viruses with a genome of 6·8kb, encoding 3 ORFs 1a/1b/2. ORF1a and 1b encode non structural proteins and the RNA dependent RNA polymerase (AdRp) respectively, while ORF2 contains the capsid protein precursor, which is expressed from a subgenomic RNA transcript. Progeny genomes are synthesised via a -ve strand intermediate by viral RdRp.

Chicken Anaemia Virus (CAV): genomic DNA clones will be generated from vaccine strain virus (P4). CAV encodes 3 ORFs, VP1, VP2 and VP3. VP1 is the capsid protein. VP2 a dual specificity phosphatase which may be involved in VP1 maturation and VP3 (also known as apoptin) specifically causes apoptosis of transformed cells. CAV has a closed circular -ve sense ssDNA genome of 3kb.

We propose to alter Packaging signal motifs within the viral genome clones in order to understand their contribution to encapsidation of the viral genome. any mutations will be, as far as practicable, conservative at the amino acid level to retain wild type (WT) function of the encoded gene product where these signals are identified within viral ORFs.

Host/vector system

Genome clones (cDNA or gDNA) will be generated and maintained in laboratory strains of E. coli. Viral genome clones will be transfected into appropriate eukaryotic cells for recovery of virus. For CAstV plasmids will be used as templates for in vitro transcription prior to transfection. CAV genomes will be regenerated by excision of bacterial vector sequences and religated to circularise the genome and establish a replication competent form.
Viral genomic RNA for CAstV (and ANV) will be provided by Dr. Victoria Smyth Agri-Food and Biosciences Institute Northern Ireland from reference virus collections used in diagnostic procedures. Strains to be used are, CAstV 11672 and 612, and ANV-1 strain G4260, which are mild strains circulating in the UK. These genomic ANAs will be used as templates from which to reverse transcribe full length eDNA clones for subsequent propagation and manipulation in E. coli. Genome clones will be flanked 5' with T7 promoter sequences, and 3' with the Hepatitis delta ribozyme and a T7 terminator to allow generation of the WT RNA without exogenous flanking sequence.

Genomic DNA of CAV (strain P4) will be isolated from a commercial vaccine and used as the basis for construction of a plasmid based genome clone.

Putative packaging signals will be identified from a library of RNN/DNA aptamers panned against CAstV/ANV/CAV isolated and purified capsid proteins. Alterations to packaging sequences in viral genome clones will be undertaken following in silico modelling and computational identification of genome nucleotide regions which are either similar by nucleotide composition or secondary structure. These regions will then be mutated, again guided by computational modelling to remove, weaken or strengthen the packaging signals and their interaction with cognate capsid protein. Alterations will be undertaken using standard restriction digest/site directed mutagenesis techniques. Mutations will be designed to maintain the WT amino acid composition of any viral OAF in which the signals fall, to retain WT function and behaviour as far as is practicable. Our proposed alterations to genome packaging signals, designed to maintain NT coding at the amino acid level, are not expected to alter host range or tropism nor alter the pathogenicity of these mutant viruses relative to WT parental strains.

Virus genomes generated in this way will be used in in vitro assays either using purified components (RNA/DNA) and protein) or within avian cells (after transfection of genome). To study the encapsidation of the genome under altered conditions. The resulting virus will be examined to identify any deficiencies in assembly and relate these to mutations introduced into the genome packaging signals to understand the contributions of these signals to the process of genome encapsidation.

**Origin & function**

The WT clones considered here should behave as circulating field strains of the virus and are highly unlikely to show altered pathogenicity or host tropism after rescue from bacterial hosts. CAstV and ANV clones are derived from UK samples and are considered clinically mild, as these are endemic viruses many birds in the population should have immunity to them. CAY clones will be derived from a live vaccine strain used to provide protection to chicks via maternal antibodies against CAV. In both cases there is likely extensive existing immunity in flocks and as such these viruses represent little risk to avian health unless introduced to unprotected young chicks. 80th viruses seem to be host restricted limiting the likelihood of transmission to non avian species.

Packaging signal mutants derived from the WT clones are expected to be highly disabled compared to WT. The distribution and strengths of these sequences in a WT genome is likely to have been selected over the course of virus evolution and could be considered optimised for the efficient encapsidation of viral genome and ultimately for production of mature virions. Likewise these signals may also have been selected to ensure the subsequent release of the genome on infection of a new host. As such it is highly likely that as we alter the strength of the Packaging signal: capsid protein interaction either increasing or decreasing it, the result will be to perturb viral assembly or disassembly in such a way as to result in defective non viable particles incapable of initiating infection. Similarly alteration of signal distribution is likely to drive genome encapsidation down kinetically trapped pathways that form incomplete non viable virions incapable of establishing further infections. In all cases it is highly unlikely that a fitness enhancing mutation would be introduced, and much more likely that mutations would have deleterious effects on genome encapsidation and virion assembly.

There is low foreseeable hazard to human or avian health from the GM CAstV, ANV and CAY proposed here.
Exposure of ideal hosts (young naive or immunocompromised chicks) could result in establishment of an infection with WT virus, or in a situation where modifications were not significantly disabling compared to WT. Handling of these agents under CL2 conditions in the CL2 in vitro lab should ensure that virus is appropriately contained and release avoided. Rescue of virus by transfection will be undertaken in Class II MSCs and all waste rendered noninfectious by treatment with virkon. For AstV exposure to 1.5% virkon for a minimum of 30min is indicated and for CAV 1% virkon for 30 minutes or more in line with the group's COP. Subsequently all solid waste will be directed to the clinical waste stream for incineration in line with site COPs.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

As the most stringent conditions are required for inactivation of AstroVirus these will be used as the minimum level for both CAstV and CAV. AstroVirus or CAV contaminated waste will be dealt with in line with published conditions for inactivation 01 Turkey AstV. For in vitro work (assembly assays/cell culture and transfection) waste will be decontaminated by exposure to 1.5% virkon for a minimum of 30 minutes. Subsequently solid waste (tips/flasks etc) will be processed through the clinical waste stream for incineration as per established site procedures In MS0-113. All cell work will be conducted in Class II MBSGs which are serviced and tested for performance annually by an external contractor. with service records maintained centrally. All contaminated waste will be decontaminated with exposure to 1.5% virkon for a minimum of 30 min. Filtered tips will be used on pipettes when handling CAstV or CAV samples. Aller exposure to virkon solid waste will be directed into the clinical waste stream for incineration. Cells containing CAstV gANA or CAV gONA will be transported within closed containers from the MBSC to the incubator. All transport containers will be surface decontaminated with 70% ethanol before removal from the MBSC. Cells will be incubated in a specific C02 Incubator, after transport tissue culture vessels will remain within the transport container without the lid to permit gas exchange but minimise the chance of drips or spills within the incubator. All contaminated material will be rendered sterile unless it is to be transported to another CI2 laboratory or stored. Disposable consumables/equipment will be used wherever practicable where this cannot be done. sterilisation will be undertaken using 1.5% virkon for 30mins minimum contact time prior to transfer to the Microbiological services department (located in the same building) for autoclaving In labelled containers.

N
**Purposes of the contained use**

SkinEthicTM (Nice, France) supply a 3D human corneal epithelial (HSC) model for use in eye irritation testing. This model is constructed from corneal cells originally derived from a cornea removed from a normal human donor. The cells were transformed using a replication defective retrovirus vector LXSN16E6E7, which encodes the human papilloma virus (HPV) type 16 E6 and E7 open reading frames and the neo antibiotic resistance gene. This cell line is used by SkinEthicTM to construct an in vitro 3-D model of the cornea. The 3D model will be purchased ready made from SkinEthicTM and used to assess their suitability as a model for assessing the mechanisms of eye irritation.

**Recipient or parental organism**

The corneal epithelial cell line was derived from primary human corneal cells isolated from a donor cornea from a 35 year old male, by Roger W. Beuerman, LSU Eye Centre, Louisiana State University School of Medicine, New Orleans, Louisiana 70112, USA.

**Host/vector system**

The corneal cells were transformed using a replication defective retrovirus vector LXSN16E6E7 (manuscript in preparation) using methods described in a previous paper (Nguyen et al., 1999). This vector (also described in 16risk99) was produced using the packaging cell line PA317 LXSN 16E6E7 (Halbert et al., 1991), obtained by introduction of retroviral vector pLXSN16E6E7 into the amphotropic packaging cell line PA17 (Miller and Buttimore, 1986; Rhim et al., 1998). The retroviral vector pLXSN16E6E7 was derived from the Moloney murine leukemia virus (MoMLV) and lacks the structural genes (gag, pol, env) required for particle formation and replication. pLXSN16E6E7 also contains

i) the HPV type 16 E6 and E7 open reading frames under the control of the 5' MoMLV LTR promoter

ii) the neo gene, which codes for kanamycin-neomycin antibiotic resistance under control of the SV40 early promoter gene

iii) pBR322 DNA containing the origin of replication (pBR322 ori) and the bacterial B-lactamase gene (ampicillin resistance).

**Origin & function**

No further genetic material was involved.

**Evaluation of foreseeable effects**

The Host: The corneal cells were derived from a normal human cornea. The resulting primary cells were cultured in vitro prior to transformation. Eukaryotic cell culture systems are normally considered as "especially disabled hosts" unless the vector can infect other hosts. In this case, the vector can enter both mouse and human host cells but it is unable to transmit viruses to other host cells. Thus the cell line cannot be termed 'especially disabled'. However, the cells would not survive outside of tissue culture conditions and would not survive in the human body. Also, the cells per se will not be subcultured in the laboratory, as the model is received ready for use and has a limited shelf-life, thus reducing risk of escape. Thus the host is a 'disabled or non-colonising' host and of low hazard.

Retroviral Vector pLXSN16E6E7: This vector is capable of integrating into both mammalian and bacterial cells and therefore the potential hazard from this vector is that of transfer to other cells, in vitro or in vivo. Vector pLXSN16E6E7 is derived from the amphotropic retrovirus MoMLV and has been multiply disabled such that it cannot further replicate and infect other cells. The packaging cell line, PA17, used to produce the vector, also has deletions in its packaging system genes to reduce packaging function transfer to vectors. Vectors produced by the PA317 cell line were shown to produce <1 helper virus/ml. At least two viral recombination events would be required to allow production of infectious virus. The ACGM guidelines state that viral vectors from which no infective virus can be produced should be regarded as minimal risk. While this is considered to be an externally unlikely occurrence, electron microscopy will be carried out initially to check for the presence of virus as well as to investigate cell ultrastructure. Any cells producing virus will be destroyed.

Genetic Inserts: The following are inserted into the vector:
HPV type 16 E6 and E7 open reading frames: These regions are responsible for cell transformation. HPV virus infection is common in humans and infects epithelial basal cells. The E6 and E7 genes are used to transform cells by interfering with cell cycle control mechanisms. Thus it is possible that this insert could be transferred to other cells, either in vitro or in vivo and cause cell transformation. However, a transformed cell is not an immortalised cell and the presence of E6/E7 sequences alone is not sufficient for immortalisation to occur. Several unknown processes are required for immortalisation and not all transformed cells become immortal. It is also considered that the risk of transfer of these genes to other cells or organisms is likely to be low. Other genes required for the production of complete HPV (e.g. L1 viral capsid protein) are not present on the vector.

Neo gene: This gene confers resistance to the kanamycin/neomycin class of antibiotics. The expression of this gene has not been optimised. There is a negligible risk associated with this gene used as a selection marker in that resistance may be transferred to the gut bacteria if ingested.

PBR322 DNA: This contains the pBR322 origin of replication and the ampicillin resistance gene. The pBR322 sequences do not produce a gene product alone and is a non-coding region of DNA. The ampicillin resistance gene expression has not been optimised. There is a negligible risk associated with this gene (used as a selection marker) in that resistance may be transferred to bacteria if ingested.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

This cell model is handled in microbiological safety cabinets, maintained on a 6 monthly basis, within an ACGM/ACDP Containment Level 2 suite. The suite is entered via a lobby and only trained personnel will handle the models. The suite also has restricted access. There are two methods of disposal - autoclave or incineration. Autoclaving is the preferred route, performed prior to disposal as clinical waste via a specialist waste contractor, and is considered to provide 100% kill of the GMO. Service of autoclaves takes place quarterly by ACE to meet standards set down in Health and Technical Memorandum 2010 Part 3. Details of temperature profiles for each run are recorded. Clinical incineration is used as a route of disposal if the cells have been treated with chemicals which are very toxic or whose toxicological properties are unknown. In these circumstances, the hazard generated from autoclaving these very toxic chemicals was considered far greater than that from any potential exposure to the GMOs. If the GMOs are intended for incineration, they are usually but not always sealed inside a container (e.g. tissue culture flask or Universal), then always double bagged on sawdust (to absorb liquid) before being placed in another plastic bag (sealed) inside non-returnable, sealed waste bins. Thus accidental release to the environment is considered highly unlikely.

In case of spillages in the laboratory, fresh 1% Virkon is the disinfectant of choice and is always readily available. Spillages are treated with Virkon, mopped up with paper towels and these are autoclaved prior to disposal.

**Project Additional Information**

**Purposes of the contained use**

The use of green fluorescent protein (gfp) has become an important tool in the investigation of gene expression in cells. Numerous bacterial clones are available with gfp-fusions inserted for example into the promoter regions of the pathogenicity islands of Salmonella spp. Such organisms can be investigated in situ using cytometric measurements of their fluorescent under a variety of physiological and non physiological conditions (eg stress) to determine gene activation. A variety of clones and organisms will be used to investigate physiological changes under simulated conditions in the environment, to test a variety of environmental challenges of food treatment...
processes or physiological changes following infection in human or animal tissue using flow and image cytometry.

Recipient or parental organism

Salmonella enterica serovars Typhimurium and Enteritidis currently called S. enterica subsp. enterica serovar Typhimurium and S. enterica subsp. enterica serovar Enteritidis are classified as class 2 pathogens, as determined by the ACDP and are food isolates from the Institute of Food Research in Norwich, UK.

Host/vector system

Mutations or gfp fusions are introduced into the chromosome of the pathogenic strains by transformed linear fragments of DNA into the cells of interest harbouring an oriR101-based temperature-sensitive plasmid (pKD20/pKD46) encoding the Red recombinase under control of the tightly regulated arabinose-inducible ParaB promoter. The fragments of DNA contain the mutated allele/reporter-gene construct and the antibiotic-resistance marker for kanamycin or chloramphenicol. The plasmids also encode ampicillin and/or chloramphenicol resistance and araC. The use of an arabinose inducible recombinase and proteins required to inactivate the host's RecBC exonuclease V system avoid unwanted recombinatorial events under noninducing conditions allowing efficient recombination of the linear DNA fragments into the host chromosome. The plasmid also encodes a temperature-sensitive RepA protein, only allowing replication of the plasmid at temperatures up to 30 degrees C. None of the genes encoded by the plasmid are considered likely to enhance the virulence of the strains harbouring them.

The organisms are cured of the plasmids and transfectants tested for the absence of Amp resistance to exclude the possibility of remaining plasmid or insertion of the resistance gene.

Origin & function

Promoter sequences for pathogenicity islands/stress response genes and the green fluorescent protein (gfp) reporter gene are amplified by PCR and fused by a recombinant PCR approach. Promoter sequences from the isolates were selected based on strength of induction upon stress as determined by the DNA array work at the Institute of Food Research. gfp variants are based on McCormak gfp-mut3 solely to indicate the activation of the promoter sequence.

Evaluation of foreseeable effects

The Host.

Salmonella is pathogenic to animals and humans, although it causes only limited gastro-intestinal infection in healthy individuals. Therefore, the consequence of hazard is restricted.

Mutants contain kanamycin and/or chloramphenical resistance genes; these are not the drugs of choice for the treatment of infections by these infectious agents and thus would present no selective advantage in the event of an accidental release.

The Salmonella strains containing the promoter-gfp fusions are anticipated to have virulence characteristics close to wild-type levels. Introduction of the fusions are not expected to enhance the virulence properties of these strains because they only contain virulence gene promoters, not the entire structural genes. In fact the inserted constructs should lead to a dilution of promoter activity as it is partially used to produce gfp instead of virulence factors.

Control measures are in place to minimise the risk for accidental release of the organism.

Genetic Material:

Plasmid pKD20/46 and its derivatives cannot replicate at 37 degrees C. Strains are cured of the plasmid prior to experimental work at Colworth thus further transfer of genetic material is unlikely.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

| None |

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Bacteria and animal tissue handled in liquid broth, buffer or on agar plates. Waste will be discarded via autoclaving which achieves effectively 100% kill and/or incineration (100% kill) depending on the contact with potentially carcinogenic dyes. Service of autoclaves takes place quarterly by ACE to meet standards set down in Health and Technical Memorandum 2010 Part 3. Details of temperature profiles for each run are recorded.

Cell culture waste for incineration is always sealed inside a container (eg tissue culture flask or Universal). Incineration waste is double bagged inside the yellow UN approved one-way bins containing absorbant in the inner and Virkon inside the outer bag. Burn bins are stored in a refrigerated container vehicle, supplied and collected by a licenced contractor.

Diluted liquid waste from the cytometer will be treated with active chlorine at 2500ppm (10 tablets/2 ltr) overnight, neutralised with 10g sodium thiosulphate. In the absence of a chlorine demand from the sheath liquid the available chlorine concentration and incubation time at room temperature will exceed the 100% kill achieved for most vegetative cells by more than 10,000 fold, for spores by more than 1000 fold.

Project Ref 55/03.1
The aim of the project is to stably express antioxidant genes (Catalase (CAT1), Cu/Zn Superoxide Dismutatse (SOD1), Mn Superoxide Dismutase (SOD2)) in immortalised cultured human cells using retroviral gene transfer. A series of pBABE based vectors have been constructed under a previous risk assessment (not notified) and these will be used to stably express the cDNAs for human CAT1, SOD1 and SOD2 in the keratinocyte cell line, HaCaT. In the appropriate producer cell lines the pBABE vectors produce eotrophic and amphotrophic retroviruses where gene expression is driven by the Moloney murine leukemia virus (Mo MuLV) LRs. All retroviruses are replication defective as many helper functions are supplied by the producer cell lines pCRIP and E. Cells that have stably integrated the retroviral expression cassette will be selected on the basis of drug resistance to puramycin and neomycin.

The packaging cell lines E pBABE (CAT1); E pBABE (SOD1) and E pBABE (SOD2) will be generated through infection of the E packaging cell line with the pBABE vectors. The eotrophic supernatant produced by these cell lines, containing secreted retroviral virions, will be used to transfect C RIP cells to produce the packaging cell lines p CRIP pBABE (CAT1); p CRIP pBABE (SOD1) and p CRIP pBABE (SOD2). In turn, the amphotrophic supernatant produced by these cells will be use to transfect the HaCaT cell line (immortalised human keratinocytes).

The risk assessment addresses the steps involved in the production of antioxidant expressing human cells as follows:

1) E cells harbouring human cDNA for the genes identified above (preparation of stable eotrophic producer cell lines);
2) p CRIP cells harbouring human cDNA for the genes identified above (preparation of stable amphotrophic producer cell lines); and
3) HaCAT immortalised human cells expressing human cDNA for the genes identified above.

The titre of the retroviral virions, secreted from the amphotropic producer cell lines described above, will be assessed through infection of human carcinoma A431 cells.
minimal sequence overlap and decreased sequence homology achieved by ‘codon woddling’.

p CRIP is a high titre amphotropic helper-free packaging cell line derived from NIH 3T3. It is ideal for use with pBABE vectors as the risk of generation of wild type virus is reduced due to extensive changes in the codon usage of the viral proteins. pCRIP were engineered by sequential co-transformation of NIH 3T3 cells with two mutant Moloney murine leukaemia virus-derived proviral genomes carrying complementary mutations in the gagpol or env regions. Each genome contains a deletion of the Psi sequence necessary for the efficient encapsulation of retroviral genomes into virus particles and additional alterations at the 3’ end of the provirus. Viral producers derived from pCRIP do not transfer the packaging function or yield helper virus.

Both the above cells were supplied by University of Wales College of Medicine, Cardiff, UK.

HaCaT cells are spontaneously immortalized human keratinocyte cell line (non-virion producing), originally derived from normal male skin at the distant periphery of a melanoma. The cells were supplied from Heidelberg, Germany.

**Host/vector system**

Each of the above cell lines will be transfected with a pBABE vector. All vectors used are based on the pBABE family of vectors and differ only in respect to the insert DNA they harbour (CAT1, SOD1 or SOD2) and the antibiotic resistance gene carried to allow selection in mammalian cells. The pBABE vectors are capable of integrating into both mammalian and bacterial cells and therefore the potential hazard from these vectors is that of transfer to other cells, in vitro or in vivo. The pBABE series of vectors are derived from the Moloney murine leukaemia virus (MoMuLV) and have been multiply disabled by deletion of the pol and env genes. Therefore, pBABE vectors on their own cannot further replicate and infect other mammalian cells. At least two recombination events would be required in order to get a functional virus. Retroviral vector produced from the packaging cell line, E, can enter mouse host cells but is unable to transmit viruses to other host cells. There is a slight risk that successive viral recombination events could occur to give risk to infectious virus producing cells. This possibility has been minimised significantly through the construction of the E cells, which are regarded by the HSE as third generation packaging cells. These cells harbour the viral structural genes, gagpol and env on separate constructs to limit the risk of recombination.

Retroviral vectors produced from pCRIP can infect the cells of their host and the cells of other species including human cells. However, they are not capable of further cycles of replication. Therefore the risk of subsequent spread of infection is minimal. The HaCaT cell line should not produce live viral vectors and this will be monitored on a 6-monthly basis.

The vectors also contain the bacterial B-lactamase gene, which confers resistance to ampicillin. The neo vectors contain the NeoR gene, which confers resistance to the kanomycin/neomycin class of antibiotics and is expressed from the SV40 early promoter of the pBABE series of vectors. The puro vectors contain the Pac gene, which confers resistance to puromycin and is also expressed from the SV40 early promoter of the pBABE series of vectors.

**Origin & function**

- pBABE neo (CAT1) and pBABE puro (CAT1) carry the human CAT1 cDNA (catalase). Catalase is an anti-oxidant and is ubiquitously expressed in mammalian cells.
- pBABE puro (SOD1) and pBABE neo (SOD1) carry the human SOD1 cDNA (Cu/Zn Superoxide dismutase). SOD1 is an anti-oxidant expressed in the cytosol of mammalian cells.
- pBABE pur (SOD2) and pBABE neo (SOD2) carry the human SOD2 cDNA (Mn Superoxide dismutase). SOD 2 is an anti-oxidant expressed in the mitochondria of mammalian cells.

Antioxidants counteract the harmful effects of reactive oxygen species generated in cells through normal metabolic processes or as a result of exposure to pro-oxidant chemicals.

**Evaluation of foreseeable effects**

THE HOST CELLS
E cells: E cells are regarded by the HSE as a third generation packaging cell line. Eukaryotic cell culture systems are usually considered as 'especially disabled hosts' except where vectors they harbour can infect other hosts. In this case the vector can enter mouse host cells but it is unable to transmit viruses to other host cells. Consequently, the genetically modified cell line cannot be termed 'especially disabled'. However, the cells would not survive outside of tissue culture conditions and would not survive in the human body. Thus the host is a 'disabled' or non-colonising' host and of low hazard.

pCRIP cells: pCRIP is a high titre amphotropic helper-free packaging cell line derived from NIH 3T3. Viral producers derived from pCRIP do not transfer the packaging function or yield helper virus. Accordingly, pCRIP cells are regarded by the HSE as a third generation packaging cell line. Eukaryotic cell culture systems are usually considered as 'especially disabled hosts' except where vectors they harbour can infect other hosts. In this case the host is used to produce amphotropic viruses. These are able to infect the cells of their host and the cells of other species including human cells. Consequently, the cell line cannot be termed 'especially disabled'. However, the cells would not survive outside of tissue culture conditions and would not survive in the human body. Thus the host is a 'disabled or non-colonising' host and of low hazard.

HaCaT cells: HaCaT cells are a spontaneously immortalised human keratinocyte cell line, originally derived from normal male skin at the distant periphery of a melanoma. All eukaryotic cells and tissue culture systems can be considered as especially disabled hosts provided that the cell line is unable to colonise the worker and contains no known adventitious agents that are potentially harmful. In this case the vector can enter both mouse and human host cells but it is unable to transmit viruses to other host cells. Consequently, the cell line cannot be termed 'especially disabled'. However, the cells would not survive outside of tissue culture conditions and would not survive in the human body. Thus the host is a 'disabled or non-colonising' host and of low hazard.

All the above cells have a selective advantage over other non-transformed cells, as they are immortalised and harbour antibiotic resistance genes (ampicillin and puromycin resistance or ampicillin and neomycin resistance). However, it is extremely unlikely that suitable culture conditions could be found outside of the tissue culture environment. There is a slight risk that the antibiotic resistance genes used as selection markers could be transferred to the gut bacteria following accidental ingestion but this is highly unlikely.

RETROVIRAL VECTOR:
All vectors used are based on the pBABE family of vectors and differ only in respect to the insert DNA they harbour (CAT1, SOD1 or SOD2) and the antibiotic resistance gene carried to allow selection in mammalian cells. The possible hazards associated with the use of these vectors will be discussed collectively. The pBABE vectors are capable of integrating into both mammalian and bacterial cells and therefore the potential hazard from these vectors is that of transfer to other cells, in vitro or in vivo. The mobilisation functions between bacteria are unknown. Therefore, it must be assumed to be mobilisable. The pBABE series of vectors are derived from the Moloney murine leukaemia virus (Mo MuLV) and have been multiply disabled by deletion of the pol and env genes. Therefore, pBABE vectors on their own cannot further replicate and infect other mammalian cells.

In addition, the packaging cell line, pCRIP, used to produce the vector, has deletions in its packaging system genes to reduce packaging function transfer to vectors. At least two viral recombination events would be required to allow production of infectious virus. The ACGM guidelines state that viral vectors from which no infective virus can be produced should be regarded as minimal risk. Retroviral vectors produced from pCRIP can infect the cells of their host and the cells of other species including human cells. However, they are not capable of further cycles of replication. Therefore the risk of subsequent spread of infection is minimal. Since the retrovirus is 'defective' for replication, the hazard is therefore limited to handling of the producer cells and their culture medium, which contains the infected virions. The potential harm from accidental infection of the worker derives from the introduction of oncogenic sequences into exposed cells which, although almost certainly incapable of giving rise to a tumour alone, might nevertheless then have an increased chance of subsequently becoming tumourigenic if they acquired further spontaneous mutations. The chance of the above event occurring is greatly reduced by the following considerations:

- Even in optimised experimental conditions (containing fusogens such as polybrene) the efficiency of infection of human cells is still very low (estimated to be less than 1%).
- These viruses are extremely fragile and are, for example, exquisitely sensitive to desiccation.
- No doubt as a result of the above factors, a model human retroviral disease (AIDS) has never been associated with airborne droplet spread. By extrapolation, it is
extremely unlikely that any such route of infection would be significant with the vectors described here. In practice therefore, the only significant route of exposure is likely to be inoculation by 'needle-stick' injury and working practices have been designed to minimise aerosol production and eliminate the risk of penetrating injuries.

As above, there is a slight risk that successive viral recombination events could occur to give rise to infectious virus producing cells. This possibility has been minimised significantly through the construction of the pCRIP cells, which are regarded by the HSE as third generation packaging cell lines. These cells harbour the viral structural genes, gagpol and env on separate constructs to limit the risk of recombination.

The HaCaT cell line should not produce live viral vectors and will be monitored during initial culture for the presence of virus by electron microscopy, and then on a six monthly basis. Any cells producing virus will be destroyed.

GENETIC INSERTS: The following are inserted into the vectors:

Anti-oxidants: pBABE neo (CAT1) and pBABE pur (CAT1) carry the human CAT1 cDNA (catalase). Catalase is an anti-oxidant and is ubiquitously expressed in mammalian cells. pBABE puro (SOD1) and pBABE neo (SOD1) carry the human SOD1 cDNA (Cu/Zn Superoxide dismutase). SOD1 is an anti-oxidant expressed in the cytosol of mammalian cells. pBABE puro (SOD2) and pBABE neo (SOD2) carry the human SOD2 cDNA (Mn Superoxide dismutase). SOD2 is expressed in the mitochondria of mammalian cells. Anti-oxidants as a class function to counteract the harmful effects of reactive oxygen species generated in cells through normal metabolic processes or as a result of chemical exposure. There is no evidence to suggest that the increased expression of any of these anti-oxidants in human cells would constitute a risk to health.

ANTIBIOTIC RESISTANCE GENES

Bacterial B-lactamase gene confers resistance to ampicillin and is harboured by all pBABE plasmids. The expression of the bacterial B-lactamase gene has not been optimised.

The NeoR gene is carried by the pBABEneo vectors and confers resistance to the kanomycin/neomycin class of antibiotics. It is expressed from the SV40 early promoter of the pBABE series of vectors. The expression of this gene has not been optimised.

The Pac gene is carried by the pBABEpuro vectors and confers resistance to puromycin. It is expressed from the SV40 early promoter of the pBABE series of vectors. The expression of this gene has not been optimised.

For all the above antibiotic resistance genes, there is a slight risk that the gene could be transferred to gut bacteria following accidental ingestion but this is highly unlikely. Furthermore antibiotic resistance is lost in the absence of selective pressure. Alternative antibiotic therapies are available which could be used to limit the proliferation of transformed cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All work surfaces will be treated with Virkon before and after handling these cultures. These cell lines are handled in microbiological safety cabinets, maintained on a 6 monthly basis, within a Containment Level 2 suite entered via a lobby, by trained personnel. The suite has restricted access and the cells are autoclaved before leaving the laboratory or are disposed of via incineration. Autoclaving is the preferred route and is considered to provide 100% kill of the GMO. Incineration will be used when the cells have been in contact with chemicals which are very toxic or whose toxicological properties are unknown. It was considered that the hazard generated from autoclaving these very toxic chemicals was far greater than that from any potential exposure to the GMOs. Incineration is via the Clinical Waste route at Colworth and is removed from site and incinerated by external contractors. Cultures and associated media are usually but not always sealed inside a container (eg tissue culture flask or Universal), then always double bagged on sawdust (to absorb liquid) before being placed in another plastic bag (sealed) inside sealed yellow one-way bins. Thus making it virtually impossible for the GMOs to escape during disposal. Accidental release to the environment is considered highly unlikely.
Servicing and validation of autoclaves takes place quarterly by specialist contractors to meet standards set down in Health and Technical Memorandum 2010 Part 3. Chart recordings of each run are examined before opening the machine to ensure that correct time and temperature have been reached. Process indicators are used with each load. Regular safety inspections are carried out in the laboratory to ensure high standards of GOSH and GMP are maintained and that the controls detailed in this assessment are in place.

Purposes of the contained use

The aim of the project is to stably express antioxidant genes (Catalase (CAT1), Cu/Zn Superoxide Dismutase (SOD1), Mn Superoxide Dismutase (SOD2)) in immortalised cultured human cells using retroviral gene transfer. A series of pBABE based vectors have been constructed under a previous risk assessment (not notified) as these will be used to stably express the cDNAs for human CAT1, SOD1 and SOD2 in the SV40 T-antigen transformed human buccal epithelial cell line, SVpgC2a and the buccal carcinoma cell line, SqCC/Y1. In the appropriate producer cell lines the pBABE vectors produce ecotropic and amphotropic retroviruses where gene expression is driven by the Moloney murine leukaemia virus (Mo MuLV) LTRs. All retroviruses are replication defective as many helper functions are supplied by the producer cell lines (Psi)CRIP and (Omega)E. (Cannot input symbols See form for correct symbols for this previous passage) Cells that have stably integrated the retroviral expression cassette will be selected on the basis of drug resistance to puramycin and neomycin.

The packaging cell lines (Omega)E pBABE (SOD1) and (Omega)E pBABE (SOD2) will be generated through infection of the (Omega)E packaging cell line with the pBABE vectors. The ecotropic supernatant produced by these cell lines, containing secreted retroviral virions, will be used to transfect (Psi)CRIP cells to produce the packaging cell lines (Psi)CRIP pBABE (CAT1); (Psi)CRIP pBABE (SOD1) and (Psi)CRIP pBABE (SOD2). In turn, the amphotropic supernatant produced by these cells will be used to transfect the SV40 T-antigen transformed human buccal epithelial cell line, SVpgC2a and the buccal carcinoma cell line, SqCC/Y1.

The risk assessment addresses the steps involved in the production of antioxidant expressing human cells as follows:
1) (Omega)E cells harbouring human cDNA for the genes identified above (preparation of stable ecotropic producer cell lines);
2) (Psi)CRIP cells harbouring human cDNA for the genes identified above (preparation of stable amphotropic producer cell lines); and
3) Cell lines SVpgC2a and SqCC/Y1 expressing human cDNA for the genes identified above.

The titre of the retroviral virions, secreted from the amphotropic producer cell lines described above, will be assessed through infection of human carcinoma A431 cells.

Recipient or parental organism

(Omega)E is a high titre ecotropic helper-free packaging cell line derived from NIH 3T3 mouse fibroblasts. It is ideal for use with pBABE vectors as the risk of generation wild-type virus is reduced due to extensive changes in the codon usage of the viral proteins. (Omega)E cells have separated gagpol and ecotropic env expression constructs with only minimum sequence overlap and decreased sequence homology achieved by ‘codon wobbling’.

(Psi)CRIP is a high titre amphotropic helper-free packaging cell line derived from NIH 3T3. It is ideal for use with pBABE vectors as the risk of generation of wild type virus is reduced due to the extensive changes in the codon usage of the viral proteins. (Psi)CRIP were engineered by sequential co-transformation of NIH 3T3 cells with two mutant Moloney murine leukaemia virus-derived proviral genomes carrying complementary mutations in the gagpol or env regions. Each genome contains a deletion of the Psi sequence necessary for the efficient encapsulation of retroviral genomes into viru particles and additional alterations at the 3’end of the procvirus. Viral producers derived from (Psi) CRIP do not transfer the packaging function or yield helper virus.

Both the above cells were supplied by Dr Christopher J Jones, University of Wales College of Medicine Cardiff, UK.
SVpgC2a is an immortalised bucal keratinocyte cell line that was derived from human buccal tissue obtained from a non-cancerous female non-smoker patient undergoing maxillo-facial reconstructive surgery. The cells were transformed using a plasmid, pRSV-T, described by Sakamoto et al, (1993). This plasmid consists of pBR322 DNA containing the origin of replication (pBR322 ori) and the bacterial B-lactamase gene (coding for ampicillin resistance), and an SV40 DNA sequence including the early promoter and the T antigen both of which are expressed from the Rous Sarcoma virus 3’ Long Terminal Repeat. The cells were supplied by Professor R C Grafstrom of the Karolinska Institute, Stockholm, Sweden.

SqCC/Y1 is a bucal carinoma cell line that was derived from a primary bucal squamous carcinoma from a human female. The cells were supplied by Professor R C Grafstrom of the Karolinska Institute, Stockholm, Sweden.

Host/vector system

Each of the above cell lines will be transfected with a pBABE vector. All vectors used are based on the pBABE family of vectors and differ only in respect to the insert DNA they harbour (CAT1, SOD1 or SOD2) and the antibiotic resistance gene carried to allow selection in mammalian cells. The pBABE vectors are capable of integrating into both mammalian and bacterial cells and therefore the potential hazard from these vectors is that of transfer to other cells, in vitro or in vivo. The pBABE series of vectors are derived from the Moloney murine leukaemia virus (MoMuLV) and have been multiply disabled by deletion of the pol and env genes. Therefore, pBABE vectors on their own cannot further replicate and infect other mammalian cells. At least two recombination events would be required in order to get a functional virus. Retroviral vector produced from the packaging cell line, (omega)E, can enter mouse host cells but is unable to transmit viruses to other host cells. There is a slight risk that successive viral recombination events could occur to give rise to infectious virus producing cells. This possibility has been minimised significantly through the construction of the (omega) cells, which are regarded by the HSE as third generation packaging cells. These cells harbour the viral structural genes, gagpol and env on separate constructs to limit the risk of recombination.

Retroviral vectors produced from (PSI)CRIP can infect the cells of their host and the cells of other species including human cells. However, they are not capable of further cycles of replication. Therefore the risk of subsequent spread of infection is minimal. Neither SVpgC2a and SqCC/Y1 should produce live viral vectors and this will be monitored on a 6-monthly basis.

The vectors also contain the bacterial B-lactamase gene, which confers resistance to ampicillin. The neo vectors contain the NeoR gene, which confers resistance to the kanomycin/neomycin class of antibiotics and is expressed from the SV40 early promoter of the pBABE series of vectors. The puro vectors contain the Pac gene, which confers resistance to puromycin and is also expressed from the SV40 early promoter of the pBABE series of vectors.

Origin & function

- pBABE neo (CAT1) and pBABE puro (CAT1) carry the human CAT1 cDNA (Catalase). Catalase is an anti-oxidant and is ubiquitously expressed in mammalian cells.
- pBABE puro (SOD1) and pBABE neo (SOD1) carry the human SOD1 cDNA (Cu/Zn Superoxide dismutase). SOD1 is an anti-oxidante expressed in the cytosol of mammalian cells.
- pBABE puro (SOD2) and pBABE neo (SOD2) carry the human SOD2 cDNA (Mn Superoxide dismutase). SOD2 is an anti-oxidant expressed in the mitochondria of mammalian cells.

Antioxidants counteract the harmful effects of reactive oxygen species generated in cells through normal metabolic processes or as a result of exposure to pro-oxidant chemicals.

Evaluation of foreseeable effects

The Host Cells:
(Omega)E cells : (Omega)E cells are regarded by the HSE as a third generation packaging cell line. Eukaryotic cell culture systems are usually considered as ‘especially disabled hosts’ except where vectors they harbour can infect other hosts. In this case the vector can enter mouse host cells but it is unable to transmit viruses to other host cells. Consequently, the genetically modified cell line cannot be termed ‘especially disabled’. However, the cells would not survive outside of tissue culture conditions and would not survive in the human body. Thus the host is a ‘disabled or non-colonising’ host and of low hazard.

(PSI)CRIP cells : (PSI) CRIP is a high titre amphotropic helper-free packaging cell line derived from NIH 3T3. Viral producers derived from (PSI)CRIP do not transfer the packaging function or yield helper virus. Accordingly, (PSI)CRIP cells are regarded by the HSE as a third generation packaging cell line. Eukaryotic cell culture systems
are usually considered as ‘especially disabled hosts’ except where vectors they harbour can infect other hosts. In this case the host is used to produce amphotropic viruses. These are able to infect the cells of their host and the cells of other species including human cells. Consequently, the cell line cannot be termed ‘especially disabled’. However, the cells would not survive outside of tissue culture conditions and would not survive in the human body. Thus the host is a ‘disabled or non-colonising’ host and of low hazard.

The SVpC2a cell line is an SV40 T antigen-immortalised buccal epithelial cell line, originally derived from human buccal tissue obtained from a non-cancerous female non-smoker patient undergoing maxillo-facial reconstructive surgery. Eukaryotic cell lines are usually considered as ‘especially disabled hosts’ except where vectors they harbour can infect other hosts. In this case the retroviral vector can enter both mouse and human cells but it is unable to transmit viruses to other host cells. Consequently, the cell line cannot be termed ‘especially disabled’. In addition, this cell line contains the pRSV-T plasmid, which is based on pBR322 DNA and contains the origin of replication (pBR322ori), the bacterial B-lactamase gene (coding for ampicillin resistance), and an SV40 DNA sequence including the early promoter and the T-antigen. The SV40 virus is a member of the papova group of small nonenveloped DNA viruses that cause lytic infection in monkey cells. Humans are non-permissive hosts for this virus, meaning that the virus cannot replicate in human cells. However, the viral DNA may become integrated into the host genome. When produced in quantity, the SV40 large and small T-antigens interfere with the normal growth regulatory systems, causing transformation. The level of transformation is low in human fibroblasts (Mayne et al, 1986). Southern blotting analysis has shown that the pRSV-T plasmid sequences were stably integrated into the genome for at least 90 passages (Kulkarni et al, 1995). Additionally, the presence of SV40 sequence alone is not sufficient for immortalisation to occur - further undefined process leads from transformation to immortalisation and not all transformed cells will become immortal. The mobilisation properties of the pRSV-T plasmid are unknown, therefore it must be considered as mobilisable but the parent vector pBR322 is considered ‘monilisation defective’ (Southern and Berg, 1982). In addition, these cells would not survive outside of tissue culture conditions and would not survive in the human body. The capacity of the parental line, SVpC2a, to produce tumours when transplanted into experimental animals has been investigated. These cells were non-tumourigenic when injected into athymic nude mice (Kulkarni et al, 1995). Thus the SVpC2a cell line is ‘disabled or non-colonising’ and of low hazard.

The S9CC/Y1 cell line was derived from a primary buccal squamous carcinoma from a human female. As above, this cell contains a vector that can enter both mouse and human host cells but it is unable to transmit viruses to other host cells. Consequently, the cell line cannot be termed ‘especially disabled’. The capacity of the parental line, S9CC/Y1, to produce tumours when transplanted into experimental animals has been investigated. These cells were tumourigenic when injected into athymic nude mice, are highly proliferative and are resistant to terminal differentiation (Kulkarni et al, 1995). Since its establishment in 1983 (Pitman et al, 1983) the S9CC/Y1 cell line has a history of safe use. However, there is a potential hazard that this cell line may be tumourigenic in humans especially for immuno-compromised individuals. Consequently, this host can not be regarded as of low hazard.

Vector DNA:
All the above cells have a selective advantage over other non-transformed cells, as they are immortalised and harbour antibiotic resistance genes (ampicillin and puromycin and neomycin resistance). However, it is extremely unlikely that suitable culture conditions could be found outside of the tissue culture environment. There is a slight risk that the antibiotic resistance genes used as selectin markers could be transferred to the gut bacteria following accidental ingestion but this is highly unlikely.

Retroviral Vector:
All vectors used are based on the pBABE family of vectors and differ only in respect to the insert DNA they harbour (CAT1, SOD1 or SOD2) and the antibiotic resistance gene carried to allow selection in mammalian cells. The possible hazards associated with the use of these vectors will be discussed collectively. The pBABE vectors are capable of integrating into both mammalian and bacterial cells and therefore the potential hazard from these vectors is that of transfer to other cells, in vitro or in vivo. The mobilisation functions between bacteria are unknown. Therefore, it must be assumed to be mobilisable. The pBABE series of vectors are derived from the Moloney murine leukaemia virus (Mo MuLV) and have been multiply disabled by deletion of the pol and env genes. Therefore, pBABE vectors on their own cannot further replicate and...
In addition, the packaging cell line, (PSI)CRIP, used to produce the vector, has deletions in its packaging system genes to reduce packaging function transfer to vectors. At least two viral recombination events would be required to allow production of infectious virus. The ACGM guidelines state that viral vectors from which no infective virus can be produced should be regarded as minimal risk. Retroviral vectors produced from (PSI)CRIP can infect the cells of their host and the cells of other species including human cells. However, they are not capable of further cycles of replication. Therefore the risk of subsequent spread of infection is minimal. Since the retrovirus is ‘defective’ for replication, the hazard is therefore limited to handling of the producer cells and their culture medium, which contains the infected virions. The potential harm from accidental infection of the worker derives from the introduction of oncogenic sequences into exposed cells which, although almost certainly incapable of giving rise to a tumour alone, might nevertheless then have an increased chance of subsequently becoming tumourigenic if they acquired further spontaneous mutations. The chance of the above event occurring is greatly reduced by the following considerations:

- Even in optimised experimental conditions (containing fusogens such as polybrene) the efficiency of infection of human cell is still very low (estimated to be less than 1%).
- These viruses are extremely fragile and are, for example, exquisitely sensitive to desiccation.
- No doubt as a result of the above factors, a model human retroviral disease (AIDS) has never been associated with airborne droplet spread. By extrapolation, it is extremely unlikely that any such route of infection would be significant with the vectors described here.

In practice, therefore, the only significant route of exposure is likely to be inoculation by ‘needle-stick’ injury and working practices have been designed to minimise aerosol production and eliminate the risk of penetrating injuries. As above, there is a slight risk that successive viral recombination events could occur to give rise to infectious virus producing cells. This possibility has been minimised significantly through the construction of the (PSI)CRIP cells, which are regarded by the HSE as third generation packaging cells. These cells harbour the viral structural genes, gagpol and env on separate constructs to limit the risk of recombination. The SVPGC2a and SqCC/Y1 cell lines should not produce live viral vectors and will be monitored during initial culture for the presence of virus by electron microscopy, and then on a six monthly basis. All cells producing virus will be destroyed.

Genetic Inserts: The following are inserted into the retroviral vectors:

- Anti-oxidants: pBABE neo (CAT1) and pBABE puro (CAT1) carry the human CAT1 cDNA (Catalase). Catalase is an anti-oxidant and is ubiquitously expressed in mammalian cells. pBABE puro (SOD1) and pBABE neo (SOD1) carry the human SOD1 cDNA (Cu/Zn Superoxide dismutase). SOD1 is an anti-oxidant expressed in the cytosol of mammalian cells. pBABE puro (SOD2) and pBABE neo (SOD2) carry the human SOD2 cDNA (Mn Superoxide dismutase). SOD2 is expressed in the mitochondria of mammalian cells. Anti-oxidants as a class function to counteract the harmful effects of reactive oxygen species generated in cells through normal metabolic processes or as a result of chemical exposure. There is no evidence to suggest that the increased expression of any of these anti-oxidants in human cells would constitute a risk to health.

Antibiotic Resistance Genes:

- Bacterial B-lactamase gene confers resistance to ampicillin and is harboured by all pBABE plasmids. The expression of the bacterial B-lactamase gene has not been optimised. The NeoR gene is carried by the pBABEneo vectors and confers resistance to the kanamycin/neomycin class of antibiotics. It is expressed from the SV40 early promoter of the pBABE series of vectors. The expression of this gene has not been optimised.
- The Pac gene is carried by the pBABEpuro vectors and confers resistance to puromycin. It is expressed from the SV40 early promoter of the pBABE series of vectors. The expression of this gene has not been optimised. For all the above antibiotic resistance genes, there is a slight risk that the gene could be transferred to gut bacteria following accidental ingestion but this is highly unlikely. Furthermore antibiotic resistance is lost in the absence of selective pressure. Alternative antibiotic therapies are available which could be used to limit the proliferation of transformed cells.
All work surfaces will be treated with Virkon before and after handling these cultures. These cell lines are handled in microbiological safety cabinets, maintained on a 6 monthly basis, within a Containment Level 2 suite entered via a lobby, trained personnel. The suite has restricted access and the cells are autoclaved before leaving the laboratory or are disposed of via incineration. Autoclaving is the preferred route and is considered to provide 100% kill of the GMO. Incineration will be used when the cells have been in contact with chemicals which are very toxic or whose toxicological properties are unknown. It was considered that the hazard generated from autoclaving these very toxic chemicals was far greater than that from any potential exposure to the GMOs. Incineration is via the Clinical Waste route at Colworth and is removed from site and incinerated by external contractors. Cultures and associated media are usually but not always inside a container (e.g. tissue culture flask or Universal), then always double bagged on sawdust to absorb liquid) before being placed in another plastic bag (sealed) inside sealed yellow one-way bins. Thus making it virtually impossible for the GMOs to escape during disposal. Accidental release to the environment is considered highly unlikely.

Servicing and validation of autoclaves takes place quarterly by specialist contractors to meet standards set down in Health and Technical Memorandum 2010 Part 3. Chart recordings of each run are examined before opening the machine to ensure the correct time and temperature have been reached. Process indicators are used with each load. Regular safety inspections are carried out in the laboratory to ensure high standards of GOSH and GMP are maintained and that the controls detailed in this assessment are in place.

The SqCC/Y1 cell line is tumourigenic when injected into athymic nude mice. Consequently there is a potential hazard of tumourigenicity through accidental exposure of the worker, although the extent of this is unknown. This hazard is limited to all use of the SqCC/Y1 cell line as well as the SqCC/Y1 derived cell lines. The potential harm from accidental infection of the worker can be greatly reduced through working practices. In this respect working practices have been designed to minimise aerosol production and eliminate the risk of penetrating injuries. The use of needles, sharps and glassware is forbidden for these experiments. Workers will use two pairs of gloves during all use of the cell lines described above and all cuts will be covered with plasters. If a worker cuts themselves during use of the cell line, the cut must be encouraged to bleed freely and then washed thoroughly with soap and water. The relevant first aid should be sought and the incident should be reported via the Colworth Incident Report system. By use of these measures, the cell line can be designated at ACDP Level 2.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The committee has unanimously agreed that this is a satisfactory risk assessment and that sufficient controls are in place to protect both human health and the environment.

Human Clinical Applications

02/03/2022
**Project Additional Information**

**Purposes of the contained use**
Identification of functionally active molecules through the use of stably-transfected HEK293 cells.

**Recipient or parental organism**
Human embryonic kidney cell line (HEK293).

**Host/vector system**
Host cells are HEK293 cells, and are transfected with a pCR3 (invitrogen) vector expressing a human cDNA.

**Origin & function**
Genetic material involved is of human origin and is exogenously expressed in a human cell line (HEK293). This new cell line created will be used to screen for inhibitors of the enzyme expressed from the vector transfected. The vector is used to give high-level expression of the enzyme in a cell line not known to express that protein.

**Evaluation of foreseeable effects**
HEK293 cells are a transformed human cell line which is commercially available. These cells are well characterised and authenticated by ECACC. HEK293 cells are human embryo kidney cells which have been transformed with sheared human Ad5 DNA. Ad5 is considered to be non-oncogenic and the use of sheared DNA to transform the cells further reduces any potential risk as no functional virus can be produced. The Ad insert has been shown to consist of a colinear segment from nts 1 to 4344 integrated into chromosome 19 (19q13.2). These cells are unlikely to survive outwith standard cell culture conditions and so pose only a very slight risk to human health.
The transfected vector contains the following elements (CMV promoter sequence driving expression of the cDNA of interest; T7 promoter; SP6 promoter; TK polyA signal; Kanamycin/neomycin resistance gene; SV40 promoter/origin; Ampicillin resistance gene; F1 replication origin). The vector is non-mobilisable and expresses a protein already present in human cells. Constitutive over-expression of this protein at levels far in excess of those naturally occurring may result in undesirable effects. However, it is very unlikely that this would occur in the human as the vector is non-mobilisable and all handling will be performed in Microbiological Safety Cabinets. Although antibiotic resistance genes are also expressed, without continued selection the vector will be lost.

The transfected cell line poses only a slightly higher risk than the parent cells. The transfected cell line will not survive without antibiotic selection and so possesses a low risk.

Eukaryotic cell culture systems are usually considered as ‘especially disabled hosts’ except where vectors they harbour can infect other hosts. In this case the vector is non-mobilisable and thus this cell line is considered “especially disabled host”.

Both the parent cells and the transfected/genetically modified cells have a history of safe use in other laboratories.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Cells will be handled in microbiological safety cabinets, maintained on a 6 monthly basis, within a containment level 2 lab. Access to room is restricted by means of a keypad lock, the number of which is only known by trained personnel. All waste will be disposed of as "clinical waste" in accordance with local codes of practice. Autoclaving is the preferred route and is considered to result in 100% cell kill. All staff using these cells have been trained in compliance with GM procedures and other workers in these labs will be GM aware. All spillages will be cleaned with 1% Virkon and gloves and bactigowns will be worn at all times when handling these cells.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All cell material and waste which has been in contact with GM materials will be sealed in autoclaveable bags, which in turn will be sealed in autoclaveable boxes. These boxes will then be autoclaved which is considered to result in 100% cell kill.

Service of autoclaves takes place quarterly by ACE to meet standards set down in Health and Technical Memorandum 2010 Part 3. Details of temperature profiles for each run are recorded.

In case of spillages in the laboratory. 1% Virkon is the disinfectant of choice and is always readily available.

### Project Additional Information

#### Purposes of the contained use

Visualisation and quantification of bioluminescent bacteria attached to surfaces and in liquid suspension.

#### Recipient or parental organism

Staphylococcus aureus Xen36: S.aureus Xen36 was derived from the parental strain Staphylococcus aureus ATCC 49525. The parental strain was initially isolated from a bacteremia patient and its pathogenic. No mutations as such have been made to disable this strain. S aureus Xen36 us a Hazard Group 2 microorganism.

Staphylococcus Aureus29: S.aureus Xen29 was derived from the parental strain S.aureus 12600, a pleural fluid isolate which is also designated as NCTC8532. Xen29 is a Hazard Group 2 organism and a pathogenic strain. No mutations as such have been made to disable this strain.
Psuedomonas aeruginosa Xen41: P. aeruginosa Xen41 was derived from the parental strain P. aeruginosa PAO1, obtained from Pesuedomonas Genetic stock Center (PGSC). PAO strains are derived from the ATCC parent strain 15692. ATCC 15692 was isolated from an infected wound and it is a pathogenic strain. No mutations as such have been made to disable this strain. P. aeruginosa Xen 41 is a Hazard Group 2 microorganism.

Psuedomonas aeruginosa Xen05: P. aeruginosa Xen 5 was derived from the parental strain P. aeruginosa ATCC 19660, a mucoid strain isolated from a clinical case of human septicemia. No mutations as such have been made to disable this strain. P. aeruginosa Xen5 is a Hazard Group 2 microorganism.

Escherichia coli Xen14: E. coli X14 was derived from the parental strain E. coli WS2572, a clinical isolate from Weilhenstephen Culture Collection. No mutations as such have been made to disable this strain. E. coli Xen 14 is a Hazard Group 2 microorganism.

Psuedomonas aeruginosa Xen41: P. aeruginosa Xen 41 possesses a single stable copy of the P. luminescens lux operon on the bacterial chromosome. There are no disabling mutations in this strain. Xen41: Tetracycline (60 ug/mL) resistance gene used as selective marker.

Psuedomonas aeruginosa Xen05: P. aeruginosa Xen5 was engineered through conjunction and transposition of plasmid carrying transposon Tn5 luxCDABE. P. aeruginosa Xen5 possesses a single stable copy of the P. luminescens lux operon on the bacterial chromosome. There are no disabling mutations in this strain. Xen05: Tetracycline (60 ug/mL) resistance gene used as selective marker.

Escherichia coli Xen14: E. coli Xen14 possesses a stable copy of the Photorhabdus luninescens lux operon on bacterial chromosome. Xen14: Kanamycin (30 ug/mL) resistance gene used as selective marker.

Host/vector system

Staphylococcus aureus X36: S. aureus Xen36 possesses a stable copy of the modified Photorhabdus luninescens Kanamycin (200 ug/mL) resistance gene used as selective marker.

Staphylococcus aureus Xen29: S. aureus Xen29 possesses a stable copy of the modified Photorhabdus luninescens lux ABCDE operon at a single integration site on the bacterial chromosome. There are no disabling mutations in this strain. Xen29: Kanamycin (200ug.ml) resistance gene used as selective marker.

Psuedomonas aeruginosa Xen41: P. aeruginosa Xen 41 possesses a single stable copy of the P. luminescens luxCDABE operon on the bacterial chromosome. There are no disabling mutations in this strain. Xen41: Tetracycline (60 ug/mL) resistance gene used as selective marker.

Psuedomonas aeruginosa Xen05: P. aeruginosa Xen5 was engineered through conjunction and transposition of plasmid carrying transposon Tn5 luxCDABE. P. aeruginosa Xen5 possesses a single stable copy of the P. luminescens lux operon on the bacterial chromosome. There are no disabling mutations in this strain. Xen05: Tetracycline (60 ug/mL) resistance gene used as selective marker.

Escherichia coli Xen14: E. coli Xen14 possesses a stable copy of the Photorhabdus luninescens lux operon on bacterial chromosome. Xen14: Kanamycin (30 ug/mL) resistance gene used as selective marker.

Origin & function

The primary objective of the inserted gene is to transform the parental bacterial strain into a bioluminescent one. As a result, growth of such bacteria can be monitored by imaging systems (such as the Caliper-Xenogen IVIS system).

In their natural host, the nematode symbiont and insect pathogen, Photorhabdus luminescens. The lux bioluminescence genes function as quorum sensing system, in which the genes responsible for bioluminescence (lux genes) are expressed in response in increasing cell density.

Five, non-regulatory, lux genes are associated with the expression of bioluminescence. The genes are present on a single operon (the lux operon). These five genes are called luxA-luxE, with luxA and B encoding the alpha and beta subunits of the heterodimeric luciferase and luxCDE encoding proteins for production of the luciferin substrate.

Evaluation of foreseeable effects

Staphylococcus aureus X36, Staphylococcus aureus Xen29, Pseudomonas aeruginosa Xen41, Pseudomonas aeruginosa Xen05 and Escherichia coli Xen14 are all commercially available bacterial strains that have been modified to contain the Lux ABCDE gene operon of Photorhabdus luminescens.

All 5 bacteria strains are classified as Hazard Group 2 and as such represent a potential hazard to human health and will therefore only be used in suitable equipped laboratory facilities.

The Lux ABCDE operon contains the genetic material required for synthesis of the luciferase enzyme and the generation of its substrate luciferin. The reaction of luciferase with luciferin generates light (bioluminescence) and so can be used as an indicative marker of both the presence of bacteria and of their viability.

Although prolonged contact with the enzyme (luciferase) is associated with skin sensitization amongst sensitive individuals, both luciferin and luciferase are commercially available as purified products and are not classified as hazardous materials.
The inclusion of the lux operon in the target bacteria is not associated with any increase in virulence, however, the plasmid vector used to transfer the organism carries an antibiotic resistance gene in order to assist in the selection of transformed strains. Consequently the transformed organisms will have a broader antimicrobial resistance spectra than the parent strains. The details are given above, but in summary, strains Xen36, Xen29 and Xen14 will display enhanced resistance to Kanamycin and the strains Xen41 and Xen05 will show elevated resistance to tetracycline.

Horizontal gene transfer of the bioluminescent lux operon from the transformed organism to the external environment is unlikely due to the contained use protocols governing the proposed experimentation. If, however, any release did occur the capacity to emit bioluminescence is not associated with any evolutionary advantage outside the specific niches of those few organisms that have evolved such a capacity. The lack of any evolutionary advantage thus makes it unlikely that the lux operon would be stably maintained in the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All cell material and waste which has been in contact with GM materials will be placed in autoclave bags, and then in autoclave boxes. These boxes will then be autoclaved which is considered to result in 100% kill. A waste form will be filled in by the GMO worker to record the type of waste being disposed of and this will accompany the waste to the autoclave. This form will be archived in the GMO autoclave log book. The autoclave is serviced and calibrated four times per year.

In case of spillages in the laboratory either a solution of 1% Virkon or 70% ethanol will be used as the disinfectant of choice depending on the chemical tolerances of the surface being disinfected.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment

The committee has unanimously agreed that this is a satisfactory risk assessment and that sufficient controls are in place to protect both human health and the environment.

### Project Additional Information

#### Purposes of the contained use

The purpose of the contained use is to investigate the physiological and molecular features of transfected (immortalised) human epithelial cells derived from the skin.

#### Recipient or parental organism

see section 17

#### Host/vector system

The genetic material will be cDNAs encoding cellular proteins that are already well characterised and in the public domain i.e. The E6 and E7 proteins of human papilloma virus. The HPV16/E6/E7 genes probably act by blocking the inhibition of cell cycle progression by inhibiting the activity of such genes as CIP-1/WAF-1/p21, Rb, p53 and p16 thus giving an increased life span, reducing DNA surveillance, and giving an enhanced opportunity for further mutations within the immortalised cells.

#### Origin & function

The expectation is that the human cells expressing th cDNAa will be capable of indefinite proliferation in culture, and will acquire an ability to form anchorage independent colonies in semi-solid medium. However, they are not expected to represent a hazard to human health as none of the cells used are capable of colonising a healthy individual and we do not expect the manipulations to alter this. The cells will not be expected to release infectious viral particles. The retroviral vectors are incapable of
replication because of the viral pol and env genes and the PT67 packaging cell line also has the requisite genes deleted to prevent such an occurrence. Forseeable effects will be the immortalisation of skin derived cell lines.

**Evaluation of foreseeable effects**

The infection of the cultured human epithelial cells with HPV16E6E7 inserts will result in the production of immortalised cell lines. The cells will continue to multiply only when grown in suitable culture conditions. The cells should not survive outside culture conditions or in the human body, and therefore, unlikely to spread or cause damage to the environment. We propose to carry out all manipulations in a Class II microbiological safety cabinet following GLP and any additional local safety guidelines appropriate to this work.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All cell material and waste which has been in contact with GM materials will be placed in autocleavable bags, which in turn will be placed in autocleavable boxes. These boxes will then be autocleaved which is considered to result in 100% cell kill. A waste form will be filled in by the GMO worker to record the type of waste being disposed of and this will accompany the waste to the autoclave. This form will be archived in the GMO autoclave log book. Servicing of autoclaves takes place quarterly to meet standards set down in Health and Technical Memorandum 2010 Part 3. Details of temperature profiles for each run are recorded. Clinical incineration is used as a route of disposal if the cells have been treated with chemicals which are very toxic or whose toxicological properties are unknown. In these circumstances, the hazard generated from autoclaving these very toxic chemicals is considered greater than that from any potential exposure to GMOs. If the GMOs are intended for incineration, they are usually but not always sealed inside a container (eg tissue culture flask), then always double bagged on sawdust (to absorb liquid) before being placed in another plastic bag (sealed) inside non-returnable, sealed waste bins. In case of spillages in the laboratory either a solution of 1% Virkon or 70% ethanol will be used as the disinfectant of choice depending on the chemical tolerances of the surface being disinfected.

02/03/2022
Purposes of the contained use

The CHO-K1 cell line has been used to generate three different clones that stably express shRNA targeting the hamster antioxidant genes Catalase (CAT), Superoxide Dismutase 1 (SOD1) or Glutathione Synthetase (GSS) and Glutamate Cysteine Ligase (GCLC), with the aim of producing cell lines with gene knockdowns for those antioxidant genes and therefore a greater susceptibility to the DNA damaging activity of pro-oxidant materials compared to normal CHO-K1 cells.

Recipient or parental organism

Chinese Hamster Ovary (CHOK-K1) cell line.

Host/vector system

The host are CHO-K1 cells, they were transfected with the pRS-Puro (Origne Inc.) vector containing a shRNA sequence targeting the hamster antioxidant genes, CAT, SOD1 or GSS or GCLC.
The genetic material involved is of hamster origin.

Pro-oxidant chemicals which generate reactive oxygen species (ROS), are often detected as genotoxic in in vitro mammalian cell based assays. In vivo, the damaging effects of ROS are counteracted by enzymes such as catalase and superoxide dismutase, as well as other antioxidants defence mechanisms, therefore it is widely regarded that pro-oxidant chemicals have a threshold below which no genotoxicity is observed. In vitro cell systems with limited antioxidant defences may be expected to be more susceptible to the DNA damaging activity of ROS and as such the genotoxicity of pro-oxidant chemicals seen in vitro may not be relevant to the in vivo situation. These CHO-K1 cell lines with gene knockdowns for CAT, SOD or GSS & GCLC antioxidant genes should show a greater susceptibility to the DNA damaging activity of pro-oxidant materials compared to normal CHO-K1 cells. These cell lines will be evaluated using in vitro genotoxicity assays such as the in vitro micronucleus assay and/or the Comet assay.

Evaluation of foreseeable effects

Host

CHO-K1 cells are commercially available epithelial cells derived as a subclone from the parental CHO cells. The cell line is not known to harbour an agent known to cause disease in healthy adult humans and is reverse transcriptase negative. The cells would not survive outside culture conditions and they would not survive in the human body. Thus the host is a 'disabled or non-colonising' host and of low hazard. The genetically modified clones described in the risk assessment have been screened for mycoplasma and bacterial contamination with negative results (i.e. no contamination detected).

Vector for CHO-K1 gene knockdowns

The HuSH shRNA cloning plasmid vector, pRS-Ouro (Origene Inc.) was used to generate three CHO-K1 cell lines with hamster gene knockdowns for CAT, SOD1 or GSS and GCLC. The vector allows stable delivery of a shRNA expression cassette into host cells by direct transfection.

The pRS-Puro plasmid vector contains the following functional elements:
- Both 5' and 3' long terminal repeats (LTRs) of the Moloney murine leukaemia virus
- Human U6 polymerase III promoter located for shRNA expression
- SV40 early promoter for regulation of the mammalian cell drug resistance marker, puromycin
- Puromycin-N-acetyl transferase gene, conferring resistance to puromycin
- pBR322 bacterial origin of replication
- Ampicillan resistance gene for bacterial selection

The pRS-Puro vectors are capable of integrating into mammalian cells therefore the potential hazard from these vectors is that of transfer to other cells in vitro or in vivo. Although these vectors could potentially be incorporated into bacterial cells, the promoters driving expression of the mammalian gene would be expected to be low non-functional. The pRS-Puro vectors contain retroviral LTRs and packaging signal but do not contain the retroviral DNA sequences gag, pol or env and therefore require a packaging cell line in order to produce a virus. The 3' LTR of the pRS vector has been mutated (has a deletion) so that the virus is self-inactivating (SIN) and therefore replication deficient. In the unlikely event that a virus is generated from this vector, the virus would not be able to further replicate and therefore could not infect other mammalian cells. The ACGM guidelines state that vectors from which no infective virus can be produced should be regarded as minimal risk.

Insert DNA

The CHO-K1 knockdown (KD) cell lines all contain a shRNA sequence targeting the hamster antioxidant genes, CAT, SOD1 or GSS & GCLC. It is unknown whether the cloned shRNAs targeting the hamster genes have sufficient sequence homology to target the human genes. However the catalase and SOD1 genes in particular are highly conserved between species. It should therefore be assumed the shRNAs have the potential to target the human genes.

Catalase (CAT)

The CHO-K1 CATKD cells contain a shRNA sequence targeting the hamster catalase gene. Catalase is ubiquitously expressed in mammalian cells where its function is to counter the harmful effects of reactive oxygen species, predominantly peroxyl radicals, which are generated in cells through normal metabolic processors or as a result of chemical exposure. Decreases in catalase activity in humans does not show life threatening harmful effects under normal levels of oxidative stress due to the presence of...
other antioxidant enzymes, such as glutathione peroxidase, which also removes hydrogen systems. Detects in the gene encoding for the catalase protein can cause acatalasaiain humans, which is a rare autosomal recessive disorder resulting from the absence of catalase activity. Although it is usually asymptomatic, a syndrome of oral ulcerations can occur.

Superoxide Dismutase 1 (SOD1)
The CHO-K1 cells contain shRNA sequence targeting the hamster SOD1 gene. SOD1 is expressed in the cytosol of mammalian cells where its product counters the harmful effects of reactive oxygen species, specifically superoxide radicals, which are generated in cells through normal metabolic processes or as a result of exposure to pro-oxidant chemicals. In mice, inactivation of SOD1 has been shown to contribute to hyperplasia in the liver and hepatocellular carcinoma through the presence of persistent oxidative damage to proliferating cells. It is therefore possible that a decrease in SOD1 activity in humans could result in an increase in oxidative DNA damage leading to cancer promotion.

Glutathione synthetase (GSS) and glutamate-cysteine ligase (GCLC)
The CHO-K1 GSS&GCLCKD cells contain a shRNA sequence targeting the hamster GSS and GCLC genes. Glutathione synthetase catalyzes the second step of glutathione biosynthesis, which is the ATP-dependent conversion of gamm-L-glutamyl-L-cysteine to glutathione. Glutamate-cysteine ligase, also known as gamma-glutamylcysteine synthetase is the first rate limiting enzyme of glutathione synthesis. It is anticipated that knockdown of both of these genes will result in decreased levels of glutathione. Glutathione is important for a variety of biological functions, including protection of cells from oxidative damage by free radicals, detoxification of xenobiotics, and membrane transport. Glutathione synthetase deficiency is an autosomal recessive disorder that prevents the production of glutathione. Individuals with the disorder often exhibit a tendency to haemolysis and in severe cases acidosis and neurological defects.

Antibiotic resistance genes
The Puromycin-N-acetyl transferase gene confers resistance to puromycin and is expressed from the SV40 early promoter in the pRS-puro vector to allow selection in bacteria. There is a slight risk associated with these genes used as a selection markers in that resistance may be transferred to the gut bacteria if ingested. However, alternative antibiotic therapies are available which could be used to limit the proliferation of transformed cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All work surfaces will be treated with Virkon before and after handling these cultures. These cell lines are handled in microbiological safety cabinets, maintained on a 6 monthly basis, within a Containment level 2 suite entered via a lobby, by trained personnel. The suite has restricted access and the cells are autoclaved before leaving the laboratory or are autoclaved or are disposed of via incineration. Autoclaving is the preferred route and is considered to provide 100% kill of the GMO. Incineration will be used when the cells have been in contact with chemicals which are very toxic or whose toxicological properties are unknown. It was considered that the hazard generated from autoclaving these very toxic chemicals was far greater than that from any potential exposure to the GMOs. Incineration is via the Clinical Waste route at Colworth and is removed from site and incinerated by external contractors. Cultures and associated media are usually but not always sealed inside a container (e.g. tissue culture flask or Universal), then always double bagged on sawdust (to absorb liquid) before being placed in another plastic bag (sealed) inside sealed yellow one-way bins. Thus making it virtually impossible for the GMOs to escape during disposal. Accidental release to the environment is considered highly unlikely.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
The committee has unanimously agreed that this is a satisfactory risk assessment and that sufficient controls are in place to protect both human health and the environment.

Purposes of the contained use

The use of bacterial bioluminescence to assess the viability of the target organism in preservative challenge testing.

Recipient or parental organism

The 14 recipient bacterial strains (listed below) were originally isolated from industrial sources with the exception of the genome reference strain Burkholderia lata strain 383 which was recovered from soil and the reference Staphylococcus spp. that originated from a clinical source. Engineered genetic control measures (Biological containment) were not employed to attenuate or disable the recipient strains; they are unchanged form their original isolation. All strains are classified as ACDP Hazard Group 2 in accordance with CoSHH.

Host/vector system

The following vector systems will be used to create bioluminescent derivatives of the recipient strain panel described above. All vector systems selected have been widely used in scientific research and have a track record of publication associated with their construction and use.

2. Gram positive broad host range plasmid vector. Plasmid pAL2 is a broad-host range vector that carries the lux-ABCDE operon from P.luminescens and an erythromycin resistance gene as a selective marker for transformants. This vector system was used specifically for the Gram-positive Staphylococcus spp. The plasmid is non-mobilisable and requires electroporation for its introduction into recipient bacteria. The construction and use of this vector has been described by Beard, S. et al. Antimicrob Agents Chemother, 2002 46(2)S38-542.

3. Integrative transposon vector. The mini-Tn5-lux vector contains the inner and outer transposase recognition sequences flanking a promotless luxCDABE operon from
P. luminescens, and a tetracycline resistance gene for transformant selection. Once mobilised and inserted into a new recipient strain, the integrated mini-Tn5 luxCDABE construct is not self transposable and is stably maintained in the absence of antibiotic. The construction and use of this vector has been described by Winson, M.K. et al. FEMS Microbiol Lett. 1998. 163(2) 193-202; Lewwnza, S. et al. Genome Res. 2005. 15(4)538-589.

4. A pseudomonas integrative vector. The ФCTX-based integration-proficient mini-CTX-lux vector is a non-replicative plasmid system that allows the integrase mediated insertion of the lux gene operon from P. luminescens at the attB sequence (phage attachment site) located on the P. aeruginosa chromosome. Following integration, unwanted sequences, including plasmid-associated promoters, integrase, and the tetracycline resistance gene marker can be removed in vivo by yeast Flp recombinase. The construction and use of this vector has been described by Hoanf, T., et al. Plasmid, 2000.43(1)59-72; Schwartz, H.P. Curr Opin Niotech, 2001. 12(5)439-445.

5. Well characterised bacterial lux-vectors from published literature will be used as necessary. The effect of using such vectors on the fitness (i.e. growth characteristics), preservative and antibiotic susceptibility will be investigated using published methodology; this will ensure the GMOs are not higher risk than the wild-type. The lux construct including selective marker, of such vectors will not be self-transmissible in recipient bacteria.

**Origin & function**

The primary role of the inserted lux gene operon is to generate a self-bioluminescent transformant of the parental bacterial strain. As a result, the growth of such bioluminescent bacteria can be monitored using an appropriate imaging system (such as Tecan Infinite M200 PRO). In their natural host, the ACDP Hazard Group 1 soil bacterium P. luminescens, the lux bioluminescence genes produce light exclusivity during the post-exponential phase of growth when the bacteria is infecting insect larval hosts at high cell densities.

Light production in bacteria requires the presence of a give-gene operon luxCDABE. The luxA and luxB genes encode the alpha and beta subunits of heterodimeric luciferase. The product of the luxC, luxD and luxE genes is predicted to form a fatty acid reductase that provides the luciferase enzyme with an aldehyde substrate.

Other than the emission of light, the lux gene system is not associated with any other known function such as antimicrobial resistance, virulence or persistence, that would confer an advantageous phenotype on recipient strains.

**Evaluation of foreseeable effects**

All fourteen bacterial strains have been assigned to ACDP Hazard Group 2 and as such may pose a threat to human health and will therefore only be used in a suitably equipped laboratory facility.

The lux ABCD operon contains the genetic material required for the synthesis of the luciferase enzyme and the generation of its substrate luciferin; the reaction of luciferase with luciferin generates light (bioluminescence). Light output from these bioluminescent bacteria is a highly sensitive reporter of metabolic activity which can be used to monitor the viability of the target organism in preservative challenge testing.

As in the case with many enzymes, prolonged or repeated exposure to luciferase may cause sensitisation in some sensitive individuals; however, both the enzyme luciferase and its substrate luciferin are commercially available as purified chemicals and are not classified as hazardous materials. The level of exposure to this enzyme within the reporter bacteria is below the risk associated with excess exposure to ACDP Hazard Group 2 bacteria.

The insertion of the lux ABCDE operon as a plasmid or into the chromosome of the target bacteria is not associated with an increase in virulence; however, the use of antibiotic resistance markers to aid selection of transformants and retention of genetic material, will confer extended antimicrobial resistance, will confer extended antimicrobial resistance spectra on the transformed bacteria relative to the wild type parental strain. However, all the antibiotic selection markers used (tetracycline, cloramphenicol, gentamycin, trimethoprim and erythromycin) have a long and safe track record of use in the genetic modification of bacteria.

Horizontal gene transfer of the bioluminescent lux operon or antibiotic resistance gene marker from the transformed bacteria to the external environment is highly unlikely due to the use of containment protocols governing the proposed experimentation. In the highly unlikely event of a release the capacity to emit bioluminescence would confer no evolutionary advantage on the organism and so is unlikely to favour the long term bioaccumulation of any released organisms in the environment. Similarly the potential
for the horizontal spread of genes encoding antibiotic resistance would not confer an evolutionary advantage outside an environment where antibiotics are in frequent use, such as a hospital.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

All of the GMOs cited under this notification are micro-organisms.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All cell material and waste which has been in contact with GM material will be sealed in autoclavable bags, which in turn will be placed into autoclavable boxes. These boxes will then be autoclaved which is considered to result in 100% kill. A waste form will be filled in by the GMO worker to record the type of waste being disposed of and this will accompany the waste to the autoclave. This form will be archived in the GMO autoclave log book.

The autoclave has an electronic chart recorder/data logger for monitoring load and drain temperatures. Before the autoclave is opened, the paper chart will be checked to confirm the required process has been achieved.

The autoclave is serviced 6 monthly and validated (according to Health and Technical Memorandum 2010 part 3) by specialist contractors quarterly. In case of spillages in the laboratory either a solution of 1% Virkon or 70% ethanol will be used as the disinfectant of choice depending on the chemical tolerances of the surface being disinfected. After treatment with disinfectant the spill will be absorbed using paper towels and all material used in this clean up will be subjected to autoclaving as above to ensure complete destruction of the GMO.

For activities involving GMMs, describe the waste management measures which will apply to the activity

For our waste management all solid and liquid waste is deactivated by autoclaving. On average there are five autoclave runs daily across the different locations in machines up to 150L volume. The autoclave performance is monitored by assigned technical staff using print-outs, direct temperature measurements and bioindicators.

CU2 Project Title GENETICALLY MODIFYING THE BIOCHEMICAL AND PHYSIOLOGICAL

Class 2
CultureVolClass2 < 1 Litre
CultureVolumeClass3-4
Project Additional Information

Purposes of the contained use
To improve understanding of plant metabolism, especially in legumes, by altering gene expression.

Recipient or parental organism
Lotus and Trifolium species
Agrobacterium rhizogenes strain C58C1 LBA9402
[Plant pathogen. Class 2. Use requires Plant Health license from DEFRA]

Host/vector system
Disabled E. coli/pUC/pLC/pBluescript/pBin19 derivatives used to transform Agrobacterium rhizogenes
Agrobacterium rhizogenes is used to transform plants genetically eg Lotus and Trifolium.

Origin & function
The Genetically Modified Micro-organism Agrobacterium rhizogenes acts as a plant vector and the modifications do not involve manipulating its plant pathogenicity.

Genes isolated from a range of bacterial and plant sources will be introduced into A. rhizogenes, which will then be used to transform plants. None of the inserted genes will be expressed in A. rhizogenes. The inserted sequences include selectable marker genes, reporter genes and known genes or non-characterised plant sequences inserted in sense and antisense orientations that will potentially alter secondary metabolism and symbiotic interactions of the plants transformed with the sequences concerned. Inserted sequences will include
a) selectable markers for antibiotic resistance - kanamycin and hygromycin (from bacteria) - and herbicide tolerance - phosphinothricin (PPT, bacteria).
b) reporter genes - glucuronidase (bacteria) and green fluorescent protein (jellyfish).
c) secondary metabolism genes from flavonoid pathway - chalcone synthase (plant), dihydroflavonol reductase (plant)
d) symbiotic genes - early and late nodulins, calcium binding protein (plant)
e) sequences isolated from plants, but whose role in the biochemical pathway is unknown, and is being determined.

Evaluation of foreseeable effects
Genetically Modified Microorganisms. A. rhizogenes:
<table>

The inserted bacterial and plant genes have no foreseeable effect on human health.

Ris to Environment

Agrobacterium rhizogenes is a soil-borne plant pathogen causing hairy root disease. Current information indicates that its pathogenicity has little economic impact on crop production. A rhizogenes is used as a plant vector and the modifications do not involve manipulating its plant pathogenicity. The inserted sense and antisense genes - antibiotic or reporter genes, known genes or non-characterised sequences related to metabolism in plants - are not expressed in the bacterium and are themselves unlikely to alter the pathogenicity of the bacterium.

While A. rhizogenes has the potential for a minor impact on the environment as a plant pathogen, the inserted genes are unlikely to increase that potential. In the unlikely event that genetically transformed A. rhizogenes were to escape and effect indigenous plants, the resultant hairy root tissue would contain and could express any of the inserted genes. However, any expression would be restricted to the hairy roots themselves and these hairy roots are unlikely to regenerate into new plants. Plant regeneration from roots usually requires very specific, controlled culture conditions, and then only occurs in a limited number of species.

The inserted gene would not be expected to confer any significant advantage on the hairy roots unless other unlikely conditions were also met. For example, hairy root tissue transformed with the PPT herbicide tolerance gene (as the result of accidental escape of A. rhizogenes) might be at an advantage if it came into contact with the herbicide. However, this herbicide is not used routinely in British agriculture and, normally, roots die without a shoot system. In a worse case scenario, these plants might be unusual and be able to regenerare shoots directly from the herbicide tolerant hairy roots.

The containment measures adopted will prevent escape of genetically manipulated A. rhizogenes. All bacterial and plant/bacterial work will be done in Class 2 safety cabinets. The bacterium will be maintained in sealed units, cultures will be contained within the laboratory and kept in growth rooms. A warning notice will be displayed next to bacterial cultures and plant cultures potentially containing A rhizogenes as agreed by DEFRA. Plant material will be rigorously tested for sterility to ensure that A. rhizogenes is removed prior to transfer to soil or equivalent in Plant Containment Level A growth rooms and glasshouses.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The resulting GM plants will be grown under established facilities under agreed procedures for Containment Level A, in a locked, insect-proof compartment with no free drainage.
All transgenic material will be free of Agrobacterium species before transfer to soil.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All waste is collected in labelled autoclave bags and autoclaved at 121 degrees C, 40 minutes, 15 psi
Autoclave is tested annually using a thermocouple and whenever autoclave is re-commissioned after maintenance work.
Autoclaved waste collected and disposed of by the local authority.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
The local Genetic Modification Safety Committee (GMSC) considers that the risk assessment meets current regulations even though the comments on the original risk assessment were made under the regulations enforced in 1993. The agreed procedures state that all manipulations using A. rhizogenes will be done in a Class 2 hood.

**Project Additional Information**

**Purposes of the contained use**

Microbial populations mutated with mobile genetic elements will be screened for transcriptional activity in response to environmental stimuli in Chromobacterium violaceum, Pseudomonas aeruginosa, Burkholderia cepacia, Pseudomonas fluorescens and Pseudomonas putida, Pseudomonas aerantiaca and Acinetobacter spp. In many cases the mobile elements will encode transcriptional reporter genes e.g. luciferase and associated genes (luxCDABE) or green fluorescent proteins (gfp/yfp) (see Section 7). Transcription of the reporter genes will be driven by the regulatory sequences ("promoter") of the gene within which the transposon has inserted (assuming the reporter gene is appropriately orientated). Thus, these reporter fusions will be used to monitor gene activity in response to environmental stimuli. Key genes identified through random mutagenesis and screening may suggest further candidates for gene-knockouts or non-disruptive reporter insertion. These could represent homologous genes identified by database searches, functionally linked components of signalling or biosynthetic pathways or adjacent co-regulated genes (part of an operon).

Directed mutagenesis will be carried out using in situ exchange of an endogenous gene with a mutated version by homologous recombination. The mutated gene will be generated by the introduction of a ‘cassette’ containing a selectable marker (an antibiotic resistance gene) and genes (luxCDABE, gfp/yfp) coding for luminescence/fluorescence.

**Recipient or parental organism**

Mutated populations will be generated in the category 2 wild type strains: Pseudomonas fluorescens, Pseudomonas putida, Pseudomonas aurantiaca; and in the following category 2 wild type strains (where strains from the same species have been identified as opportunistic animal/human pathogens): Chromobacterium violaceum, Pseudomonas aeruginosa, Burkholderia cepacia and Acinetobacter spp.

**Host/vector system**

The following genetically mobilisable systems based on transposon Tn5 (de Bruijn and Lupski JR. 1984 Gene27:131-149) will be employed:

(i) Mini - Tn5 transposon (de Lorenzo et al., 1990, J. Bact. 172 172; 6568-6572) derivatives to include a promoterless luxCDABE operon (Winson et al., 1998 FEMS Microbiol Lett. 163:193-202) or gfp (encoding green fluorescent protein (Miller & Ludow 1997 191;149-153)). The mutants generated in this way will include one or a combination of elements containing a gene coding for resistance to kanamycin, streptomycin, chloramphenicol and tetracycline introduced into the bacterial strain on the pUT suicide plasmid (the suicide plasmid will not be maintained within the bacterial cell).

(ii) Genetic constructs for marker exchange will be introduced into recipient strains by conjugation from an auxotrophic E. coli S17-1 pir donor using the following suicide vectors which lack a suitable origin of replication for maintenance in the target strain. (A) pUCMOB = pUC18 origin of mobilisation (oriT) cloned from pSUP5011 (Simon et al., Mol.Gen. Genet. (1984) 196: 413-420; Winson (1991) PhD UW Bangor "Molecular Biological Studies on Catabolic Plasmids").

(B) pMOB variants 1,2,3,4 all containing oriT and kanamycin resistance genes. Variants pMOB2 and 3 encode levansucrase (sacB) whilst pMOB3 and pMOB4 encode chloramphenicol resistance. (Schweizer (1992) Mol. Microbiol. 6, 1195-1204). (C) The REDIRECT (Rapid Efficiently Direct Recombination) construct pK20 which encodes the hygB gene which confers hygromycin resistance. In this system recombination efficiency between a cloned DNA segment and the target DNA is aided by recombinate (Datsenka KA, Wanner BL. 2000) "One-step inactivation of chromosomal genes in Escherichia coli K-12 using PCR products". Proc Natl Acad Sci USA.;97:6640-5).

**Origin & function**

**MUTAGENESIS USING MOBILE GENETIC ELEMENTS**

Origins: The introduced genetically mobile elements are derived from the Tn5 transposon which was originally isolated from the Gram-negative bacterium Escherichia coli (Herrmann et al., 1978 Mol Gen Genet 159:171-8). However, unlike the original Tn5, the transposase function for these mini-Tn5 elements is placed outside of the
Functions: For the mini-transposon based reporter system two functions are expected 1) disruption of the gene/operon within which the element inserts and; 2) reporting the upstream promoter activity of the disrupted gene/operon. The reporter element consists of either 1) a promoterless luxCDABE operon which encodes both luciferase and enzymes responsible for generating the aldehyde substrate leading to bioluminescence when driven by a promoter outside and upstream of the inserted element or 2) gfp which provides for a fluorescent phenotype when driven by a promoter outside and upstream of the inserted element. 

Introduction of a mini-Tn5 reporter element leads to random mutation of the genome in the target strain and each individual mutant strain isolate is expected to possess a different single transposon-disrupted gene.

MUTAGENESIS USING MOBILE GENETIC ELEMENTS

The use of Mini-Tn5's and plasposons will allow the derivation of mutant populations which are likely to exhibit either no apparent difference or a reduction in "fitness". These will be screened to identify individuals which are altered in their ability to detect and respond to environmental stimuli. It is considered extremely unlikely that mutagenesis will result in strains with either increased general "fitness" or virulence. 

Expression of the luxCDABE operon in mini-Tn5 elements will have no effect on bacterial fitness or virulence. However, insertion of selectable markers possessing their own promoter sequence into mini-Tn5 and plasposons could activate the genes flanking the inserted locus. In a measure to reduced these effects the selectable marker and promoter is directed so that transcription is driven into and not out of the main body of the genetic element.

MUTAGENESIS USING MOBILE GENETIC ELEMENTS. This form of mutagenesis further reduces the chance of unpredictable effects since the target is well defined and the likely effects of selectable marker promoter-mediated activation are known. Thus, in each case the effects of recombination mutagenesis will be to have either no effect or reduced fitness/virulence.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

None

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All experiments will be carried out in designed Category 2 containment facilities. These are located in F22 of the Cledwyn Building and SF1, SF2 and SF21 of the Edward Llwyd Building Annex. Entry to each laboratory is via keypad-controlled doors; floors are all sealed and only dedicated lab-coats are worn within the laboratory. These
never leave the category 2 laboratories and are periodically autoclaved and washed. All workers leaving the lab must thoroughly wash their hands using bactericidal soap in a hand washbasin located at the lab entrance. All cultures are grown within the category 2 facility and all spent bulk liquid cultures are disinfected and autoclaved prior to disposal. All glassware is autoclaved after use. Petri dishes and contaminated plasticware are collected in autoclave bags. All spills are treated with hycolin and absorbed onto paper towels. These are placed in an autoclave bags. All items which are due to be autoclaved are placed within two autoclave bags (one within the other) and sealed. Bags destined to be autoclaved are not allowed to accumulate. These are transported to the autoclave within a clearly marked metal container. Following autoclaving and cooling all waste is disposed of as domestic waste.

A large capacity autoclave is available in F35 and provides a full read-out which is recorded. Annually, the performance of this autoclave is independently tested using a EBRO EBI-125A logger for which the manufacturers provide a calibration certificate.

Date Project Ceased | 02/03/2022
Purpose of the contained use

Overall purpose: Populations of bacterial pathogens mutated with mobile genetic elements will be screened for altered interactions with the model plant species - Arabidopsis and tobacco (Nicotinia tabacum).

(A) The introduced mobile "transposable" genetic elements are derived from Tn5. These encode selectable antibiotic resistance genes to kanamycin or tetracycline whose transcription is driven by upstream regulatory sequences ("promoter"). We propose to use these mobile elements to abolish gene function and following screening identification of genes whose mutation leads to reduced virulence. In certain cases the mobile elements will encode transcriptional reporter genes luciferase (luxCDABE) (see Section 7). Transcription of this reporter cassette will be driven by the promoter of the gene within which the transposon has inserted (ie. outside of the introduced genetic element and assuming the reporter is appropriately orientated). Such reporter fusion's will be used identify bacterial genes which respond to plant-derived signals by enabling their activity to be monitored during plant-pathogen interactions.

(B) Key genes identified through random mutagenesis and screening may suggest further candidates for gene-knockout. These new targets could represent (1) homologous genes identified by database searches, (2) functionally linked components of a signalling or biosynthetic pathway or (3) adjacent co-regulated genes (ie. part of the same "operon").

Directed mutagenesis will be carried out by homologous recombination using in situ exchange of the endogenous gene with an introduced mutated version. Within the introduced mutated gene will contain an antibiotic resistance gene so that successful integrations into the genome to be selected for (where integration has not occurred the bacterium will not display the specified antibiotic resistance, See Section 7).

Recipient or parental organism

We propose to manipulate the following species of Pseudomonas syringae - all of which are bacterial plant pathogens.

Pseudomonas syringae pathovar phaseolicola - isolated from French Bean
Pseudomonas syringae pathovar tomato - a wide host range including tomato and arabidopsis.
Pseudomonas syringae pathovar tabaci - isolated from tobacco.
Pseudomonas syringae pathovar syringae - though originally isolated from lilac this species exhibits a wide host range.

Individual species vary in their host range and degree of virulence. Pseudomononas syringae pathovar tabaci cause "wildfire disease" which, as the name suggests, is a highly aggressive infection.

Host/vector system
The following genetically mobilisable systems based on transposon 5-Tn5 (de Bruijn and Lupski JR. 1984 Gene27:131-49) will be employed -

(i)  Mini -Tn5 "transposons" (de Lorenzo et al., 1990, J. Bact. 172, 172; 6568-6572) derivatives to include a promoterless luxCDABE operon.  (Winson et al., 1998 FEMS Microbiol Lett. 163:193-202)  The inserted transposons include tetracycline or kanamycin resistance genes and will be introduced into the bacterial strain on the pUT suicide (ie. this will not be maintained within the bacterial cell) plasmid.

(ii)  Plasposons/TnMod - Integration of a mobile element will result in the introduction of an selectable marker (tetracycline or kanamycin resistance) and bacteriophage CoIE1 origin of replication bounded by Tn5 "inverted repeats" which mark the beginning and end of the mobile genetic element.  TnMod-encoding kanamycin and tetracycline resistance will be introduced into bacterial cells on the suicide plasmid - pTnMod-OTC respectively (Dennis and Zylstra, 1998, App.  And Environmental Microbiol. 64, 2710-2715).  Mutated genes may be easily isolated by extracting genomic DNA from the mutated lines, restriction enzyme digestion, ligation (to form DNA "circles") and transformation of E. coli cells.  Only the circularized mutated gene fragment will possess both an origin of replication and a selectable antibiotic marker, to allow maintenance in E. coli and selection of transformed cells.

Candidates for marker exchange will be introduced into the desired strains on the following suicide vectors.

(ii)  pMOB variants 1, 2, 3, 4 HP all containing oriT and kanamycin resistance genes.  Variants pMOB2 and 3 encodes levansucrase (sacB) whilst pMOB3 and pMOB4 encode chloramphenicol resistance.  (Schweizer [1992] Mol. Microbiol. 6, 1195-1204).

(iii)  The REDIRECT (Rapid Efficiently Direct Recombination) construct PKD20 which encodes the hygB gene and confers hygromycin resistance.  In this system recombination efficiency between a cloned DNA segment and the target DNA is aided by recombinase which is encoded on the same plasmid (Datsenko KA, Wanner BL. [2000] One-step inactivation of chromosomal genes in Escherichia coli K-12 using PCR products.  Proc Natl Acad Sci USA.;97:6640-5).

Mutagenesis using mobile genetic elements

Origins:  The introduced genetically mobile elements are derived from the Tn5 transposon which was originally isolated from the Gram-negative bacterium Escherichia coli (Herrmann et al., 1978 Mol Gen Genet 159:171-8).  The luxCDABE operon on the Mini-Tn5 was isolated from Photorhabdus luminescens (Winson et al., 1998 FEMS Microbiol Lett. 163:193-202).

Functions:  For Plasposons, it is expected to disrupt genes in Pseudomonas syringae and isolate of the mutated gene in E. coli.  However, for Mini-transposon based systems - two functions are expected -disruption of gene/operon at the site of integration and reporting the mutated gene/operon's promoter activity.  This is carried out using a promoter-less luxCDABE operon which encodes genes making both luciferase and its substrate.  Bioluminescence will only be observed when transcription of the luxCDABE operon is driven by a promoter outside of the inserted element.

Strains will be randomly mutated throughout their genomes; thus individual strains possess different gene "knock-outs".  Over entire population it is expected that most genes encoded by the bacteria will be mutated.

Mutagenesis by homologous recombination

Origins:  All vectors used to introduce genes for mutagenesis will be derived from sequences originating from either E.coli or bacteriophages.

Functions:  The introduced plasmids will allow the homologous recombination between gene sequences encoded by the plasmid and genomic gene sequences.  Successful integration is indicated through the stable acquisition of an antibiotic resistance the transcription of which is driven from its own promoter.  Target genes to be mutated will be to a great extent determined by the outcome of the mutant screens (see Section 6).
Evaluation of foreseeable effects

MUTAGENESIS USING MOBILE GENETIC ELEMENTS
As the nature of the proposed genetic manipulation is a gene- "knock-out", it is considered unlikely that mutagenesis will result in strains with either increased general "fitness" or virulence. Expression of the luxCDABE operon in Mini-Tn5 elements in themselves will have no effect on bacterial fitness or virulence.

Nevertheless, two identifiable risks exist. The selectable marker genes possess their own promoter sequence which could activate the genes around the inserted genetic element by "read-through". Additionally, gene activation could also occur if the mobile element inserts and abolishes the function of the gene(s) that suppresses the activity of other genes or their products. Hence, abolition of such a gene could result in the expression/display of eg. virulence gene(s) or product(s). But as mutation of such a suppressor function would undoubtedly have occurred naturally in the wild type population, it is not expected that this scenario would result in strains which were more virulent than already described for that particular pathogen.

MUTAGENESIS BY HOMOLOGOUS RECOMBINATION. This form of mutagenesis further reduces the change of unpredictable effects since the target is well defined and the likely effects of selectable marker promoter-mediated activation are known. The targets for mutagenesis will be virulence determinants or involved in other aspects of pathogenic interactions with plants (eg detection) and thus genetic manipulation will result in reduced fitness/virulence.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

It is envisaged that mutated Pseudomonas syringae strains will be at some stage used to challenge GM plants. The generation of transgenic plants is covered by DEFRA licence PHF123/3011 and the facilities used to generate, maintain, store seed and dispose of transgenic material are subject to twice yearly DEFRA inspection.

Transgenic plants will be germinated and grown in dedicated greenhouses (T4 and T5) and the header-house at the University Garden Penglais Hill or in the Transgenic Growth Rooms (Edward Llwyd Building Annex). The greenhouses have double doors and key pads control entry. Entry is via a positively pressured entrance vestibule or "air-lock". All compartments within the glasshouses are positively pressured within the exception of the central vestibule at "ambient" pressures. These pressures are maintained by "forced air" over-head, or in-wall fans where the input air is passed through 5 um filters. The net effect of these measures is to prevent the entry of insects into the glasshouses or into the plant growing compartments. Blue-coloured lab coats are placed within the entrance vestibule which all users MUST wear to prevent transfer to fungal spores from the general environment into the glasshouses and also transgenic pollen to the outside. The blue-coats are periodically autoclaved.

There are no drains in the glasshouse and the sparse volumes of run-off water are collected using dedicated "liquid" vacuum cleaners and autoclaved prior to disposal with the common liquid waste. Any loose-leaf material will be collected for autoclaving. Any plants (which must be non-flowing) to be transported to the main laboratory (~500 yards distant) are transferred in a van which is dedicated for garden use. All loose soil or leaf material will be collected and autoclaved. After completing an experiment, all plants, soil and plastic pots will be autoclaved.

Transgenic plants are also maintained in Transgenic Growth Rooms (TGR1-8), which are located in the basement of the Edward Llwyd Building Annex. Entry to TGR1-8 is via keypad controlled double doors. TGR1-8 is positively pressured to prevent insect and fungal spore entry. Blue coats are also used in these facilities.

AUTOCLAVING: All GM plant material, pots and soils will be autoclaved. Designated green-coloured bins have been placed in the main laboratories - GF20b, FF1, FF2 and FF16 Edward Llwyd Building and TGR1-8. Large capacity autoclaves have been placed in the immediate vicinity ofGF20b, FF2 and TGR1-8 and also in the Penglais Hill Garden Header-house. These autoclaves provide a paper report slip which is examined and stored. All autoclaves are checked yearly using EBRO EB1-125A logger.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All experiments will be carried out in designed Category 2 containment facilities. These are located in GF20a, GF20b, and FF2 of the Edward Llwyd Building Annex. Entry to each laboratory is via keypad-controlled doors; floors are all sealed and only dedicated lab-coats are worn within the laboratory. These never leave the category 2
laboratories and are periodically autoclaved and washed. All workers leaving the lab must wash their hands using bactericidal soap in a hand washbasin located at the entrance. All cultures are grown within the category 2 facility and spend broth is treated with effective detergents (eg. hycolin) prior to disposal. All glassware is autoclaved after use. Petri dishes and contaminated plastic-wear are collected in autoclave bags. Spills are treated with hycolin, absorbed on to paper towels and then placed in autoclave bags. GF20a is also negativity pressured to prevent pathogen aggress and the designated lab-coats are maroon in colour. All items to be autoclaved are placed within two autoclave bags (one within the other) and sealed. These are moved to the autoclave within a metal container.

A large capacity autoclave is positioned immediately outside GF20a/b and provides a full read-out which is recorded. This autoclave is annually tested using EBRO EB1-125A logger. Bags destined to be autoclaved never allowed to accumulate eg around the autoclave or in the labs. Following autoclaving and cooling all waste is disposed of as domestic waste.

Date Project Ceased 02/03/2022

02/03/2022 Page 2118 of 15326
Schistosomiasis remains a significant cause of morbidity and mortality within countries of the Developing World, with an estimated 200 million active infections and a further 600 million people in the tropics and sub-tropics at risk from infection. Although there is highly effective antihelmintic (praziquantel) to treat the disease, the re-infection of treated individuals often occurs. There is an urgent need for an effective vaccine, as well as novel second-line anthelmintics to deal with emerging praziquantel resistance in the parasitic schistosome worms responsible for this neglected tropical disease.

We have established that many of the 29 S. mansoni SCP protein family members are differentially expressed throughout the various life stages of the parasite, and at least some are recognised by the host immune system. The purpose of this study is the functional characterisation of SCP proteins in S. mansoni to understand their role in the biology of the parasite, and their potential involvement in the human immune response to schistosome infection.

Recipient or parental organism

- Escherichia coli strains K12, TOP 10 and BL21 Star (Invitrogen)
- Saccharomyces cerevisiae strains AH109 and Y187

Host/vector system

- E.coli Top 10/pGEM-t Easy
- E.coli BL21 Star/pET30a C-term 6x His
- S.cerevisiae/pGBKT7 and /pGADT7 Rec

Origin & function

Origin

Some SmSCP/TAPS genes will be amplified from cDNA synthesized from total RNA previously extracted from various life-cycle stages of S. mansoni. Others will be amplified directly from pCR-TOPO 2.1-SCP/TAPS (Invitrogen) constructs already available to us.

No living parasite material, or exposure of workers to live parasites, is necessary for generating any of these source DNAs.

Function

The pGEM-t Easy constructs will be used for the initial cloning and maintenance of the genes from PCR products. The pET30a plasmid constructs containing cloned S. mansoni SCP genes will be made solely for the purpose of overexpression of SCP proteins.

pGBLT7 will be used to express Val proteins as fusions with the GAL 4 DNA binding domain.

pGADT7-Rec will be used to express host proteins of interest as a fusion with the GAL 4 activation domain (AD). These constructs constitute respectively the "bait" and "prey" components of the BD MatchMaker yeast 2-hybrid system.
The SCP/TAPS family of proteins have a very wide distribution throughout the natural world. The biological function of most family members is unknown [1], but they are thought to be involved in many fundamental biological processes, for example sperm/egg recognition and plant stress responses (for a review, see [2] below). Whilst a very limited number of SCP/TAPS genes encode proteins with either pathogenic or allergenic characteristics [3], a large number of SCP/TAPS proteins have already been safely expressed and purified from bacterial or eukaryotic hosts[2].

Our preliminary data [4] suggest that in S. mansoni, some SmSCP/TAPS proteins are recognized by the human immune system, may modulate cellular responses, and are secreted during penetration through the dermis of the infective ( cercarial ) stage of the parasite. However, life cycle expression analysis, coupled with phylogenetic evidence of considerable gene duplication and divergence suggest that no one SmSCP/TAPS protein has an overreaching role in invasion or immune modulation.

As SCP cannot act in isolation from the pathogen (e.g. have no intrinsic toxicity) and limited evidence of allergenicity, we suggest that the SCP family of S. mansoni proteins present a low risk to human health. Thus, SCP expressing E. coli and yeast strains will be inherently safe to work with providing all manipulations of GM material are carried out in adequate Laboratory Containment Level 2 facilities, and best microbiological practice is adhered to throughout. In the event of escape from these containment facilities the E. coli and yeast strains will have no selective advantage in the environment as S. mansoni SCP could only increase fitness within a pathogenic host (and not auxotrophic laboratory strains of E. coli and yeast). Further, the use of non-mobilisable vectors, and microbiological containment of all GM material will effectively eliminate the possibility for transfer of the sequences to other organisms. The widespread distribution of SCP/TAPS family proteins throughout the plant and animal kingdoms suggests that the highly improbable accidental transfer of any SmSCP/TAPS sequence to other organisms would have essentially benign consequences.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid and liquid cultures of GM material, and all disposable plasticware and glassware that has been in contact with GM organisms, will be sterilized (100% kill) by wet heat (121°C/15 mins) in an approved autoclave housed within the CL2 containment facility. The process cycle will be monitored using a single calibrated thermocouple linked to a recorder producing a printout of cycle performance will be monitored according to the standards outlined in HPA national standard QSOP6 (http://www.hpa-standardmethods.org/documents/qsop/pdf/qsop6.pdf)

Autoclaved waste will be disposed of to landfill (solid waste) or to sluice (liquid).

Laboratory coats used within the CL2 facility will be autoclaved prior to being sent for cleaning.

All laboratory work surfaces, and equipment used for the culture or processing of GM material, will be routinely cleaned and disinfected with a peroxygen- based disinfectant (‘Virkon’) at an ‘in use’ dilution of 1% (100% kill). The laboratory floor will also be cleaned and disinfected weekly with 1% Virkon.

Procedures for the containment and disinfection (100% kill) of accidental spillages of GM material within the CL2 facility are the subject of a separate SOP (attached)

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
The local Genetic Modification Committee considers that the risk assessment meets current regulations. The project seeks to over-express Schistosoma mansoni Sperm Coating Proteins (SCP) in E. coli in volumes of 1-6L. The biological function of most SCP/TAPS family of proteins is unknown and the involvement of a very limited number of SCP/TAPS genes with either pathogenic or allergic characteristics, indicates that this work should be classified as a Class 2 activity. The work will be done in a newly refurbished Containment Level 2 laboratory, containing its own autoclave for destruction of GM materials.

Give brief details of the genetic modification safety committee

Y

02/03/2022
Genetic Modification and Bio-Safety Committee

Terms of reference

(i) To consider, monitor, provide guidance and make recommendations to the Safety and Occupational Health Committee on matters relating to safety in work involving Hazard Group 3* dangerous pathogen activities under the Control of Substances Hazardous to Health (as amended) Regulations 2002, Regulation 7(10) Schedule 3, "Additional provisions relating to work with biological agents". In exceptional circumstances only will this remit extend to non-GM Hazard Group 2 dangerous pathogen activities.

(ii) To consider, monitor, provide guidance and make recommendations to the Safety and Occupational Health Committee on all matters relating to safety in work involving genetic modification as defined in the Genetically Modified Organisms (Contained Use) (as amended) Regulations 2000.

(iii) To consider, monitor, provide guidance and make recommendations to the Safety and Occupational Health Committee on all matter relating to safety in work involving the deliberate release of any genetically modified organism into the environment as detailed under the Genetically Modified Organisms (Deliberate Release) (as amended) regulations 2002.

(iv) To consider, monitor, provide guidance and make recommendations to the Safety and Occupational Health Committee on all matters relating to safety in work involving animal pathogens under Schedule 1 of the Specified Animal Pathogens Order 2008.

(v) To consider, monitor provide guidance and make recommendations to the Safety and Occupational Health Committee on matters relating to safety in work involving agents under Part 7, Schedule 5 of the Anti-Terrorism, Crime and Security Act 2001.

(vi) To receive for scrutiny, review and notification to the relevant authority, Project Proposals, Risk Assessments, Codes of Practice and Standard Operating Procedures for activities (I), (ii), (iii), (iv), and (v) above.

(vii) To approve items in (vi) above such that work may commence with the exception of Activity Class 1 projects which may be approved for commencement by the Biological Safety Officer prior to formal review by the GMBSC and HSE notification.

(viii) To consider and make recommendations to the Safety and Occupational Health Committee on reports received from the Biological Safety Officer on procedures adopted by Schools on work in the fields specified in (I), (ii), (iii), (iv) and (v) above.

(ix) To conduct safety inspections of work and facilities identified in (I), (ii), (iii), (iv) and (v), to monitor implementation of the regulations, and to review the outcomes of these inspections.

Membership:
- Chair appointed by Council
- The Biological Safety Officer
- A technically competent member (one each) from the various disciplines in Medicine, Life Sciences and Engineering
- Two members of the academic staff (one each from the Highfield campus and Southampton General Hospital campus)
- Two members from the dissolved Biosafety Committee
- A member of the Divisional?School Genetic Modification Liaison Officers
- The Faculty Safety Adviser for Medicine or representative of the Central Health and Safety Group
Two postgraduate students (one from Life Sciences and one from a group based at SGH)

* This group of dangerous pathogens will also include three specified Hazard Group 2 agents, listed in Part V of COSHH Schedule 3: Bordetella pertussis, Corynebacterium diphtheriae, Neisseria meningitidis. Other agents may be considered as judged appropriate or necessary.

+ Appointed after consultation by the Chair of the Committee

For activities involving GMMs, describe the waste management measures which will apply to the activity
Virkon and Trigene are used widely (final concentrations as appropriate) to inactivate GMMs in liquid cultures. Concentration x Time values vary from species to species and media to media. Inactivated liquids are discharged direct to foul sewer (drain) and flushed with copious amounts of water.

Contaminated non-disposable labware that cannot be autoclaved is soaked as above in appropriate disinfectants with appropriate Ct values.

All other waste (primarily solids) is autoclaved in validated loads, is double bagged, and disposed via landfill. Waste containing clinical items are disposed via the incineration route.

Autoclaves are initially validated according to types of loads and are then serviced annually. Subsequent self-validation using biological indicators is exercised for Activity Class 1-2 waste autoclaves. Autoclaves handling Activity Class 3 waste are validated professionally on an annual basis. All autoclaves handling GMM waste are required to have recording capabilities.

The attached risk assessment is the template used to assess the human and environmental risks for any activity involving GMMs (Form A), Gm Animals (Form B), GM Plants (Form C) or Clinical Trials (Form D).

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The attached risk assessment is the template used to assess the human and environmental risks for any activity involving GMMs (Form A), Gm Animals (Form B), GM Plants (Form C) or Clinical Trials (Form D).
### Project Additional Information

#### Purposes of the contained use

The aim of the project is to i) to perform functional screening of cDNA libraries, including the identification of new tumour specific T cell antigens; ii) to investigate the processing and presentation of antigens to T cells.

#### Recipient or parental organism

1) Vaccinia virus (Western Reserve strain which is attenuated, and Modified Virus Ankara which is replication incompetent in normal cells); Moloney Murine Leukaemia virus (which is replication defective)

#### Host/vector system

- Non-mobilisable pUc-based vector containing amp(r), lacZ and the vaccinia 7.5K promoter. CDNA expression library in non-mobilisable, commercial vector (ViraPort retrovirus DNA marketed by Invitrogen).

#### Origin & function

- i) Non-functional proteins and protein fragments which can be processed by infected cells for presentation to T cells.
- ii) cDNA expression libraries from normal and tumour cells.

#### Evaluation of foreseeable effects

The vaccinia virus is the WR strain which was used world-wide for vaccination against smallpox. It has been extensively investigated and attenuated. It has a fairly broad mammalian host range and would be transmitted efficiently by the needlestick route. Recombinant virus is modified by recombination into the thymidine kinase gene which reduces virulence by 10(6) fold (Buller et al Nature 317, 813, 1985). Clinical inoculation with high titre virus carries a 1:10(6) risk of viral encephalitis. This risk is reduced to 1:10 in the GMM. The insert should not increase pathogenicity of the GMM and in isolation does not have toxic, oncogenic or allergenic properties.

- ii) Influenza A strains include H1N1 (A/PR/8?1934), H2N2 (A/JAP/305/1957), H3N2 (A/Aichi/1968) and have been extensively investigated. They have a fairly broad mammalian host range and would be transmitted efficiently by aerosol. These organisms are not genetically modified.

- iii) Moloney Murine Leukaemia virus used are replication defective since production of infectious virus requires functions supplied in cis on three separate plasmids. These have minimal or no sequence overlap and the chance of homologous recombination creating competent virus is extremely low. CDNA from tumour cells is likely to contain some oncogenic sequences. However, oncogenic transformation requires multiple events and we will not develop retroviruses expressing multiple co-operating oncogenes. The viruses are inactivated by human complement. There is a very low environmental risk as viral particles are extremely labile and do not survive on environmental surfaces.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Immunisation of mouse strains with influenza A and GM vaccinia would be carried out under level 2 containment and post-mortem tissue produced in the laboratory also level 2 containment.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

- none

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- Liquid waste containing GMMs and disposable items such as pipette tips will be submerged in 1% virkon disinfectant and sealed in plastic before terminal disinfection by autoclaving. All animal waste such as bedding will be disinfected by autoclaving and carcasses by incineration.
1) Project approved as required level 2 containment.
2) Sharps and sharp-precursors must not be used unless essential. Gloves will be worn and any abrasions covered with surgical tape in all procedures where exposure to virus is possible.
3) Centrifuge buckets and rotors will be disinfected by autoclaving according to manufacturer’s instructions.
4) Requirements for work with non-GMMs must comply with relevant regulations and necessary approvals must be in place before this part of the work is commenced.
5) Staff who work in the level 2 facilities where the viruses are used must be registered with the University occupational health group. Registered workers will be offered vaccination where appropriate.

**Project Additional Information**

**Purposes of the contained use**

The aim of this project is to use the modified viruses to achieve extended focal expression of pro-inflammatory and anti-inflammatory cytokines in models of human disease.

**Recipient or parental organism**

Human adenovirus Group C (Ad5) The vectors are all based on adenovirus serotype 5 (Ad5), which is a double-stranded DNA virus comprising over 40 serotypes all of which are categorised as hazard group 2 biological agents. Ad5 is a respiratory pathogen and in vivo infections are generally limited to the epithelial cells lining the respiratory tract. Unmodified Ad5 is classified in biological agents hazard group 2. Ad5 is generally associated with mild respiratory infections in children, and it is thought that the majority of the population is likely to have antibodies to the wild-type virus. Immunity to adenovirus infections is thought to be life-long following primary infection, although latent infection of tonsil and adenoid tissues is a frequent occurrence following childhood infection by Ad5. The precise mechanism of latency is unknown, but free virus is only rarely detected in lymphoid tissue and is present in <1 in 107 cells. Reactivation of latent Ad5 can lead to serious complications in immuno-compromised individuals and it has been isolated at high frequency from patients with AIDS. Human serotypes do not normally infect other animals and there are few reports of virus replication following inoculation of experimental animals. The cotton rat, a species not indigenous to the UK, provides an animal model of infection. Group C viruses (eg Ad5) are non-oncogenic. However, all human adenoviruses, including Group C, transform rat cells in culture. Despite this, there is no evidence of any association between adenoviruses and human cancer.

**Host/vector system**

Disabled human adenovirus Group C (Ad5) (E1 and E3 deleted)  
The lytic cycle of Ad5 is divided into the early and late phases. The early genes are expressed from four regions of the genome. The two transcription units of the early region 1 (E1a and E1b) are responsible for cell transformation and tumourigenicity. Both alter transcriptional regulation during infection and transform by directly interacting with cell proteins involved in transcription and cell cycle regulation (eg p53 tumour suppressor protein). The vectors used under this application are E1 and E3 deleted. The E1 deletion region prevents the expression of E1a and E1b genes. The viruses are unable to replicate except in complementing cell lines such as 293 (a human embryonic kidney cell line which expresses the left 11% of the Ad5 genome. Thus the replication deficient viruses do not generate infective units following the initial infection of susceptible cells other than 293 cells. The replication defective Ad vectors have no mechanism for long term maintenance in cells; expression in the lining of the respiratory epithelium declines with time and is limited to ~2 months. In the absence of any significant episomal replication of E1a deleted Ad5 in normal human cells, long term maintenance requires integration into the host chromosome. This can occur at a frequency of about 1 per 10e5 pfu in exponentially growing cultures of primary human cells. Deletion of the E3 region (which is non-essential for in vitro growth) allows inserts of up to approximately 8 kb to be cloned. An E3 deletion also reduces the likelihood of a GMM causing harm as a consequence of making the virus less able to establish and maintain an infection within the cells of an infected individual. It should be noted, however, that there is little evidence that the pathogenicity of an E3-deleted virus, in any cells which do become infected, will be reduced.
The genetically modified replication deficient viruses were produced by manipulation of partial viral genomes in bacterial plasmids by the co-transfection of overlapping plasmids into 293 cells to allow the generation of complete genomes by homologous recombination as previously described (1). The following genes were introduced into the E1-E3 deleted region: XCMVhumanIL-1b, XCMVmurineTNF-wt, XCMVmurineTNF-membrane bound, XCMVmurines B7.1, XCMVTFGFb1, XCMVTFGFb1 (active), XCMVmurineIL-10, XCMVmB7.1/IL-2, XCMVmLymphotoactin, XCMVmLymphotoactin/IL-2, XCMVbv-gal, or XCMVd170-30 (control), or similar (no material difference). After 5-7 days, recombinant viral particles were released by freeze-thawing the transfected 293 cells. The vectors were purified by plaque assay and a viral stock was generated on CsCl gradients. The stocks were titrated by plaque formation (3 x 10^13 pfu/ml) and checked for integrity of viral DNA (by HIRT, restriction digest and Southern Blot), expression of the desired cDNA (by Western Blot) and presence of replication - competent virus (by PCR to detect E1 sequences as described (2)). Additionally, presence of endotoxin was monitored by the amebocyte horseeshow crab lysate method (E-toxate assay, Sigma). No E1 sequence or endotoxin could be detected in the stocks. The intended function of the inserted genetic material is to give rise to the focal over expression of cytokines in experimental models. The introduction of the non-adenoviral genetic material is not expected to alter the infectivity profile (only humans) of the replication deficient adenovirus. Indeed, the cytokines are likely to increase the level of the inflammatory response, which will give rise to an increased rate of clearance. Tissue tropism is also not expected to be different in the GM adenoviruses.

Evaluation of foreseeable effects

Wild-type adenoviruses are non-enveloped, relatively resistant to desiccation stress and can survive in aerosols. But there is no evidence that human Ad serotypes can naturally infect animals, and replication is very limited in rat cells, for example. Replication has been shown to occur in the lungs of experimentally infected cotton rats administered a high doses of virus. However, the replication deficient adenoviruses cannot replicate outside 293 cells and the insertion of the cytokine genes will not alter this characteristic. Homologous recombination between E1a- Ad and wild-type virus (or viral sequences in the 293 cells lines) may occur at low frequency, but, were this to happen the packaging limits of Ad would be expected to delete the transgene ir naje sytg a recombinant unviable. It has also been shown that recombination only occurs between serotypes within a subgenus and not between subgenera. Co-replication between E1a deletants and WT could also occur due to transcomplementation. This requires co-infection of both viruses and has so far only been demonstrated at high multiplicities of infection (moi). As no new virus or viral stoc ks are to be generated in Southampton, the likely hood of a recombination event, occurring under this proposal would be highly improbable. Overall, it is not thought that the modified virus would pose a serious risk to the environment. The main environmental risk would be to susceptible children. However, the modified viruses will be employed in very small volumes (<1µl), which are unlikely to enter the atmosphere.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The modified virus is replication deficient and no threat to the environment is likely. The preparation of aliquots from stock virus will be performed in a biological safety cabinet. Staff will be specifically trained in the safety aspects of this work with written training records being kept. Waste materials will be autoclaved with 100% kill. Appropriate, validated disinfectants will be used to decontaminate exposed work areas. These containment and control measures will protect both the workers and the environment.

02/03/2022
The genetic modification safety committee recommended that the project should be assigned to activity class 2. The laboratory facilities will be inspected by members of the committee prior to work commencing.

Page 2132 of 15326
### Purposes of the contained use

Pleiotrophin (Ptn) has been suggested to induce differentiation of progenitor cells to an osteoblast phenotype and to recruit osteoblasts to the site of new bone formation. This study aims to investigate the action of Ptn on human stem cells and its role in bone formation. Cells transduced with adenovirus expressing pleiotrophin will be implanted in diffusion chambers in nude mice to study ex vivo bone formation.

### Host/vector system

| Adenovirus, specifically the AdEasy Adenoviral Vector System. Plasmids will be propagated in E. coli DH5α, XL10-Gold and BJ5183. Adenovirus serotype 5 with genes E1 and E3 deleted. Virus is propagated in HEK293 cells. |

### Origin & function

In human pleiotrophin gene will be used in this study. Ptn is oncogenic in certain cell lines and is expressed in various tumours. Ptn also stimulates neurite outgrowth, angiogenic and an osteoblast stimulating agent. Pleiotrophin is associated with lung cancer, may be an early indicator of lung cancer and serum levels correlate with the stage of the disease. In this study, the specific activity that will be examined is the potential for stimulation of osteoblast function.

### Evaluation of foreseeable effects

The most hazardous GMM is adenovirus expressing pleiotrophin. E. coli strains are disabled and non-colonising bacteria, non-pathogenic to humans; all are derived from K12 strains. Adenovirus Ad5 with E1 and E3 deleted is replication deficient. Hazards associated with adenovirus are from inhalation. Airway epithelia are fairly resistant to infection by adenoviral vectors therefore, the risk of infection is low and may cause the symptoms of a mild cold. The persistence of infection with a replication deficient virus would be limited.

Potential exists for the emergence of replication competent adenoviruses (RCA). RCAs can result from double crossover events during amplification in the HEK293 cell line which carries the E1 region. Care is taken to always plaque purify the recombinant virus and to keep the HEK293 cells passage number low, ideally less than 4. This double crossover event results in the loss of the recombinant protein.

The primary human bone marrow cells are not screened for adventitious agents and are treated as potentially pathogenic.

Ptn is oncogenic in certain lines and is expressed in various tumours. Potential exists for expression of Ptn in the respiratory tract before immune clearance of the virus if inhaled and potential for alteration of lung tissues. Pleiotrophin is associated with lung cancer, may be an early indicator of lung cancer and serum levels correlate with the stage of the disease.

The recombinant virus is replication deficient and as such, is actually less pathogenic than the wild-type. Therefore, there is little capacity for colonisation. If exposed to the environment it is unlikely to survive for extended periods.

If the virus were released into the environment, potentially, humans could be infected with consequences the same as for the laboratory worker. There is no evidence to suggest that plants or animals could be infected with adenovirus (with the exception of the cotton rat which is not indigenous to this country).

In the extremely unlikely event of an animal becoming infected with the GMM, Ptn would probably be expressed transiently. If the animals cells could respond to human Ptn
the result may be mitogenic activity, recruitment of osteoblasts to the site of the infection, or angiogenesis.

There is no evidence to suggest that Ptn has any involvement in pathogenicity, nor is it likely to be expressed on the surface of the virus or on any cell surface.

Potentially, the recombinant virus could recombine with a wild-type adenovirus producing a replication competent virus expressing Ptn.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Although animals will be used in this study, they are not GM animals. The GMM will be maintained within the diffusion chamber and since the GMM is replication deficient, virus will not be passed to the animal.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All bacterial waste used in the construction and propagation of the plasmid vectors is decontaminated in freshly prepared 1% (v/v) Hycolin for a minimum of 16 hours. The solid waste is then autoclaved, liquid is poured to waste with copious amounts of water. All cell culture waste is disinfected in freshly prepared 1% (w/v) Virkon and solid waste autoclaved, liquid is poured to waste with copious amounts of water. Cell culture waste, both solid and liquid, that includes adenoviral waste is disinfected in 1% (w/v) Virkon, and remains in Virkon until autoclaved. The autoclave is located within the hospital building. Waste is transported in sealed containers avoiding public corridors where possible. The autoclave is validated for disinfection of waste. Both Virkon and Hycolin are used according to the manufacturers recommendations and have been validated for decontamination of bacterial and viral agents.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The risk assessment for this project was first discussed at the GMSC meeting of 21 January 2003. Members agreed that the project was borderline AC1/AC2 and agreed to seek advice from the HSE. The response from the HSE was carefully considered, as was the guidance in ACGM Newsletter 31, regarding the risk assessment of GMMs expressing cytokines. Following discussions with the project leader, all parties agreed that the project should be classified as AC2, and the notification process initiated. It was advised that the animal work should receive particular attention in the risk assessment, as no MSC or isolator will be used.

The chair of the GMSC and the two University BSOs will carry out an inspection of these laboratory facilities in November 2003.

THE USE OF CELL LINES, GENETIC CONSTRUCTS (PLASMIDS), ADENOVIRUSES AND TRANSGENIC MICE TO ASSESS THE MOLECULAR MECHANISMS LEADING TO NEUROPATHOLOGY IN POLYGLUTAMINE DISEASES WITH A FOCUS ON HUNTINGTON'S DISEASE

I will construct and propagate new/already available plasmids and adenoviruses that express proteins with polyglutamine stretches fused or not fused to green/red fluorescent proteins, various neuroprotective heat shock proteins and dominant negative forms of protein kinases in order to express the transgenes in cell lines and primary neuronal cells in vitro to investigate their effects on cellular function (eg mitochondrial function) and neuronal survival. I will also use brain cells for in vitro studies of transgenic mice. This approach will be used to identify and elucidate important cellular signaling pathways that may be altered during pathology induced by expanded glutamine stretches in various polyglutamine diseases with a focus on Huntington's disease. This research will lead to a better understanding of these pathologies and may contribute to the identification of novel therapies for these currently untratable neurological disorders.

I will use various cell lines for over-expression studies (see below for over-expressed transgenes). Routinely used cell lines will be HEK293 and 911 cells (in order to propagate the Adenovirus; these cells are E1 complementing cells); COS-1 and COS-7 cells (monkey origin), an immortalized striatal full-length huntingtin knock-in mouse cell line, NT-2 cells (mouse neuronal precursor cells), SK-N-SH, SH-SY5Y, HeLa, 143B cells that express the Huntington's disease Exon 1 With/without glutamine expansions upon induction with the antibiotic doxycycline (PC12 Tet-On Q23, Q43, Q53, Q74), PC12 naïve (rat origin) and some other not yet specified mouse and human cell lines. I will also use primary neurons of the mouse and/or rat cerebrocortex, hippocampus, striatum, celineblum and peripheral nervous system into which the transgenes (see below) are transfected. Furthermore, I will use primary neurons of huntingtin Exon 1 with/out polyQ expansion or full length mouse huntingtin where a
polyQ expansion has been “knocked-in” at the HD locus (knock-in mice). The transgenic mice are already available.

The recipient micro-organisms are bacterial and adenoviral vectors. All the transgenes in plasmid vectors and Adenovirus are driven by CMV promoters. However, we intend to use a series of Adenovirus vectors expressing huntingtin Exon 1 with/without polyglutamine expansion fused to the red fluorescent protein (mRFP) that are driven by the neuronal specific synapsin-1 promoter in conjunction with the WPRE (woodchuck post-transcriptional regulatory element, from woodchuck hepatitis virus; see reference below, Glover et al., 2002). The use of the WPRE sequence has recently been reported to bear a risk of tumor formation in mice (SACGM information note, see also www.advisorybodies.doh.gov.uk/genetics.gtac/). Therefore the GTAC has called for special attention for the use of the WPRE sequence in an open letter until further notice and recommended containment level 2 for all use with WPRE sequences. I will use WPRE sequences only for in vitro experiments where Adenovirus bearing WPRE sequences are expressed in primary neuronal cells in vitro and we will strictly follow the current recommendation of the GTAC including changes in future recommendations.

In collaboration, I intend to construct and use lentivirus that expresses the same transgenes as the ones expressed by the Adenovirus (htt Exon 1, see above). The WPRE sequences will NOT be used for the construction and use of lentivirus. The lentivirus will be used in an identical way compared to the Adenovirus (infection and expression of transgenes in primary neuronal cell cultures).

Hazards to human health

Hazards associated with the various cell lines
There are no known adverse effects.

Hazards associated with the recipient micro-organism (e.g. bacterial host or viral vector)
Inhalation or ingestion of adenovirus could be harmful. Hence the transmission route could be "oral". Infection is generally limited to the epithelial cells lining the respiratory tract. However, the Adenovirus is modified in that the E1 gene is missing and hence the adenovirus is replication deficient. Unmodified Adenovirus serotype 5 is classified in hazard group 2 under the COSHH regulation. Bacterial strains are classified in hazard group 1.

Identification of any hazards to the environment.

Hazards associated with the recipient microorganism (e.g. bacterial host or viral vector)
It is thought that recombination negative Adenovirus serotype 5 would not pose a risk to animals and plants in the environment because there is no evidence that human adenovirus can infect animals or plants.

The potential hazards of sequences within the GMM being transferred to related microorganisms
Recombination with animal wild type adenovirus or virus fragments would not pose a risk other than above if it occurred.

The recipient micro-organisms are bacterial and adenoviral vectors. All the transgenes in plasmid vectors and Adenovirus are driven by CMV promoters. However, we
intend to use a series of Adenovirus vectors expressing huntingtin Exon 1 with/out polyglutamine expansion fused to the red fluorescent protein (mRFP) that are driven by the neuronal specific synapsin-1 see reference belwo, Glover et al., 2003). The use of the WPRE (woodchuck post-transcriptional regulatory element, from woodchuck hepatitis virus; reported to bear a risk of tumor formation in mice (SACGM information note, see also www.advisorybodies.doh.gov.uk/genetics/gtac/). Therefore the GTAC has called for special attention

Host/vector system

Recipient bacterial strains used:
For the production and propagation of the transgenes and adenoviruses I will use E.coli (disabled, K12) that are either recombinant deficient (Dalpha, TG1, JM101) or recombinant proficient (BJ5183).

List of vectors used:
- Adenovirus 5 (pAdEasy-1/2, the 33.4 kb plasmid containing the Adenovirus serotype 5 genome with E1 deleted, this adenovirus is replication deficient)
- plasmid vectors: pcDNA1, pcDNA3, pCMV5, pEGFP-N1, pEGFP-C1, pShuttle, pShuttleCMV, pAdTrack, pAdTrack-CMV, pECFP, pEYFP-C1, pmRFP, GFPu (destablized GFP)

Origin & function

DNA for the wildtype, constitutively active and/or dominant negative forms (mutant) of the following genes will be used:
1) Kinases/other: JIP-1, MEK1/2, M KK3
2) Bcl-2 family proteins: Bcl-2, E1B19K
3) Huntington's disease genes and fragments fused or not fused to green/red fluorescent protein or other proteins tags: httExon 1 Q25/47/72/103 with/out NLS (nuclear localisation signal), htt aa500Q17/68, full-length httQ15/130, huntingtin Exon1 Q20, Q40 and Q50 GST- fusion DNA
4) Heat shock proteins: Hsp22/25/27, alphaB crystalline, members of the Hsp40, Hsp60, Hsp70 and Hsp90 family
> Please see the appendix on page 7 & 8 for details of each gene and its function/activity with selected references and for information relating to which vector system will be used for each transgene.

Human Health

Hazards arising directly from the inserted gene product Incetracellular expression of heat shock proteins could be cancerpgenic because it could prevent cells from dying. The opposite effect could occur by expressing polyglutamine proteins or dominant negative forms of kinases by decreasing the activity of intracellular survival pathways or activation cell death pathways. No immune response is expected. The WPRE sequence has been recently associated with an oncogenic risk (see above).

Hazards arising from the alteration of existing traits No alterations of existing traits are expected because no viral genes are expressed and no alteration of the capsid or of any receptor is attempted.

Environment

Hazards arising directly from the inserted gene product Expression in animals of the transgenes would produce similar harmful effect as in humans because the cellular pathways targeted by heat shock proteins, dominant negative forms of the kinases and the polyglutamine proteins are expected to be evolutionary conserved.

The potential hazards of sequences within the GMM being transferred to related microoganisms The genes would not represent a hazard if it were to recombine into a wildtype adenovirus other than outlined above. The risk of formation of replication proficient adenovirus (expressing the transgene) is minimal since I will perform a diagnostic polymerase chain reaction for the presence of the E1 gene on each preparation of the E1 gene on each preparation of Adenovirus produced in the E1-positive mammalian cell lines before use. Should there be a positive Adenovirus preparation it will be appropriately destroyed (see below).
Evaluation of foreseeable effects

Given the identification of the potential hazards and detrimental effects on human health and the environment described above it is evaluated that the foreseeable effects are generally of a minor risk.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

I will breed transgenic mice ubiquitously over-expressing the heat shock protein 27 (Akbar et al., 2003; see belwo) or expressing the first Exon of the human huntingtin gene with a polyglutamine mutation (R6/2 strain, Davies et al., 1997; see below) or full length mouse huntingtin where additional glutamines have been "knocked-in" (Shelbourne et al., 1999, see below). These mice will be held and bred according to standard procedures in the transgenic mouse facility.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not Applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All the work procedures are not likely to produce aerosols. All the waste including bacteria (E.coli) and adenovirus and material/plastics that have been in contact with GMMs described above will be disposed off by VIRKON treatment (disinfectant concentration: 1 per cent; time of treatment: 24 hours). This disinfectant will be made up on a weekly basis (it is stable for up to 6 days). VIRKON is a balanced stabilised blend of peroxygen compounds, surfactant, organic acids and an inorganic buffer system and is recommended disinfectant for the 100 per cent killing -off of a large variety of pathogens including the GMMs proposed to use in this application. Liquid GMM material treated with VIRKON in this way is then disposed off conventionally (sink). All non-liquid material (such as plastic culture dishes and wells) will additionally be autocleved and after that process treated as conventional waste.

Process of testing: To ensure that all GMMs are killed to 100 per cent efficiency, VIRKON treated samples (see above) will be tested in the following way:

1) Bacterial waste-> after VIRKON treatment described above, a whole sample of E.coli will be centrifuged at standard speed in order to pellet potentially living E.coli cells (10,000 rpm) and subsequently plated on LB agar plates and incubated at 37C for 24 hours. No growth of colonies is expected if E.coli cells have been killed off. My previous experiences has shown that this is the case.

2) Adenoviral waste-> E1-expressing mammalian cells such as HEK293 known to complement the E1-deficient Adenovirus will be exposed to the adenovirus containing sloution after VIRKON treatment (see above) for 60-90 minutes. Because 1 per cent VIRKON has a toxic effect on the HEK293 cells, the VIRKON containing sloution will be diluted appropriately (1:50). After 60-90 minutes the medium will be replaced by normal growth medium containing 1 per cent fetal bovine serum. The HEK293 cells will then be observed over a 2-3 week period for the production of a visible CPE (cytopathic effect). A single viable viral particle will be sufficent to induce such a CPE within 48 hours which then will be amplified and easily visible after 2-3 weeks in the culture dish (CPE, positive cells will round-up and detach from the culture dish). As a positive control a non-VIRKON treated sample of a similar viral particle dilution will be used.

These two procedures (1 and 2, see above) have been previously tested successfully. These procedures will be performed once on each purchase of VIRKON before use.
The Biological Safety Officer made the following comments on the draft project proposal/risk assessment that was initially submitted:

"Although replication deficient adenovirus alone would be classified at AC1, I assume that expression of htt, polyQ and/or EGFP in human cells, in vivo, is being considered as potentially harmful to the individual, and therefore AC2 selected. AC2 projects require notification of the HSE, and for this purpose the risk assessment needs to be somewhat more detailed - the rubric in each section of the GMM form is very helpful in this respect. In general, all statement should be justified. The ACGM Compendium of Guidance is useful (http://www.hse.gov.uk/infection/gmo/acgm/acgmcomp/index.htm), in particular the section on adenoviral vectors. The following comments also help: Part 1 (b)(ii) Which cell lines will be used? Cells in culture are considered to be microorganisms, and they are also "recipients". (b)(iv) Are the activities and functions of the individual genes/proteins known? If so, they should listed, either here or in an addendum. References may be helpful. Particular attention should be paid to genes to be expressed in adenovirus. Stress that the adenovirus is replication deficient and not wt. Part 2 (a)(I) Hazard group of wt adenovirus and vector strain? How is it disabled? Transmission route? Cell tropism? (a)(ii) What are the potential effects of polyQ, EGFP and hsp expression? Immune response expected? (a)(iii) No, but justify no alteration of existing traits. Not viral genes. Not incorporated into capsid. Not receptors. (a)(iv) Possible recombination with wt virus or virus fragments - see ACGM Compendium. State risk of formation of replication proficient virus expressing transgene. (c) (I) This is the risk assuming that release to the environment has already occurred. Does the vector infect indigenous species? (c)(ii) Would expression of the transgenes in animals produce the same harmful effects as in humans? Why? 9c)(iv) Recombination with animal wt adenovirus or virus fragments? (d)(ii) Disinfectant concentration, time in contact, made up daily? Validated for adenovirus by manufacturer/externally? (d)(viii) Would workers with known immunological defects be permitted to work with viral vectors? Or with eczema? Route of infection? Would they be referred to occ.health? (d)(x) Training overseen by project leader? What procedures? (e) What will be the max volume of culture? (f)(I) E.coli manipulations. (f)(ii) Adenovirus manipulations. (g) Highest level of containment is CL2 using class II MSCs?"

The project proposal/risk assessment was modified accordingly.

At a meeting of the GM Committee on 20/01/05, members felt that it would be prudent to insert an additional sentence in the notification form to indicate that there is an awareness of the oncogenic potential of some of the constructs (namely, the ones expressing Bcl-2 and E1B19K), and also a familiarity with the relevant HSE guidelines. It was agreed that the work should be classified as AC2, and that the HSE should be notified once the required amendments had been made to both the risk assessment and this notification form.

**Project Ref** 57/06.1

**Date Ackn’ed** 20/04/2006

**CU2 Project Title**

The use of genetic constructs to assess pathogen survival and growth in the environment.

**Historical Significant Changes**

**Historical Date of Additional Info**

**Withdrawn** NO

**Tick if notifying a connected programme of work** NO

**Project Additional Information**

**Purposes of the contained use**

The work concerns the use of genetic constructs to:

a) Elucidate the genes involved in biofilm formation by Staphylococcus aureus and Pseudomonas aeruginosa. For S. aureus, this will involve the use of genetically modified sensor strains to identify and quantify which of four different autoinducing peptide (AIP) types the wild type strains produce. For P. aeruginosa, green fluorescent protein (GFP)-based reporters under the control of the inducible tac promoter of pMEKm12 or the mutD gene encoding DNA polymerase III for detecting mutagenesis within biofilms in situ and in real time.

b) To enable microscopy detection on surfaces of HG2 E. coli (wild type NCTC 12900), Salmonella enterica serovar Thompson (RM 2311 and RM 2313) and Campylobacter jejuni (RM1997 and RM2112) containing the green fluorescent protein (GFP) or similar fluorescent protein such as cyan (CFP) or yellow (YFP). Also, that after microbial extraction from environmental samples, the HG2 microorganisms can be detected clearly on membranes or agar media. In this way the efficiency of bacterial extraction procedures can be monitored and novel methods for bacterial detection and decontamination investigated.

c) To enable microscopy detection on surfaces of HG3 enterohaemorrhagic E. coli O157 (RM2323, RM2325 and ATCC 43890) containing GFP or similar fluorescent protein such as CFP or YFP. Also, that after microbial extraction from environmental samples, the HG3 microorganisms can be detected clearly on membranes or agar media. In this way the efficiency of bacterial extraction procedures can be monitored and novel methods for bacterial detection and decontamination investigated.

**Recipient or parental organism**

S. aureus, P. aeruginosa, E. coli, S. enterica and C. jejuni are known human pathogens that are spread by contact or ingestion. They are defined as Hazard Group 2 organisms by the Advisory Committee for Dangerous Pathogens. They can cause skin rashes and septicaemia, or food poisoning if ingested in contaminated food. There is also a risk of infection by parenteral routes. Enterohaemorrhagic E. coli are Hazard Group 3 organisms that can cause food poisoning and kidney failure if ingested in...
contaminated food. The S. aureus mutants have lost AIP production, making them less virulent and able to function as sensors of AIP produced by wild types strains. P. aeruginosa, E. coli, S. enterica and C. jejuni contain the green fluorescent protein (GFP) of Aequorea victoria, encoded by the reporter gene gfp, or the cyan and yellow variants. These fluorescent proteins have been expressed in a wide variety of micro organisms for research purposes and have no known toxicity toward humans. For the purposes of risk assessment the expressed gene product can be considered to be non harmful and do not change the hazard grouping of the organisms.

**Host/vector system**

1. **S. aureus** For the construction of the GMM strains the P3 promoter of the Agr system is linked to the beta-lactamase gene on a plasmid (Lyon et al., 2000, 2002). A shuttle vector, pRN7035, was used that contains plasmid replicons for E. coli and S. aureus along with antibiotic resistance cassettes: ampicillin for E. coli and erythromycin for S. aureus. This plasmid was constructed by cloning a PCR product containing the 180-nt agr P2P3 region into the pUC polylinker site of plasmid, pRN7034, which contains a beta-lactamase reporter gene. In the new construct, the P3 promoter is fused to the beta-lactamase reporter gene. Plasmids pRN7062, pRN7105, pRN 7107 and pRN 7131 were constructed by cloning PCR fragments containing agrC, agrA, and downstream termination signals from the pUC polylinker of pRN7035. These strains are not able to produce AIP themselves; however when exogenous AIP is added it activates the P2 and P3 promoters and therefore the beta-lactamase enzyme is transcribed. In order to be able identify the specific AIP produced by the test strains and to study the effect of AIP on biofilm formation, filtered supernatant taken at various stages from the test strains will be used to activate the bioassay. 2. **P. aeruginosa** Green fluorescent protein (GFP)-based reporters will be used for detecting mutagenesis within biofilms in situ and in real time: i) GFP expression will be placed under the control of the inducible tac promoter of pMEKm12 (Lu et al., 2002); in the absence of the IPTG inducer, GFP expression will be repressed and no fluorescence is observed. If mutations occur in the tac control region, de-repression can occur and allow for GFP expression. A similar GFP reporter system was used to detect mutagenesis in E. coli batch cultures (Cariello et al., 1998). ii) We will generate a GFP reporter containing a +1 DNA frameshift in its coding region - this GFP will be non-fluorescent unless a frameshift mutation causes reversion to the wild-type. iii) The gfp gene will be fused to the regulatory region of the mutD gene of P. aeruginosa. This gene encodes the highly error-prone DNA polymerase III, the expression of which leads to increased mutation frequencies in P. aeruginosa. Using these reporter systems, we will investigate biofilm development in glass flow cell reactors and examine the spatial and temporal distribution of mutagenesis during biofilm development. 3. **E. coli**, S. enterica and C. jejuni Campylobacter jejuni and Salmonella enterica serovar Thompson have already been genetically manipulated to contain plasmids containing either GFP (pWM1001 or pWM1007), YFP (pWM1008 or pWM1011) or CFP (pWM1009 or pWM10012) (Miller et al., 2000; Brandl and Mandrell., 2002). Each plasmid contains a kanamycin resistance gene (kan) and the mob (mob) and repB (rep) genes required for replication. Non-toxigenic E. coli O157 is the NCTC strain 12900 lacking the Shiga toxin genes and will be used to receive the plasmids containing the fluorescent proteins from the S. enterica strains. 4. **Enterohaemorrhagic E. coli**. coli O157:H7 strains RM2323 and RM2325 will be obtained from ATCC, and introduced into strain PAO1 (obtained from Australia). S. enterica and C. jejuni Campylobacter jejuni and Salmonella enterica serovar Thompson have already been genetically manipulated to contain plasmids containing either GFP (pWM1001 or pWM1007), YFP (pWM1008 or pWM1011) or CFP (pWM1009 or pWM10012) (Miller et al., 2000; Brandl and Mandrell., 2002). Each plasmid contains a kanamycin resistance gene (kan) and polymerase III, the expression of which leads to increased mutation frequencies in P. aeruginosa. Using these reporter systems, we will investigate biofilm development in glass flow cell reactors and examine the spatial and temporal distribution of mutagenesis during biofilm development. 3. **E. coli**, S. enterica and C. jejuni Campylobacter jejuni and Salmonella enterica serovar Thompson have already been genetically manipulated to contain plasmids containing either GFP (pWM1001 or pWM1007), YFP (pWM1008 or pWM1011) or CFP (pWM1009 or pWM10012) (Miller et al., 2000; Brandl and Mandrell., 2002). Each plasmid contains a kanamycin resistance gene (kan) and the mob (mob) and repB (rep) genes required for replication. Non-toxigenic E. coli O157 is the NCTC strain 12900 lacking the Shiga toxin genes and will be used to receive the plasmids containing the fluorescent proteins from the S. enterica strains. 4. **Enterohaemorrhagic E. coli**. coli O157:H7 strains RM2323 and RM2325 will be obtained from ATCC, and introduced into strain PAO1 (obtained from Australia). S. enterica and C. jejuni Campylobacter jejuni and Salmonella enterica serovar Thompson have already been genetically manipulated to contain plasmids containing either GFP (pWM1001 or pWM1007), YFP (pWM1008 or pWM1011) or CFP (pWM1009 or pWM10012) (Miller et al., 2000; Brandl and Mandrell., 2002). Each plasmid contains a kanamycin resistance gene (kan) and the mob (mob) and repB (rep) genes required for replication. Non-toxigenic E. coli O157 is the NCTC strain 12900 lacking the Shiga toxin genes and will be used to receive the plasmids containing the fluorescent proteins from the S. enterica strains. 4. **Enterohaemorrhagic E. coli**. coli O157:H7 strains RM2323 and RM2325 will be obtained from ATCC, and introduced into strain PAO1 (obtained from Australia). S. enterica and C. jejuni Campylobacter jejuni and Salmonella enterica serovar Thompson have already been genetically manipulated to contain plasmids containing either GFP (pWM1001 or pWM1007), YFP (pWM1008 or pWM1011) or CFP (pWM1009 or pWM10012) (Miller et al., 2000; Brandl and Mandrell., 2002). Each plasmid contains a kanamycin resistance gene (kan) and the mob (mob) and repB (rep) genes required for replication. Non-toxigenic E. coli O157 is the NCTC strain 12900 lacking the Shiga toxin genes and will be used to receive the plasmids containing the fluorescent proteins from the S. enterica strains. 4. **Enterohaemorrhagic E. coli**. coli O157:H7 strains RM2323 and RM2325 will be obtained from ATCC, and introduced into strain PAO1 (obtained from Australia). S. enterica and C. jejuni Campylobacter jejuni and Salmonella enterica serovar Thompson have already been genetically manipulated to contain plasmids containing either GFP (pWM1001 or pWM1007), YFP (pWM1008 or pWM1011) or CFP (pWM1009 or pWM10012) (Miller et al., 2000; Brandl and Mandrell., 2002). Each plasmid contains a kanamycin resistance gene (kan) and...

Evaluation of foreseeable effects

S. aureus: Pathology of S. aureus includes: Superficial lesions (abscesses wound infections and skin rashes), deep seated and systemic infections (osteomyelitis, endocarditis and pneumonia, and toxemia syndromes, toxic shock syndrome, scarlet fever and food poisoning); mastitis in livestock. In most cases treatment from various antibiotics is readily available, irrespective of the ampicillin and erythromycin resistance markers used in the GMM constructs. The beta-lactamase reporter gene is expressed by a wide variety of microorganisms, and has no known toxicity toward humans. For the purposes of risk assessment the expressed gene product can be considered to be non harmful and does not change the hazard grouping of the organisms. E. coli, S. enterica and C. jejuni: Pathology of Campylobacteriosis includes: diarrhoea, vomiting and has been linked with neurological disorders such as Guillain-Barre syndrome and Miller-Fisher syndrome, which are forms of reactive arthritis. Treatment is readily available for the disease. A person infected with Salmonella usually has fever, abdominal cramps, and diarrhea beginning 12 to 72 hours after consuming a contaminated food or beverage. The illness usually lasts 4 to 7 days, and most persons recover without antibiotic treatment.
do not change the hazard grouping of the organisms. Enterohaemorrhagic E. coli O157 has been shown to cause hemorrhagic colitis and can also cause hemolytic uremic syndrome. These strains produce Shiga toxins that cause the characteristic sequential process of the disease and have been designated as HG3. Following an incubation period of 1-5 days, watery diarrhea develops, often accompanied by abdominal cramping and vomiting. Diarrhoea becomes bloody in 1-2 days in most patients. Fever is present in about a third of cases. Illness duration is typically 4-10 days. Cattle and sheep are the reservoir (EHEC is a common inhabitant of the animal intestine) and humans can serve as a reservoir for person-to-person transmission. Transmission occurs through ingestion of contaminated food, primarily inadequately cooked beef, beef products, or foods that contact bovine-exposed soil (such as alfalfa sprouts). Waterborne transmission has also been associated with outbreaks, such as fecally contaminated drinking water and swimming pools. Non-toxigenic E. coli O157 lack the Shiga toxin genes and are designated HG2 pathogens.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

For laboratory operations the use of standard Containment Level 2 and 3 facilities, and good microbiological practice, will be sufficient to limit contact with humans and the environment.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

S. aureus: Waste material containing GM S. aureus will be pretreated by immersion in the microbiocide Virkon 1%, for two hours. Virkon will be made fresh, at the time of disinfection. Validation of the effect of Virkon on S. aureus has been carried out by the manufacturer. The waste will then be followed by autoclaving at 121°C for 30 minutes, on a solids or liquids cycle, as appropriate. The autoclave used for waste is located in the building; all waste to be transported is double bagged in autoclave bags and then sealed in a plastic container. The autoclaves are validated for waste decontamination once per year. P. aeruginosa, non-toxigenic E. coli, S. enterica and C. jejuni: Waste material will be disposed of by autoclaving at 121°C for 30 minutes, on a solids or liquids cycle, as appropriate. The autoclave used for waste is located in the building; all waste to be transported is double bagged in autoclave bags and then sealed in a plastic container. The autoclaves are validated for waste decontamination once per year. Enterohaemorrhagic E. coli: Waste material will be disposed of by autoclaving at 121°C for 30 minutes, on a solids or liquids cycle, as appropriate. The autoclave used for waste is located within the CL3 laboratory itself. Indicator tape will be used on the containers to show that the working temperature as been met. Monthly monitoring will be undertaken using Browns tubes, and an annual validation of the autoclave by independent means will be performed. The final waste bag can then be disposed of as normal Category 1 laboratory waste. Work surfaces in both CL2 and CL3 laboratories will be cleaned with the microbiocide Hycolin (2% final concentration; validated by the manufacturer to completely kill the pathogens described here).

Is an emergency plan required according to regulation 20? [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

Comments on the project proposal/risk assessment forms originally submitted. These points were addressed in the final versions. The Committee's members were in agreement with the levels of containment proposed, and therefore the final activity class designation.

Project Containment
Hepatitis C virus (HCV) is a positive strand enveloped virus belonging to the family Flaviviridae. It is also a hepatotrophic blood borne human pathogen that often establishes a life-long chronic infection in infected individuals and is responsible for significant morbidity and mortality throughout the world. Currently there is no therapeutic intervention that is able to eliminate viral infection effectively, and as such the ACDP guidelines require that handling of wild type virus be done under containment level 3. The purpose of the proposed work is to identify host and viral proteins, as well as viral RNA structures that are important in controlling and maintaining viral replication within cells. It is also planned to examine how viral infection of hepatocytes modulates host cell immune responses, the effect of which enables chronic HCV infection to be established. Delivery of HCV genetic material into mammalian cells will either be through DNA transfection, RNA transfection or baculovirus transduction. It should be noted that the use of baculovirus to deliver HCV genetic material into cells means that this GM entity can be considered both as a recipient organism and as a vector (for the purpose of this application it will be referred to as a vector although associated risks will be assessed in both contexts). It is hope that this work will shed light on aspects of HCV infection that may facilitate improved clinical intervention strategies.
Bacterial strains:

(1) DH5α: F- 80lacZ M15 (lacZYA-argF) U169 deoR recA1 endA1 hsdR17(rk-, mk+) phoA supE44 thi-1 gyrA96 relA1
(2) DH10Bac: F- mcrA (mrr-hsdRMS-mcrBC) 80lacZ M15 DlacX74 endA1 recA1 deoR (ara,leu)7697 araD139 galK galU rpsL l- / bMON14272 / pMON7124

Both strains are commonly used laboratory strains derived from E.coli K-12 and are considered to be able to survive in the human gut. DH5α will be used for the cloning and propagation of pUC-based plasmid vectors containing HCV genetic material. DH10Bac will be used for the generation and maintenance of bacmids (a genetically modified attenuated baculovirus genome that maintains itself as a low copy episome within the bacteria (Luckow et al. (1993) J. Virol. 67. 4566-4579). Work with these genetically-modified bacteria will be deemed to be a class one activity unless the plasmid/bacmid they contain has a cDNA copy of a full length infectious HCV genome under the control of a constitutive mammalian promoter. Under such circumstances this work will be deemed a class two activity and will be performed under containment level 2 (This represents a slight amendment to what was originally proposed and relates to comments from GMSC-see section 15). This is in case of the extremely unlikely event that a sharp injury to lab personnel could lead to such constructs being taken up and transcribed to generate an infectious virus in the cells of that individual (the reason why this is considered a low risk is that naked DNA transfects cells poorly and initiation of infection would most likely require uptake by hepatocytes rather than any other cell line).Human cell lines:(1) HepG2 cells: cells derived from human hepatocellular carcinoma cell line (ECACC 85011430),(2) Huh7 cells: human hepatoma cell line (Japanese Cancer Research Resources Bank Number JCRB0403),(3) HeLa cells: human carcinoma cell line (ECACC 93021013),(4) Primary human hepatocytes.No latent viral infection such as EBV is known to exist in the first three transformed cell lines. The intention is to introduce HCV genetic material under the control of either a constitutive or tetracycline-regulable mammalian promoter into these cell lines, either stably or transiently, using plasmid transfection or baculovirus transduction. As with the bacterial work, most cell culture work will be deemed to be a class one activity. However, if the plasmid or baculovirus used contains a cDNA copy of a full length infectious HCV genome, this work will be considered a class 3 activity. If genetic material is introduced into the cells such that, were a recombination event to occur, an infectious viral genome could in theory be reconstituted this work will be considered a class 2 activity. As a result, these latter work activities will be performed under containment level 3 and 2 respectively.

Hepatitis C virus:

The subgenomic replicon: Modifications that will be made to the viral genome will for the most part be profoundly disabling for viral infectivity. A large amount of work will use the HCV sub-genomic replicon (Lohmann et al. (1999) Science), a construct that is already widely used throughout the HCV research community. The sub-genomic replicon is capable of replicating within select tissue culture cell lines but lacks the viral structural proteins necessary for virus particle formation and is therefore non-transmissible. Foreign genetic materials that will be inserted into the replicon are listed below. Most represent reporter genes or selectable markers that allow assessment of sub-genomic replicon replication. Some inserted genetic materials will be derived from other viruses but do not represent pathogenic determinants that would lead to increased virulence or a change host range. As such none of the constructs will represent any greater risk than an 'empty' sub-genomic replicon (a more detailed description of these genetic elements is presented in section 6)Selective markers: neo, bsd, hyg, pac.Reporter genes: lacZ, Luciferase gene from Photinus pyralis, Luciferase gene from Renilla mullerei, secreted alkaline phosphatase gene, green fluorescent protein gene.Host genes: Ubiquitin gene.Non-HCV viral sequence:

Encephalomyocarditis virus (EMCV) internal ribosome entry site (IRES), Foot and Mouth disease virus (FMDV) 2A protease, Hepatitis delta virus (HdV) ribozyme.

All work undertaken with the HCV subgenomic replicon will be considered a class 1 activity unless, as stated earlier, work in these constructs is performed with concomitant expression of HCV structural proteins from a second DNA-based construct (plasmid or baculovirus). Under such circumstances it is possible, however unlikely, that multiple recombinations events could in theory lead to reconstitution of the full length HCV genome. Such work will considered a class two activity and be performed under containment level 2 conditions. It should be emphasised that should such an unlikely event occur, the resulting genome would be expected to represent no more of a risk to human health or the environment as wild type HCV, as no other non-HCV pathogenic determinants will be present in the constructs used.Full length viral constructs: Some work will be undertaken with the purpose of mammalian expression constructs (plasmid and baculovirus) are used for the purpose of transcribing HCV transcripts which contain and express the entire HCV open reading frame but lack either the 3’ or 5’ untranslated region of the viral genome (both these RNA elements are essential for replication of the virus (Freibe et al. (2001) J Virol 75, 12047-12057; Freibe and Bartenschlager (2002) J Virol 76, 5326-5338)). As such these constructs will be profoundly replication deficient and handling of them will be considered a class 1 activity. In contrast, work that involves the introduction of full length wild type or genetically modified HCV transcripts into mammalian cells (either by RNA transfection, poli-based delivery using plasmid transfection or baculovirus transduction) is designated as a class 3 activity and will be performed under containment level 3. All genetic modifications to the full length HCV genome will either be as a result of directed point mutation, or through introduction of the same non-pathogenic foreign genetic sequence that is proposed for use with the subgenomic replicons (see above). Therefore, any HCV-related
material produced will represent no more of a risk to human health or the environment than the parental HCV virus itself.

Host/vector system

Baculovirus: As well as using RNA and plasmid transfection to introduce HCV-related transcripts into mammalian cells, this work will also rely on transduction of cells by the baculovirus Autographa californica nuclear polyhedrosis virus, which has already been shown to be more efficient than DNA transfection (McCormick et al. (2002) J Gen Virol 83, 383-394). Generation of recombinant baculovirus will be achieved using the commercial Bac-to-Bac system supplied by Invitrogen. This system relies on transposition of genetic material from a donor plasmid vector into baculovirus shuttle vector (bacmid) propagated in the E.coli strain DH10Bac (Lucow et al. (1993) J. Virol. 67, 4566-4579). The parental bacmid contains a modified baculovirus genome which is maintained in E.coli as a large (approximately 130kb) low copy number plasmid by virtue of a mini-F replicon cassette with the genome. Transposition into the bacmid is required as the bacmid genome is too large to be modified easily by standard genetic manipulation. The bacmid genome is attenuated through deletion of the polyhedrin gene, the product of which is necessary for survival of the virus under conditions of environmental stress (desiccation, u.v. inactivation, etc.) and is requisite for transmission of the virus to an uninfected host during the natural life cycle of the virus (Rohrmann (1986) J Gen Virol 67, 1499-1513). Recombinant bacmids are constructed by transposing a mini-Tn7 element from a donor plasmid into the mini-attTn7 attachment site on the bacmid, which is brought about by Tn7 transposition functions that are provided in trans by a helper plasmid. Recombinant baculoviruses are then generated through transfection of the bacmids into the insect cell line Sf9, and the viruses used to transduce mammalian cells. Use of recombinant baculovirus to introduce HCV-related material into mammalian cells is not anticipated to represent any additional hazard above and beyond that encountered from transfecting cells with the comparable RNA transcripts. In other words, working with a recombinant baculovirus that expresses an HCV replicon lacking the viral structural genes represents the same risk as working with the stable cell line in which the same HCV replicon is being stably maintained. Justification for this statement is based on a number of arguments. The first is that baculovirus and HCV represent two completely different classes of viruses and possess such divergent mechanisms to facilitate replication in host cells it is unlikely that a virulence factor from one of these two viruses would provide a selective advantage to the other. Moreover the two types of virus infect do not infect related host species (baculovirus host range is limited to insects and crustaceans and HCV is limited in host range to humans and chimpanzees) making it even more unlikely that a change in host tropism could occur through introduction of HCV genetic material into the baculovirus genome. Furthermore, recombinant baculoviruses will be attenuated through lack of the polyhedrin gene, and so are unlikely to survive or propagate should accidental release occur. In addition, previous studies suggest that in the extremely unlikely event that the attenuated virus was able to be propagated outside a laboratory environment, there is selective pressure for foreign DNA to be lost by spontaneously deletion (Pijlman et al. (2003) J Gen Virol 84, 2669-2678). Finally, the virus is extremely susceptible to complement through environmental stress (desiccation, u.v. inactivation, etc.) and is requisite for transmission of the virus to an uninfected host during the natural life cycle of the virus (Rohrmann (1986) J Gen Virol 67, 1499-1513). Recombinant bacmids are constructed by transposing a mini-Tn7 element from a donor plasmid into the mini-attTn7 attachment site on the bacmid, which is brought about by Tn7 transposition functions that are provided in trans by a helper plasmid. Recombinant baculoviruses are then generated through transfection of the bacmids into the insect cell line Sf9, and the viruses used to transduce mammalian cells. Use of recombinant baculovirus to introduce HCV-related material into mammalian cells is not anticipated to represent any additional hazard above and beyond that encountered from transfecting cells with the comparable RNA transcripts. In other words, working with a recombinant baculovirus that expresses an HCV replicon lacking the viral structural genes represents the same risk as working with the stable cell line in which the same HCV replicon is being stably maintained. Justification for this statement is based on a number of arguments. The first is that baculovirus and HCV represent two completely different classes of viruses and possess such divergent mechanisms to facilitate replication in host cells it is unlikely that a virulence factor from one of these two viruses would provide a selective advantage to the other. Moreover the two types of virus infect do not infect related host species (baculovirus host range is limited to insects and crustaceans and HCV is limited in host range to humans and chimpanzees) making it even more unlikely that a change in host tropism could occur through introduction of HCV genetic material into the baculovirus genome. Furthermore, recombinant baculoviruses will be attenuated through lack of the polyhedrin gene, and so are unlikely to survive or propagate should accidental release occur. In addition, previous studies suggest that in the extremely unlikely event that the attenuated virus was able to be propagated outside a laboratory environment, there is selective pressure for foreign DNA to be lost by spontaneously deletion (Pijlman et al. (2003) J Gen Virol 84, 2669-2678). Finally, the virus is extremely susceptible to complement through activation of both classical and alternative pathways. This means that if an individual was accidentally exposed to recombinant baculovirus virus, the possibility that HCV or other foreign genetic material would be expressed is remote and based on in vivo animal studies using baculovirus would certainly be limited to at the site of injury alone (Hoare et al. (2005) J Gene Med 7, 325-333). Accordingly, generation and propagation of baculovirus constructs containing genes encoding individual HCV proteins, HCV subgenomic replicons or HCV genomes lacking either the 3' or 5' untranslated region will be considered a class 1 activity. In contrast, generation and propagation of baculovirus constructs containing an unmodified HCV genome or a genetically modified full length HCV genome will be considered class 3 activities and performed under containment level 3.

Origin & function

HCV genome

activity. This proteolytic activity has also been shown to suppress host innate immune responses. NS4A: acts as a co-factor for the NS3 protease. NS4B: induces membrane alterations in cells, a process thought to be required for formation of HCV replication complexes where viral RNA synthesis takes place. NS5A: both necessary for viral RNA synthesis and affects a number of cell signaling pathways in the host cell. NS5B: RNA-dependent RNA polymerase. Selectable markers: neo: encodes resistance to the aminoglycosidic antibiotic G418. bsd: encodes resistance to the nucleoside analogue blastcidin. hyg: encodes resistance to aminoglycosidic antibiotic Hygromycin B. pac: encodes resistance to aminonucleoside antibiotic puromycin. Reporter genes: lacZ: encodes for bacterially derived $beta$-galactosidase. Luciferase gene from Photinus pyralis (North American firefly). GFP: green fluorescent protein.

Non-HCV viral genetic material

EMCV internal ribosome entry site (IRES): The IRES represents an alternative way to use a 5’ cap structure to recruit translationally active ribosomes to RNA transcripts. While EMCV is a picornavirus that displays a wide host tropism and is infectious to humans, infection rarely leads to clinical complications. The EMCV IRES itself is not a virulence factor for the virus and it’s use in this work is merely to allow a second open reading frame to be introduced into the replicon transcript. FMDV 2A protease: This is an extremely small protein present within the FMDV genome. The role of it is to facilitate cleavage at the FMDV 2A/2B boundary without the requirement for additional viral or host cell protease activity. Recent data suggest that cleavage occurs not as a result of protease activity but due to a novel ribosome ‘skip’ mechanism. No other functions have been assigned to FMDV 2A and non-viral homologues that also make use of the ribosome ‘skip’ mechanism are known to exist. Use of the 2A protease allows generation of sub-genomic replicons were reporter gene or selectable marker expression can be maintained while also allowing HCV IRES-directed expression of the HCV non-structural proteins. HdV ribozyme: A RNA sequence from hepatitis delta virus capable of cleaving itself away from RNA located at its extreme 5’ boundary. Use of the HdV ribozyme allows precise definition of the 3’ end of RNA transcripts produced from the polII-derived expression systems.

Mammalian promoters

Immediate early CMV promoter: Widely used constitutively active polII promoter derived from cytomegalovirus that functions well in the majority of mammalian cell lines. ‘CAG’ promoter: Widely used constitutively active polII promoter/expression cassette that is a composite between an immediate early CMV enhancer element, a minimal chicken b-actin promoter and human b-globin polyadenylation signal.

Tetracycline responsive promoter: A composite genetic element where multiple copies of a tetracycline response element (which is recognised by the tTA element in the absence of tetracycline; see below) is upstream of a minimal immediate early CMV promoter.

Other genetic elements

tTA element: A widely used artificial protein where the Herpes Simplex virus VP16 trans-activating domain is coupled to the tetracycline repressor (tetR) protein of E. coli, giving a protein that enables transcription from a second separate ‘tetracycline-responsive’ promoter to occur (Gossen & Bujard (1992) PNAS 89, 5547-5551). The tetracycline-responsive promoter is inactive alone, and when the tTA element is expressed, transcription from it is also suppressed in the presence of tetracycline. The tTA element will be expressed from a different DNA construct to the DNA constructs containing the HCV genetic material. Ubiquitin: Small host protein that is attached onto and targets cellular proteins for degradation. This will be used as has been done previously (Blight et al. (2002) J Virol 76, 13001-13014; Friebe et al. (2005) J Virol 79, 380-392) to physically separate selectable markers and reporter genes from the HCV polyprotein as a result of protease cleavage at the extreme carboxy-terminus of the ubiquitin sequence.

Evaluation of foreseeable effects

Hazards to human health

(i) Hazards associated with the recipient micro-organism: Plasmid and RNA based HCV constructs: HCV is an ACDP hazard group 3 blood-borne virus that establishes a chronic infection in humans. In the majority of individuals this leads to chronic infection, which progresses to cirrhosis in about 20% individuals after 20 years. Treatment of chronically infected individuals with current regimens (pegylated interferon-b and ribavirin) leads to long term viral eradication in 55% of cases. However, >95% receiving treatment within the first six months following infection have long-term responses to therapy. Replication of the virus is almost exclusively within hepatocytes of the liver, although it is likely that a very low level of replication also occurs within leukocytes. No vaccines are currently available for HCV. Almost all cloned full length infectious HCV genomes are unable to replicate in tissue culture without the presence of culture-adapted mutations. Interestingly, although inclusion of culture-adapted mutations within the HCV genome results in efficient replication of the viral transcripts within cells, the formation of virus particles is still blocked. Moreover, these culture-adapted mutations are detrimental to viral infectivity and have been seen to revert to wild-type sequence when culture-adapted genomes are introduced into chimpanzees (the only robust animal model for HCV infection). A recently identified full length infectious clone (termed JFH-1) is currently the only HCV isolate that can be propagated in tissue culture and which is able to infect chimpanzees.
Baculovirus-based HCV constructs: Baculovirus will also be used to introduce full length HCV genomic constructs and full length HCV replicons into cells in tissue culture. This is an ACDP hazard group 1 virus whose replication is limited to insects. While baculoviruses can transduce (introduce their genome to the cell nucleus) mammalian cells in tissue culture viral replication does not occur and there is no evidence to date that baculoviral promoters are able to drive viral gene expression in mammalian cells. All baculovirus constructs used lack the polyhedrin gene, required for transmission of the virus under natural conditions. Furthermore, recent reports demonstrate the extreme difficulty in using baculovirus to transduce cells in vivo due to rapid inactivation of the virus by complement (Hoare et al. (2005) J Gene Med 7, 325-333).

(ii) Hazards arising directly from the inserted gene product Plasmid and RNA based HCV constructs: The inserted genes to be introduced into the full length HCV constructs will Hazards to human health(i) Hazards associated with the recipient micro-organismPlasmid and RNA based HCV constructs: HCV is an ACDP hazard group 3 blood-borne virus that establishes a chronic infection in humans. In the majority of individuals this leads to chronic infection, which progresses to cirrhosis in about 20% individuals after 20 years. Treatment of chronically infected individuals with current regimens (pegylated interferon-b and ribavirin) leads to long term viral eradication in 55% of cases. Replication of the virus is almost exclusively within hepatocytes of the liver, although it is likely that a very low level of replication also occurs within leukocytes. No vaccines are currently available for HCV.

Almost all cloned full length infectious HCV genomes are unable to replicate in tissue culture without the presence of culture-adapted mutations. Interestingly, although inclusion of culture-adapted mutations in the viral genome results in efficient replication of the viral transcripts within cells, the formation of virus particles is still blocked. Moreover, these culture-adapted mutations are detrimental to viral infectivity and have been seen to revert to wild-type sequence when culture-adapted genomes are introduced into chimpanzees (the only robust animal model for HCV infection). A recently identified full length infectious clone (termed JFH-1) is currently the only HCV isolate that can be propagated in tissue culture and which is able to infect chimpanzees. Baculovirus-based HCV constructs: Baculovirus will also be used to introduce full length HCV genomic constructs and full length HCV replicons into cells in tissue culture. This is an ACDP hazard group 1 virus whose replication is limited to insects. While baculoviruses can transduce (introduce their genome to the cell nucleus) mammalian cells in tissue culture viral replication does not occur and there is no evidence to date that baculoviral promoters are able to drive viral gene expression in mammalian cells. All baculovirus constructs used lack the polyhedrin gene, required for transmission of the virus under natural conditions. Furthermore, recent reports demonstrate the extreme difficulty in using baculovirus to transduce cells in vivo due to rapid inactivation of the virus by complement (Hoare et al. (2005) J Gene Med 7, 325-333).

(ii) Hazards arising directly from the inserted gene product Plasmid and RNA based HCV constructs: The inserted genes to be introduced into the full length HCV constructs will either be widely used selectable markers to allow for selection of cells carrying the construct (neo, bsd, hyg, pac) or widely used reported gene constructs to assess viral replication (Firefly and Renilla luciferase, b-galactosidase, secreted human placental alkaline phosphatase or GFP). By themselves, none of these genes or gene products are thought to constitute a biological risk, nor is there any reason to consider that they would represent a greater risk when expressed from an HCV construct than if they were absent from the construct. In order for these constructs to function it is also necessary to physically separate the expression of the viral polyprotein from the inserted gene product. This will be done either by using the EMCV IRES (which will drive translation of the viral polypeptide while expression of the inserted gene product will be driven by the HCV IRES) or by use of ubiquitin or FMDV 2A protease. Inclusion of the EMCV IRES is unlikely to represent a hazard as the native HCV genome already has an IRES. Indeed the EMCV IRES already been included in a number of full length HCV constructs and in one case using JFH has been shown to reduce the fitness of the virus (Wakita et al. (2005) Nat Med 11, 791-796). Use of FMDV2A is not thought to constitute an additional risk as the only ascribed function for this protein is facilitation of ribosome stuttering that breaks the peptide link between FMDV2A and the protein sequence downstream from it. Finally the use of ubiquitin is also thought unlikely to enhance virulence, as although insertion of ubiquitin sequence into the related bovine virus diarrhoea virus (BVDV) does lead to the virus developing a cytopathic phenotype (Tautz et al. (1993) 197, 74-85), this is because of enhanced cleavage of the NS2/NS3 boundary which in non-cytopathic BVDV undergoes only minimal cleavage (Agapov et al. (2004) J Virol 78, 2414-2425). In contrast, the boundary between NS2 and NS3 in HCV is already rapidly cleaved in the wild type virus and so alterations to this trait would not be expected to increase virulence.Baculovirus-based HCV constructs: With regard to insertion of HCV genetic material into baculovirus, given that their modes of replication (baculovirus is a large DNA virus that replicates in the insect cell nucleus, HCV is a small RNA virus that replicates in the cytoplasm) and host cell tropisms are so different, there is negligible risk that inclusion of HCV genetic material into a genetically modified baculovirus would alter baculovirus host range or pathogenicity. The other possibility, that HCV could acquire baculovirus genes due to chance recombination events while propagating recombinant baculovirus carrying HCV constructs, is remote. However, if such events took place it is not envisaged that the resultant recombinant HCV virus would pose any greater risk than wild type HCV.

(iii) Hazards arising from the alteration of existing traitsThere is no reason to believe that the full length HCV constructs will have altered pathogenicity or host range tropism as a result of the genetic modification proposed. The same applies for recombinant baculoviruses carrying HCV genetic material.
(iv) The potential hazards of sequences within the GMM being transferred to related microorganisms: Plasmid and RNA based HCV constructs: Because HCV is a positive strand RNA virus with no DNA intermediate, and has replication machinery that is unlikely to be able to process other viral RNAs, there is already little chance that any inserted gene in HCV would be able to be transferred to another pathogen. In addition, as stated before it is likely that an HCV construct carrying the proposed inserted genes would have an attenuated phenotype and so would not persist as effectively as an unmodified HCV virus. Finally, none of the genes proposed to be introduced into HCV would be likely to represent a risk if expressed by another organism. Baculovirus-based HCV constructs: As stated before, replication of baculovirus is limited to insect cells, the baculovirus constructs we are using are unlikely to be transmitted in the natural environment due to lack of the polyhedrin gene, and foreign gene inserts are known to be lost during multiple rounds of viral propagation. For this reason if an accidental release of the recombinant virus was to occur, there is little chance that this would result in transfer of the HCV genetic material to another insect virus. Moreover, if such a transfer did occur, there are at present little or no insect transmissible viruses found within the UK, yet further reducing the opportunity for recombination of the HCV genetic material with other human viral pathogens.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**Not applicable.**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Literature supplied by the manufacturer (Dupont) of the disinfectant Virkon, detailing the effectiveness of this product in independent tests, indicates that 1% Virkon is effective at destroying HCV after a 10 minute contact time at room temperature. The details of this study are somewhat limited (it appears that inactivation of the virus was probably ascertain through use of RT-PCR to detect viral genome), but the results are consistent with another study looking at the virucidal activity of Virkon on Yellow Fever Virus and West Nile Virus (both in the same virus family as HCV) where a solution of 0.4% Virkon was sufficient to completely inactivate both of these viruses after 10 minutes (and 0.1% Virkon sufficient to inactivate all virus after 30 minutes). The literature available on the effectiveness of Virkon for inactivation of baculovirus is limited, but numerous reports exist demonstrating the effectiveness of a 1% solution of Virkon for the inactivation of Herpes and Pox viruses (both enveloped dsDNA viruses like baculovirus) and in these instances similar contact times of 10 to 20 minutes were employed. We therefore plan to disinfect all liquid waste from both class 2 and class 3 activities by addition of Virkon to a final concentration of 2% (w/v), and allowing the resultant solution to sit overnight at room temperature before being disposed of down the sink. Prior to commencing work, an independent study will also be performed to confirm the effectiveness of Virkon at inactivating baculovirus under the conditions just described. No such study can as yet be performed for HCV, as we are not at a point in time where we can propagate HCV in tissue culture (this is because the institute's containment level 3 facility is still under construction). Once we are at this stage, tests examining the effectiveness of Virkon will be extended to look at inactivation of HCV. Solid waste from class 2 and class 3 activities will be sterilized by autoclaving at 126ºC for 30 minutes in an autoclave that is checked periodically to ensure adequate performance (in the case of class three activities, this will be done within the confines of the containment level 3 facility with a browning tube included in each autoclave run to confirm effective sterilization) and then sent for incineration.

**Is an emergency plan required according to regulation 20?**

**If yes, tick to confirm that it is attached to this form**

**Tick to confirm that you have attached a risk assessment to this form**

**Tick if you are claiming exemption from disclosure for section of the risk assessment**
The committee's members agreed with your categorisation of certain aspects of the project as Activity Class 2 and others as Activity Class 3. As such, these parts of the project will require HSE acknowledgement or approval, respectively, prior to their commencement. With regard to the elements that you have classified as Activity Class 1, the committee's members were slightly concerned with the handling at containment level 1 (CL1) of DNA or RNA constructs incorporating a full complement of hepatitis C genes. In theory, such genes could be expressed if the nucleic acid were to gain access to the operators cells via, for instance, mucous membranes, abrasions or needlestick. Virus replication may result from this expression. Handling such constructs at CL1 would suggest that there was no risk, or an insignificant risk, to normal healthy individuals. This may be the case, but please explain why this is the case. (NOTE: Modifications were subsequently made so that DNA constructs that contained a full length HCV genome under the control of a constitutive mammalian promoter would be handled under containment level 2. Handling of full length naked RNA transcripts will still be a designated a containment level 1 activity, as this form of nucleic acid is extremely labile and recovery of infectious virus from it is known to require direct intrahepatic inoculation. This was discussed with the biological safety officer and deemed acceptable.) Also, members of the GMSC were interested to know where it is proposed to carry out the AC3 work, as the University does not currently have a working containment level 3 laboratory. The Committee recommended that personnel intending to work on the AC2 or AC3 aspects of the project should be referred to the Occupational Health department for assessment of their baseline hepatitis C status, prior to the commencement of work. This can be dealt with at the OH department here at SGH, but they have asked me to inform them of the staff names prior to referral.

The project aims at gaining a deeper understanding of the mechanisms steering the immune response to self, infection, and tumors and the ensuing tissue repair responses. For this purpose, we will make use of a range of mammalian cell lines either overexpressing specific genes, or cell lines in which genes have been silenced via small inhibitory ribonucleic acids (siRNA, e.g. small hairpin ribonucleic acids, shRNA). We will use Lentiviral particles, which are a third generation, self-inactivating retroviral expression system, to stably express either transgenes or siRNAs in mammalian cell lines and primary cells. Our studies will focus on understanding the interaction and signalling of cellular receptors, on trafficking of molecules within the cells, and on the effect of metabolic alterations within the cell. Furthermore, we will define the role of microRNAs in host defence and in modulating the immune response. To complete this goal, we will study viral infection employing human rhinovirus (HRV).

Human Rhinovirus (HRV) is a positive strand, non-enveloped RNA virus belonging to the Picornaviridae family and is one of the major causes of the common cold. It is also implicated in acute exacerbations of asthma in all age groups, which is a major cause of morbidity and mortality. Currently there are no established methods for effective prevention or treatment of rhinovirus infections. In order to elucidate and understand the nature of rhinoviral replication in human lung cell culture models, and the effect of microRNAs on this process, we propose to construct a recombinant form of HRV with a reporter gene. This will involve the generation of full-genome HRV cDNA in which a reporter gene is inserted either between the 5’ UTR and ORF or between structural and non-structural, i.e. P1 and P2, regions of the genome. RNA transcribed in vitro and introduced into cells is predicted to replication and produce virus, based on similar studies with other picomaviruses. Such a virus will be used to re-infect cell lines and replication will be assayed by level of reported gene expression. This system will allow the analysis of primary infection and bystander effects in a human lung explant model. Some of the cell lines will have been previously stably transfected with lentiviral particles, in order to evaluate the role of different microRNAs in the cellular immune response.

Viral strains:
(1) Human rhinovirus — 16
(2) Human rhinovirus — 1 f3

Host/vector system

Host: We will be using a third generation lentivirus system comprising different plasmid vectors for individual components of the final virus particle. The retroviral genes in these vectors have been modified/truncated to make recombination/replication impossible (i.e. they are self-inactivating). Furthermore, the packaging signal for the virus particles is encoded by a different plasmid vector from the target sequence.

The pathogenic properties of any modified form of the rhinovirus genome are likely to be reduced relative to wild type virus. The proposed wild type picornaviruses are classified by the ACDP as hazard group 2. (J Virol 1998 Jan; 72 (1): 20-31)

Vectors: The genes of interest (GOI) are transferred into a lentiviral transfer vector, such as pSIHl-H1-PURO, pHRsinl8, WPT, pLVTHM, pLV/ITR_KRAB_Red, or pLKO.1-puro. The GOI is now flanked by the non-coding retroviral LTRs, while no retroviral genes are encoded on this plasmid and therefore no retroviral genes transferred into the particles.

In order to obtain the modified rhinovirus, modifications will be made to viral cDNA contained in standard non mobilisable DNA plasmids, grown in laboratory adapted strains of Escherichia coil that are unlikely to survive in the human gut (Eur J Clin Microbiol 1982 Jun; 1(3): 186-92)

Origin & function

In the first part of the project human genes will be identified that affect the immune response to self, infection, and tumors and the ensuing tissue repair responses. For this purpose mammalian cells will be subjected to gene silencing by lentiviral particles, which will be generated from the GeneNet H.50K siRNA lentiviral plasmid library. As a readout we will use functional assays as well as recombinant fluorescent immunoreceptors or antibody based approaches. Promising cell clones will be FACS sorted and the genes responsible for their individual phenotypes will be sequenced.

In the second part of the project, specified individual human genes will be targeted in various human cell lines by gene silencing (using 5hRNA encoding lentiviral particles). This is to confirm the findings of part one of the project. In the third part of the project we will overexpress individual genes in various human cell lines. The rational for overexpressing these genes will be derived from the first two parts of the project.

In a second project, we will identify genes that affect the immune response to self, infection, and tumors and the ensuing tissue repair responses by overexpressing mammalian genes in eukaryotic cells. For this purpose mammalian cells will be subjected to gene overexpression using lentiviral particles, which will be generated from a
human lentiviral open reading frame cDNA libraries. As readouts, we will use functional assays, recombinant fluorescent immunoreceptors or antibody based approaches. Promising cell clones will be FACS sorted and the genes responsible for their individual phenotypes will be sequenced.

Finally, we will overexpress, in different mammalian cell lines and primary cells, microRNAs to study their role in immune responses and tissue repair. One & the main goals will be to evaluate the role of these microRNAs in the cellular host defense against viral infection. This will be tested employing human rhinovirus (HRV).

Generation of full-genome HRV cDNA constructs in which a reporter gene (green fluorescent protein, LacZ or luciferase) is inserted either i) between the 5' un-translated region (UTS) and PRF or ii) between structural and non-structural regions of the genome. RNA transcribed in vitro and introduced into cells is predicted to replicate and produce virus. Such a virus will be used to re-infect cell lines and replication will be assayed by level of reporter gene expression. This system will allow analysis of cell-entry and early events in viral infection in culture.

Well documented 'reporter' genes expressing proteins such as Green Fluorescent Protein, @-Galactosidase or Luciferase, are non-toxic, non-allergenic and are not predicted to alter the nature of the virus.

The genes of interest (GOI) are transferred into a lentiviral transfer vector, such as pSINHi-PURO, pHRsinI8, WPT, pLVTHM, pLViTR_KRAB_Red, or pLKO.1-puro. The GOI is now flanked by the non-coding retroviral LTRs, while no retroviral genes are encoded on this plasmid and therefore no retroviral genes are transferred into the particles. This construct is packaged into particles using a HEK293T cell or HEK293FT cell based packaging system. For the packaging the HEK293T or HEK293FT cells are co-transfected with additional plasmids (such as pLP1 and pLP2, pPAX2, pMD2G, or pFIV-34N/pVSV-G). These plasmids express the envelope protein from VSVg and the non-structural proteins of the virion; none of these genes are transferred into the particles since they lack the packaging signal, which is only present on the lentiviral transfer vector plasmids. After transfecting the producer cells, the particles can be harvested from the supernatant over the next three days.

Hazard to Human Health:

The Lentiviral Expression Systems used include the following key safety features:

• They contain a deletion in the 3' LTR (AU3) that does not affect generation of the viral genome in the producer cell line, but results in "self-inactivation of the lentivirus after transduction of the target cell. Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing packageable viral genome.
• The number of retroviral genes that are used in the system has been reduced to three (Le. gag, p0!, and rev.
• The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 or other retroviral envelope genes.
• Genes encoding the structural and other components required for packaging the viral genome are separated onto three to four plasmids. All plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus.
• Although the packaging plasmids used in these system allow expression in trans of proteins required to produce viral progeny (e.g. gal, p01, rev, env) in the HEK293T or HEK293FT producer cell lines, none of them contain LTR5 or the LI) packaging sequence. Therefore, none of the retrovirus structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced.
• The lentiviral particles produced in these systems are replication-incompetent and only carry the gene of interest. No other viral species are produced.
• Expression of the gag and pol genes from LP1 has been rendered Rev-dependent by virtue of the HIV-1 RRE in the gag! pol mRNA transcript. Addition of the RRE prevents gag and p01 expression in the absence of Rev.
• A constitutive promoter (RSV promoter) has been placed upstream of the 5' LTR in the pLenti expression vector to offset the requirement for Tat in the efficient production of viral RNA.

The Modified rhinoviruses present no more human hazard than wild type virus. The infection resulting from such an exposure is predicted to be significantly reduced relative to wild type virus, due to the reduced replication efficiency of the modified virus, based on previous studies with other members of the picomaviridae family of viruses 1,2 The effect of expression of a non toxic reporter gene product in infected cells would be negligible relative to the effect of normal wild-type virus replication which destroys the cell. The growth of replication-defective mutants is likely to be very inefficient. Furthermore, in the context of a natural infection, the genetic instability of the inserted gene combined with normal in vivo selection pressures is predicted to cause rapid reversion to a genotype effectively identical to wild-type1.

Infection of stably transfected cell lines, that were previously transduced with lentiviral particles don’t pose an additional hazard to standard infection experiments. As mentioned above, none of the retrovirus structural genes
are actually present in the packaged viral particles, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced and no cross-recombination can occur. Finally, regarding the hazard that inserted genes could pose, we will exclude from this expression system genes encoding:

a) proteins of retroviral origin
b) toxins
c) oncogenes

In the specific gene expression approaches, genes that will be used for overexpression or silencing are involved in the immune or repair response and metabolism. There are no described adverse effect regarding their overexpression in healthy organisms, tissues or cells. In addition, gene silencing of mammalian genes in cell lines using whole genome libraries (such as the one used in our project) has not been described to be hazardous.

Environmental and Activity considerations:
We are confident that the final lentiviral GMMs pose no hazard to the environment. Lentiviral particles are very inefficient infecting cells (They need very specific experimental conditions, including manipulating the charge of the cell surface by adding the chemical substance Polybrene before transduction of the virus particles to the cells), and are unable to replicate (self-inactivating replication-incompetent viruses are used). Lentiviruses have a short half-life and are unstable at room temperature. In addition, as described above, lentiviral particles are low infective and unable to replicate (self-inactivating). Although VSVG-pseudotyped virus particles can transduce, in theory, all mammalian cells, transduction is also highly dependent on the concentration of the virus particles in a given medium. In addition, primary cells are much more difficult to transduce with lentivirus particles than in vitro generated cell lines. For these reasons, it is very unlikely that the lentivirus particles pose a risk for the environment.

Oral ingestion of lentiviral particles will be prevented by standard laboratory working practices. Aerosol formation resulting from an accident outside of the class II safety cabinet and involving Lentivirus particle-containing liquid may lead to transduction of a limited number of the laboratory workers’ skin or mucosal cells with modified viruses. However, these modified virus particles carry an extremely low risk for humans. Firstly, they are replication-incompetent. Secondly, these particles carry an extremely low infection risk, and transduction of a laboratory worker’s skin or mucosa is virtually impossible. In addition no genes encoding toxins, oncogenes, or pathogen-derived genes are used in our studies. In the unlikely event of accidental transduction of a laboratory workers skin or mucosa by lentivirus particles, this will be self-limited, due to natural shedding of superficial epithelial skin and mucosal cell layers.

For work involving HEK293FT cells to produce the lentiviral particles the following procedures will be deployed:
Work with these cells will be conducted within a class 2 microbiological safety cabinet (MSC). The MSC is serviced and tested (inflow/downflow) on a regular basis. The cells will be maintained in closed tissue culture vessels and incubated in a dedicated incubator within the laboratory. Harvesting of the lentiviral particles will be carried out 1 8-72hrs-post transfection. The culture vessels will be transferred to the class 2 cabinet, and only then will the lids be opened. In some cases the lentiviral particle containing media will be used directly to transduce cells in culture. In other cases the virus particle containing media will be decanted into sealable centrifuge containers and the particles pelleted by centrifugation. The supematants will be directly used for cell transduction or decanted directly into a 1% w/v Virkon solution. The culture vessels will then be given fresh media and be returned to the class 2 MSC. The pellets will be re-suspended in PBS and then be transferred to a —80°C freezer.

The particles will then be used to transduce cell lines by adding a small amount (~500ul) of particle suspension (with up to 1 x10⁷ particles per ml) to the host cells. Effective transduction of mammalian cells requires the addition of the chemical Polybrene (5-15 microgramms/ml) to the cell cultures. 24h later transduced cells will be passaged at least once before analysis of gene expression by FACS calibur (which will be flushed with a “clean” solution (provided by Becton Dickinson) containing bleach. After at least 2-3 passages, when no viral particles will be present anymore in
the culture medium, the transduced cells will be sorted using FACS. Before FACS sorting the cell culture medium will be checked for the presence of infectious virus particles by transducing HeLa cell line (in the presence of polybrene) and FACS analysis of this cell line (GFP fluorescence of the HeLa line after “transduction” with culture cell medium). Upon passage of the transduced cells infectious particles are no longer present and special containment measures won’t be necessary in the FACS facility. Subsequent work will then be carried using good microbial practices.

When working with HRV, the following procedures will be contemplated:

The primary route of transmission for HRV is by aerosol droplet inhalation. Oral ingestion will be prevented by standard laboratory working practices. Aerosol formation resulting from an accident outside of the class II microbiological safety cabinet and involving HRV-containing liquid may lead to infection of laboratory workers with modified viruses. The infection resulting from such an exposure is predicted to be very much reduced to that resulting from wild type virus, due to the reduction in viral replication described previously. Infection of the community at large with a modified virus is unlikely for reasons of genetic instability described earlier.

There would be negligible economic or ecological consequences of a major escape. No infection of animals with wild type or recombinant HRV has been reported.

The existing containment (CL2) and normal working practices in use for work with wild type HRV are sufficient to reduce the risk of aerosol infection of laboratory workers to a very low level. These include the use of a class II cabinet for all cell culture manipulations to prevent formation or escape of aerosols from samples taken outside of the cabinet (eg. Samples contained in plastic screw-capped vials, centrifugation carried out in sealed rotors etc.)

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste containing viral particles is inactivated by overnight treatment with Virkon (2% final concentration). Fresh Virkon solution will be made up before each daily experiment. All viral exposed materials, except for ultracentrifuge tubes and work bench surfaces, will be disinfected with Virkon. Ultracentrifuge tubes and work bench surfaces will be disinfected with 70% ethanol. After virus inactivation dry waste goes into the yellow bags (which will be collected by the contractor, macerated, autoclaved and landfilled with the hospital’s clinical waste). Class II cabinets are tested once a year by the KI discus method as recommended by HSE guidelines (NOTE: Lentivirus particles are irreversibly inactivated by 20% - 75% Ethanol; Virkon irreversibly inactivates all enveloped viruses). The manufacturer of Virkon (DuPont/Antec International) was consulted on the effectiveness of this disinfectant against rhinoviruses. Their response was “Unfortunately we have no direct efficacy test data for Virkon against Rhinoviruses. However, Rhino viruses are from the same family of viruses as F M 0 and Polio (picornaviridae) for which we do have data. Therefore we can advise that Virkon will be effective against rhino viruses. Polio virus is considered to be the most resistant to biocides therefore if Virkon is effective by extension it should be effective against Rhinovirus.” Their efficacy data is attached.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form

None

Tick to confirm that you have attached a risk assessment to this form

None

Tick if you are claiming exemption from disclosure for section of the risk assessment

Y
Lentivirus project (extract of the minutes of a meeting of the Genetic Modification and Biosafety Committee held on 15 January 2008):

"Use of lentiviral practices automatically required classification at Activity Class 2 and these components of the project would therefore require USE notification. A draft of the notification was currently being prepared. Work on this component of the project could not begin until USE acknowledgement was received. The work would take place in an appropriate CL2 laboratory.

Some concern had been expressed about FACS sorting and the potential for infection — however each cell would be washed to remove infectious particles before any FACS sorting took place. The remaining cells could not infect because they were replication-incompetent.

(A member) raised queries about disposal (waste) particularly as the researchers were new to the University. (It was) commented that he had discussed this with them in detail, and emphasised that the P1 had undertaken similar work in Switzerland, including FACS work. It might however be appropriate to schedule the laboratory for a visit relatively soon.

Resolved That the elements of the project relating to the propagation of plasmid vectors in E Coil be approved as Activity Class 1; and that the remaining elements be classified as Activity Class 2, requiring HSE notification."

Rhinovirus (extract of the minutes of a meeting of the Genetic Modification and Biosafety Committee held on 17 October 2007):

"Members supported the assessment that this project contained both AC1 and AC2 components. USE notification was therefore required for the AC2 elements, and work could not begin until USE agreement was received. It was confirmed that sharps would not be used,

Resolved That the elements of the project proposal relating to propagation of the plasmid and generation of RNA transcripts be approved at Activity Class 1; and that the elements relating to the transfection of RNA transcripts into cells and the infection of recombinant virus into primary cell cultures be approved at Activity Class 2."

## Project Additional Information

### Purposes of the contained use

Our strategy is to employ a live attenuated bacterial strain to mimic a bacterial infection in otherwise healthy mice or mice with ongoing neurodegeneration (ME7 prion infected mice). We believe that this can only be achieved using live bacteria, rather than heat-killed bacteria or bacterial products such as lippolysaccharide (LPS). While LPS induces inflammation and is widely used in animals to model aspects of bacterial infection, it does not mimic the dynamics of a real live infection, characterised by prolonged, often low grade exposure to replicating bacteria. Attenuated Salmonella strains are ideal for our studies due to its potential to elicit all three forms of immunity: mucosal, systemic and humoral with a low risk to induce human disease. A second advantage is the well characterised innate and acquired immune responses in mice following infection with Salmonella.

### Recipient or parental organism

Wild-type Salmonella enterica serovar Typhimurium is an intestinal pathogen which causes infection in mice and human. In this project we propose to use the attenuated strain SL3261, an AroA mutant. This mutation makes the bacteria unable to grow but will persist in the antigen presenting cells in host tissue for several weeks, but it is not likely to cause disease.

Hoiseth et al were the first to introduce the aroA mutation and measured the level of attenuation between SL3261 and its parent strain SL1344. In this study, 3x10 cfu of the AroA mutant SL3261 did not cause ill effects in mice while the LD50 for SL1344 was only <20 cfu. From this study it can be concluded that the level of attenuation of SL3261 is 6 log reduction in cfu relative to its (grand) parent strain, SL1344. (Hoiseth SK and Stocker BA, Aromatic-dependant Salmonella Typhiumurium are non-virulent and effective as live vaccines. Nature 1981 May 21:291 (5812):238-9)

Salmonella organisms do not multiply significantly in the natural environment (out of digestive tracts), but they can survive several weeks in water and several years in soil if conditions of temperature, humidity and pH are favourable. When working in a laboratory it is unlikely that the SL3261 strain will survive in the environment. Furthermore, laboratory mice that have not been exposed to predators or finding their own food would be unlikely to survive for long in the environment should escape occur. Salmonella may be shed in the faeces of exposed animals and increase the risk of exposing other animals.

Innocation of mice with a high dose of SL3261 strain may cause sickness behaviours in mice, such as pilperection, hunched posture, which may persist for weeks. Overt symptom including fever and diarrhoea may occur when high doses ie 10 (8) 0 10 (9) cfu of SL3261 are used.

Many attenuated Salmonella vaccines have been constructed and used in experimental conditions and some attenuated Salmonella vectors have already been evaluated in humans for clinical use. None of these studies have reported side effects, despite using relative high doses of bacteria ie 10(9) cfu. In our project we will not exceed does of 10 (8) cfu and, therefore if bacteria are accidentally ingested or needle stick accidents occur, there is low risk for human disease. Based on this information we consider the most hazardous GMM to be a ME7 prion infected mouse inoculated with 10 (8) cfu/ml of attenuated S.Typhimurium SL3261.

### Host/vector system

The GMM Salmonella strain SL3261 will be used, but no further genetic modification undertaken.
**Origin & function**

The GMM Salmonella strain SL3261 will be used, but no further genetic modification undertaken.

**Evaluation of foreseeable effects**

The GMM Salmonella strain SL3261 will be used, but no further genetic modification undertaken. The characteristics of this strain are detailed above.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

In this project we will use the ME7 prion agent to induce chronic neurodegeneration. Our animal facility has designated rooms that are level 2 containment. If we use bacteria to infect animals or genetically modified animals, such as mice deficient for cytokines, we will use the same control measures as the ME7 prion infected mice. The measures include inactivation of bacteria in cage and consumable using a 10 minute soak in 1:10 diluted chlorine bleach. Animal tissue will be autoclaved to inactivate bacteria prior to incineration.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

We will use disposable consumables for bacterial cultures and preparation of glycerol stocks. Bacterial cultures that are discarded will be neutralized with freshly prepared chlorine bleach or by 30 minutes treatment at 121°C using an autoclave. The autoclaves we will use are validated for a bacterial waste management cycle ie 30 minutes at 121°C and we will regularly check the inactivation of bacteria (for example S.Typhimurium SL3261) using sterilization indicator ampoules. The autoclaves are a LTE300SH and a Kestrel. It has been shown that steam heated to 121°C for at least 15 minutes will inactivate all fungi, bacteria, viruses and also bacterial spores. Work benches will be wiped down with freshly prepared Chlorine bleach to inactivate any spilled bacteria and we will take regular bacterial swabs to check the inactivation of bacteria on work benches. Chlorine bleach is an accepted liquid sterilizing agent. Household bleach consists of 5.25% sodium hypochlorite. To inactivate S.Typhimurium SL3261, we will use a 1:10 dilution. The dilution factor must take into account the volume of any liquid waste that it is being used to sterilize. Bleach will kill many organisms immediately, but for full sterilization is should be allowed to react for 20 minutes. Bleach will kill many, but not all spores. It is highly corrosive and many corrode even stainless steel surgical instruments. Bleach decomposes over time when exposed to air, so fresh solutions should be made daily.

Use of bacteria in vivo:

In this project we will inject bacteria in otherwise healthy mice and mice infected with ME7 prion agent. We will use disposable needles to inject mice with bacteria. Gloves will have to be worn during the injection procedure and needles will be disposed of using incineration containers. To minimise the risk of needle stick injury, only experienced workers in the facility will be allowed to inject the bacteria. We will assess this by an appropriate animal handling assessment. Bacteria may be shed in the faeces of exposed animals. Infected animals will be housed in such a way that there will be an appropriate barrier to the possible spread of infection. For example, mice will be kept in filter top cages in separate holding room and animal’s handlers must wear gloves and wash their hands after handling infected mice. At the end of the experiment, we will inactivate bacteria that are left in the cage, including bedding, cage lid and animal tissue that will not be used for further analysis, using an autoclave (bacterial waste management cycle 30 minutes 121°C). We will use an autoclave located in the animal facility. This autoclave will be validated for inactivation of bacteria using sterilization indicator ampoules and the inactivation of bacteria will be checked regularly using similar sterilization indicator ampoules. Inactivated animal tissue, in particular those that contain ME7 prion agent, will be incinerated after autoclave treatment. Incineration will burn any organism to ash and is used to sanitise medical and other bio hazardous waste before it is discarded with non-hazardous waste. Work benches will be wiped with 1:10 diluted bleach to neutralise any spilled bacteria and bacterial swaps taken to check the inactivation of bacteria.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

02/03/2022

Page 2158 of 15326
Committee members commented that there appeared to be some conflicting sentences in the original proposal regarding the degree of hazardousness – if a safety cabinet was to be used for the work, did this not imply there was a potential risk to health? It was commented that work involving wt salmonella would usually require level 2 containment, but that in this instance as the S.Thyhmurine strain to be used was highly attenuated, perhaps CL1 would be appropriate? (the prion work as part of the project would of necessity require CL2 – work with this agent had already been approved). It was suggested that a good case had been made regarding the safety of the salmonella strain. Perhaps it would be useful to find out how the collaborators on the project classified their work with this salmonella strain? Alternatively advice might be sought from the HSE.

It was resolved that enquiries would be made from the collaborators as to how they classified this work; and that further advice would be sought from the HSE if necessary. After the meeting, the collaborators were contacted. It was confirmed that work with this salmonella strain had been classified as AC2. Therefore, it was decided to classify the work with this strain at Southampton as AC2.

- **Historical Significant Changes**: No
### Project Additional Information

**Purposes of the contained use**

To investigate if surfactant protein D can be used as a therapeutic against influenza A virus infections.

**Recipient or parental organism**

The two recombinant avian H5N1 influenza strains are attenuated viruses and candidate strains for the human vaccine against avian H5N1 influenza. They are made by reverse genetics at the 'National Institute of Biological Standard and Control' (NIBSC). The genes encoding the 'internal' of the virus is from human H3N2 PR/8/34 and the 'external' is avian H5N1 genes in a mix of 6:2. Furthermore, the basic amino acids in the region cleaved in haemagglutinin has been genetically modified to contain neutral amino acids. These precautions ensure that the strains will not replicate well in human beings.

**Host/vector system**

Genes encoding for viral proteins are cloned into plasmids, each gene into an individual plasmid. The plasmids are transfected into a cell line and a recombinant influenza strain is generated according to the genes cloned into the plasmids. The recombinant influenza strain is then amplified in embryonated hen eggs according to established procedures. The specific information can be obtained from NIBSC.

**Origin & function**

The external of the recombinant H5N1 virus strains are originally isolated from human clinical samples. The internal of the recombinant H5N1 strains are from the PR/8/34 influenza strain which is a human attenuated strain and has a track record of being a safe strain to use for human vaccines against influenza viruses. These recombinant virus strains are candidates to be used in the human vaccine against the H5N1 influenza A virus. These two recombinant H5N1 strains will be used as 'model H5N1' strains' when evaluating the potential of surfactant protein D as a therapeutic against influenza infections.
These viruses are made so they replicate well in embroyolated hen eggs (standard amplification procedure) but will have a low pathogenicity to human beings. The risk for humans contracting and being infected with these recombinant H5N1 strains is therefore minimal. The constellation of these recombinant viruses, with an external H5N1 surface and internal genes from H3N2 PR/8/34, together with the removal of basic amino acid residues in the hemagglutinin, is an efficient two-step procedure to ensure the low pathogenicity of the viruses. During several amplification rounds at the NIBSC no mutations were found in the HA of the viruses verifying that these viruses are stable viruses.

Evaluation of foreseeable effects

These viruses are made so they replicate well in embroyolated hen eggs (standard amplification procedure) but will have a low pathogenicity to human beings. The risk for humans contracting and being infected with these recombinant H5N1 strains is therefore minimal. The constellation of these recombinant viruses, with an external H5N1 surface and internal genes from H3N2 PR/8/34, together with the removal of basic amino acid residues in the hemagglutinin, is an efficient two-step procedure to ensure the low pathogenicity of the viruses. Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not Applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Pathogenicity has been assessed by NIBSC using the intravenous chicken pathogenicity test, a ferret pathogenicity test, a test for plaquing in absence of trypsin and a test for lethality in eggs. In the chicken pathogenicity test, both strains showed no pathogenicity with a score of 0.0. In the ferret pathogenicity test, both strains was less pathogenic than the original H5N1 strains (which was only slightly pathogenic) and similar to PR8 which was non-pathogenic. In the plaquing test, both strains produced plaques on MDCK cells in the presence of trypsin but not in the absence of trypsin. On egg passage, bot strains grew to high titre and all embryos survived; in contrast, passage of the original H5N1 strains in eggs resulted in the deaths of all embryos. In addition, gene sequencing of the HA segment in both recombinant strains confirmed the absence of the polybasic amino acids that determine pathogenicity. In conclusion, these strains are considered to be non-pathogenic. Following six additional serial passages in eggs, both NIBRG-14 and NIBRG-23 were assessed for pathogenicity in eggs and stability of HA sequence through the deleted polybasic cleavage site. Both strains grew to high titres in eggs and all embryos survived. Results of sequencing confirm that these recombinant strains do not contain the polybasic cleavage site of the original wildtype virus and has retained the mutations introduced to prevent a new site reforming.

The strains are of low pathogenicity for humans and can be used in a normal CL2 laboratory setting with controlled management. i.e. neutral air pressure, the laboratory can only be entered by appropriately trained staff and all waste is disinfected by virucidal solution (1% Virkon solution) followed by autoclaving before disposal. The work will take place in a class II safety cabinet with HEPA filtration of air prior to exhaust, staff will be offered seasonal influenza vaccination before working with the viruses and antiviral drug, as Tamiflu, will be available as prophylaxis if required.

All work with viable virus will take place in the specified laboratory. If further analysis of virus infected samples are required outside the laboratory, virus will be killed with 4% paraformaldehyde and solid materials will be wiped down with a 1% Virkon solution before leaving the laboratory.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste (both solids and liquids) will be subjected to a double-inactivation procedure to ensure 100% kill of the virus: Initial, all waste will be soaked in 1% Virkon solution for a minimum of 30 minutes before disposal in an autoclave box followed by autoclaving for a minimum of 20 min at 1210C.

Monitoring that viruses are killed 100% can be detected using a plaque assay to detect viable virus from wipe tests from solid waste or liquids, respectively.

02/03/2022
The University GM & Biosafety Committee reviewed this project proposal and associated risk assessment on the 29th September 2009 and approved the recommendation that the work be classified as Activity Class 2 and could be safely conducted in a Containment Level 2 laboratory with the recommended safety precautions.

BCL-2 family proteins are key regulators of apoptosis, a form of programmed cell death. The primary aim of this work is to investigate the function of the pro-apoptotic BIM protein in controlling apoptotic cell death. The secondary aim is to compare the function of BIM with other structurally and functionally related BCL-2 family proteins.

Virus: Lentivirus, originally derived from HIV-1. The virus is disabled and transfection of cells with the lentiviral plasmids will not result in the formation of replication competent virus.

Recipient cells: Established cell lines derived from human solid and liquid malignancies. We will also use the viruses to infect malignant and non-malignant primary human cells. Non-malignant cells will be obtained from healthy individuals or from patients with non-malignant disease. Malignant cells will be from clinical samples.

A three plasmid lentiviral system will be used. Lentiviral plasmids:
- pCMVR8.91 (containing gag/pol/rev/tat)
- pMD.G (containing VSV-g)
- pCG-H and pCG-F (containing measles virus glycoproteins hemaglutinin (H), fusion protein (F))
- plasmid encoding the feline immunodeficiency virus (FIV) coat protein RD114
- Backbone vector for expression of target siRNA or protein

Various measures have been taken to ensure transfection of cells with these lentiviral plasmids will not result in the formation of replication competent virus, as mentioned below.

This project will create replication incompetent lentivirus carrying shRNA to reduce expression or RNA to overexpress specific BCL-2 family proteins that normally act to regulate apoptosis.

BCL-2 family proteins are key regulators of apoptosis, a form of programmed cell death. Over 25 individual mammalian BCL-2 family proteins have been identified to date (listed and described in detail at BCL2DB). These proteins share primary sequence and structural homology and act together via protein:protein interactions to coordinately control apoptosis, at least in part, by regulating the release of pro-apoptotic factors from mitochondria. Individual BCL-2 family proteins act to either promote or suppress apoptosis and therefore function as potential tumour suppressors or oncproteins in malignant disease. For example, BCL-2, BCL-XL and MCL-1 suppress apoptosis whereas BIM, BAK and BAK promote apoptosis. Overexpression of certain anti-apoptotic molecules and deletion of certain pro-apoptotic genes has been shown to promote tumour formation in experimental animals.

The goal of our work is understand the functional significance of BCL-2 family proteins in cancer. Our principle focus is the pro-apoptotic protein BIM and we aim to decrease expression of BIM using RNA interference technology (using shRNA to decrease BIM RNA) or overexpress the BIM-encoding RNA to determine to what extent its expression levels modulate apoptosis susceptibility in different cell types and to understand the mechanisms by which it modulates apoptosis.
Since BIM functions as part of a family, it will also be important to consider the role of other related BCL-2 family proteins and a secondary aim will be to compare these results with those obtained by modulation of other functionally and structurally related BCL-2 family proteins. This will also involve shRNA-mediated knock-down or RNA overexpression.

Bcl-w Bok Bmf Bad
Bfl-1 Bcl7 Noxa Bnip1
Mcl-1 Bcl-rambo Puma Bnip2
Bcl210 Bfk Hrk Bnip3
BAG-1

We will also utilize viruses to overexpress CD38. This is a cell surface protein and will be used to monitor infection efficiency (following antibody staining) and as a marker to select transduced cells.

We will also utilize viruses to overexpress GFPs. These naturally fluorescent proteins will be used to monitor infection efficiency.

Evaluation of foreseeable effects

The lentivirus will be used to transfecet either siRNA or expression constructs into the CLL cells, causing either knockdown or overexpression of the proteins in the CLL cells. Various measures have been taken to ensure transfection of cells with these lentiviral plasmids will not result in the formation of replication competent virus, including the use of three physically separate plasmids and deletion of the packaging sequence on helper plasmids. This prevents helper/packaging sequences from entering fully formed virus, so the virus cannot make structural proteins and hence cannot propagate once inside the target cells. The multiple plasmid system also reduces the chances recombination into replication competent virus. The national gene vector laboratory at the National Institutes of Health has screened over 60 liters of lentiviral products and has not been able to detect any recombinant, replication competent lentivirus (recombinant DNA advisory committee guidance document, NIH 2006). The virus is self inactivating as the U3 sequence, required to prevent loss of DNA during replication, has been deleted. The 5' promoter region is lost upon replication. Additionally no pathogenic HI'V accessory proteins, such as Vif, Vpr, Vpu and Nef, required for viral RNA synthesis and processing and other replicative functions, are present. The use of alternative coat proteins also prevents recombination into replication competent virus. Heterologous envelope proteins such as VSV-g or proteins from feline immunodeficiency virus or measles virus will be used. Therefore the risk to human health is small. The genetic inserts, such as the BIM shRNA, pose a slight risk as work in experimental animals has shown that overexpression of certain anti-apoptotic molecules and deletion of certain pro-apoptotic genes promotes tumour formation. Although expressed highly in poor prognosis groups of leukemia, CD38 has not been shown to act directly as an oncprotein and is therefore considered of lower risk.

The lentivirus produced will have coat proteins compatible with entering human cells. The target cells of the study are from humans so this cannot be avoided. Therefore there is some risk associated with using this lentiviral system, though this is small, and the health and safety procedures will provide sufficient protection to workers.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste: decontamination in Trigene Advance from MediChem International (1 in 10 dilution) for 4 hours within the biosafety cabinet. Trigene has been validated for use against lentivirus. After 4 hours the liquid waste will rinsed down the sink with lots of running water.

Solid waste: Decontamination of solids waste will be by autoclaving prior to disposal as clinical waste for incineration.

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMBSC agreed that this work could safely be considered an Activity Class 2 project and carried out under standard Containment Level 2 conditions. It was agreed, contingent on the adoption of safe systems of work, that the use of 2nd generation lentiviral vectors with inserts from the BCL-2 family of proteins posed minimal risk to human health or the environment.

Project Ref  57/10.1

Date Ackn'd  19/07/2010

CU2 Project Title  Genetic transformation of Chlamydiae

Class  Class 2

CultureVolClass2  < 1 Litre

CultureVolumeClass3-4

Non-GMM  Consent Granted
### Purposes of the contained use

Genome sequencing has now provided a significant DNA resource to make the task of searching for chlamydial gene function much easier. Genomic evidence has been accumulating that chlamydia can exchange genetic information by recombination during natural infections. This has now been clearly demonstrated experimentally in the laboratory in the USA and it is now possible to transform Chlamydia using allelic exchange. However, this approach of direct transformation targeting the chromosome imposes some limitations – the unique chlamydial developmental cycle is thought to involve up to 30% of the genome coding capacity and mutations in these genes are likely to cripple the host organism and possibly render it unable to further infect cells. Our overall goals are to use and improve the recently developed transformation techniques (Binet and Maurelli, 2009 PNAS 106, 292-297) to produce simple stable vectors that can be used to study the basic genetics of chlamydial development.

### Host/vector system

We will use C.trachomatis and Chlamydophila strains, these are all classified as Hazard group 2 micro-organisms. We do not plan to genetically modify the host chromosomal DNA but to complement function with homologous genes. Our vector systems will be based on well-characterised endogenous chlamydial extrachromosomal elements: the endogenous chlamydiaphage and the cryptic plasmid.

### Recipient or parental organism

We plan to use only well-characterised, attenuated laboratory strains of Chlamydiae. Adaptation of Chlamydia to growth in cell culture causes mutations in a virulence factor attenuating the strains for mouse infectivity (and thus presumably human infectivity). There are no foreseeable effects from our proposed work that will increase the virulence of the strains in our study. We do not plan to modify the virulence attributes of Chlamydiae.

### Origin & function

In addition to the chlamydial replicon sources described under ‘host/vector’ we will include the following nonchlamydial markers (either singly or in combination): beta-galactosidase, beta lactamase, chloramphenicol acetyl transferase, the green fluorescence protein as well as other non selected markers from the chlamydial genome.

### Evaluation of foreseeable effects

This project is intended to optimise a plasmid transformation protocol for Chlamydia (mainly C.trachomatis). Success in the project will not generate a more hazardous recipient strain than already exists because the selectable markers
we want to use are not used in chlamydial treatment. However, despite its poor infectivity C.trachomatis and C.pneumoniae are exclusively human pathogens and are both categorised as hazard group 2 microorganisms; transformation to express the selectable or indeed the non-selectable markers listed above will not increase virulence of the host GMM. Thus there are no foreseeable effects that will allow the construction of GMO (GMM) that is more virulent than the original host. This risk assessment places the work at level 2 simply because C.trachomatis/C.pneumoniae are HG2 microorganisms and no increase in hazard to human health or the environment is envisaged. Thus containment and handling precautions will be the same as for the control untreated chlamydia.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virkon is the accepted treatment of choice for inactivating Chlamydiae because it has been demonstrated to destroy both vegetative bacteria and spores. Virkon is a hypochlorite based disinfectant and can be corrosive. Liquid waste will be neutralised with Virkon but then additionally treated by autoclaving and therefore finally destroyed by incineration. We will use only diposable consumables for chlamydial cultures and preparation of stocks. Thus solid waste will take the form of pipettes (1 - 20ml), micro pipette tips and general cell culture plasticware (24 and 6 well trays and flasks from T25 to T175 and tissues. All will be soaked in Virkon before being sent for autoclaving. All work handling/manipulating infected material will take place within the class 1 cabinet in laboratory LC78 and performed on impermeable, white, plastic spill-control trays. This work surface will be wiped down with freshly prepared 70% methanol prior to work commencing. At the end of each day/experimental procedure (whichever is the more frequent) the spill control tray will be wiped down with 5% Virkon. As an alternative we also have Virusolve which is a modern triamine disinfectant that destroys RNA and has been proven effective in killing clostridial spores. Virusolve is used to inactivate C.trachomatis by the HPA in the routine handling of clinical samples containing wild - type chlamydia.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The University of Southampton's GMBSC reviewed the risk assessment via electronic circulation and approved this project proposal on 16 July 2010.

Project Containment
Project Additional Information

Purposes of the contained use

The epithelial-specific integrin alphavbeta6 is not expressed on normal epithelium, but is upregulated in numerous cancers, particularly squamos cell carcinomas. We have shown previously that alphavbeta6 promotes tumour cell invasion directly, and also indirectly through modulating normal cells within the tumour stroma. This latter effect is predominantly mediated through integrin-dependent activation of TGF-beta 1. TGF-beta 1 is a pleiotropic cytokine, which is involved in many signalling pathways, and through its activation, alphavbeta6 modulated many processes associated with acquisition of a malignant cell phenotype ("hallmarks of malignancy"), including motility, metastasis, apoptosis, growth, metabolism and immune evasion. These data suggest that alphavbeta6 is an attractive tumour target: it is not expressed on normal cells, it is expressed on the cell surface and it has tumour promoting function. The aim of this study is to use lentiviral and retroviral vectors to overexpress or silence genes that mediate alphavbeta6/TGFbeta signalling, in order to gain further understanding of the biological functions controlled through these pathways.
Producer cell lines
293T Cell Line is derived from the 293 Cell Line and stably expresses the SV40 large T antigen controlled by the human cytomegalo-virus (CMV) promoter. Producer cell lines. The 293 parental cell line was established from primary embryonal human kidney transformed with sheared human adenovirus type 5 DNA.

Phoenix-Ampho HEK293T is a second-generation retrovirus producer line for the generation of helper free amphotropic retroviruses. The lines are based on the 293T cell line. The lines were created by placing into 293T cells two separate constructs capable of producing gag-pol, and envelope protein for ecotropic and amphotropic viruses.

Plasmid production
Plasmids will be propagated in E. coli K-12 strains such as DH5, JM109 and TOP10, One Shot (R) Stbl3™ which have been demonstrated to be non-pathogenic and have well-understood, stable genetic lesions in the bacterial chromosome, which render the microorganism auxotrophic and dependent upon nutrients that must be supplied in the culture media. Furthermore, these strains are often rendered incapable of colonising mammalian hosts, either due to introduced biological restrictions or sensitivity to common agents. Thus these E. coli strains are non-colonising and disabled.

Recipient cell lines
For the study of the gene function we will use panels of well-characterised cancer cell lines from head and neck cancers, colorectal cancers, pancreatic cancers, oesophageal cancers, breast cancers etc as previously.

Primary epithelial cells and fibroblasts from healthy donors will also be used as previously.

Host/vector system

A) Lentiviral (replication-incompetent)
Third generation lentiviral expression vectors contain a deletion in the 3’LTR (∆U3) that does not affect the generation of the viral genome in the producer cell line, but results in “self-inactivation” of the lentivirus after transduction of the target cell. Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing packageable viral genome.
The number of genes from HIV-1 used in the system has been reduced to three (i.e. gag, pol, and rev). The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 envelope.
Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids. All four plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus. Although the three packaging plasmids allow in trans expression of proteins required to produce viral progeny (e.g., gag, pol, rev, env) in the 293FT producer cell line, none of them contain LTRs or the ψ packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced.
The ViraPower Lentiviral System (Invitrogen) contains additional features:
Expression of the gag and pol genes from pLP1 has been rendered Rev-dependent by virtue of the HIV-1 RRE in the gag/pol mRNA transcript. Addition of the RRE prevents gag and pol expression in the absence of Rev.
A constitutive promoter (RSV promoter) has been placed upstream of the 5’ LTR in the pLenti expression vector to offset the requirement for Tat in the efficient production of viral RNA.

B) Bacterial (replication incompetent)
Second generation retroviral vectors have the genes and sequences required for retroviral production split between 3 vectors. The backbone of the retroviral vector retains only the packaging signal and LTRs between which the transgene of interest is inserted. Other genes required for synthesis of retrovirus are supplied in trans by Phoenix-Ampho HEK 293T packaging cells which have been transduced with gag, pol and env genes (expressed from 2 different inserts).
Vectors:
pBABEpuro based on the Moloney Murine Leukemia Virus (MoMuLV). Inserted genes are expressed from the MMLV Long Terminal Repeat, which has been proven to be more efficient than most internal promoters in a number of cell lines.
pMSCVpuro and pSUPER retro are vectors based on Murine Stem Cell Virus. These vectors contain a specially designed long terminal repeat (LTR) from the murine stem cell PCMV virus. This LTR differs from the MMLV LTR by several point mutations and a deletion that together enhance transcriptional activation and prevent
transcriptional suppression. As a result, the PCMV LTR drives high-level, constitutive expression of the target gene in mammalian cell lines. The pSUPER retro vector uses the polymerase-III H1-RNA gene promoter, as it produces a small RNA transcript lacking a polyadenosine tail and has a well-defined start of transcription and a termination signal, and is therefore suitable for delivery of sHRNA sequences. pSUPERIOR retro is an inducible version of pSUPER retro.

Packaging cells:
The Amphotropic Phoenix-Ampho HEK293T packaging cell line is a second generation and thus the gag, pol and env genes are expressed from 2 different inserts.

Origin & function

Genes to be expressed/silenced relate to alphavbeta6/TGF-beta signalling and related genes: The following list identifies specific genes, and likely function:

Components of the canonical and non-canonical TGF-beta signalling pathway - alphavbeta6, TGF-beta, TGFBRI, Smad, smurf, SCF/Roc, MAP kinase, NOX, nrf2, keap1, ATM, CHK, ATR, BMI1, p53 GLI1, RAS.

TGF-beta-dependent genes-thrombospondin, regulators of EMT, VEGF, Transglutaminase, PKC, caveolin alphavbeta6-dependent genes - regulators of motility, - fyn, Akt, MMPs, serine proteases, COX-2, PI3 kinase.

Regulators of alphavbeta6-dependent cell adhesion/spreading -Rho, Rac, cdc42, Rap

Regulators of alphavbeta6-dependent actin cytoskeletal rearrangement -WASP, Wave, eps8, ARP2/3, abi1, sos myosin light chain.

Regulators of alphavbeta6 function CtBP, EGRF, EP4, Talin, Kindin, Her2, clathrin.

TGF-beta dependent genes regulating the stromal response, SMA, HGF, periostin, p16, -21, FAK, fibronectin, H2AX, cMET.

Reporter genes eg Firefly and Renilla luciferase, Fluorescent proteins (EGFP, YFP, BFP, RFP). These have no molecular/physiological function.

Evaluation of foreseeable effects

The major risk in this project is from transduced (virus-producing) 293T cells (and pertains to human infections).

a) potential for generation of replication-competent lentivirus or retrovirus
b) potential for oncogenesis

a) The risk is mitigated by the safety features of these latest generation vector systems, detailed above, including:

1) Lentiviral vectors
   - separation of vector and packaging functions onto four or more plasmids
   - use of additional safety features (e.g. they do not encode Tat, which is essential for replication of wild-type HIV-1)
   - a deletion in the 3'LTR (ΔU3) that results in "self-inactivation" of the lentivirus after transduction of the target cell

2) Retroviral vectors
   - the genes and sequences required for retroviral production split between 3 vectors. The backbone of the retroviral vector retains only the packaging signal and LTRs between which the transgene of interest is inserted. Other genes required for synthesis of retrovirus are supplied in trans by Phoenix Amphi HEK293T packaging cells which have been transduced with gag, pol and env genes (expressed from 2 different inserts).

Although the virions are replication-incompetent, as an added precaution, target cells are routinely tested for production of replication competent viruses by transferring condition medium onto virgin 3T3 fibroblasts and testing for drug resistance.
b) although no single gene can induce malignant transformation in vivo, the pathways to be investigated in this proposal could be regarded as potentially oncogenic in certain circumstances (eg perhaps if expressed constitutively at high levels). Since lentiviral vectors can infect primary human cells, precaution against inadvertent infection by the user must be taken.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid Waste: Everything that contacts virus-containing solutions or vessels is decontaminated or contained before exiting the containment level 2 room. Solid waste is collected in a biohazard bag inside the tissue culture hood. Pipette tips are collected in a disposable plastic box (e.g., an empty P-1000 box), and the box closed and deposited into the biohazard bag (in the tissue culture hood) at the end of the work session. At the end of the work session, the biohazard bag is closed, sprayed with 70% EtOH, and deposited into a further biohazard bag, sealed and autoclaved, (15 ins at 121°C and ultimately incinerated.

Liquid Waste is aspirated into a vacuum flask containing appropriate disinfectant eg 1/10 volume concentrated bleach (or 1% Virkon or Klosept [10,000ppm of chlorine]). At the end of the work session, 25-50ml of concentrated bleach is aspirated through the vacuum tubing, into the vacuum flask. The vacuum flask has a final concentration of at least 10% bleach, for a minimum time of 30 minutes prior to drain disposal. Liquid waste that is not aspirated is treated with bleach, to a final concentration of at least 10%, in the hood, allowing a minimum time of 30 minutes to activate virus. Liquid thus treated is disposed to drain.

02/03/2022
The molecular pathogenesis of myeloproliferative neoplasms and related disorders

This risk assessment covers the production of amphotropic lentivirus for use in the transfection of human cell lines and human primary cells. The genes we wish to transfet will be oncogenes identified as pathogenic in MPNs and genes encoding micro-RNAs and small interfering RNAs (siRNAs). Mammalian gene products that are either wild-type or inactivated/activated by mutation will be transfected by lentiviral particles human cell lines or primary cells.

Cell lines covered by this risk assessment are restricted to those with a history of safe use, offering no known hazard to human health or the environment and therefore regarded as of low risk (ACDP hazard group 1). All will be handled at Containment Level 2.

Producer cell lines
The cell line HEK293T is derived from the 293 cell line and stably expresses the SV40 large T antigen controlled by the human cytomegalo-virus (CMV) promoter.

Plasmid production
Plasmids will be propagated in E. coli K-12 strains such as TOP10, DH5 or One Shot® Stbl3 which have been demonstrated to be nonpathogenic and have well-understood, stable genetic lesions in the bacterial chromosome, which render the microorganism auxotrophic and dependent on nutrients that must be supplied in the culture medium. Furthermore, these strains are often rendered incapable of colonising mammalian hosts, either due to introduced biological restrictions of sensitivity to common agents. Thus these E. coli strains are non-colonising and disabled.
Recipient cell lines
For the study of gene function we will use panels of well-characterised human cancer cell lines derived from leukaemias (UT-7, K562, EOL-1, HL60 and EBV-immortalised B cells), cervical cancer (Hela), fibrosarcomas γ-2A derived from 2C4), and those with a stem cell like phenotype (EML-1). Additionally, leukocytes derived from peripheral blood and bone marrow will also be used as recipients for lentiviral transfection.
Peripheral blood or bone-marrow derived primary cells are not able to survive without growth factors in vitro. However, using patient material does carry risk from undiagnosed infections (e.g. hepatitis, HIV), but the culturing of these cells will be for a minimal time duration using standard techniques widely used at WRGL at containment level 2.

Host/vector system

A) Description of the Lentiviral Expression System:

The gene of interest is cloned into a lentiviral vector, with a typical structure of:

- PRSV/5'LTR - Ψ -RRE-PCMV - Transgene - WPRE - Δ3-3'UTR

More specifically, the destination vectors proposed for use here are the pLenti-DEST vectors that are adapted for use with Invitrogen's ViraPower Lentiviral Expression system. Depending on the antibiotic marker chosen and the promoter strength, the following expression vector will be selected:

- Plenti6/V5-DEST or PLenti6-2/V5-DEST: CMV and blastidicin
- PLenti4/V5-DEST: CMV and Zeocin

Inserts (gene of interest or non-coding RNA) of up to 10kb can be packaged into the Lentiviral expression vector. The insert will originate from PCR from cDNA or DNA and will be mammalian in origin.

The packaging plasmids each carry genes which separately encode the structural and assembly units for packaging a viral genome, and allow the creation of a replication-incompetent, HIV-1-based lentivirus that can deliver the target gene to mammalian cells. The three packaging plasmids comprising the ViraPower Lentiviral Expression system are:

- PLP1: CMV - gag/pol - RRE
  The RRE signal is a HIV-1 Rev response element, and permits Rev - dependent expression of the gag and pol genes.
- PLP2: RSV - rev ORF - HIV-1 LTR
  The Rev ORF encodes the Rev protein that interacts with the RRE on pLP1 to induce gag and pol expression, and on the pLENTI6 expression vector to promote the nuclear export of viral RNA for packaging into viral particles. The HIV-1 LTR allows efficient transcriptional termination and polyadenylation of mRNA.
- PLP/VSVG: CMV - VSV-G
  VSV-G encodes the envelope G glycoprotein from VSV to allow production of a pseudotyped retrovirus with a broad host range.

B) Safety features of the Lentiviral Expression System

- The pLenti expression vector contains a deletion in the 3' LTR (ΔU3) that does not affect generation of the viral genome in the producer cell line, but results in 'self-inactivation' of the lentivirus after transduction of the target cell (Yee et al., 1987; Yu et al., 1986; Zuffrey et al., 1998). Once integrated into the transduced target cell, the lentiviral genome is separated onto four plasmids. All four plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus (Dull et al., 1998).
- Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the HEK293T producer cell line, none of them contain LTRs or the Ψ packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced.
- The lentiviral particles produced in this system are replication-competent and only carry the gene of interest. No other viral species are produced.
- Expression of the gag and pol genes from pLP1 Has been rendered Rev-dependent by virtue of the HIV-1 RRE in the gag/pol mRNA transcript. Addition of the RRE prevents gag and pol expression in the absence of Rev (Dull et al., 1998).
- A constitutive promoter (RSV promoter) has been placed upstream of the 5' LTR in the pLenti expression vector to offset the requirement for Tat in the efficient production of viral RNA (Dull et al., 1998).
Genes to be expressed/silenced relate to the pathogenesis of MPNs. The following list identifies specific genes and likely functions:

- Components of signalling pathways, including signalling intermediates (for example, JAK2, SH2B3), or cell surface receptors, (for example MPL, EPOR or integrins), or extracellularly secreted proteins, (for example EPO, SCF).
- Epigenetic proteins (i.e. histone modifiers, and demethylases, for example EZH2, SUZ12, DNMT3A,)
- Transcription factors (for example, STATs, MYB, MECOM)
- Splicing factors (for example, SH3BP1)
- Non-coding RNAs (for example, microRNAs such as miR-181a, or si RNAs against genes like EZH2)
- Reporter genes (for example, Firefly and Renilla luciferase, fluorescent proteins like GFP, YFP, RFP, all of which have no physiological function)

**Evaluation of foreseeable effects**

The major risk in this project is from transduced (virus-producing) HEK293T cells, and pertains towards personnel conducting the experiment.

a) Potential for generation of replication-competent lentivirus
b) Potential for oncogenesis.

a) The risk is mitigated by the safety features of these latest generation vector systems, detailed above, including:
- Separation of vector and packaging cell line system.
- Use of additional safety features (e.g. the vectors do not encode Tat, which is essential for replication of wild-type HIV-1)

b) Regarding accidental exposure of skin or mucosal tissue to infectious lentivirus, there is a theoretical risk of oncogenesis, caused by insertional mutagenesis or integration and expression of the gene encoded on the vector. However, there is currently no evidence that wild-type or mutant forms of the gene products listed previously are oncogenic in mucosal epithelial cells. This application does propose the transfection of mutated genes that have been shown to contribute to the initiation of MPNs, and it is conceivable that high expression of wild-type as well as mutant proteins could be potentially dangerous in the event of being delivered to the appropriate target tissue. However our current understanding is that oncogenesis would only occur if the proposed genes were integrated into a rare subset of cells within the bone marrow. It is conceivable that these sequences may have other unknown oncogenic effects. Altogether, precaution against inadvertant infection by the user must be taken.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

| N/A |

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

| N/A |

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

**Solid waste:** All items that contact virus-containing solutions or vessels will be decontaminated or contained before exiting the containment level 2 room. Solid waste is first decontaminated with 2% Virkon and left for a minimum time of 30 minutes, sealed and then collected in a biohazard bag inside a metal container beneath the tissue culture hood. Pipette tips are collected in a disposable plastic container (i.e. an empty medium bottle) and the box closed and deposited in the biohazard bag, under the tissue culture hood, at the end of the work session. Serological pipettes will be disinfected prior to removal from biosafety cabinet by placing in 2% Virkon for a minimum of 30 minutes before being transferred to the biohazard bag for disposal. At the end of the work session, the biohazard bag is sealed, sprayed with 70% ethanol, and deposited into a further biohazard bag. This is then sealed and autoclaved (10 minutes at 135 degrees with chamber pressure of 3130Mb, taking an appropriate total cycle time of 28 minutes), and ultimately incinerated.

Liquid waste is placed into a sealable plastic container (an empty medium bottle) containing ~20 ml 2% Virkon, and left for a minimum of 30 minutes, before being disposed of down the drain with plenty of water.
The original risk assessment was recorded as Activity Class 1. Members disagreed with the AC1 classification; some elements were considered to be more akin to AC2. A short critique on why the project was judged to be AC2 was sent to the PI and the researcher(s). This was then agreed by the PI and the BSA and the project was approved as AC2.

**Project Additional Information**

**Purposes of the contained use**

The experiments carried out in the laboratory involve culturing Mtb, measuring mycobacterial growth, infecting cells, harvesting supernatants and mRNA and developing 3-dimensional human granuloma models. In order to carry out these studies, Mycobacterium tuberculosis (Mtb) will be cultured and maintained in the containment level 3 facility. The primary strain used will be H37Rv. Clinical strains known to be fully drug susceptible will also be cultured within the facility, and genetically modified Mtb that are either luminescent or fluorescent will be utilised in specific experiments. No drug resistant Mtb strains will be cultured within the facility, apart from kanamycin or hygromycin resistant GMTB. These antibiotics are not used to treat patients with tuberculosis. Human cell cultures (A549 cells, primary human bronchial epithelial cells, peripheral blood monocytes, alveolar macrophages, fibroblasts and THP-1 cells) will be infected with Mtb. The supernatants of these cells and cells themselves will be analysed at specified time points after infection. For the development of 3-dimensional granuloma models, we will mix cells and live Mtb with collagen/alginate mix (50:50) and we will electrostatically generate beads to form spherules using a bead generating machine housed within the class I MSC in the TB lab. We will study the cell supernatants and cells themselves at the specified time points.

The genetically modified strains are Mtb (H37Rv) or clinically isolated strains which are fully sensitive to existing anti-tuberculosis drugs that contain fluorescent reporters GFP or mCherry and luminescent reporters from Photorhabdus luminescens, or the luciferase genes from Firefly or Gaussia princesses. The GFP strain contains pSMT3LxEGFP which a dual reporter plasmid containing fluorescent enhanced EGFP gene and bacterial luciferase. Positive clones were selected by growing on plates and media supplemented with µg/ml hygromycin. The mCherry strain contains codon optimized mCherry genes inserted into pSMT3, an E.coli - mycobacterium shuttle vector containing hygromycin resistance (pCherry3) and selected similarly as a EGFP positive Mtb (H37Rv). The plasmids in luminescent reporters are pMV306hsp+FFlucWT for Firefly luciferase, pJ201:26462 for Gaussia luciferase and pSMT3+Lux for bacterial luciferase encoding vectors. The Firefly luciferase plasmid is a pMV306hsp encoding the codon optimized for M.tuberculosis and kanamycin resistance. The bacterial luciferase contains vector containing the LuxABCDE operon from P. luminescens modified for expression for M. tuberculosis namely mc2 6030 and mc2 7000 which have deleted RD1 region, which is the main pathogenicity island of Mtb. All strains were previously reported in published articles and for this programme of work we are using the already transformed bacteria so the depth of the work is limited to the introduction of the bacteria to cell culture or monitoring the growth of bacteria following interventions.

**Recipient or parental organism**

Mycobacterium tuberculosis strain H(37)Rv and fully drug sensitive field isolated of M.tuberculosis strains (Beijing, Indo-Oceanic, Eurasian).

**Host/vector system**

- **pSMT3LxEGFP** - A plasmid based on pSMT3 Esherica coli/mycrobacteria shuttle vector and containing the human codon-optimized and fluorescence-enhanced EGFP gene from pEFP cloned under the control of the mycobacterial 19kDa protein promoter, and the luxAB genes from Vibrio harveyi under the control of hsp60 promoter. The shuttle vector has hygromycin resistance (Hygr) originally.
- **pCHERRY3** - It is developed on pSMT3 backbone with hygromycin resistance (Hygr) to give a high copy number using site-directed mutagenesis. After that, a strong promoter Psmyc was introduced to codon optimized Pshe60 and then the mCherry sequence was cloned which are codon optimized for Mtb codon preferences.
- **pMV306hsp+FFluc** - This is vector which is based on Mycobacterial integrating vector (pMV306) which holds kanamycin resistance gene (Kmr) and part of E. coli cloning vector encoding the firefly luciferase (Ffluc) codon optimized for Mtb.
- **pMV306hsp+GlucWT+SS** - This is vector which is based on Mycobacterial integrating vector (pMV306) which holds kanamycin resistance gene (Kmr) and part of cloning vector encoding the Gaussia luciferase gene including the secretion signal (GlucSS) codon optimized for Mtb.
- **pMVhsp+LuxAB+G13+CDE** - This is developed on pSMT3 backbone with hygromycin resistance (Hygr) in which the promoter Pshe60 is replaced with G13 promoter (PG13) and cloned front of luxC of LuxABCDE operon.

**Origin & function**
* **pSMT3LxEGFP** - The plasmid confers the Mtb strains to express green fluorescent proteins (GFP) under control of hygromycin resistance. GFP has excitation of 475 nm and emission of 509 nm in fluorescent microscopy.

* **pCHERRY3** - The plasmid confers the Mtb strains to express red-shifts excitation and emission maxima (558nm and 583nm respectively) protein under control of hygromycin resistance.

* **pMV306hsp+Ffluc** - The plasmid gives ability Mtb strains to express firefly luciferase (Ffluc) and emit light upon the addition of D-luciferin (benzothiazole) which can be detected at 557nm.

* **pMV306hsp+GlucWT+SS** - The plasmid confers Mtb strains to express blue light (480nm) of Gaussia princeps upon addition of coelenterazine.

* **pMVhsp+LuxAB+G13+CDE** - The strains which contain this plasmid produce light in the wavelength 490nm (blue range) without exogenously added substrate

**Evaluation of foreseeable effects**

The parent Mycobacterium tuberculosis or Mycobacterium tuberculosis derivatives which contain inserts incorporating fluorescent reporters such as GFP or mCherry, luminescent reporters such as the lux operon from Photorhabdus luminescens, or the luciferase genes from Firefly or Gaussia princeps have no resistance to clinically used anti-TB drugs. They contain hygromycin or kanamycin resistance (Himar1 and hyg-R, respectively), but these antibiotics are not used for treatment of human disease, which is treated with rifampicin, isoniazid, pyrazinamide and ethambutol. All the genes are well characterized and have been used in many applications and has no hazard arising from alteration of existing traits of the host in terms of alteration of pathogenicity, host range or tissue tropism. Therefore, the genetically modified strains of Mtb have no greater virulence than the recipient of Mtb strains.

Mtb is exclusively a pathogen of man and transfer of the plasmids/part of plasmids to other pathogens has not reported previously. The work is done in Category III laboratory and all waste for disposal will be chemically disinfected then autoclaved prior to release from the lab. The chance of GMO being transferred to other microorganisms is nil.

Despite widespread use in research laboratories, H37Rv has not caused any documented cases of tuberculosis (TB), suggesting it has become attenuated through repeated passage. Typically, Mtb is passed from person to person in a community by the droplet route and the site of infection is the respiratory tract. The creation of aerosols therefore represents the major risk to laboratory workers. The survival of Mtb in aerosols is less than 1% at 1 hour, though surviving mycobacteria can then persist in the environment for long periods. Therefore any dust particles should be regarded as potentially infectious. Live Mtb is susceptible to 70% ethanol or commonly used laboratory disinfectants (10% Surfanios, a disinfectant detergent which gives >9 log kills in 3 hours, 3% Hycolin or 3% Virkon), though secondary autoclaving after chemical disinfection is necessary to ensure sterility. The highest risk procedure here is the culturing and handling of Mtb (or its derivatives).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

* Liquid waste - 10% final concentration Surfanios treatment overnight then autoclaving in Rodwell autoclave within CL3. Surfanios (10%) was demonstrated to be the most effective detergent tested at killing Mtb in studies comparing different detergents, with a >9 log kill withing 3 hours. This may not achieve full sterility so is followed by autoclaving which will kill all Mtb. Liquid waste will include TB cultures and cell cultures.

* Solid waste - Autoclaving in Rodwell autoclave within CL3. Autoclave load temperature of 126 degree C for 30 minutes is significantly greater than the time needed to kill Mtb, so will ensue灭ility. For example, milk Pasteurisaton kills Mycobacteria completely and this is a much shorter, lower temperature treatment. Solid waste includes
culture plates, pipette tips, eppendorfs, absorbent towel, cell scrapers, falcon tubes plus waste from the lobby used for hand drying.

* Autoclavig is done using Rodwell autoclave which is exclusively used for TB work. It will have 6-monthly service visit with annual 12 calibration run, and records will be kept from each run for 6 months.

* The back-up autoclave will be in the adjacent laboratory in the CL3 suite. Therefore, if required, waste will be double contained, taken along the CL3 suite corridor (approx 3 meters) and autoclaved in next room with assistance from the CL3 suite manager.

After chemical treating and autoclaving, the waste will be placed in the hospital yellow bag waste route and will be incinerated.

Is an emergency plan required according to regulation 20? N

Project Ref 57/14.1

Date Ackn’d 30/01/2014

CU2 Project Title Use of retro viral vectors to reprogramme mammal cells cultured in vitro

Class 2

CultureVolClass2 < 1 Litre

Non-GMM Consent Granted

Date Project 02/03/2022
The aim of this research is to use patient-specific stem cell technology (1) to understand the role of genetic defect in the development of retinal degeneration; (2) to screen potential drugs for the personalized treatment; (3) to generate (induced pluripotent stem cells) iPCs using non-oncogenic factors for the treatment of retinal degenerative diseases (proof of principle study).

To do this, we will drive human and mouse somatic cells to iPSCs, using pluripotent transcription factors. Transcription factors (including Sox2, Oct4, cMyc, Klf4) will be over-expressed in mammalian cells using retroviral particles. This is a widely used iPSCs reprogramming protocol developed by Yamanaka, who won the Nobel Prize (Physiology/Medicine) for the ground-breaking discovery of iPSCs generation in 2012. Recently Yamanaka's work has also shown that these factors along with Lin28 can generate iPACs from peripheral blood cells. This low invasiveness cell/tissue collection is very attractive for clinical use. In addition, to promote cell differentiation towards retinal cells in vitro, retinal genes, such as Pax6, Crx, Otx2, Chx10, NeuroD, rhodopsin or their combination are also to be used in this study.

Recipient or parental organism
- Human cells derived from the eye, blood and skin
- Mouse cells derived from the eye and skin

Host/vector system
Moloney Murine leukemia Virus (MoMuLV) expression systems are used as vector system, which include the following features:
- All the genes required for producing full length viral RNA and packaging it into viable viral particles (gag-pol, rev and env) have been removed from the pRRL plasmids. Gag-pol and rev are expressed separately as is the VSV-G coat protein. The plasmids have been engineered so as to have no recombination sequences that would allow these genes to be inserted into the pRRL plasmid. This allows for a viral particle to be produced that can enter dividing cell, but that once inside does not have the relevant genes necessary to re-package itself or to re-generate full length viral RNA following genomic integration.
- This MuMLV retro Expression Systems used include the following key safety features:
  - The number of retroviral genes that are used in the system has been reduced to three (i.e. gag, pol and rev)
  - The VSV-G gene from Vesicular Stomatitis Virus is used in place of other retroviral envelope genes.
  - Genes encoding the structural and other components required for packaging the viral genome are separated onto three plasmids. All plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus.
  - The packaging plasmid encodes for the gag and pol proteins in trans. It also retains the minimal cis acting viral sequences necessary for packing, reverse transcription and integration. The envelope plasmid encodes for the envelope protein in trans. So, when the virus particles are assembled, the accessory genes required for subsequent viral replications are not included, therefore, making the vector replication deficient.
  - The viral particles produced in these systems are replication-incompetent and only carry the gene of interest. No other viral species are produced.

Above genetic materials are from human.
### Evaluation of foreseeable effects

Approximate 0.01-0% cells will be reprogrammed into iPSCs following infection with four pluripotent markers (such as Sox2, Oct4, cMyc and Klf4). They may exhibit embryonic-like stem cell features. The appearance of iPS colonies will be assessed following infection in the culture plates. These colonies will be subject to purification, subculture and characterisation using immunocytochemistry, RT-PCR, Western Blotting etc. The iPSCs should have the ability to retinal specific markers and exhibit relevant functionality. Cell phenotypes will be examined using immunocytochemistry, RT-PCR, Western Blotting etc. Functionality will be assessed using ion indicator, electrophysiology etc.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Cells infected with retroviral vectors may be subcutaneously or intramuscularly injected into immunodeficient mice or transplanted into the eyes of mice after continuing passaging and subculture. This will be done in a certified animal facility. The transplanted cells will be subjected to long-term culture and washed thoroughly prior to injection, thus no infectious agent will be present in the eyes or under the skin of the animals. Experimental animals will not be subjected to further breeding. No GM animal or plant will be produced in the project.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No application for any derogation from containment for the class activity

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- **Liquid waste**, such as spent media and culture supernatant, will be subjected to chemical inactivation using Virkon. This has been validated for retroviral inactivation (antec-biosentry).

- **Solid waste**, such as contaminated laboratory plastics, gloves, will be soaked in Virkon before being autoclaved and sent for incineration.

### Is an emergency plan required according to regulation 20?  N

### If yes, tick to confirm that it is attached to this form  N

### Tick to confirm that you have attached a risk assessment to this form  Y

### Tick if you are claiming exemption from disclosure for section of the risk assessment  N
Received The risk assessment

This project could be AC1 or AC2. Mr Lockey suggested that he seek clarification of some issues; he confirmed that the work would be carried out at Containment Level 2. If the project was confirmed at AC2, it would require notification to the HSE. Professor K proposed that the project be confirmed at AC2. If the researchers accepted this classification, there is no need to re-submit the project. However, if there was any dispute, the researchers would be asked to attend a meeting of the GM&BSC to put their case for a different classification.

Resolved That the project be confirmed at Activity Class 2, subject to acceptance of this by the researchers.

GMBSC meeting 21st January 2014 item 9.3 GMBSC 72 (minute 06.3)

Mr L reminded members that they had recommended approval of this project at Activity Class 2. He confirmed that the researchers had accepted the recommendation and were preparing for the HSE notification.

### Project Additional Information

#### Purposes of the contained use

Previous studies of biofilm formation in *S. pneumoniae* have shown the emergence of a sub-population of pneumococci with a small colony morphology (SCV) and distinct phenotypic differences compared to the parent strain, namely increased biofilm formation, reduced capsule production and slower growth rate. We have found that all SCV's contain mutations within the DNA-directed RNA polymerase delta subunit (RpoE). To confirm that the phenotype seen in the SCV sub-population is a direct result of the mutations this work aims to generate a ΔpoE) knockout (KO) mutant in *S. pneumoniae*.

Biofilm formation in *Pseudomonas aeruginosa* is controlled by the bacterial second messenger cyclic dimeric guanosine monophosphate, (c-di-GMP). Intracellular levels of c-di-GMP are modulated by diguanylate cyclases (DGCs) and phosphodiesterases (PDEs). Work from the PI has shown that nitric oxide (NO) plays a role in the regulation of bacterial biofilm formation through altering PDE activity. Other groups have independently described the role played by NO in signalling pathways that control the activity of PDEs. We aim to investigate the role of DGCs and PDEs in biofilm formulation, and the mechanism by which their activity is regulated by NO, targeted deletion of these genes in *P. aeruginosa*.

**Recipient or parental organism**

A clinical isolate of *Streptococcus pneumoniae* serotype 22F.

*Pseudomonas aeruginosa* PAO1 (Stover et al., Nature 406, 959-64 (2000))

**Host/vector system**

For streptococcus pneumoniae, the aim of this work is to disrupt the RpoE gene by targeted mutagenesis using a PCR mutagenesis approach. An RpoE KO will be generated via PCR ligation mutagenesis (PLM) by allelic replacement as previously described (Lau et al PCR ligation mutagenesis in transformable streptococci: application and efficiency 2001). This method of mutagenesis requires no vector construct. The KO construct will be generated by PCR amplification and ligation of regions of homology approximately 500 bp 5' and 3' of the RpoE gene. These regions of homology will include approximately 120bp of the RpoE gene to ensure specificity. The 5' and 3' regions of homology will be ligated using Acl and FseI, respectively, either side of a erythromycin cassette. Once generated the cassette will be transformed into a clinical isolate of *S. pneumoniae* serotype 22F isolated during an on-going carriage study at University Hospital Southampton.

For *Pseudomonas aeruginosa* two methods will be used - insertional mutagenesis, and allelic replacement as described below:

1. We plan to make use of a commercially available library of transposon mutants for *P. aeruginosa* (Jacobs MA, et al. Comprehensive transposon mutant library of P.
eurigonsa. Proc Natl Acad Sci USA 100, 14339-44, 2003). This is held at the University of Washington Department of Genome Sciences. The library was created using transposons ISphoA/hah (4.83 Kb) andIslacZ/hah (6.16 Kb), derived from the ISSOL element of transposon Tn5 and generate alkaline phosphatase (phoA0 or beta-galactosidase (lacZ) translational gene fusions where inserted in a target gene in the appropriate orientation and reading frame. The transposons contain the tetracycline resistance gene tet. The mutants are shipped on antibiotic free medium without selection, but on receipt will be maintained on media containing tetracycline.

2) Allelic replacement. The allelic replacement strategies that we will use to make mutations in genes for NbdA, FimX, MucR and BifA, as examples the genes listed in Appendix 1 are described in the supplementary documents. The protocols outlined are derived from previously published descriptions of mutagenesis of these genes as described, and it is anticipated that one or more of the strategies identified will be appropriate to knock out any of the DGC or PDE-coding genes listed in Appendix 2. The knockout constructs will be electroporated into wild-type P. aeruginosa.

Origin & function

We will use vectors and knockout strategies, as previously published for the deletion of the P. aeruginosa DGC and PDE-containing genes: pGEM T-Easy, PEX100T, pEX18, pFLP2, pS858. See addended documentation for further information and source references.

For Streptococcus pneumoniae the erythromycin gene cassette will be obtained from the pCR2-ΔrpoE plasmid as previously described (Xue et al. Lack of the delta subunit of RNA polymerase increases virulence related traits of Streptococcus mutans, PlosOne, vol6, issue 5, 2011)

We will also make use of antibiotic resistance elements for the purpose of i) disruption of the target genes described and ii) to provide a selectable marker to confirm the successful generation of mutant strains.

The function of the genetic material is to disrupt the gene function of the target genes to better understand their role within the organism and to provide a selectable marker.

Evaluation of foreseeable effects

Introduction of an erythromycin cassette into a clinical S. pneumoniae strain introduces a source of antibiotic resistance. Introduction of gentamicin or tetracycline resistance into P. aeruginosa introduces a source of antibiotic resistance.

There are no expected changes to the hazards associated with these organisms other than in acquiring the antibiotic resistance genes. In S. pneumoniae, the delta subunit of RNA polymerase RpoE is thought to play a role in environmental adaptation and stress response regulation, and therefore deletion of RpoE is likely to be deleterious for the survival and pathogenicity of the organism (reduced human hazard). While few studies have examined RpoE function in S. pneumoniae, other work has shown that inactivation of RpoE in the human dental caries pathogen Streptococcus mutans causes impaired growth and loss of important virulence traits, including biofilm formation, resistance to antibiotics, and tolerance to environmental stresses (Xue et al. The delta subunit of RNA polymerase, RpoE, is a global modulator of Streptococcus mutans environmental adaptation, J bacteriol 192, 19, 2010), although can also lead to an increase in some virulence-linked traits including a broader substrate spectrum (Xue et al. Lack of the delta subunit of RNA polymerase increases virulence traits of Streptococcus mutans, PlosOne, vol 6, issue 5, 2011). Further work in other species including Bacillus subtilis and Streptococcus agalactiae have shown RpoE mutants to have increased sensitivity to killing in whole-blood bacteriocidal assays, suggesting attenuated virulence (Jones et al The Delta subunit of RNA polymerase is required for virulence of Streptococcus agalactiae vol 71 issue 7 Infect Immun 2003). However the relevance of these findings to S. pneumoniae has not previously been investigated.

For P. aeruginosa, certain virulence-associated traits are controlled by multiple DGCS and PDEs through alterations in c-di-GMP levels. There are numerous studies from many laboratories worldwide demonstrating that insertions in different DGC and PDE genes result in distinct phenotypes, including alterations to motility and biofilm formation (e.g,Kulasakara et al., 2006. Analysis of Pseudomonas aeruginosa diguanylate cyclases and phosphodiesterases reveals a role for cyclic-di-GMP in virulence. PNAS vol. 103 pp 2839-2844). In the latter study, a set of P. aeruginosa mutants in DGC- and PDE-encoding genes exhibited attenuated virulence in a mouse infection model. In this study, we will examine mutations in the genes previously studied by Kulasakara et al., (2005) for alterations in their ability to respond to NO during the process of biofilm dispersal.

Although there may be a risk of interspecies transfer, the knockout constructs used are thought to be low-risk as described above. All work is undertaken in a containment...
level II laboratory. The knock-out strategies employed are commonly used for other Streptococcus pneumoniae and Pseudomonas aeruginosa GM Studies.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

This work will not involve the use of GM animals or plants.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

All work with HG2 organisms will be carried out in a containment level II laboratory. No derogation is required.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All GM waste will be discarded in clearly labelled GM DispoSafe jars and autoclaved at 121°C and subsequently incinerated according to the University of Southampton local code of practice:

- **Solid waste** - sterilisation by autoclaving (double-bagged in clear autoclave bags or DispoSafe jars with lid loosely attached and placed in a clear autoclave bag (followed by disposal in yellow bin bags into yellow Eurocart).

- **Liquid waste (small volumes)** - collection onto absorbent material, sterilisation by autoclaving (double-bagged in clear autoclave bags or DispoSafe jars with lid loosely attached and placed in clear autoclave bag) followed by disposal in yellow bin bags into yellow Eurocart.

- **Sharps** - placed in orange or yellow lidded sharps bins, sterilised by autoclaving, tagged and placed in yellow Eurocart.

All uncontaminated waste (paper hand towels, outer packaging, etc) will be placed in black bin bags and taken to purple Eurocart.

Any Bacterial spills will be disinfected with 70% Ethanol and absorbent qirls bluw roll before discarding as GM waste. Bacterial liquid culture or solid medium, will be autoclaved at 121°C and subsequently discarded according to the University of Southampton local code of practice:

If spill is of a large volume (over 100 ml) and involves an aerosol forming agent and is outside of a MSC, vacate the laboratory and prevent other users from entering. Spill can then be cleaned providing a respirator is worn to protect from aerosol risk (this would be done by a specialist contractor). However, large volumes of such agents are not planned and risk assessments detail how aerosol producing agents must be securely contained prior to being removed from a MSC.

All other cases, use absorbent material (such as blue roll) to soak up the spill. This material should then be treated as contaminated solid waste. Surface will be decontaminated with 70% Ethanol.

Please enter comments on the GM safety committee on the risk assessment
GM risk assessment GMBSC/0080 was sent to GMBSC members by email for review prior to the next meeting on the 13th May.

The GMBSC had the following question:

"Are the antibiotic resistance genes being introduced ones that can be found in wild isolates or are there the group creating S. pneumoniae and P. aeruginosa strains with new antibiotic resistance profiles nor normally seen? If it is the latter it would be good to see justification for why they have chosen the resistance genes they have."

The response from the researcher was as follows:

For Streptococcus pneumoniae, an erythromycin gene was selected because the strain to be transformed is both phenotypically and genetically sensitive to erythromycin (MIC 0.06 µg/ml) and previous work has used erythromycin as a selectable marker for this organism. Erythromycin resistant clones are found in the wild so we are not creating an new antibiotic profile here for Streptococcus. Likewise, for Pseudomonas aeruginosa, we have selected antibiotics (Gentamicin and Tobramycin) to which our laboratory strain is normally sensitive, which are used widely as slectable markers for genetic studies in P. aeruginosa, and for which P. aeruginosa strains with resistance to both Gm or Tb have previously been reported to occur naturally in a variety of environmental and clinical settings.

The GMBSC approved the project as AC2 by email and this approval will be officially noted on the minutes of the next GMBSC meeting on 13th May.

### Project Ref 57/14.3

**Date Ackn'd** 22/07/2014

**CU2 Project Title** Investigating the pathogenesis of infection with Neisseria species

**Class** Class 2

**CultureVolClass2** ≤ 1 Litre

Non-GMM Consent Granted

Project notified under transitional arrangements N

**Withdrawn** N

Tick if notifying a connected programme of work N

**Historical Significant Changes**

**Historical Date of Additional Info**

02/03/2022
The aim of this programme is to investigate the pathogenesis of neisserial infection by studying bacteria both in culture and interacting with eukaryotic cells. Overall, we aim to identify and characterise bacterial interactions with eukaryotic cells and the concomitant cellular responses made by eukaryotic cells to the presence of infection. We aim to improve our basic scientific understanding of the mechanisms of sepsis-inducing diseases.

**Recipient or parental organism**

**Neisseria gonorrhoeae**: Strain FA1090, Strain MS11; Strain 1291, Strain 35/02, Strain DGI18, Strain FA6140, Strain FA19, Strain PID18, Strain PID1, Strain PID24-1, Strain PID332, Strain SK-92-679, Strain SK-93-1035, Strain DG12, Strain F62 and mutant derivatives thereof. See: [http://www.broadinstitute.org/annotation/genome/neisseria_gonorrhoeae/GenomeDescriptions.html#Ng_1291_V1](http://www.broadinstitute.org/annotation/genome/neisseria_gonorrhoeae/GenomeDescriptions.html#Ng_1291_V1) for derivation information.

**E. coli**: Strains of E. coli to be used are all derivatives of the disabled K12 strain (e.g. Dh5-alpha, JM-series, TG-1, C600, XL1-Blue and K12 strain AW405, a chemotactic, motile variant of K12. The exception is BL21, which will be used for high-level expression of some genes. BL21[DE3] is considered inherently safe, in the sense that it is broadly equivalent to K12, and offers no additional risks to the use of K12 derivatives.

**Salmonella enterica sv. Typhimurium**: Strains of S. enterica sv. Typhimurium to be used include: Strain LT2/SGSC1412/ATCC 700720, SL1344 NCTC 13347, D23580, DT104 NCTC 13348, DT2

None of the GMOs are anticipated to have increased pathogenicity over the wild type strains. All strains of pathogenic Neisseria and any genetically-modified Neisseria lactamica will be handled as a Category II pathogen regardless of resistance phenotype. Non of the antibiotics to which the GMOs are resistant are used clinically to treat Neisseria/Salmonella infection.

pGCC4 and derivatives: A plasmid for use in complementing mutations using the NICS (Neisseria intergenic complementation site) system. Inserts a functional copy of the gene ectopically at an unlinked chromosomal locus between the lctP and aspC genes under the control of lac regulatory sequences, and linked to an Erythromycin (Ery) resistance cassette.

pEN11 and derivatives: A plasmid based on the pFP10 E.coli/Neisseria shuttle vector containing the origin of replication of a naturally occurring gonococcal plasmid, a lac-derived promoter and ribosomal binding site of the highly expressed omp85 gene, plus Ndel and AatII sites for subcloning of any ORF. The shuttle vector has chloramphenicol (Cam) resistance.

Homologous genetic material to be (re) introduced:

   A comprehensive list of putative virulence-associated genes (Table 1 therein) and potentially phase variable genes coding for proteins responsible for the interaction of Neisseria meningitidis with eukaryotic cells (Table 2 therein) are included in this Reference. NB: Gene nomenclature provided refers to MC58 complete genome sequence, though Ng. and NI. Homologues can be accessed online:
   FA 1090: http://microbes.ucsc.edu/lists/neisGono_FA1090_1/refSeq-list.html
   MS11: http://www.broadinstitute.org/annotation/genome/neisseria_gonorrhoeae/GenomesIndex.html
   ST-640: http://www.xbase.ac.uk/genome/neisseria_lactamica-y92-1009
   Where appropriate, homologous genes in Salmonell enterica sv. Typhimurium will be targeted:
   http://bacteria.ensembl.org/salmonella_enterica_subsp_entnerica_serovar_typhimurium_str_ltt2/Info/Index

   Members of the Neisseria meningitidis nssR regulon (Table 2 therein). These genes are de-repressed in response to high concentrations of nitric oxide such as those encountered under conditions of nitrosative stress. They function to promote survival of the bacterium under these conditions. Gene nomenclature provided refers to MC58 complete genome sequence: see online resources above for Ng. and NI. Homologues.

   Members of the Neisseria meningitidis fur modulon (Fig 2 therein). The expression of these genes is modulated by the availability of free iron, a process involving the Ferric Uptake Regulator (Fur protein. Gene nomenclature provided refers to MC58 complete genome sequence: see online resources above for Ng. and NI. Homologues.

Heterologous genetic material to be introduced:

Codon-optimised (Neisseria) enhanced Green Fluorescent Protein (eGFP) from Aequoria victoria and derivatives, such as mCherry, which are designed to fluoresce at different wavelengths.

Luciferase from Firefly and Renilla reniformis
lux gene operon from Vibrio fisheri bacterial species
B-galactosidase from E.coli
Bacteriophage T7 RNA polymerase gene
FLP Recombinase (and derivatives), originally isolated on the 2 micron plasmid from yeast
Bacillus subtilis levansucrase; SacB
Transposon Tn10 tetracycline responsive repressor protein; tetR
Neisseria meningitidis: The sole biological reservoir of Neisseria meningitidis is the human nasopharynx, and between 10-30% of a given population is carrying the organisms as a nasopharyngeal commensal. The transmission of Neisseria meningitidis is through droplet inhalation and via close contact with carriers of the bacterium. Large increases in the number of carriers in a population typically precede an epidemic outbreak. The incidence of cases of invasive meningococcal disease is relatively small, with less than 1000 cases of disease per annum in England and Wales. A majority of these cases are caused by serogroup B strains of Nm, which express a non-immunogenic polysaccharide capsule. The number of cases is predicted to decrease further however, following the advent of multivalent protein vaccines derived from invasive serogroup B strains. Invasive meningococcal disease is a rapid onset, potentially fatal infection characterised by sepsis syndrome: including microcirculatory collapse, multiple organ failure and death in approximately 8% of cases. Symptoms of meningococcal disease involve lethargy, fever and vomiting, aversion to light, sore neck and headache in the early stages, though not all cases present with all symptoms. In cases of meningococcal septicaemia, there is the development of a petechial and purpuric rash and death can occur within as little as 4h. Between 5-30% of survivors of meningococcal disease have significant neurological sequelae. Laboratory workers manipulating high numbers of meningococci are at risk of becoming colonised. If colonised with a disease-causing strain, there is a risk that the organism will cross the nasopharyngeal epithelium and cause invasive meningococcal disease. Humans vary greatly in their susceptibility to invasion and disease, but the risk of disease, given colonisation with a hypervirulent lineage of serogroup B or C ranges from 1:10,000 - 1:100,000. The laboratory serogroup B strain Neisseria meningitidis MC58 was originally isolated from a patient in the Gloucester area in 1991 (Mcguines et al. (1919) Lancet. 1991Mar2;337(8740):514-7). Untyped isolates obtained from participants in either of the two human lactamica carriage studies conducted by the Read group are, by definition, carriage isolates and are no more likely to cause invasive meningococcal disease than any other strain used in these studies. Clinical treatment of meningococcal disease involves injection of cephalosporin antibiotics, to which MC58 and its GMO derivatives remain sensitive.

Neisseria gonorrhoeae: The gonococcus is sexually transmitted and can colonise the genital tract and the oropharyngeal mucosa. Occasionally it may cause a conjunctivitis in babies when the mother is infected. It is exclusively a human pathogen. A laboratory worker could theoretically become infected if they auto-inoculated the oropharynx or genital mucosa. The infection could then be passed on with high efficiency to their sexual contacts. The laboratory strain MS11 was originally isolated by J S in the 1960's from an uncomplicated infection, whilst FA1090 is a serum-resistant proline-requiring strain isolated from a patient with disseminated gonococcal infection.

NB: Neisseria species - The inserted gene products do not carry additional pathogenicity or virulence factors that would increase the overall pathogenicity of GMO strains beyond that of the wild type.

Salmonella enterica sv. Typhimurium: Salmonella enterica sv. Typhimurium is an intracellular pathogen, causing a non-fatal morbidity in infected humans and a typhoid-like illness in mice. Infections with Salmonella begin by ingestion of the bacterium, where different studies have shown a median infective dose in humans ranging from 200-10^6 bacteria, depending on the strains used and the immunological competence of patients. Infection of humans with nontyphoidal Salmonella typically results in a self-limiting gastroenteritis, with symptoms emerging between 6 to 48 h after ingestion and characterised by nausea, vomiting and diarrhoea. Preence of fever is not clinically useful, but may occur - with increased likelihood of fever in immunocompromised individuals, who are also more at risk of developing enteric fever or Salmonellosis. Standard therapy for uncomplicated typhoid consists of 15 mg/kg day of a fluoroquinolone such as ciprofloxacin or ofloxacin, administered orally for 5 to 7 days. As such, introduction of antibiotic resistance genes into Salmonella for the purposes of selection do not pose an increased clinical risk, beyond the further dissemination of these genes to other intestinal commensals.

Echerichia coli: E.coli K12 and its derivatives are multiply disable and are designated as Class 1 organisms. Good microbiological practice will be followed when using these organisms. For protein expression in E.coli we will preferably use BL21[DE3] or B21[DE3]pLysS and its derivatives as expression strain of choice. This strain is essentially equivalent to K12 (Chart et al. (2000) J. Applied Microbiol. 89: 1048-1058). It is believed to be unlikely to colonise and establish a persistent infection in the gut of a healthy individual. Overall, E.coli is considered inherently safe.

NB: Escherichia coli: The vectors proposed for use in cloning neisseria genes are non-mobilisable. Sequences of neisseria DNA inserted into cloning vectors will not increase the pathogenicity of E.coli.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

As meningococci are passed from person to person by the droplet route and the site of colonisation is the human nasopharynx, the creation of aerosols represents the major risk to laboratory workers. Infection with Salmonella enterica sv. Typhimurium requires the bacteria to be ingested, so Good Laboratory Practice should preclude infection. All Neisseria are acutely susceptible to common disinfectants (Kendall, A. I. (1928). The Meningococcus-Gonococcus group. Bacteriolog: general, pathological and intestinal (3rd ed., pp. 292-309)) and are fastidious organisms that do not survive for long outside of their biological niche. Neisseria can be inactivated by exposure to 1% sodium hypochlorite, 70% ethanol, phenotics, 2% glutaraldehyde, formaldehyde, and peracetic acid (Rutala, W. A. (1996). APIC guideline for selection and use of disinfectants. American Journal of Infection Control, 24(4), 313-342), and 1% Virkon, although secondary autoclaving after chemical disinfection is necessary to ensure sterility.

Contaminated plasticware such as tips, spreaders and inoculating loops will be disinfected with 2% Virkon solution overnight before decanting into suitable labelled "Biological Hazard" bins (blue) for movement to the HPS autoclave on Level A, Southampton General Hospital. Contaminated petri dishes will be placed in the same tins with the lids on: colonies of Neisseria on culture plates are not robust and will expire outside of the CO2 incubator overnight.

Decanted, infected supernatants will be chemically disinfected with 2% Virkon overnight. Autoclaving will result in 100% kill of potentially infectious agents.

Please enter comments on the GM safety committee on the risk assessment
GMBSC Meeting 15th October 2014 item 10.4 GMBSC 52 - Investigating the pathogenesis of infection with Neisseria species (Medicine)

Received The risk assessment

Mr L explained that the researcher was waiting for approval. The laboratory was already set up for what would be a long-term GM and a non-GM project. The HSE had been notified in respect of work at a previous university, but further notification was required, as this was a change of premises and a new employer. Mr L suggested that this was an AC2 project, and would be notified to the HSE as required for biological agents under Part 1 of schedule 3 of the COSHH regulations. He proposed to audit the project in a year's time.

Members had a query over a statement of keeping a 'door closed' and also the use of both white laboratory coats and blue surgical gowns. The project was approved subject to satisfactory responses to these queries.

Resolved That the project be approved as Activity Class 2 subject to satisfactory responses to the queries (action: Mr L). [Post meeting note: The risk assessment has been changed to reflect that at CL2 the door must remain closed and that the staff will wear oversleaves while working in the MSC instead of using two different lab coats.]

GMBSC Meeting 21st January 2014 item 11 Project amendment: GMBSC 52

Received The amended risk assessment.

Mr L reminded members that this project had received GMBSC approval at AC2 in January 2013 but work had not started as the researchers were waiting to submit an amendment to the original risk assessment before notifying the HSE. The researchers had submitted an amended risk assessment of which the only difference from the original was the addition of a new bacteria; this would be of the same nature as the one in the original risk assessment, the amendment could be notified at the same time if approved today.

GM&BSC was content to approve the amendment at AC2 but asked for a list of the genes contained in the risk assessment to be circulated. Subject to this circulation, the amendment was approved and the project could go forward for HSE notification.

Resolved That the project amendment be approved at Activity Class 2, and a list of the genes contained in the risk assessment to be circulated.

Project Ref 57/14.4
The use of lentivirus to investigate phosphoinositide metabolism and function

Phosphoinositides are lipids that function as messenger molecules that control various cellular functions such as membrane trafficking and endocytosis and in doing so impact on cell proliferation and apoptosis. These lipids are also present in the nucleus where their function is not completely understood. We will use attenuated lentiviral transduction vectors to knockdown or overexpress genes that modulate the levels of phosphoinositides or that might act as downstream targets. In this manner we expect to understand how signalling through phosphoinositides impacts on cellular functions that are relevant to human diseases such as cancer, neurodegenerative and myopathies.

Well established human and mouse cell lines.

HIV derived lentiviral vectors
PLKO1 and 2, and pRRL backbone
Overexpression vectors based on promoters driven by EF1a

The genetic material has either been chemically synthesised and amplified using PCR and then cloned into suitable vectors. Alternatively the genetic material was amplified from established mouse or human cell lines and then cloned in appropriate vectors.

The genetic material is aimed to
1. Suppress the expression of endogenous genes in murine or human cell lines in order to establish their functional properties.
2. To modify human and mouse cell lines in order to overexpress fragments, mutants or whole proteins in order to establish what their functional role in cells might be.
3. To identify novel targets that might be useful for the development of therapeutic molecules to treat human diseases.
Evaluation of foreseeable effects

We expect that genetically modifying cell lines with the vectors described above will lead to:
1. Increased growth characteristics
2. Suppression of growth and the induction of cell cycle arrest or apoptosis
3. Effect differentiation of cells down different cell lineage pathways
5. Change morphological characteristics.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

We will not modify plants or animals but will modify well established mouse or human cell lines. All studies with these cell lines will be carried out in a containment level 2 facility. Hazards to human workers from the GMO are minimal and are limited to ingestion or percutaneous injection of the cell lines. Even in this unlikely event the immune system and the foreign environment will likely prevent any further growth. Possible local inflammation from percutaneous injection can be effectively monitored and controlled. Genetic transfer from the modified cell line is gag, pol genes as well as VPR, VIF, VPU and NEF (required for immune host evasion), and require co-transfection of other plasmids for the generation of competent virus.

Controls in place.
1. No needles will be used with the genetically modified cells thereby minimising the likelihood of percutaneous injection.
2. All studies will be carried out in a class 2 microbiological safety cabinet in a secure room (access to the laboratory is restricted and training is required to gain card access).
3. Aerosols and splashes will be minimised by using good laboratory practice and minimal use of centrifuges.
4. Spills will be cleaned immediately with 1% VIRKON
5. All tissue culture usage will be decontaminated by VIRKON and by autoclaving.
6. Personal protective equipment is mandatory in this laboratory and includes a change of laboratory coat when entering, and the use of safety glasses and gloves.
7. Hand washing facilities are present.

For only GMMs - application for any derogation from full containment for the class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste from either the GMM or the GMO will be treated with 1% VIRKON disinfected for 2 hours. Solid waste (cell culture lactic) will be treated with 1% VIRKON and then double bagged and autoclaved at 121 degrees for 15 minutes. Tissue waste will be double bagged and autoclaved.

Both the GMM and the GMO are susceptible to killing by either 1% virkon or by the use of 70% ethanol. Accidental splashes will be contained by wiping with tissues and 70% ethanol followed by Virkon (1%) disinfectant. All tissues used for clean up will be immediately placed in biohazard bags for decontamination by autoclaving. After treatment with VIRKON and Autoclaving the final solid waste will be placed in the normal waste disposal. The liquid waste after treatment with VIRKON will be disposed of in the drainage system.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
GMBSC meeting 14/10/14
That the project be approved in principle at Activity Class 2, subject to clarification of containment level of the lab and evidence of a code of practice in place for the lab. Official approval to be suspended until these concerns are resolved.

The laboratory was reviewed confirmed as CL2 by the University BSA on 31/10/14. The local code of practice has been reviewed with regard to the new AC2 project and circulated to all users.

Approval given by the University BSA prior to the next GMBSC meeting on 13/1/15

### Project Ref 57/15.1

- **Date Ackn'd**: 06/05/2015
- **CU2 Project Title**: The pathogenesis of bacterial infection and development of vaccines
- **Class**: Class 2
- **Culture Vol Class**: < 1 Litre
- **Consent Granted**: Non-GMM

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

### Project Additional Information

02/03/2022
The generation and use of several GMOs are as follows:

1. We will generate Neisseria meningitidis strains containing individual gene deletions through insertional inactivation with non-clinically utilised antibiotic resistance cassette(s). The genes of interest are those that have been identified as important for pathogen interactions with eukaryotic cells and genes regulating or contributing to neisserial virulence and/or pathogenesis. For example, we will generate knock-out organisms that lack the adhesin complex protein (ACP), macrophage infectivity potentiator (MIP) proteins, ABC transporter proteins amongst others and also the corresponding knock-in strains [Hung et al., 2011, 2014]. It is anticipated that other genes with known function will be deleted in Neisseria spp. These genes can be found in the published genome sequence(s) and are also mentioned in our proteome studies (Williams et al., 2009, 2014).

2. Generation of green fluorescent protein-containing Neisseria species, Pseudomonas spp and E. coli spp (for plasmid maintenance). GFP-Neisseria will be produced according to the paper of Christodoulides et al (2000) and GFP-Pseudomonas will use the plasmid from Alice Prince, Columbia University, New York. We will also acquire several strains of PAO-1 and PA14 that are deficient in expression of pili, flagellae and type-1 III secretion systems. These reporters will be used in human cell infection experiments to investigate bacterial interactions. PA-14 strains will be provided by Prof. George A. OToole of the Geisel Schoof of Medicine at Dartmouth; and PAO-1 GFP strains by Professor Tolker-Nielsen in Copenhagen, Denmark.

3. We will also construct E.coli strains using commercially available cloning and expression vectors for the production of recombinant proteins for vaccine studies [Phillips et al., 2013]. In addition, reporter gene-fusions, e.g. for beta-galactosidase or other defined enzymes will be made in order to quantify the expression of pathogenesis-associated gene(s) during experimental infection or growth.

4. Strains of Streptococcus agalactiae, deficient in several virulence factors will be provided by Or. Kelly Doran, San Francisco, USA. They include mutants that do not express beta-haemolysin/cytolysin, lagA, CiaR, PilB, Srr-1 components. Selective antibiotics for these mutants are chloramphenicol and kanamycin. These strains are all susceptible to drugs used to treat clinical infection and will be used to study host cell-pathogen interactions in vitro.

5. Strains of Haemophilus influenzae and Staphylococcus aureus will be sourced (from ATCC or collaborators) for ex vivo infection studies as future projects are developed in respiratory disease and skin infection.

The experiments to be done involve i) culturing bacterial pathogens, ii) measuring bacterial growth in the presence and absence of additives/anti-microbials iii) infecting human cell cultures and tissue explants, iv) harvesting supernatants and developing appropriate models to investigate bacterial interactions with human cells in vitro v) generating recombinant pure bacterial proteins in heterologous host (E.coli) for investigating vaccine potential and for structure-function studies. For this programme, all bacterial pathogens named will be grown in LC91 containment level 2 laboratory, Molecular Microbiology, Level C, South Laboratory and Pathology Block, Southampton General Hospital.

Recipient or parental organism

1. Neisseria meningitidis strains MC58, MC58.6.SiaD (Cap-), Opa+/-, Pil+/-, Opc+/-, ACP+/-, MIP+/- and other derivatives phenotypically selected.
2. Neisseria gonorrhoeae Strain P9, FA1090, MS11 (and phenotypic variants selected).
3. Escherichia coli BL21 (DE3), DH5α, TOP10 and TOP10F, JM109; K1; IH3080
4. Pseudomonas aeruginosa PAO-1, PAO-1 tn7-GFP, flimtn7-GFP, pilAtn7-GFP, flim pilAln7-GFP, PA14-GFP (pUCP19)
6. Streptococcus agalactiae strains A909; H36B; 18RS21 ; NEM 316; 2603V/R; COH-I; COH-1 HY106; NCTC 10/84, strains mutated in CytE, Srr-1, Pi IS; lagA, CiaR.
7. Haemophilus influenzae HiS (Pillman type strain)
8. Staphylococcus aureus ATCC strain(s), e.g. Newman.

Host/vector system

1. pRSET A plasmid (Invitrogen, UK) - maintained in E. coli DH5α (Invitrogen, UK) will be used for cloning a gene encoding MIP (Macrophage Infectivity Potentiator Protein), Adhesin Complex Protein (ACP) and other vaccine antigens; E. coli BL21 (DE3)/pLysS (Invitrogen, UK) will be transformed by recombinant pRSET A for protein expression.
2. pGEM®-T Easy Vector System I (Promega, UK) - E. coli TOP10 (Invitrogen, UK) will be transformed with this vector carrying 6.mip-kanamycin construct, this plasmid will be used to create N.m. Mess .6.mip mutant (with pTOPO kanamycin cassette inserted). The same process will be used for other knock-outs e.g. ACP, and other genes.
3. pGCC4 plasmid (personal communication, UK) - E. coli TOP10 (Invitrogen, UK) will be transformed with this vector, N.m. MC58 .6.mip mutant will be transformed with this plasmid to obtain the complemented strain N.m. MC58 .6.mip(mip). The same process will be used for generating other complemented strains.
4. pTOPO plasmid (Invitrogen, UK) - source of the kanamycin cassette for constructing of the N.m. MC58.6.mip mutant; pACYC177 plasmid (New England Biolabs, UK) - alternative source of the kanamycin cassette.
5. pEN11 and derivatives: a plasmid based on the pF10 E. coli/Neisseria shuttle vector containing the ORF of a naturally occurring gonococcal plasmid, a Lac-derived promoter and ribosomal binding site of the highly expressed OMP85 gene, plus Ndel and AattI sites for subcloning of any ORF and chloramphenicol resistance.
6. pUCP19-GFP; P9-cryptic plasmid-GFP.
7. pET-24a-d(+). The pET-24a-d(+) vectors carry an N-terminal T7’Tag® sequence plus an optional C-terminal His’Tag® sequence. These vectors differ from pET-21a-d(+) only by their selectable marker (kanamycin vs. ampicillin resistance).
8. Pseudomonas aeruginosa complementation: PA14 .6flgk pUC19-f1gK; PA14 fipop8, pUC19-popB; and also the PA14 .6.f1gK pUC19 and the PA14 .6.popB pUC19.

Origin & function

1. MIP (Macrophage Infectivity Potentiator) gene will be inserted into N.m. MC58 .6.mip mutant to obtain a complemented strain reverting to the wild-type N.m. MCS8 strain in functionality; this gene encodes for MIP protein, which is a surface exposed lipoprotein in N.m., a bacterial pathogenicity factor.
2. ACP (adhesin complex protein) gene will be inserted into N.m. MC58 MC7 mutant to obtain a complemented strain reverting to the wild-type N.m. MCS8 strain in functionality; this gene encodes for ACP protein, which is a surface exposed protein in N.m., a bacterial pathogenicity factor. For both MIP & ACP, a kanamycin cassette will be inserted into N.m. MC58 for selection purposes (provides the resistance to kanamycin antibiotic). Also an erythromycin cassette will be inserted into N.m. MC58 for selection purposes (provides the resistance to erythromycin antibiotic).
4a) Aequoria victoria Green fluorescent protein (GFP) and newer derivatives, e.g. mCherry, which are designed to fluoresce at different wavelengths. b) Luciferase from Firefly and Renilla reniform is. c) Lux gene operon from Vibrio fisheri bacterial species. d) E. coli β-galactosidase enzyme. e) Bacteriophage T7 RNA polymerase gene. These will be introduced into bacteria for imaging and selection purposes.
5. For bacteria belonging to genus Streptococcus, Haemophilus, Staphylococcus, Pseudomonas for which mutants will be provided by collaborators, no further genetic manipulation is expected.

Evaluation of foreseeable effects

Due to removal of virulence-associated genes, none of the GMOs will have increased pathogenicity over the wild type strains. The bacteria and strains that carry induced gene-deletions are attenuated, i.e. they show a reduced capacity to interact with human cells. Any inserted gene products (for complemented strains) will not carry additional pathogenicity or virulence factors that would increase the overall pathogenicity of GMO strains beyond that of the wild type organisms. Furthermore, bacteria that carry GFP plasmids will be similar to wild-type organisms; in our experience, these GFP-bacteria show no difference to wild-type organisms with respect to host cell interactions. All strains of pathogenic Neisseria and other Class II organisms are handled as hazard group 2 pathogens, regardless of their resistance phenotype. None of the antibiotics to which the GMOs are resistant are used clinically to treat infections caused by these bacteria. Risk assessments for handling bacteria have been conducted and below are descriptions of the pathogens and potential outcomes of infection. With appropriate risk assessment and good microbiology practice, and where all materials are chemically killed and then autoclaved, the possibility of GMO
bacteria infecting laboratory workers is effectively reduced to nil. The most hazardous procedures are growth and manipulation of high titre bacterial cultures in the Class II microbiological safety cabinets, CO2 incubators and floor standing sealed shaking incubator, which could generate aerosols in the event of significant spillage. Risk assessments for all procedures handling bacterial pathogens are available.

1. Neisseria meningitidis (meningococcus, Nm): is a causative agent of bacterial meningitis and septicaemia in humans. The organism is a strict human pathogen that colonises the mucosal epithelium of the nasopharynx. The organism can be considered as a commensal that is present in 15-25% of the population, but for reasons still unclear can become invasive for a few susceptible individuals, dependent on co-infection, genetic pre-disposition and naïve immunity. Transmission of Nm is through droplet inhalation and close contact with carriers of the bacterium. The organism can cause isolated and sporadic outbreaks in temperate countries to epidemics in Sub-Saharan countries. In the UK, annual incidence of Nm disease is ~1000-1500 cases, with ~10% mortality rate. Invasive meningococcal disease caused by capsulated bacteria is a rapid onset and potentially fatal disease exhibiting as a meningitis and/or sepsis. Sepsis is characterised by disseminated intravascular coagulation, intravascular inflammation, petechial rash, multi-organ failure, ARDS and death, if untreated within 4h. Meningitis is characterised by lethargy, photophobia, vomiting, neck pain and headache. Survivors can be left with permanent neurological and physical sequelae, ranging from deafness to brain damage to limb loss. Vaccines are available for all major serogroups causing disease, except MenB, although new licensed vaccines are now available from 2014. Clinical treatment involves the injection of cephalosporin antibiotics (MC58 and GMO strains are sensitive).

2. Neisseria gonorrhoeae (gonococcus, Ngo): the sister organism to meningococci, is non-capsulated and a strict human pathogen that colonises the lower reproductive mucosal epithelium of men and women. In men, infection causes inflammation, painful urethritis with a purulent discharge, whereas in women, infection can be asymptomatic and ascending into the upper reproductive tract. Untreated infection in women can lead to pelvic inflammatory disease, a syndrome characterised by endometritis, salpingitis, pelvic pain, peritonitis, tubal infertility and ectopic pregnancy. The organism is transmitted sexually and cases are increasing again in the UK and US, often in tandem with Chlamydia. Reports of antibiotic-resistant gonococci are increasingly (including to cefixime, no longer used). Ceftriaxone still has clinical efficacy in combination with one of two oral antibiotics, either azithromycin or doxycycline (CDC recommendation).

3. Streptococcus pneumoniae (pneumococcus, Spn): is a causative organism of invasive (meningitis, septicaemia, pneumonia, empyema) and non-invasive (otitis media, ocular infection) disease. Pneumococcal disease affecting the young and elderly has fallen significantly with introduction of effective capsular polysaccharide conjugate vaccines (Prevenar 7, 13). Antibiotic-resistance has been increasing, but clinical treatment (depending of invasive or noninvasive) involves the use of antibiotics including amoxicillin (otitis), fluoroquinolones (sinusitis), cephalosporin (ceftriaxone or cefotaxime) for pneumonia, macrolide (or doxycycline) for community-acquired pneumonia, vancomycin plus ceftriaxone or cefotaxime at meningcal doses (meningitis).

4. Streptococcus agalactiae and Escherichia coli K1 are intestinal organisms that are the major causative pathogens of neonatal meningitis; transmission from mother to foetus can occur intra-amniotically or during birth. Neonatal infection is particularly devastating, characterised by sepsis and meningitis with high mortality (50%) and high morbidity for survivors (e.g. 50% will suffer permanent sequelae, bra in damage). No vaccines currently exist for immunisation of pregnant mothers and pre-screening for GBS/E.coli carriage prior to birth is not universal. Clinical treatment involves the use of intravenous penicillin, ampicillin, or cefazolin (for exposed individuals and for mothers prior to birth and ampicillin for neonates). Escherichia coli vectors proposed for use in cloning Neisseria and other pathogen genes are non-mobilisable. Sequences of Neisseria and other bacterial pathogen DNA inserted into cloning vectors will not increase the pathogenicity of E. coli. GMO strains of laboratory-grown E. coli used for protein production are extremely unlikely to
demonstrate increased virulence. E.coli K12 and its derivatives are multiple-disabled and designated as Class I organisms (attenuated). Good microbiological and laboratory practice will nevertheless be used when handling these stains. Strains BL21 (OE3) is a K12 derivative used for heterologous protein expression and unlikely to colonise healthy individuals.

5. *Pseudomonas aeruginosa:* is a saprophyte and opportunistic human pathogen, demonstrating a wide range of pathophysiologies. Often found in ocular infection and in cystic fibrosis patients, *Pseudomonas* can form persistent biofilms. No vaccines are available for prophylaxis. Clinical treatment involves the use of fluoroquinolones, ciprofloxacin or ofloxacin (PAO-1, PA14 are sensitive to these antibiotics).

6. *Haemophilus influenzae* was an important pathogen causing sepsis and meningitis; with the HiB-conjugate vaccines, this organism now does not cause significant reported disease. Non-typeable strains are increasingly found in respiratory infections.

7. *Staphylococcus aureus* is a commensal organism and ubiquitous in the population; it is involved in many infections as an opportunist pathogen and antibiotic-resistance is a serious concern.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Prior to describing waste management procedures, some information on CONTROL measures is warranted.

**'CONTROL MEASURES'**

1. **Security, Isolation and Segregation**

Understanding the pathogenesis of infections caused by these organisms requires the use of live, virulent bacteria, especially for investigating the role of specific virulence factors. Any laboratory adaptation does not represent the natural biology of the organisms during host interactions.

Entry to Molecular Microbiology, Level C, South Laboratory and Pathology Block, Southampton General Hospital is restricted behind code-locked and swipe-card locked outer and inner doors. Access by the public is prevented and only members of the Academic Unit of Clinical and Experimental Sciences can gain access through the inner doors with University approved swipe-identity cards. The LC91 containment level 2 laboratory is locked when not in use by authorised users, and is accessible to non-authorised users only by 1) agreement with the PI or the Level C laboratory manageress, in his absence, 2) in the presence of an authorised user or 3) when equipment to be inspected/serviced has been decontaminated and a permit to work has been issued (with prior consultation with the PI). Access to unauthorised users is PROHIBITED, especially when pathogen handling is being done. In addition, the names of authorised workers is listed on the door and updated regularly.

All live bacterial strains will be handled within this room ONLY and in no other laboratory. The PI has several measures in place to limit access: 1) all staff handling pathogens are inducted in safety and handling procedures according to COSHH guidelines 2) staff are given written permission to use this room only after training and competency evaluation 3) cleaning staff and service engineers are allowed access ONLY when no pathogen handling is being done and only after consultation and agreement with the PI, or in his absence, the laboratory manageress and safety officer. Operator numbers in the laboratory are restricted with a booking system for cabinet use.

2. **Controlling exposure**

All operators will wear appropriate PPE - in the containment level 2 laboratory this also means wearing designated
blue gowns, that are not allowed outside the laboratory except for cleaning. Class II microbiological safety cabinets are required for the handling of all pathogens (wild-type and GMO alike). Class I microbiological safety cabinets will be used only when handling bulk volumes of bacteria, e.g. E.coli for recombinant protein expression or other organisms for antigen extraction and purification. Splashes are contained within the cabinets and aerosol generation is not a significant risk. All cabinets are safety-inspected and tested every 6 months. All procedures for pathogen handling have been assessed for risk according to COSHH guidelines and assessments are in place.

3. Transport
For transporting cultures within the laboratory, all primary containers (Bijoux, universals, cell culture flasks, etc.) must be screwed closed during transit. Centrifuge tubes must be transported within sealed centrifuge buckets. Cell culture plates carrying infected cells must be carried with closed lids and in a plastic box. All experimental flasks, samples etc. must be labelled with name, cell type, organism and date. Materials in freezers must be clearly labelled and sealed in secondary containers.

If the need to transport organisms outside of the laboratory arises, we will use a re-usable sealed transport container, Biological Substance-Category B (UN3373). Movement of waste: each Cabinet holds a bucket with a solution of 2% (v/v) virkon into which all contaminated plasticware such as tips, spreaders and inoculating loops is placed. Such plasticware is left overnight as a minimum before decanting and disposal into blue autoclave bins. These bins are moved from Level C to HPA autoclave on Level A in large sealed plastic carriers with "Biological Hazard" markings. Contaminated petri dishes and cell culture flasks are placed in the same blue bins for autoclaving. Decanted, infected supernatants will be chemically disinfected with the addition of 2 % (v/v) Virkon overnight.

Shipment and receipt of biological material - some of these biological agents will be moved within the UK or overseas. Hazardous agents and materials will be packaged by qualified personnel according to the World Health Organisation guidance on regulations for the transport of infectious substances and transportation will use approved couriers and follow the advice of the University DGSA. Bacteria and strains will be received from overseas as part of ongoing research collaborations. These receipts will be frozen stocks on dry ice or cultures on agar slopes or lyophilised samples. Samples sent from overseas collaborators will be subject to strict regulations and packaged according to international regulations and the conditions of carriage applied by the courier(s). Transportation of bacterial cultures and cell cultures by air follows the WHO guidance on regulations for the transport of infectious substances (guidelines from the International Air Transport Association (IATA)( http://www.iata.org/Pages/default.aspx) and the ADR-carriage of dangerous goods, HSE (http://www.hse.gov.uk/cladg/manualadrcarriage.htm).

4. Storage and inventory - Long term storage of GMO bacteria will be in LN2 storage, the dewar kept in the containment level 2 laboratory. E.coli strains will be stored usually at -80C. Operators must refer to the relevant Risk Assessments for handling and growth of bacteria in force for PI and all laboratory users. Material being stored in liquid nitrogen must use cryovials with screw-cap lids to prevent explosive thawing (NUNC cryotubes must only be used). Removal or addition of potentially infectious material from/to LN2 will be performed by authorised users wearing appropriate PPE (face visor, cryo-compatible gloves over nitrile gloves, laboratory coat) and be done with emergency spill kits - including virkon satchets for disinfection - immediately to hand. For biological samples maintained in liquid nitrogen and at -80C , the PI holds a master file that identifies the pOSitions of each sample in the reservoirs. Each vial is identified by content, date of deposition and users initials. Only the PI has access to this information and has the authority to make changes depending on sample removal and/or replacement. Any samples unaccounted for must be reported to the PI immediately. Samples that appear to be 'lost' are invariably a result of not being replaced; the biological hazard of samples left outside the storage facilities is negligible as viability is compromised.
1. Liquid waste - Virkon chemical (2% v/v solution overnight) before disposal. Virkon is sufficient to kill the Class II pathogens (both Gram positive and negative) used. Bactericidal activity is observed within hours of treatment. Liquid waste is disposed down appropriate laboratory sinks.

2. Solid waste - physical (autoclave). Disposable plastic waste (loops, pipettes) will be chemically disinfected overnight (with 2% v/v Virkon solution). On the following day, the disinfected waste will be placed into a blue autoclave bin. Petri dishes, cell culture plates etc will also be placed in blue autoclave bins. These bins are autoclaved in the HPA autoclave, Level A, SGH.121 C for 15-30 minutes, at 2.68 Kg/cm², is sufficient to kill bacterial pathogens and to ensure sterility.

3. Use of centrifuges - for large volumes of medium containing pathogens or bacterial extracts. For cell culture infection experiments, bacterial pathogens need to be centrifuged. Up to 100 ml of potentially-infectious material, with a maximum concentration of 10⁸ cfu/ml (20 ml volume maximum in sealed universal) will be centrifuged. Risk assessments for the handling of bacteria and centrifugation of infectious material are documented and must be consulted before procedures are started. For the preparation of recombinant proteins in E.coli laboratory strains, the maximum culture volume is 21 (4x 21 flasks, each containing 500 ml growth medium). Culture of such volumes is done in a floor-standing shaking incubator and volume handling in a Class I microbiological safety cabinet. Preparation of centrifuge buckets and balancing must be done in the Class I microbiological safety cabinet. All infectious material for centrifugation will be contained in sealed biological safety buckets, which can only be opened in Class 1111 cabinets. In the event of leakage/spillage, for decontamination and waste management, if the leakage was confined to a sealed bucket, open the centrifuge, sterilise the compartment with an alcohol spray (70% methanol) and wipe-down, sterilise the outside of the bucket before removing it to the nearest Class II microbiological safety cabinet. If spillage is within a Cabinet, open the centrifuge bucket and decontaminate by adding 2% (v/v) Virkon solution or 70% (v/v) alcohol, allowing at least overnight contact time before decanting of waste material into the Virkon-containing bucket kept inside the cabinet. For the preparation of bacterial extracts and other components from pathogens and the growth of E.coli for recombinant protein expression, larger volumes may be required. In the unlikely event of breakages within ultracentrifuge rotors, the additional concern of aerosol production needs to be considered. Thus, decontamination of ultracentrifuge(s) and removal of waste should be done only within Class I cabinets using appropriate decontamination solutions (alcohol, Virkon).

4. Use of incubators - infected cultures will usually be cell cultures in flasks (25 ml volume maximum per flask) or in plates (lidded, up to 6 well containing 5 ml) that have been challenged with bacteria for periods of up to 24-48h (depending on human cell viability). Cultureware are kept on static shelves. All cultures/flasks/plates must be labelled with organism, operator and date. Waste samples from these experiments are disposed of as follows: flask supernatants decanted into Virkon (2% v/v) bucket. Culture plate wells emptied by sterile pipette into same solution. All plasticware in contact with pathogens are placed into blue autoclave bins for transport to HPA autoclave on Level A, Southampton General Hospital. In the event of a spillage inside the CO2 incubator, the incubator should be closed, turn off the incubator to allow aerosols (if generated, but unlikely) to settle. Open the incubator after 24h and spray internal compartment with 70% v/v solution of alcohol, wipe down and then clean with dilute Virkon solution to disinfect. All wipes must be disposed of within blue autoclave bins.

5. For bacterial cultures grown in orbital shakers inside a CO2 incubator, these will be done in either 15 ml or 50 ml Bio-Reaction tubes (CellTreat Scientific Products), which contain a 0.22 um filter in the lid for gas-exchange and the prevention of aerosol generation inside the incubator. Tubes will be clamped and shaking of cultures will not exceed 200 rpm. Staff trained in the use of the orbital shaker will also be trained to carry out routine, dynamic risk assessment of the incubator and shaker when they open the outer door of the incubator: any accidental spillage of
bacterial culture can be identified by visual inspection through the inner glass door. In the event of spillage, the orbital shaker(s) will be switched off at the wall socket and an excess period of 6 hours given for any potential aerosols to settle. Evacuation of the laboratory is unnecessary as the aerosols will be contained within the gas-tight incubator. Spills can then be decontaminated and cleaned up using a 2% Virkon solution and at least 15 minutes of contact time. All paper waste will be disposed of as contaminated biological waste for incineration in blue autoclave bins.

For E.coli cultures for recombinant protein production, appropriate glass culture flasks are microbiologically sealed and shaken within a floor-standing shaker (Sony Gallenkamp). Any breakage within the shaker can be observed through the glass lid, which is sealed to prevent potential aerosol escape. In the unlikely event of a breakage, turn off the incubator, DO NOT open the lid and leave the incubator closed for at least 24 hours to allow any aerosol to settle and bacteria to die. Decontamination will involve absorbent paper for spillage, followed by alcohol and Virkon decontamination. Paper waste will be disposed as above.

For spillages that may occur on lab equipment such as incubators or centrifuges, after decontamination, it is advisable to swab the cleaned area and culture on appropriate agar media to demonstrate sterility, prior to subsequent use.

6. PPE contamination - in the containment level 2 laboratory, ONLY side-fastening blue gowns must be worn. These gowns are kept in this lab only and must NOT be worn elsewhere. The gowns must not share same hooks as standard white laboratory gowns. The blue gowns provide cover from the neck to beyond the knee. When appropriate (e.g. every fortnight), the blue gowns will be placed into a designated, labelled bin for washing and will be replaced with fresh gowns by the lab technician. Gowns are taken, in sealed bag/box, to the HPA facility on Level A, Southampton General Hospital for cleaning. In the unlikely event of a spillage onto the gown, operator should remove the garment and decontaminate by spraying initially with alcohol (70% v/v) and then washing with diluted Virkon solution. Place the washed garment immediately into a bag for cleaning.

7. Personal hygiene - disposable nitrile gloves (all sizes XS, S, M, L) are available to operators. These gloves do NOT leave the laboratory, if contaminated they are discarded into autoclave bins. The laboratory has a sink for hand-washing, with a pH neutral soap solution as well as an alcohol gel. Hands MUST be washed before leaving the laboratory. The laboratory also holds an eye-wash bottle solution.

8. Animal work with bacterial pathogens - at present, infection of animals with any of these GMO agents is NOT anticipated. If this becomes necessary in the future, the Biomedical Research Facility has dedicated Class II microbiology containment facilities and cabinets for infection work and holding pens for infected animals, next to decontamination and autoclaving facilities.

Comments from the University GMBSC held on 14/10/14.
This project was clearly Activity Class 2; it did not fulfil the criteria for assignment to Activity Class 3. The project was approved as Activity Class 2 subject to notification to the HSE.

### Project Additional Information

**Purposes of the contained use**

This project aims to investigate the use of novel acellular strategies for tissue repair. In this project we will deliver as part of our activities, genetic material to cells for bone regeneration. These strategies will be compared to conventional methods of intracellular delivery, such as lentivirus delivery.

**Recipient or parental organism**

Lentivirus particles produced by 2nd generation packaging system
**Host/vector system**

- psPAX2, pMD2.G, pSIN

**Origin & function**

- Human gene sequences for:
  - VEGF (stimulates angiogenesis)
  - HIF1a (transcription factor used in hypoxic conditions)
  - BMP2 (bone and cartilage development)
  - GFP (Green Fluorescent Protein - control gene providing a fluorescent marker)

**Evaluation of foreseeable effects**

- The cells to be transfected are primary tissue from human samples. All samples are from patients undergoing routine hip replacements. Patients are screened for Hepatitis B prior to surgery. We have consent from all patients to use their samples.
- We only receive cell samples from haemotologically normal patients.
- We are not generating the viral particles.
- The viral particles cannot replicate. Once a cell replicates, the viral particle load is split between daughter cells.
- The more a cell replicates, the lower the cellular viral load. Hence, if the operator becomes inoculated then the affect of the gene will be limited to only a few cellular replications.
- The inserted genes are normally expressed in human bone cells. Over-expression of the genes may make the cells form bone quicker than normal, but without significantly changing there normal traits.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

| N/A |

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

- No derogation

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

- Waste will be exposed to 1% Virkon solution (final concentration) for minimum of 1 hour prior to autoclaving at adjacent NHS site. 100% kill.
- Liquid waste will be treated with Virkon to 1% final concentration for at least 1 hour according to manufacturer's instructions.
- Solid waste will be immersed in 1% Virkon for at least 1 hour according to manufacturer's instructions.

### Project Additional Information

**Purposes of the contained use**

As a retroviral vector system to express protein constructs of interest on human peripheral blood mononuclear cells.
Recipient or parental organism

N/A

Host/vector system

Retroviral vectors pMIGR1 (derived from MSCV- Murine Stem Cell Virus vector) and SFG (derived from Moloney Murine Leukemia Virus vector) and helper plasmids to allow transduction of proliferating human PBMCs

Origin & function

The vector pMIGR1 is derived from MSCV (Murine Stem Cell Virus) vector. The vector SFG is derived from Moloney Murine Leukaemia virus vector. Vectors will be used to introduce cDNA encoding gene constructs for cell surface proteins into PBMCs.

Inserted in the vector are genetic material encoding parts of the following proteins:

Antibody Fragments
Fragments of anti-CD20 antibodies encompassing the antigen binding domains, cloned by PCR from original antibody constructs made in house, allowing recognition of CD20 on cell surfaces.

Signalling domains from the following proteins, generated by GeneArt as oligonucleotides (commercial company):

Human CD28
CD28 is a co-stimulatory molecule expressed on the surface of T lymphocytes, NK cells and plasma cells and is required for T cell activation and signaling. The cytoplasmic region interacts with signaling molecules including to allow cell activation upon antigen recognition. Uniprot ref: P10747.

Human CD137:
CD137, also referred to as 4-1BB in literature, is a member of the tumour necrosis factor receptor (TNFR) superfamily present on lymphocytes and acts as a costimulatory molecule for T cell signaling. It consists of four cysteine rich extracellular domains and a small cytoplasmic tail. A sequence annotation of the translated protein is available in the Uniprot database (reference: Q07011).

Human CD3 ζ:
CD3 ζ is a protein expressed on T lymphocytes as part of the CD3-TCR (T-cell receptor) complex. It comprises a short extracellular domain, helical transmembrane domain and a signaling cytoplasmic tail encompassing three ITAM domains. These ITAMs interact with signaling molecules in the cell and, once phosphorylated at the tyrosine residues, help to initiate T cell activation. The transmembrane regions allow dimerization and interaction with the TCR. Uniprot ref: P20963.

The cellular function of all these signalling domains will be to induce cell activation upon antigen recognition. The antigen recognition will be elicited by the antibody fragments.

Vector constructs will be transfected into producer 293T cells. The viral supernatant produced will be used to infect PBMCs and then removed, neutralised and discarded. The PBMCs will then be washed of all virus supernatent and used in subsequent experiments.

Evaluation of foreseeable effects

Environmental risks:
The viral vectors used pose no environmental risks. They are incapable of replicating and would not be able to survive or be infective outside of laboratory conditions.

Risks to human health:
The viral vectors pose a minimal risk to human health. They are infective but non-replicative so do not multiply inside any host cell. The only potential harmful foreseeable event would be intravenous injection to a human with concentrated viral particle-containing supernatant. However, no sharp instruments are used throughout the protocol, and the volumes handled are kept to a minimum at any one time. There is minimal risk posed by any cells in culture throughout this process when they are incubated within the viral supernatant. They will only be incubated in the viral particle-containing media for a short period of time and then all virus will be neutralised. The resulting cells will then be safe to use.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

### Please enter comments on the GM safety committee on the risk assessment

GMBSC meeting 12/5/15

AC1 project GMBSC-71 Structure function studies of cell surface proteins re-submitted with additional vectors. Amendments were received and the Committee decided that these added vectors had an increased risk and this project should now be classified as AC2.

Comments from the GMBSC

Application to use amphotropic packaging line to transduce human cells, requiring change from CL1/AC1 to CL1/AC2 - this should be CL2/AC2

Amphotropic now means significantly more hazardous (to humans). We will now need a harmless insert, SIN vector, and 3rd generation packaging to remain at AC1. Otherwise it will become AC2.

The Committee requested that the Researcher fill out a new risk assessment form taking into account the additional vectors.

Resolved: Mr Lockey to request that the researcher complete an AC2 RA form.

GMBSC - 71 re-submitted as an AC2 project and approved by committee via SharePoint

Researcher placed project on hold until December 2015

Project Additional Information

Purposes of the contained use
One excellent drug target in S. aureus is the signal transduction system SaeRS two component system TCS, which is conserved in all clinical S. aureus strains; the SaeRS TCS controls production of more than 20 important virulence factors including toxins, coagulates, adhesins and enzymes. We plan to utilise this TCS for the development of antistaphylococcal drugs. Using the USA300 strain we plan to screen organic molecules synthesized in the laboratory to identify the potential inhibitors

Recipient or parental organism
Staphylococcus aureus USA300 FPR3757
Staphylococcus aureus USA300-0114, Yes this strain will be used experimentally

**Host/vector system**

pCL55, contains the ori and the AmpR gene from pBR322, can be selected in E. coli. Plasmid pCL55 also contains a CmR gene for selection in S. aureus.

**Origin & function**

gfp (green fluorescene protein)

**Evaluation of foreseeable effects**

S. aureus can cause sometimes a multitude of diseases via direct infection particularly when skin/mucosal barriers have been breached, or due to production of toxins by the bacteria. However, our reporter strain has one of its gene (i.e. alpha-hemolysin) replaced with benign gfp gene. Since there are many other virulent factors, the virulence seems to remain unchanged.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not relevant

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not necessary

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All the manipulation will be carried out in the class II MSC hence the exposure due to aerosol or splashes will be minimum. Transport within the laboratory is minimal. Cell culture flasks will be transferred between the shaker incubator, Class II MSC and the centrifuge, which are all located within the same laboratory. All the liquid waste generated will be treated with 2% Virkon (contact time 1 hour) before discarding it. All other waste will be autoclaved and only after autoclaving the waste would be transported through the building to the bins located at the rear of the building. Further details are given in the form GM Section 3.2

**Project Additional Information**

02/03/2022
Purposes of the contained use

His project is concerned with understanding the biology of certain members of the Flaviviridae family of viruses and develop novel intervention strategies. Flaviviridae family members are positive strand RNA viruses that encode their structural and non-structural proteins as a single polyprotein that gets processed into individual proteins by host and viral-encoded proteases. Viruses or viral constructs worked on will be derived from hepatitis C virus (HCV), Bovine Viral Diarrhoea Virus (BVDV), Dengue Virus (DV), Yellow Fever Virus (YFV) genomes.

Pre-existing approved GM applications already allow us to undertake certain HCV work at containment level 1, 2 and 3 and BVDV work at containment level 1. This application extends the GM work we will be undertaking for HCV and BVDV as we are now proposing to use a novel Venezuelan Equine Encephalitis Virus (VEEV) replicon to express HCV and BVDV non-structural proteins for genetic complementation studies. For such studies stable VEEV-replicon containing cell lines will be generated where the VEEV replicon not only expresses its own non-structural proteins, but also expresses either HCV or BVDV non-structural proteins. The cell lines will then be transfected with an HCV or BVDV replicon carrying various lethal mutations in order to see whether rescue of these constructs is possible. Genetic complementation using this system has already been shown to be safe and effective for HCV work (Kazakov et al. (2015) Plos Pathogens 11(4):e1004817), and the authors of this report will be collaborating with us to get the system working in Southampton.

We will also use the same VEEV system to express flavivirus non-structural proteins for comparable genetic complementation studies with YFV and DV. As with the above HCV and BVDV work, we will restrict ourselves to transfecting VEEV-containing stable cell lines with subgenomic DV and YFV replicons that do not express viral structural proteins.

Finally, work will focus on critical elements of the full length YFV genome important for replication as well as intervention strategies to either block, or detect YFV replication in vitro and in vivo. For this we will use the full length 17D-204 vaccine strain of YFV. In this instance, viral transcripts will be generated from a 17D-204 cDNA clone by in vitro transcription and transfected into Vero cells to recover virus to ensure we are generating a ‘safe’ low passage defined working stock of virus. Virus will be propagated in BHK-21 cells and Vero cells. Any changes made to the 17D-204 backbone will be ones expected to be neutral or further attenuate the virus. Insertion of foreign genetic material will be restricted to epitope tags, GFP and luciferase coding regions. No changes will be made that reverse any of the nucleotide substitutions which are potentially linked to the 17D-204 attenuated phenotype (Hahn et al. (1987) PNAS 84;2019; Galler et al. (1998) Vaccine 9-10:1024).

The GM work being performed doesn't easily lend itself to being categorized into "Recipient organism" and "host/vector system". For this reason I am listing all viral and subgenomic viral constructs to be made in this category.

Recipient or parental organism

The GM work being performed doesn't easily lend itself to being categorized into "Recipient organism" and "host/vector system". For this reason I am listing all viral and subgenomic viral constructs to be made in this category.

HCV: HCV is a human hepatotropic virus, exposure to which typically results in a life-long chronic infection that in a significant minority of cases can lead to severe morbidity and mortality due to liver cirrhosis, hepatocellular carcinoma and liver failure. Over the last few decades, the advent of new direct acting antiviral drugs means that cure rates for HCV now approach 100%, although treatment costs mean that these new drugs can only be afforded by a small proportion of the global population. Transmission of HCV is almost exclusively by parenteral means, typically as a result of being given contaminated blood products, poor tattooing practices or intravenous drug users sharing needles. Work using full length infectious HCV currently requires containment level 3 facilities. In contrast, work with HCV replicons, RNA transcripts that do not express the viral structural proteins, is typically permitted at containment level one. HCV constructs we will be using will be exclusively subgenomic replicons that do not express any structural proteins and which will only be modified to express non-pathogenic foreign genetic elements that enable detection (epitope tags and luciferases), visualization (GFP) or facilitate expression of polypeptide cassettes in certain contexts (e.g. Internal Ribosome Entry Sites and the "Stop-Go" sequence found in Foot-and-Mouth Disease Virus 2A protein that allows ribosome stuttering and separation of translated products from a single open reading frame).

BVDV: Is a pestivirus responsible for causes self-limiting diarrhoea in adult cattle, but which if it infects calves in utero causes either embryonic death or a persistent infection that limits growth and milk production. Persistently infected cows shed high levels of virus and are susceptible to mucosal disease, a form of BVDV induced pathology that is associated with contracting viral strains carry naturally occurring re-arrangements of the BVDV genome and which is invariably fatal. BVDV is endemic across most of Europe, including the UK. Work with full length infectious BVDV can be carried out at containment level 1. This application is to cover work carried out using BVDV subgenomic replicons lacking structural proteins and expressing the same range of foreign genetic elements described for the HCV replicons (see above).
DV: DV is a mosquito-borne virus that causes an acute fever which ranges in severity, but which at its most extreme results in dengue haemorrhagic fever and dengue shock syndrome, both of which are associated with significant mortality. While infection results in life-long protection against the same serotype of DV, the existence of separate serotypes represents a significant hurdle to vaccine development. Indeed, there is good evidence that the non-neutralizing antibody response generated from a prior DV infection enhances the pathogenicity of subsequent infections with other DV serotypes. DV is endemic in tropical regions of the globe, but is not found in Europe due to the climatic conditions being unable to support vector-based transmission. Containment requirements for work with DV infectious virus and replicons typically mirrors that of HCV. This application is to cover work carried out using DV subgenomic replicons lacking structural proteins and expressing the same range of foreign genetic elements described for the HCV replicons (see above).

YFV: YFV is another mosquito-borne virus that causes acute haemorrhagic disease. Symptoms of infection include fever, headache, jaundice, muscle pain, vomiting and fatigue. A small proportion of those contracting YFV will develop severe symptoms which carry a risk of death 7-10 days after the start of infection. As with DV, the virus is only endemic in tropical countries where the climate allows for productive mosquito borne transmission. Current vaccination for YFV involves the injection of a live attenuated form of the virus (typically referred to as the 17 strain) developed by serial passage of the virulent Asibi strain in chicken embryo cells. The vaccine is considered to be both effective and safe, producing life-long immunity in 99% of vaccinated persons within 30 days of a single injection. Severe complications do occur, but are rare. Yellow fever vaccine-associated neurological disease (YEL-AND) occurs for between 0.19 and 0.8 cases per 100,000 whereas the incidence of yellow fever vaccine-associated viscerotropic disease (YEL-AVD) is between 0.004 and 0.4 per 100,000 doses. For YEL-AVD at least, evidence suggests that these rare events are not due to the virus reverting to a virulent phenotype but is due to some other co-factor.

Regards the pedigree of the 17D virus used for vaccine production, the 17D actual virus stock is no longer available, and it is closely related sub-strains derived from it (17DD, 17D-204) that serve as seed stocks for vaccine production. Sequencing of these vaccine strains and another 17S sub-strain (17D-213) show that there are a total of 67 nucleotide substitutions compared to the virulent Asibi strain, 48 of which are common to all 3 attenuated strains and which are assumed to be responsible for the attenuated phenotype (Galler et al. (1998) Vaccine 9(10):1024). These 48 substitutions result in 22 amino coding changes as well as 4 nucleotide alterations in the 3'UTR of the virus, all of which have the potential to contribute to virus attenuation. Work involving the use of fully virulent YFV needs to be performed at containment level 3, whereas work involving YFV replicons would typically be allowed in a laboratory with containment level 1 facilities. This application is to cover work carried out using 17D-derived YFV replicons, similar to those described for HCV, BVDV and DV. It is also to carry out work with the full length 17D vaccine strain of yellow fever, either using unaltered vaccine strain virus recovered from an infectious cDNA clone (Bredenbeek et al. (2003) JGV 84:1261)) or using the same 17D infectious cDNA clone but modified to express a non-pathogenic insert to enable detection (specifically either an epitope tag, a fluorescent protein such as GFP or a luciferase). It is the work with full length YFV that we consider to be part of the class 2 activity within this project.

VEEV: VEEV is a mosquito-borne alpha virus that can be lethal for equine species and which exists as enzootic and epizootic subtypes. Like the other viruses we are working with it is an enveloped positive strand RNA virus, but derives from a different virus family, being an Alpha Virus. Enzootic subtypes tend to be localized to discrete areas, maintained through a local mosquito-rodent transmission cycle, and while they can cause human illness, do not present a problem to horses. In contrast, epizootic subtypes can spread rapidly and affect both human and horses alike. The virus causes an acute infection in humans, with healthy adults typically displaying mild to moderate flu-like symptoms and suffering no long-term sequelae. In contrast, viral infection of the young and old can result in a life-threatening illness. A vaccine strain, TC-83, has been developed for military personnel and laboratory workers at risk of contracting VEEV, but which can result in side effects and does not fully immunize the patient. Infectious VEEV has to be handled at containment level 3 and is also a SAPO3 agent. However, as with other positive strand RNA viruses, removal of the structural genes to generate a replicon dramatically reduces risk. We have already sought assurances that handling of VEEV replicons does not require a SAPO license. We are seeking approval to use VEEV replicon cDNA carries non-structural coding regions from BVDV, YFV and DV, to make stable replicon-containing cell lines. These stable cell lines will then be transfected with the same HCV, BVDV, DV or YFV replicons described above. We will not transfet full length 17D vaccine strain YFV into the VEEV replicons. While no structural proteins will be expressed/present during this work, this is the second part of our project where we feel there is the potential for it to need to be categorized as a class 2 activity due to the complex nature of the genetic elements being introduced into the same cellular environment.
The various genetic elements to be used in this project are listed below:

Genetic elements foreign to the Flaviviridae and Alpha Virus family: These are all non-hazardous genes with no known pathogenic potential. They are the neomycin resistance gene (NPTII), the puromycin resistance gene (PAC), green fluorescent protein (GFP), Firefly luciferase, Renilla luciferase, Nanoluciferase, the EMCV IRES, the FMDV2A ribosome stutter element, ubiquitin and epitope tags such as FLAG, V5, myc. Their intended use is to allow us to select for stable replicon containing cell lines, to monitor replicon and virus replication, to facilitate gene expression from viral subgenomic RNAs and to visualize/detect replicon and viral proteins.

HCV non-structural proteins: Recoded versions of HCV non-structural proteins NS3, NS4A, NS4B, NS5A and NS5B will be inserted into the VEEV replicon. In some instances these genetic elements may carry additional non-hazardous gene elements, specifically the same as those listed above (i.e. GFP, luciferase, etc). The intention is to study the potential of these genes to complement defects present in an HCV replicon carrying a lethal mutation in the same genes.

BVDV non-structural proteins: Recoded versions of BVDV non-structural proteins NS2, NS3, NS4A, NS4B, NS5A and NS5B will be inserted into the VEEV replicon. In some instances these genetic elements may carry additional non-hazardous gene elements, specifically the same as those listed above (i.e. GFP, luciferase, etc). The intention is to study the potential of these genes to complement defects present in a BVDV replicon carrying a lethal mutation in the same genes.

DV and YFV non-structural proteins: Recoded versions of DV and YFV non-structural proteins NS2A, NS2B, NS3, NS4A, 2K, NS4B and NS5 will be inserted into the VEEV replicon. In some instances these genetic elements may carry additional non-hazardous gene elements, specifically the same as those listed above (i.e. GFP, luciferase, etc). The intention is to study the potential of these genes to complement defects present in a DV or YFV replicon carrying a lethal mutation in the same genes.

Evaluation of foreseeable effects

All replicon vectors lack any structural proteins and are therefore non-transmissible and non-hazardous. The 17D vaccine strain infectious virus that will be generated from a cDNA clone will possesses the same pathogenic potential as the vaccine strain of YFV used to vaccinate against YFV. As such it only represents a hazard to at risk groups for whom vaccination is advised against (see below). The genetic elements to be introduced into the 17D infectious virus are non-hazardous and therefore expected to have either have no impact on virulence or further attenuate the virus. Any personnel who would normally be excluded from 17D vaccination because of being in a higher risk category will not be allowed to work with the 17D infectious constructs that will be generated.

The guidelines for administration of 17D YFV are that WHO advise is that pregnant women should ideally avoid travelling to areas where there is YFV transmission. However, if travel is necessary then the benefits of vaccination outweigh the risks. Vaccination is contraindicated for infants under 6 months of age and not recommended for those aged 6-8 months. Vaccination is not recommended for those with severely immunocompromising conditions. Conditions and treatments considered to be severely immunocompromising include: primary immunodeficiencies, thymus disorder, symptomatic HIV infection or CD4 T-cell values <200 per mm3, malignant neoplasm treated with chemotherapy, recent haematopoietic stem cell transplantation, drugs with known immunosuppressive or immunomodulatory properties (e.g. high-dose systemic corticosteroids, alkylating drugs, antimetabolites, TNF-α inhibitors, IL-1 blocking agent, or other monoclonal antibodies targeting immune cells), and current or recent radiation therapies targeting immune cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Yellow Fever Virus is currently classified as a HG3 pathogen. We are not wishing to work with virulent YFV but are instead applying to work with the attenuated 17D vaccine strain of YFV only, one of the safest and most effective vaccines there is. Modifications we will make are expected to be neutral or cause further attenuation of virulence. We will not reverse any of the potential nucleotide substitutions that might be associated with loss of virulence. 17D virus titres typically reach levels no more than 10^6 pfu/ml and vaccination involves administration of ~3.5 x 10^4 viruses. When working with unconcentrated viral supernatant we believe it is inconceivable that accidental transmission would involve volumes of more than 35 microliters of viral supernatant being injected into a lab worker as any rare exposure event would likely involve...
splashes and abrasions and hence much smaller volumes entering the body. However, if working with concentrated virus the risk of exceeding the vaccination threshold of 3.5 x 10⁴ viruses increases. For this reason any worker involved in concentrating 17D YFV or handling of concentrated 17D YFV stocks will undergo prior YFV immunization as a precaution.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All biological (human and non-human) fluids will be inactivated in a freshly prepared 1% virkon solution for a minimum of 30 minutes before being disposed of via the sink. The manufacturer of Virkon claim to have tested their against a range of viruses including Flaviviruses. Given that both these viruses are enveloped and thus more susceptible to chemical inactivation than non-enveloped viruses which are also inactivated by 1% Virkon there is reason to think that 1% Virkon is well above the threshold of the chemical needed for complete inactivation of the viruses we will be handling. Indeed our in house testing of Virkon against baculovirus, another enveloped virus, suggests that exposure of virus to 0.1% Virkon for 2 minutes when in a solution of 10%FCS is enough to result in a 10⁵ drop in infectious titres and exposure to 1% Virkon for 2 minutes reduces titres to below a detectable level. Once we have the 17D YFV infection system up and generating sufficient titres to carry out this sort of testing, we will look at the effectiveness of Virkon against this virus as well. Cell lines carrying replicons will be even more susceptible to inactivation by Virkon and would be unable to survive more than a few minutes outside a cell culture environment. Because of this reason and because material from these cell lines is not infectious we do not deem it necessary to test the effectiveness of Virkon on cell killing.

All biological (human and non-human) samples that are non-fluids will be disposed via the blue boxes which when full are placed in sealed metal boxes and transported to the HPA facility one floor below the labs for disposal by autoclaving. The HPA routinely validate their autoclaves to confirm that they are operating at the required specifications to ensure complete microbial sterilization and maintain these records.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Please enter comments on the GM safety committee on the risk assessment
Use of genetic complementation to make comparisons of the different replication mechanisms used by members of Flaviviridae family

Dr CM was the author of the brief and explained the project to the committee and clarified that it was low risk.

Dr CM informed the committee that he had put a GM application in to bring the plasmid across from America, which was approved.

Dr CM felt that the project should be a AC2 activity but that he needed confirmation from committee.

It was noted that the collaborators view was that it is not a higher risk but Dr CM was slightly concerned it was higher risk and so stalled the project.

It was clarified that there was secondary containment around anything that involved plates and dishes.

Professor BK asked Dr CM if it was possible for him to specify that he will not work with any other strains at the same time. Dr CM felt that this was very restrictive for him.

Dr CM informed the committee that it would be vetted by HSE as well.

Professor BK noted that he could see that Dr DC had thoroughly researched the project.

Resolved: That this project be approved for Activity Class 2 subject to HSE notification.

Non-GMM Consent Granted

Project notified under transitional arrangements N
Acute Myeloid Leukemia (AML) remains an unmet medical need with ~20,000 new cases and ~10,000 deaths in US alone each year. Current treatments for AML fail to induce long-term tumour regression, demonstrating the need for new therapies. Recent studies demonstrate a role for leukocyte immunoglobulin-like receptors (LILRs) in regulating leukocyte function, and that inhibitory LILRs (LILRBs) are dysregulated in haematological malignancies, including AML. We have produced and extensively characterised a unique panel of monoclonal antibodies (mAb) specific for human LILRB3. Using the previously generated reagents and established pre-clinical platforms and our expertise in mAb and chimeric antigen receptor (CAR) T cell therapy, we propose to develop LILRB3-specific CAR-T cells and evaluate their capacity against AML in vivo.

This proposal aims to 1) generate and optimise autologous T cells targeting LILRB3, CD33 and other unique antigens highly expressed on AML cells, and 2) evaluate the efficacy and safety of CAR T cells in humanized AML and patient-derived xenograft mouse models.

In order to study cell surface receptors as potential therapeutic targets:

These will comprise single chain variable fragments (scFvs) derived from antibodies (eg, anti-human LILRB3, CD33) linked to various protein domains to allow expression and signaling within the T cell. This will be used to investigate the differences in response when alternative scFvs are included and the roles of protein domains in the signaling pathways of the cell. The chimeric receptors will be expressed using lentiviral vectors, detailed below, in established cell lines and primary human peripheral blood mononuclear cells. Some will be transferred to immunocompromised NSG mice to look at target cell depletion elicited by the CAR-expressing cells.

Recipient or parental organism

Human peripheral blood mononuclear cells from healthy donors and humanised mice.

Second generation replication incompetent lentiviral plasmids will be used, which include delta 8.9, VSV-G and pAdvantage constructs.

Origin & function

Human CD28

CD28 is a co-stimulatory molecule expressed on the surface of T lymphocytes, NK cells and plasma cells and is required for T cell activation and signaling. The molecule consists of 3 domains; an immunoglobulin extracellular domain, a transmembrane helical domains and a cytoplasmic signaling tail. The extracellular domain binds ligands CD80 and CD86 on target cells whilst the cytoplasmic region interacts with signaling molecules including PI3kinase. CD28 is expressed as homodimer, linked by disulphide bonds. Uniprot ref: P10747.

Human CD137:

CD137, also referred to as 4-1BB in literature, is a member of the tumour necrosis factor receptor (TNFR) superfamily present on lymphocytes and acts as a costimulatory molecule for T cell signaling. It consists of four cysteine rich extracellular domains and a small cytoplasmic tail. A sequence annotation of the translated protein is available in the Uniprot database (reference: Q07011).
Human CD3ζ:
CD3ζ is a protein expressed on T lymphocytes as part of the CD3-TCR (T-cell receptor) complex. It comprises a short extracellular domain, helical transmembrane domain and a signaling cytoplasmic tail encompassing three ITAM domains. These ITAMs interact with signaling molecules in the cell and, once phosphorylated at the tyrosine residues, help to initiate T cell activation. The transmembrane regions allow dimerisation and interaction with the TCR. Uniprot ref: P20963.

Other modifications include the use of leader sequences, transmembrane and hinge regions (eg, human CD8) and CD20 receptor. Depending on the project directions, other co-stimulatory molecules and target genes may be included in the future.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
The use of microbiological safety cabinets are standard for all cell culture techniques. Spillages are reduced by good aseptic technique. Spillages are only considered a risk in this project when dealing with Amphotrophic viral media as this poses a low risk threat to humans. The work with this media will be carried out in a containment 2 laboratory and the following procedures adhered to:
Use racks and keep samples capped whenever possible to reduce risk of spillage.
Use Virkon solution to clean up any spillages using paper towels, then clean the area again with Trigene 1:50 and 70% ethanol.
At completion of experiment, wipe area with Trigene then 70% IMS.
All plates of infected cells will be sealed prior to removal from safety cabinet

4.7 GMBSC-0283 Generating chimeric antigen receptor leukocytes for immunotherapy of cancer

GMBSC felt the project was borderline Activity Class One or Two and needed clarification as to where the project was taking place.

The Chair stated that if the principal investigator was getting the cells in and not handling the virus then the project would be classed as Activity Class One, if handling the virus then this must be AC2.

Clarification was requested and the risk assessment was approved as AC2.
Project Additional Information

Purposes of the contained use

Bronchial epithelial cells (16HBE14o- cell line) will be grown in a sealed microfluidic device for 5 days (to enable barrier formation), cells will then be apically challenged with respiratory bacterial pathogen S. pneumoniae and left for 1 day to analyse the changes in the epithelial barrier through electrical readouts (magnitude of impedance and phase) and analysis of basolateral collections. This will allow us to better understand the disease pathogenesis of S. pneumoniae.

Recipient or parental organism

Streptococcus pneumoniae strain TIGR-4, Serotype 4, Strain P1672
**Host/vector system**

Green Fluorescent Protein (GFP) construct

**Origin & function**

Streptococcus pneumoniae (TIGR-4, Serotype 4, Strain P1672) originally from a clinical isolate, Primarily from Tim Michell (University of Birmingham) provided to Jeremy Brown (University College London) and being given to University of Southampton by Caroline Weight (University College London).

GFP construct was originally obtained from Jan-Willem Veening (University of Groningen, Netherlands). The Green Fluorescent Protein (GFP) construct was then combined with the S. pneumoniae strain by Caroline Weight (University College London) to form GFP-TIGR4 by inserting GFP into an inactive area of the S.pneumoniae genome (into histone like protein A locus). The GFP insertion is not expected to have increased the risk of the modified strain (GFP-TIGR4) so can be treated in the same way as the wild-type strain (TIGR4).

The GFP construct enables tracking of S. pneumoaniae across the epithelial barrier and increases ease of endpoint analysis.

**Evaluation of foreseeable effects**

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not Applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid and solid waste is submerged in chemical decontaminant solution (4% Virkon) for at least an hour. Virkon’s efficiency has been independently proven highly effective against over 100 strains of viruses in 22 viral families, over 400 strains of bacteria and over 100 strains of fungi, which includes streptococci, where a 1:100 dilution provides bactericidal efficacy. ([https://relyondisfection.com/fileadmin/user_upload/RelyOn_Virkon_UK.pdf](https://relyondisfection.com/fileadmin/user_upload/RelyOn_Virkon_UK.pdf) and [virkon.com/product/biosecurity-products/biosecurity-disinfectants/virkontm-s/proven-chemistry-proven-results/](https://virkon.com/product/biosecurity-products/biosecurity-disinfectants/virkontm-s/proven-chemistry-proven-results/)). This can also be validated by trying to grow organisms using agar plates after decontamination. After chemical decontamination solid waste is incinerated with other decontaminated biological waste.

In addition to this the isolate of S. pneumoniae being used is self inactivating in liquid culture (8 hours) or when grown on agar plates (24 hours), so the risk of infection from waste to workers who collect and transfer waste is very low.

**Is an emergency plan required according to regulation 20?**  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment  N
The University of Southampton Genetic Modification and Biological Safety Committee reviewed the risk assessment on line. The following questions were asked by the Committee:

- Bronchial epithelial cell line 16HBE14O is a genetically modified cell line, could you confirm that the use of this is on an approved risk assessment, and if so please add the risk assessment number to section 1.1.
- Is the Lung on Chip system sealed, and only opened within the class II MSC?
- What is the risk of aerosolised S. pneumoniae being produced during incubation?
- Is the incubator and perfusion system entirely within the MSC?

The questions were answered satisfactorily and the Committee approved the risk assessment as AC2.

Page 2226 of 1532
The project aims to investigate whether the filamentous fungus Aspergillus fumigatus has the potential to undergo sexual reproduction. Recent genome analysis has revealed the presence of a series of genes involved with sexual reproduction, some of which are known to be expressed. However, the fungus is only known to reproduce by asexual means. Resolving this question is of major significance to understanding the population biology of this species in the wild and related management of the fungus. Insights into the sexual potential of the species might also allow exploitation of the sexual cycle in classical genetic studies to study inheritance of traits such as fungicide sensitivity/resistance or pathogenicity determinants.

There are two broad areas in which recombinant gene technologies will be used.

A) Cloning of putative genes involved in sexual development from A. fumigatus into E. coli hosts and vectors. This comprises genes regulating sexual compatibility, genes involved in sexual pathway signalling and genes involved with fruit body development.

B) Transformation of fungal genes involved in sexual development into fungal hosts. This encompasses:

- Transformation of putative sexual genes from A. fumigatus into class 1 ADCP host strains which lack the ability to undergo sexual reproduction as a result of previous gene disruption. This will allow complementation studies to assay the functionality of the A. fumigatus genes.
- Transformation of known functional sexual genes from class 1 ADCP host strains into A. fumigatus. These genes will be either under the control of native, constitutive or inducible promoters. Such studies may result in enhancement/restoration of sexual development in A. fumigatus, allowing possible exploitation of the sexual cycle.

Such studies have already been performed with sexual and asexual relatives of the plant pathogens Cochliobolus and Bipolaris species in the USA.

Fungal strains. Aspergillus fumigatus is a common environmental species, widespread in soil and in decomposing vegetation. It is not normally a risk to healthy persons. However, it occasionally causes aspergillosis, an invasive disease of the lungs and other organs, upon opportunistic infection of immunocompromised patients. It may also cause opportunistic infections of patients with existing medical disorders. The spores may in addition cause allergic reactions in certain patients. Thus the fungus is classified as ACDP class 2 (a potentially pathogenic microbe). More detail available in risk assessment.

Bacterial strains. The E. coli strains to be used are all Rec A-derivatives such as DH5a, XL1-Blue, SURE and TOP10. These strains are disabled and non-colonising and are equivalent of ACDP category 1 organisms (ie non pathogenic to humans or animals). They have limited survivability in the environment as they require specific nutrients supplements not required by wild-type organisms.

Host/vector system

Fungal vectors. These are pUC and pBR322-derived plasmids that will be maintained in E. coli host before transfer to a fungal host organism. Some plasmids will have
fungal promoters that are either constitutive or induced under certain environmental conditions. Vectors are integrated into the fungal genome and considered non-mobilisable or mobilisation defective.

Bacterial vectors. These are pUC derivatives encoding ampicillin, zeomycin or other antibiotic resistance markers. Considered to be non-mobilisable.

**Origin & function**

Inserts are genes involved with sexual development in filamentous fungi. These may be categorised into three main areas:

a) Genes involved with determination of sexual compatibility. Examples include mating-type (MAT) genes determining sexual identity, pheromone precursor genes involved with production of short chain amino-acid pheromones; pheromone processing genes involved with enzymatic modification of pheromone precursor molecules.

B) Genes involved with sexual signalling pathways. Examples include pheromone receptor genes encoding transmembrane surface receptors, a series of MAP kinase elements involved with signal transduction, and final transcription factors activating sexual development.

C) Genes involved with fruit body development. These include genes encoding hormonal factors regulating hyphal morphogenesis, and transcriptional factors altering developmental pathways.

These genes are not virulence determinants so unlikely to alter the pathogenicity of the host organism. The antigenicity of these proteins is not known. Previous work with similar genes involved with sexual development in fungi has not revealed any risk, so the protein products are considered unlikely to pose a toxic hazard.

**Evaluation of foreseeable effects**

*Aspergillus* is classified as an ACDP class 2 organism (a microbe potentially capable of causing human disease). It is a common environmental fungus associated with decomposition of organic matter in soil and vegetation. It is not normally a risk to healthy persons. However, it occasionally causes aspergillosis, an invasive disease of the lungs and other organs, upon opportunistic infection of immunocompromised patients. It may also cause opportunistic infections of patients with existing medical disorders. The spores may in addition cause allergic reactions in certain patients.

The potentially most hazardous GMMs to be constructed in this work are the transformed strains of the ACDP class 2 fungus *Aspergillus fumigatus*. However, it should be stressed that these will be transformed with genes involved in sexual reproduction, which themselves have no known link to virulence or pathogenicity. They are not involved with toxin production, so unlikely to alter the pathogenicity of the host organism. Also the strains to be transformed will be pre-screened to ensure that they are sensitive to the main antifungals (Amphotericin B and Litraconazole) used in clinical treatments.

The genes under study, those involved with sexual reproduction in ascomycete fungi, are widespread in numerous ascomycete fungi in the wild with the same functional gene families present in many harmless fungi. Thus potential transfer of such genes is not considered a risk, as it is stressed again that the genes under study do not related directly to the pathogenic potential of *A. fumigatus*.

There is the potential hazard that resultant GMM strains of *A. fumigatus* may have enhanced sexual fertility, which may be spread into wild-type strains of *A. fumigatus* through sexual recombination, promoting gene flow within the species. This might conceivably include flow of genes linked to virulence. However, there is no known occurrence of a sexual cycle of *A. fumigatus* in the wild and it is thought that *A. fumigatus* reproduces only by asexual means. Thus, if sex does occur in the wild it is at likely to be of very low occurrence if at all. Therefore there is low risk of spread of genes promoting sexual fertility. The hazard of spread of antibiotic resistance genes, used as selective markers, is thus also considered low risk.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
Solid waste and plasticware exposed to GM material will be autoclaved prior to disposal.
Liquid waste and glassware exposed to GM material will be autoclaved prior to disposal/wash up.
Class 2 autoclave disposal facility available in same lab suite.

2% trigene will be used to swab benches and disinfect as required. It has been shown by the manufacturer to be effective for control of filamentous fungus and is used in accordance with their instructions.
Standard procedure for spillage/breach of containment involves absorbing onto paper towels followed by cleaning of area with disinfectant (2% Trigene). Paper towels then sent for autoclave.

Project Additional Information

Purposes of the contained use

| Laboratory - based, preclinical studies developing gene therapy for cancer |

Recipient or parental organism

| Adenovirus; cell lines and primary tumour material |

Host/vector system
E1-deleted, replication-defective adenovirus vectors; probably E3-deleted. The wild-type fibre gene will be substituted with genetically modified derivatives intended to permit binding to integrins (e.g. by insertion of peptide motifs into the HI loop). Binding to the normal receptor (CAR) will initially not be modified, but may be ablated in later vectors. The viruses will be generated from transfected plasmid DNA constructs, and grown, in cells that complement the E1 deficiency, e.g. HEK293 cells.

Origin & function

The vector sequences are derived via plasmid cloning from adenovirus type 5; integrin-binding motifs designed based on known binding motifs. Some cancers, e.g. chronic lymphocytic leukaemia (CLL) have only low levels of the coxsackie and adenovirus receptor CAR, and so adenoviral gene transfer to these is very inefficient. Retargeting the virus by insertion of integrin-binding peptide motifs into the capsid fibre protein is expected to allow more efficient delivery of therapeutic genes to the cancer cells and, if the natural CAR-binding ability is simultaneously removed, may confer some selectivity of gene delivery to the cancer cells. A range of transgenes may be inserted into the E1 region of the viral vectors; the initial risk assessment covers reporter genes (e.g. green fluorescent protein); and the potentially therapeutic genes CD80, 4-1BB ligand, CD40 ligand, and GM-CSF (secreted or membrane-anchored).

Other potentially therapeutic genes may also be inserted under this connected programme of work including e.g. other immunomodulatory genes; prodrug activating enzymes; tumor-suppressor genes; we understand these would not require further notification to HSE if the GMSC agrees on the basis of risk assessments that there is no significant increase in the potential hazard.

Evaluation of foreseeable effects

No significant biological effects expected from expression of reporter genes. The immunomodulatory genes may have potential to induce local inflammatory responses in the event of contamination, and would be expected to enhance immune responses against the infected cells. Systemic or long term adverse effects are unlikely. The retargeting of the vectors is expected to alter the relative efficiency for entering different cell types. There is a theoretical possibility for recombination e.g. with wild type virus, which could generate a replication-competent virus carrying the modified fibre. Containment conditions and working practices will minimise this risk. Such recombination would lead to concomitant deletion of the exogenous transgenes inserted in the E1 region.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid virus containing waste is bagged and placed in a designated metal container which is removed to the autoclave. Liquid virus waste is discarded to bottles which are placed in a designated metal container for autoclaving. All liquid waste is treated by autoclaving before disposal to drain. Disposable solid waste is also autoclaved before removal as "clinical waste" by specialist contractors, with final disposal by incineration. The exceptions are:-

Sharps and pipettes are soaked in 1% Virkon for a minimum of 15 minutes before disposal in an approved sharps box. The disinfectant is discarded down the sink. Glassware used in this virus room is soaked overnight in 1% Virkon before removal for normal tissue culture wash up processing. Disposable plastic pipettes may also be decontaminated by immersion in Virkon as above.

Autoclaving achieves effectively 100% kill of GMMs. Manufacturer's data indicates efficacy of Virkon against a variety of adenoviruses at 15 concentration, and also against a number of strains of E.coli at dilutions ranging from 0.125% - 1%. We have demonstrated that 15 minutes exposure to 1% Virkon achieves >4log kill for adenoviral infected cell pellets and >6log kill of adenovirus seed stocks.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
The risk assessments were circulated to the committee and discussed with the applicant at a specially convened meeting on 8/5/2001. The committee noted that the potential for homologous recombination with wild type E1 sequences to result in the inadvertent generation of replication-competent, retargeted virus, and the potential hazard of such a virus was discussed. It was noted that the HSE/ACGM Guidance contained an example of a risk assessment for a retargeted, replication competent adenovirus (RCA), which indicated level 3 containment. Following discussion, the GMSC agreed that such recombination was a rare event in complimenting cell lines, and the committee was assured that the safest practicable complimenting cells would be used. Stocks would be monitored for RCA, and any found to be contaminated would be safely inactivated. Working practices to prevent cross-contamination were described. The committee agreed that the work could be safely conducted at containment level 2 and was therefore class 2. Any unexpected results from the work that might affect the assessment of safety, and any accidents involving the viruses will be reported to the committee. Other points of detail were clarified, and the final risk assessments modified in line with these discussions. The work has therefore now been approved by the GMSC.

Tick if notifying a connected programme of work Y

Historical Significant Changes TRANSFERRED TO GM CENTRE 116 - 4/4/06.
**Purpose of the contained use**

Studying the roles and regulation of cell signalling proteins.

**Recipient or parental organism**

Mammalian cell cultures.

**Host/vector system**

E1-deleted, replication-defective adenovirus vectors. The viruses will be generated from transfected plasmid DNA constructs, and grown, in cells that complement the E1 deficiency, e.g. HEK293 cells.

**Origin & function**

The cell signalling proteins to be expressed will be derived from human or other mammalian species. In addition to the wild type forms, constitutively active or dominant negative mutants may be generated. They will have various roles (which are under investigation) in cell signalling pathways. The risk assessments included with this notification relate to Rho family proteins, and phosphoinositol-3 kinase (P13 kinase); as detailed in the risk assessments these are regulators of cell movement and proliferation.

(Risk assessments for other cell signalling proteins expressed in similar adenovirus vectors have been approved by the GMSC as class 1; these include phospholipase D, Arf family (GTPases, PIP kinases). Similar adenovirus vectors encoding other cellular signalling proteins may also be generated and used in this connected programme of work; it is our understanding that these would not require further notification to HSE if the GMSC agrees on the basis of risk assessments that there is no significant increase in the potential hazard.

**Evaluation of foreseeable effects**

The cell signalling proteins that are to be expressed will have a variety of roles in the regulation of various cellular responses, eg inflammation, cell survival, control of apoptosis, proliferation, migration. For proteins of negligible apparent hazard, the viruses are classified as class 1. Viruses categorised as class 2 will express cell signalling proteins that have some association with harmful processes, eg. some may have been associated with a role in oncogenic transformation; however a role in cancer would only be in conjunction with many other oncogenic events, and so the degree of hazard from their transient expression in an E1-deleted adenovirus is only modest.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

No derogation applied for

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Autoclaving is preferred means of decontamination (effectively 100% kill). Liquid waste is autoclaved and disposed to drains. Disposable solid waste is also autoclaved before being removed as clinical waste, with final disposal by incineration.

The exceptions to the above are:
"Sharps", including scalpel blades, needles and disposable tips for micropipettors may be decontaminated by drawing up 1% Virkon disinfectant and soaking in Virkon for a minimum of 120 minutes. Disposable plastic pipettes may also be decontaminated by immersion in Virkon as above. Virkon has effectively 100% kill rate.

There was discussion regarding the boundary between class 1 and 2 risk assessments, reaching agreement with that shown on the risk assessments. Points of detail have been clarified, and the final risk assessments modified in line with these discussions.

Historical Significant Changes

TRANSFERRED TO GM CENTRE 116 - 4/4/06.
## Project Additional Information

### Purposes of the contained use

Identification of human tumour antigens; characterisation of immune response to tumour antigens; possible future investigation of role in cell signalling pathways.

### Recipient or parental organism

Virus vectors are used in order to achieve efficient gene transfer and expression of the tumour antigens in target cells in vitro for immunological assays. In the first instance, replication-deficient adenoviruses (E1-deleted) will be used. Future work may involve other well-established virus vectors, such as vaccinia virus (particularly for immunological assays) or replication-defective retroviruses (signalling studies).

### Host/vector system

**E1-deleted, replication deficient adenovirus.** Virus production in cells that complement E1 deficiency, eg HEK293 cells. Target cells for immune responses include human dendritic cells, fibroblasts, lymphocytes, epithelial cells.

Future work is likely to involve other virus vectors, particularly vaccinia or replication-defective retroviruses.

### Origin & function

The polycomb proteins BM1-1 and EZH2 were identified using the SEREX screening technique, using the serus of patients with hepatocellular carcinoma, and their potential utility as tumour-associated antigens will be further investigated in this project. This family of proteins are transcriptional regulators of haematopoiesis, and have been implicated in growth transformation of cells, hence may play a direct, contributory role in tumour development.

This work is leading to the investigation of other members of the polycomb family, and other tumour-associated antigens, some of which may also be involved in growth-regulatory pathways.

The main interest in this project is recognition of these antigens by the immune system and their potential as targets for cancer immunotherapy. Future work may also investigate their role in cell signalling pathways. Their potential contribution to the multistep process of oncogenesis warrants containment of these viruses at containment level 2.

### Evaluation of foreseeable effects

Stable incorporation of these genes into cells, and subsequent high level or ectopic expression of these proteins may contribute to cellular transformation processes. However, the adenoviruses carrying these constructs do not result in stable, long term expression in infected cells; they are also replication-defective and so unable to
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No application for derogation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste is treated by autoclaving typically at 130 degrees C for 60 mins, before disposal to drains.
Disposible solid waste which is or may be contaminated with GMMs is also inactivated by autoclaving at 130 degrees C for 30 mins, before removal as "clinical waste" by specialist contractors, with final disposal by incineration.

The exceptions to the above are:
"sharps", including scalpel blades, needles (with or without attached syringes), and disposable plastic tips for micropipettors, may be decontaminated by drawing up 1% Virkon disinfectant, and soaking for a minimum of 10 minutes.
Disposable plastic pipettes may also be decontaminated by immersion in Virkon as above.
Final disposal by incineration.

Expected degree of kill:
Autoclaving achieves effectively 100% kill of all GMMs.
1% Virkon has been validated to give >10 (to the power of 6) - fold reduction in titre.

Is an emergency plan required according to regulation 20?  N

### Project Additional Information

**Purposes of the contained use**

This project involves use of recombinant CMV viruses to stimulate T lymphocytes in vitro, from blood of virus carriers. In addition to the current batch of recombinant CMV viruses we may in future seek to undertake work with recombinant CMVs that are deficient for other novel immune evasion genes and/or different combinations of the above described immune evasion genes. Also we may wish to acquire/construct a CMV virus incorporating a non-harmful reporter gene such as green fluorescent protein (GFP).

We do not expect the hazards associated with such viruses to be any greater than the once we currently plan to work with. Prior to embarking on such new studies we would submit a new or modified risk assessment to the GMSC.

**Recipient or parental organism**

- **Host:** MRC5 fibroblasts, U373 cells (Astracytoma cell line that is permissive to CMV), endothelial cells, human fibroblasts.

**Host/vector system**

- **Vector:** Human CMV
Genetic material: 1: Cytomegalovirus genes.

CMV is a lymphotropic/epitheliotropic beta-herpesvirus that is carried as an asymptomatic life-long infection by the majority of individuals in all communities. Control of CMV infection is thought to be due to the potent cellular immune response that is detected in healthy immunocompetent virus carriers. Laboratory strains of CMV such as AD169 and Towne are highly restricted in host cell range, namely fibroblasts. This is believed to be attributed to the loss of genes over passage time in vitro (Bolovan-Fritts C, Wiedeman JA. 2001. Human cytomegalovirus strain Toledo lacks a virus-encoded tropism factor required for infection of aortic endothelial cells. J Infect Dis. 184:1252-61. Sinzger C, Schmidt K, Knapp J, Kahl M, Beck R, Waldman J, Hebart H, Einsele H, Jahn G 1999. Modification of human cytomegalovirus tropism through propagation in vitro is associated with changes in the viral genome. J Gen Virol. 80:2867-77.)

It is a general consensus that recombinant CMVs made from such parental strains will not acquire the potential to replicate in other cell types (Thomas Jones - personal communication).

The following genes are deleted in the recombinant viruses.
RV798 (all of US2 to US11),
RV35 (US6 to US11) and
RV47 (US2 to US3 only)

The functions of each gene product are described.

US2: The US2 gene product is expressed in the early phase of the viral replication cycle. This protein induces rapid degradation of newly synthesized MHC class 1 molecules, reducing the half life from over 6 hours to less than 2 minutes. It appears that US2 proteins bind to MHC class 1 molecules causing the transport of these complexes to the cytoplasm (Jones et al. 1997). After deglycosylation, both US2 proteins and MHC class 1 molecules are degraded. CMV also interferes with MHC class II expression in several ways as described elsewhere (Miller et al. 1998; Phillips et al. 1998; Tomazin et al. 1999).

US3 &US11: The US3 and US11 genes are expressed in the immediate early phase and encode for products that physically associates with MHC class 1-B2m complexes. Whereas the US3 protein causes the retention of MHC class 1 molecules in the ER(Jones et al. 1996), US11 binds to MHC class 1 molecules and directs their translocation to the cytoplasm (Wiertz et al. 1996).

US6: The US6 gene is expressed much later in the delayed or late phase and subsequently remains expressed throughout the virus life cycle. US6 interferes with peptide loading of MHC class 1 molecules in the ER (Ahn et al. 1997). This is achieved by US6 proteins transiently associating with the complex containing TAP, MHC class 1-B2m (and other proteins such as Tapasin and calreticulin). This interaction results in the inhibition of peptide translocation across the ER membrane and efficiently blocks assembly of the trimeric MHC class 1-B2m-peptide complex.

US8: Human cytomegalovirus US8 is a type 1 membrane protein that partially colocalizes with cellular endosomal and lysosomal proteins. Although US8 does not have discernible effects on the processing and cell surface distribution of major histocompatibility complex (MHC) class 1 products, it is demonstrated that US8 binds to MHC class 1 heavy chains in the endoplasmic reticulum (Tirabassi & Pleogh, J Virol 2002 Jul;76(13):6832-5).

The other genes replaced (US4, US7, US9, US10) are not fully characterized with regards to function. They appear to be cytoplasmic proteins and may have some function in immune subversion also (Huber et al. J Virol. 2002 Jun;76(11):5748-58).
The pp65 gene is deleted in the RVAd65 virus. pp65 is a structural protein located in the viral tegument. Pp65 is expressed during the late phase of viral replicative cycle. Pp65 has been demonstrated to have kinase activity and co-immunoprecipitates with a cellular kinase (Plk-1) but is dispensable for virus growth in vitro. Although it has been reported to have immune evasive properties, pp65 itself is the target of a massive immune response (both cellular and antibody mediated). It is believed that parent CMV (strain AD169) preparations contain non-infectious viral particles known as dense bodies which contain a large excess of this protein. This is thought to bias towards stimulation of T cells specific for pp65. Therefore the absence of this gene may allow for other peptides to be presented by MHC class 1 molecules and the T cell reactivities to be detected.

**Evaluation of foreseeable effects**

The genes that have been deleted are involved in either immune subversion or part of the virion structure. The consensus view of prominent CMV virologists is that their absence does not appear to alter the pathogenic capacity of CMV. In fact it is more likely that these viruses will be more immunogenic and provoke a more vigorous response than parent CMV due to the less hindered presentation of a variety of antigens. The absence of pp65 is expected to allow for the presentation of other immunodominant CMV antigens such as IE-1, pp150 and pp50. One possibility to be considered is that an enhanced immune response may also result in greater inflammation at the site of infection. It is envisaged that this will be self-limiting and restricted to the site of infection.

The presence of prokaryotic gene sequences in these recombinant viruses are not believed to increase the pathogenicity or host range of these viruses.

CMV does not immortalise human cells in vivo or in vitro - the removal of immune-subversive genes should render the virus more immunogenic, and not confer transforming properties.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

No derogation.

<td></td>
</tr>
</tbody>
</table>
Deregulation of cell controls affecting proliferation and apoptosis is a sine qua non of cancer development. This programme of work will use lentivirus vectors to aid analyses of the functions of cellular and viral genes involved in cell cycle regulation and cell survival. The lentivirus vector system will enable the efficient transduction of human and murine cells grown in tissue culture with either cDNAs encoding cellular and viral genes or cassettes encoding short interfering RNAs (siRNA).

Recipient or parental organism

The lentivirus vectors to be used in this programme of work are severely disabled derivatives of human immunodeficiency virus type 1 (HIV-1). A number of genes required for HIV-1 replication and virulence have been deleted from the lentivirus sequences contained in the vector. The virus vectors are propagated as plasmids in E. coli strains. Packaged virus able to infect human, mouse and other animal species are produced by cotransfection of the lentivirus vectors with other plasmids which provide proteins required for packaging in trans. Although the packaged lentivirus is able to transduce efficiently genes cloned in the lentivirus vector plasmid, the virus is totally unable to replicate in these cells. No infectious virus can therefore be produced.

Host/vector system

The standard vectors to be used are based on deleted/mutated HIV-1 genomes, pseudotyped with a vesicular stomatitis virus (VSV) envelope (VSV-G) allowing infection of a broad range of cell types. In some cases these recombinant HIV-1 will encode a green fluorescent protein (GFP) from a bicistronic transcript allowing the identification of infected cells by fluorescence microscopy or flow cytometry. In other cases the vector will encode a gene for drug resistance (e.g., Neomycin or Hygromycin). The delivery systems to be used involve three separate plasmids that are transiently cotransfected into the human 293T cell line to produce pseudotyped, packaged viruses. One plasmid encodes the HIV-1 derived vector, one encodes the VSV-G and one provides functions in trans for packaging. Two very similar systems will be used which only differ in the details of generating infectious virus:

SYSTEM A PLASMIDS
1. pAG131 - the HIV-IRES-GFP expression construct from which env, vif, vpr, vpu genes have been deleted and the tat gene is inactivated by inverting its open reading frame. These deletions and inversion make the resulting recombinant virus completely incapable of replication in the absence of helper proteins encoded by additional plasmids. The AG131 plasmid still encodes HIV-1 Gag and Pol and will include the cDNA of interest or encode the siRNA.
2. pME-VSV-G - this is a plasmid encoding the VSV-G envelope protein for pseudo-typing the lentivirus.
SYSTEM B PLASMIDS
1. pAB286 or pHOX-GFP or pHOX with GFP replaced by the siRNA cassette from pSUPER plus target sequence [see Brummelkamp et al. (2002) Science 196, 550-553.] or a cDNA. These plasmids all encode self-inactivating (SIN) lentivirus with a 400-nucleotide deletion in the 3’ LTR. This deletion abolishes all LTR promoter activity and therefore the vectors are incapable of replication. The HIV-1 Vpr, Vif, Vpu, Nef and Tat genes are also deleted in the vector.
2. pRD1274 (pMD.G). This plasmid encodes the VSV-G envelope for pseudotyping the lentivirus.

Origin & function
The cDNAs carried by the lentivirus vectors will comprise two classes: (1) cellular and viral genes encoding proteins that promote cell proliferation and/or decrease apoptosis - such genes are generally, but not exclusively, oncogenes and (2) cellular and viral genes encoding proteins that inhibit cell proliferation and/or promote apoptosis - such genes are generally, but not exclusively, tumour suppressor genes. The siRNA cassettes will also comprise two classes: (3) siRNAs directed against cellular and viral genes encoding proteins that promote cell proliferation and/or decrease apoptosis and (4) siRNAs directed against cellular and viral genes encoding proteins that inhibit cell proliferation and/or promote apoptosis. These are described in more detail below:

(1) Lentiviruses carrying cellular and viral cDNAs encoding proteins that promote cell proliferation and/or decrease apoptosis.

Only single growth-promoting (for example EBNA-2, EBNA-3C, LMP1, RUNXI, RUNX3, Id2 and B-myb) and anti-apoptotic genes (for example Bcl-2) will be transduced in this programme of work. As cancer development is a multistep process, transduction with such genes will not transform the infected cells. This programme of work will not include viral oncogenes which have multiple oncogenic activities such as the SV40 T antigen, nor will it include clusters of genes such as HPV16 E6-E7. Genes encoding toxins will not be included in this work.

(2) Lentiviruses carrying cellular and viral cDNAs encoding proteins that inhibit cell proliferation and/or promote apoptosis.

These genes, which include tumour suppressor genes (for example p53, ASPP, RB, P130) and pro-apoptotic genes (for example Bax, Bik and Bad), are expected to inhibit cell growth.

(3) Lentiviruses encoding siRNAs directed against cellular and viral genes encoding proteins that promote cell proliferation and/or decrease apoptosis.

Short interfering RNAs (siRNA) are designed to ablate expression of a specific gene target. Ablation of oncogene expression, for example, would in many instances inhibit cell cycling or promote cell death. Expression of this class of siRNA (for example siRNAs directed against EBNA-2, EBNA-3C, LMP1, RUNXI, RUNX3, Id2, iASPP, mdm2, RAS and B-myb), would be equivalent to that outlined in (2) above. That is, cell growth is likely to be inhibited. It is noted that siRNA sequence specificity is very precise, and generally there is insufficient homology between the mRNA target sequences of mouse and human genes for cross-species interference to occur. For example, siRNAs directed against mouse genes are unlikely to affect growth of human cells.

(4) Lentiviruses encoding siRNAs directed against cellular and viral genes encoding proteins that inhibit cell proliferation and/or promote apoptosis.

Expression of siRNAs which ablate tumour suppressor gene function has the potential to promote cell growth. Lentiviruses expressing siRNAs directed against, for example, p53, ASPP, RB and p130 may predispose cells to further oncogenic events, but would not by themselves transform the cell. This programme of work will be restricted to expression of a single siRNA directed against this class of genes, or the expression of multiple siRNAs which affect the same regulatory pathway. Examples of the latter include the p53 pathway (eg ablation of p53 or ASPP would be expected to have similar consequences) and the RB pathway (eg ablation of RB and p16 INK4a is likely to be equivalent).
Evaluation of foreseeable effects

Lentivirus vectors are designed to infect efficiently both actively proliferating and resting cells of many different species and lineages. The two major foreseeable effects are accidental transduction of laboratory personnel and animal species such as mice. In this respect, it should be noted that these vectors are replication-defective and the risk is therefore limited to cells accidentally transduced with the packaged vector. The consequences for animal species are therefore negligible, since even in the extremely unlikely event that mice were exposed to the packaged vector, the virus could not propagate.

Exposure of laboratory personnel to packaged vectors containing growth promoting genes such as oncogenes or anti-apoptotic genes (see (1) above) could result in some growth advantage of transduced cells. Similarly, transduction with lentiviruses encoding siRNAs directed to growth inhibitory genes such as tumour suppressor genes and pro-apoptotic genes (see (4) above) could also result in a growth advantage. It should be noted, however, that the single genes targeted in these studies can not by themselves result in cell transformation, even in highly responsive rodent cells. Targetting of combinations of genes with the potential to cause cell transformation has been specifically excluded from this programme of work. It should also be noted that with the saacale of production to be used, it is extremely unlikely that accidental transduction will occur in stem cells at risk of carcinogenic development.

Accidental exposure of laboratory personnel with packaged vectors carrying genes that inhibit cell proliferation and/or are pro-apoptotic (see (2) above) is very unlikely to have any consequence. Similarly, transduction with lentivirus vectors encoding siRNAs directed to growth promoting genes such as oncogenes and anti-apoptotic genes (see (3) above) would only inhibit the growth of the cells infected. In principle, transduction of stem cells could inhibit their growth and prevent them participating in tissue maintenance. In practice, it is unfeasible that sufficient stem cells would be affected in this way to have any consequences for human health.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be collected in double autoclave waste bags and subjected to autoclaving under approved conditions. 100% kill is achieved with this procedure.

Liquid waste will be collected in polythene contains and treated for 24 hours with 1% Chloros. This achieves 100% kill.

Small laboratory spills will be treated with 70% ethanol; high concentrations of alcohol effectively kill enveloped lentiviruses (van Engelenburg et al., 2002, J. Hosp. Infect. 51:121-125). Larger spills will be cleaned with 1% Chloros. Contaminated paper towels are treated as solid waste.

Extracts will be made from tissue culture cells for biochemical and cell biological procedures (eg microscopy). The simple act of infection inactivates much of the input virus as it becomes uncoated upon entry into the cell. When making cell extracts, residual virus will be inactivated by detergent treatment (ie 1% SDS or 0.5% NP40). Studies have shown that HIV is very sensitive to inactivation even with non-ionic detergents (Ukkonen et al., 1988 Eur. J Clin. Microbiol. Infect. Dis. 7:518-523). The effectiveness of the detergent treatments will be validated by plating transduced cell extracts on indicator cells and selecting for antibiotic resistance carried by the vector. For flow cytometry and microscopy techniques, the transduced cells will be fixed with 70% ethanol or 4% formaldehyde or 4% paraformaldehyde. These treatments achieve 100% kill.

Is an emergency plan required according to regulation 20?

Y

02/03/2022
It was unanimously agreed that Containment Level 2 was appropriate in view of the slight theoretical risk to human health of transducing genes designed to alter cellular growth controls. It was noted that other groups working with lentivirus vectors had also designated their work as a Class 2 Activity.

Project Additional Information

02/03/2022
Purposes of the contained use

The generation of bacterial artificial chromosomes (BAC) containing entire herpesvirus genomes allows the use of powerful bacterial cloning strategies to introduce precise modifications into the virus. These modified herpesvirus BACs can be transfected into mammalian cells to study the impact of these mutations in the context of the entire genome. By stimulating the lytic cycle, infectious virus can also be recovered from these transfected cells.

Recipient or parental organism

Sequences comprising the Epstein-Bar virus (EBV) and herpesvirus saimiri (HSV) A11-S4 genomes will be inserted into BAC vectors, which will then be cloned and propagated in attenuated E. coli strains DH5 and DH10. Modified BAC constructs will be transfected into mammalian cell lines to generate virus stocks. It is envisaged that HEK 293 cells will be used initially to generate EBV stocks. Replication-defective EBV will be propagated in a 293 line containing an integrated full-length EBV genome to provide replication factors in trans. HSV will initially be propagated in either owl monkey kidney cells or marmoset embryonic fibroblasts, in which the virus is spontaneously lytic. In principle, infectious virus can be generated in any mammalian cell line if the replication cycle is stimulated, and other lines may be used to propagate virus as they become available.

Host/vector system

BAC vectors are F-factor-based plasmids which are conjugated-deficient, and are therefore extremely unlikely to transfer to bacteria in the environment. The HVS A11-S4 genome has already been inserted into a BAC vector at the University of Leeds (White et al., J. Gen. Virol., in press). This HSV strain is attenuated and lacks the stpA gene required for oncogenic transformation. Details of the proposed HVS modifications are given in the accompanying risk assessment. EBV sequences to be cloned include the entire wt sequence and derivatives with modifications of immortalisation genes, insertion of non-hazardous marker genes and viral genes as specified in GM217/99.2

Origin & function

The nature of modifications to be introduced to the EBV genome using BACs are broadly the same as those reflected in previously approved protocol GM217/99.2, namely the deletion or alteration of immortalising genes, the insertion of non-hazardous marker genes or sequences and the construction of viruses that conditionally express defined viral genes. Because modifying herpesvirus BACs does not require full viral function, we will also modify or delete viral genes or structural DNA regions involved in virus latency, replication and packaging, and in the co-ordination of the viral transcription programs. The aim of our work with HVS is to identify the viral genes and DNA motifs involved in the latent and lytic replication and packaging functions of HVS, and to develop the virus as a gene delivery system. This will be achieved by 1) deletion (and subsequent complementation) of genes involved in these processes. 2) in situ modification of these genes (eg fusion to GFP or other tags; mutation of putative domains) to dissect their function. 3) Addition of marker genes (eg antibiotic resistance, luciferase) driven by various promoters to identify differences in gene expression between integrated and episomal expression systems. 4) Tagging the viral episome and arrays of Tet operator repeats to allow the visualisation of the episome in live cells. 5) Cloning human and mouse genetic loci to study expression and regulation of mammalian genes in their natural context. Such work will initially comprise analysis of MHC and immunoglobulin gene loci, but may be extended to other gene loci, however, this work will exclude cloning of oncogenic or other potentially harmful genes.

Evaluation of foreseeable effects

Propagation of BAC-transformed attenuated E. coli strains is not expected to have any adverse effect. The BAC plasmids would be exceedingly difficult to transfer to wt E. coli and other bacterial species, and in any case viral genes would not be expected to be expressed in these bacteria. Generation of virus in transfected mammalian cell lines will give rise to recombinant virus that potentially will be able to replicate in certain primate species, including man. Both EBV and HSV are gammaherpesviruses, which have a restricted host range and grow slowly in vivo. Pathogenesis associated with A strains of HVS have not been observed in man, and the A11-S4 strain to be used has been further attenuated by removal of the transforming stpA gene. EBV is normally transmitted through exchange of saliva, and it is therefore unlikely that the virus would be transmissible under Containment Level 2 conditions. As outlined above, in the event that the recombinant EBV or HSV viruses to be used in this project were accidentally transmitted to laboratory workers, the pathogenicity of the viruses would be no greater, indeed probably less, than the wt viruses.

Release of the recombinant viruses into the environment would have no adverse effect, as both infect only primates.

It was unanimously agreed that work on manipulating EBV and HVS sequences in BAC vectors in E. coli could proceed at Containment Level 1. Generation of recombinant EBV and HVS viruses by transfection of mammalian cells will be a Class 2 activity. Similarly, infection of mammalian cells in culture with the recombinant viruses will be carried out at Containment Level 2.

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

Recombinant vaccinia virus will be grown and used in containment level 2 facilities with class II cabinets.

**Recipient or parental organism**

GMO: Recombinant vaccinia virus WR strain with disrupted TK gene and insertion of either influenza nucleoprotein or a peptide (366-374) from the influenza nucleoprotein.

TK disruption will attenuate pathogenicity of the virus.

Insertion of influenza nucleoprotein or peptide will not have any foreseeable effect.

**Host/vector system**

Recombinant vaccinia will be cultured in vitro in TK143 cells.

**Origin & function**

Influenza nucleoprotein is an RNA binding protein that encapsidates the viral genome. It comes from influenza virus.

The influenza nucleoprotein peptide comprises amino acids 366-374 of the nucleoprotein and has no intended function. It serves as a peptide epitope presented by the MHC class 1 molecule Db. It comes from influenza virus nucleoprotein.

The F5 T cell receptor is a T cell receptor that recognises the influenza nucleoprotein 366-374 peptide presented by the MHC class 1 molecule Db.
### Evaluation of foreseeable effects

Disruption of the vaccinia virus TK gene will be attenuate pathogenicity.

Insertion of the coding sequence for influenza nucleoprotein or the nucleoprotein peptide 366-374 into the vaccinia virus will allow for expression of the protein/peptide within cells of infected mice. This will stimulate a T cell response to the nucleoprotein.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

**Laboratory.**

- **Solid waste:** Treatment with 1% Virkon for minimum of 10 minutes. 100% kill. This has been validated on the Antec (Virkon) website. The product has been tested to be effective at 1% solution and 10 minutes contact time. The website will be monitored for any changes in specification.

- Solid waste will be placed in sterilin bags and put in specially designated grey boxes within the laboratory or cold room. When these are full, they will be tied using a specially designated yellow tag and sent for autoclaving.

- Solid waste will be autoclaved at 134 degrees centigrade for a minimum of 30 minutes. A 12 point thermocouple test is conducted every 6 months on a simulated worst case worst load to establish that an effective and validated sterilisation temperature and time is achieved in all areas of the load. An internal thermocouple monitors the chamber temperature on every run. The current autoclave program sets temperature of 134 degrees C for 30 minutes and this ensures that all parts of a worst case load will always achieve a validated lethal temperature for the microorganisms mentioned in this assessment.

- **Liquid waste:** Treatment with 1% Virkon for minimum of 1 hour. 100% kill. This has been validated on the Antec (Virkon) website. The product has been tested to be effective at 1% solution and 10 minutes contact time. The website will be monitored for any changes in specification.

**CBS**

- **Mouse bedding and cages:** These will be removed for cleaning and decontamination by CBS staff. Bedding will be autoclaved at 134 degrees C for 30 minutes and disposed of via the clinical waste route. Cages will be autoclaved at 121 degrees for 15 minutes and then wasted for re-use.

<td>1-50 Litres</td>
<td></td>
</tr>
</tbody>
</table>
Purposes of the contained use

Generation of herpes viruses containing natural proteins linked to a marker - Green Fluorescent Protein (GFP). This will allow detection of fusions in living cells and analysis of pathways involved in virus assembly. Use of mutated proteins linked to GFP will further aid understanding of mechanisms involved.

Recipient or parental organism

Routinely used mammalian cell lines, e.g. Vero, COS, etc. all are well characterised and authenticated with a history of safe use.

Host/vector system

HSV-1 strains, e.g. HSV-1 strain 17, Macro Plaque and tsB7.

Origin & function

Native marker genes fused to the marker gene for Green Fluorescent Protein (GFP) which is available commercially. Work involving mutated genes will also be undertaken. GFP has fluorescent activity which enables the location of the fusion protein to be determined. Insertion will be into the natural region of the gene under investigation. Gene sequences of interest are either regulatory, for transcription initiation, or are structural.

Evaluation of foreseeable effects

The inserts display no potential for a pathogenic phenotype. Expression will be identical to that of native viral genes. The recombinant virus will be identical to the parental strain except for expression of the desired candidate gene linked to GFP.

If the modification were to affect the virus it is most likely to disrupt the function for example, by the recombinant protein being to large to permit viral development. No effect on viral susceptibility to anti viral drugs such as acyclovir is envisaged.

The likelihood of an environmental hazard is negligible as herpes virus particles are labile and inactivated by drying.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste (tissues, gloves, plasticware) is autoclaved at 121°C for 15 minutes (as measured in load) to give effectively 100% kill.

Sharps (needles used in gradient harvest) are disinfected by contact with 1% Virkon overnight prior to disposal into a sharps bin. Manufacturers validation states 100% kill when left in contact with 1% Virkon for a minimum of 10 minutes.

Waste media is inactivated by addition of Virkon tablets to a final concentration of not less than 1% and left overnight. Manufacturers validation states 100% kill when left in contact with 1% Virkon for a minimum of 10 minutes.

Pipettes are decontaminated by complete submersion in 1% Virkon overnight. Manufacturers validation states 100% kill when left in contact with 1% Virkon for a minimum of 10 minutes.

If the use of glassware is unavoidable, this is decontaminated by complete submersion in 1% Virkon overnight. Manufacturers validation states 100% kill when left in contact with 1% Virkon for a minimum of 10 minutes.

### Project Additional Information

#### Purposes of the contained use

The resulting recombinant virus will be tested for susceptibility to antiretroviral drugs. This will be used to determine whether RT and protease from the patient isolates demonstrate evidence of anti-retroviral drug resistance.

#### Recipient or parental organism

HIV is a human retrovirus, which is able to integrate into host DNA and persistently produce virus. Infection with HIV leads to severe immunosuppression, ultimately leading to AIDS. Prolonged and sub-optimal therapy has lead to the emergence of viral strains with reduced susceptibility to antiretroviral drugs. The RT and protease genes from infected patients failing therapy will be amplified by PCR and recombined with the pol deleted HXB2 clones.

#### Host/vector system

There are 2 replication deficient clones based on the well characterised lab adapted HIV virus HXB2. Plasmid pHXB2^RT has a 777 base deletion between codons 2-261 of HXB2 RT and is cloned into the pSP64 vector. The pHXB2^Pr similarly has a 297 base deletion between codons 1-99 of protease. Both these clones have been developed by the Department of Virology at the University Hospital in Utrecht in The Netherlands.

#### Origin & function

The deletion clones have been donated by the Department of Virology at the University Hospital in Utrecht in The Netherlands. The HXB2 deletion clones have no function as they are replication incompetent. The patient derived viral inserts encode RT or protease, 2 enzymes required for HIV replication.

#### Evaluation of foreseeable effects

HIV is ACDP Hazard group 3. The recombination experiment has 2 outcomes. If recombination does not occur, the HXB2 clone remains replication deficient. Recombination of the clones with the inserts will result in replication competent infectious HIV. This virus has the biological and pathogenic properties of HXB2, except for RT or protease encoded for by the patient derived insert. As a consequence, the resulting virus may have increased resistance to the drugs mentioned in 6. The presence of resistance mutations may result in a decrease in replicative capacity. There is no evidence that these mutations will result in an increase in viral fitness compared to wild type strains.

In the event of accidental infection of a laboratory worker, therapeutic options may be limited by the presence of resistance mutations present in the recombinant virus. However, in this event there are a number of therapies available which successfully treat patients in the clinic.

The recombinant virus should not pose a serious risk to animals and plants as envelope has not been modified, therefore the virus is only capable of infecting primates.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

None

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste material including plastics will be inactivated in Basol overnight and then autoclaved on site and disposed of by incineration. Any spillages will be flooded by an excess of Alcide, the degree of kill being 100%

**Historical Significant Changes**

- Transferred to GM43 University of Cambridge 28/09/2011

**Project Additional Information**
Purposes of the contained use

Fundamental research in virology and vaccine development.

Recipient or parental organism

The genetically modified viruses will have characteristics either similar to the parent virus, or of reduced virulence.

The expression of foreign genes by vaccinia virus will not increase the hazard posed by the virus and often the insertion of these recombinant viruses is associated with a reduction in virulence because the gene is inserted into a site in the virus genome that affects virulence. The foreign proteins pose no toxic hazard and are designed to promote appropriate immune responses that will be beneficial in preventing or reducing disease caused by infectious disease and cancer.

The deletion of existing vaccinia virus genes will either be neutral or, more often, decrease virus virulence. Removal or genes affecting the ability of the virus to be released from infected cells and spread to other cells is accompanied by a dramatic reduction in virulence. Removal of genes encoding proteins that aid virus escape from the immune system also reduces virus virulence since the virus infection is better recognised and cleared by the host immune response.

Other poxviruses to be used include the orthopoxviruses cowpox and camelpox virus and the yata poxviruses tanapox and yaba-like disease virus. Cowpox virus is similar to, and often confused with, vaccinia virus and poses a similar hazard. Camelpox virus is a less well characterised orthopoxvirus that causes a severe disease in camels but does not cause disease in man. Tanapox virus and yaba-like disease virus are simian viruses that have caused rare zoonoses in man. Such zoonoses usually produce a single lesion that heals without adverse consequence.

Host/vector system

Vaccinia virus is the live vaccine used to eradicate smallpox and has been used widely as an expression vector since 1982. For cowpox virus, yaba-like disease virus and tanapox virus see comments above under section 7. All these viruses will be treated as for vaccinia virus and pose similar or reduced risk to man. All viruses will be housed in our category 2 containment laboratory and will not be released from that laboratory. The genetic manipulation of all these viruses requires construction of plasmids in bacterial vectors (level 1 GM work).

Origin & function

Each genes to be deleted from or inserted into vaccinia virus or other class 2 poxviruses are described in detail in the accompanying document.

In summary, the genes to be deleted from these viruses encode proteins that either enable the virus to be released better from infected cells, or affect interactions with the host immune system. The latter group of proteins interfere with the host response to infection, and the deletion of these genes therefore may reduce virulence and enhance immunogenicity.

Foreign genes to be expressed in these viruses are either marker proteins that enable the virus to be detected in cell culture, such as β-galactosidase or green fluorescent protein, or antigens from other micro-organisms against which an immune response is sought. These latter proteins are not toxic but are important targets for immune responses that help prevent or reduce disease.

Evaluation of foreseeable effects

The foreseeable effects of deleting genes from vaccinia virus and other class 2 poxviruses are to make the virus less fit, less virulent and less able to cause disease and survive in nature. These virus genes selected encode proteins that aid virus dissemination from infected cells or to aid virus escape from the immune system. It follows that deletion of such genes, will reduce virus virulence and fitness. The foreseeable effects of expressing foreign genes in vaccinia virus are to make the virus a candidate vaccine for different infectious diseases or cancers. The foreign proteins to be expressed pose no toxic hazard and the immune responses to them are likely to be beneficial.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All material from our virus containment room will be autoclaved, or incubated in 1% (weight/volume) virkon overnight to ensure no infectious virus remains.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Project Ref 77/01.3

Date Ackn’d 15/03/2001

CU2 Project Title ANALYSIS OF RECOMBINANT RESPIRATORY SYNCYTIAL VIRUS (RRSV) IN AN INFECTION MODEL

Class Class 2  
CultureVolClass2 < 1 litre

Non-GMM Consent Granted not applicable

Project notified under transitional arrangements N
## Project Additional Information

**Purposes of the contained use**

rRSV was synthesized externally (as part of GM558/999). This will be safely transported to Imperial College in sealed approved containers where it will be assessed for its ability to replicate in vitro and in vivo and to elicit an antiviral immune response.

**Recipient or parental organism**

Parental organism is respiratory syncytial virus, laboratory adapted strain A2.

**Host/vector system**

The host is RSV. It does not contain any vector.

**Origin & function**

Recombinant RSV will be provided externally (see ref GM 558/999). Specific mutations were introduced into the RSV genome by site-directed mutagenesis (SDM) in order to either (i) destroy the initiation codon of the full-length G protein (Met 1) so that only secreted form of RSV G is expressed or (ii) destroy the initiation codon of the secreted form of RSV G (Met 48) so that only the anchored form is expressed. These rRSV's will be assessed in an infection model to understand the roles played by the anchored and secreted forms of the RSV attachment (G) protein in immunopathology.

It is not known which glycosylation sites on G protein are critical for infection and it is unclear whether glycosylation contributes to the immunopathology associated with RSV infection. Thus, rRSV was made in which specific N and O glycosylation sites were abolished. Some of these mutants are expected to be non-infectious in vivo and others may be similar to parental A2 strain. The effect of these mutations upon infectivity and immunopathology will be assessed. Assessments of these deletion and substitution RSVs will be carried out in an established mouse infection model at Imperial College.

**Evaluation of foreseeable effects**

Glaxo Wellcome PLC has already notified generation of these recombinant RSVs (see GM 558/999). To date, it has been shown that they have a slower growth rate and are less pathogenic in in vitro cell cultures in comparison to wild-type RSV A2.

RSV is a category II organism. All the mutants generated will have deletion or loss of function mutations resulting in reduced pathogenicity. No insertion of extraneous material will be performed. Thus, the recombinant RSVs generated should also be classified as category II.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Class 2

Culture Volume Class 2 < 1 litre

Project notified under transitional arrangements  N

Historical Significant Changes

Tick if notifying a connected programme of work  Y

Historical Date of Additional Info

02/03/2022
### Project Additional Information

#### Purposes of the contained use

rVV will be used to prime mice to elicit an anti-viral immune response

#### Recipient or parental organism

Parental organism is vaccinia pox virus (WR strain)

#### Host/vector system

The host is rVV. Vectors are ‘pAB174’ or ‘pVV192.76’ containing individual RSV genes, influenza genes, or bacterial B-galactosidase under the SV40 or other promoter.

#### Origin & function

RVV were a gift from Birmingham, Alabama, USA, and Madrid. RVV will be used to induce an immune response by priming in vivo, using an established mouse infection model at Imperial College.

The inserted gene products are expressed on the infected cell surface and induce an immune response. Subsequent infection with RSV allows us to study the phenotype of the immune response and the factors involved in subsequent observed immunopathology.

#### Evaluation of foreseeable effects

Vaccinia virus is a category II organism. Despite extensive characterisation in vivo and in vitro, none of the inserted genes or gene products are known to alter the pathogenicity of vaccinia virus. The gene product is not incorporated into the vaccinia virion structure, and therefore does not affect the behaviour of the virus except for the effects of disrupting the site of insertion. The inserted genes could reduce the pathogenicity in some host species.

Vaccinia virus infection is almost always self-limiting, no specific treatment is necessary (or available). This is unaffected by the inserted gene product.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Project Additional Information

Purposes of the contained use

The isolation, culture, and study of recombinant human cytomegalovirus strains with lesions in gene regulatory genes, in order to elucidate the important and essential regulatory processes which occur during human cytomegalovirus infection.
Retroviral packaging intended for the generation of human cell lines with altered characteristics, which will serve as complementing hosts for defective human cytomegalovirus strains.

**Recipient or parental organism**

Activity 1: E.coli K12 strains
Activity 2: Human cytomegalovirus, laboratory and clinical strains
Activity 3: Cultured human fibroblast cells, Amphotropic third generation packaging cell line 0NX-A
Activity 4: Cultured human fibroblast cells.

**Host/vector system**

Activity 1: Bacterial artificial chromosomes (BACs), based on the vector pBAC108L
Activity 2: Generation by recombination between human cytomegalovirus and plasmid replacement vectors based on plasmids pGEM, pBluescript or pUC. Otherwise, direct regeneration from transfected BACs (see activity 1).
Activity 3: Amphotropic and Pan-tropic retroviral vectors from third generation packaging cell lines
Activity 4: Amphotropic retroviral vectors from transiently transfected third generation packaging cell lines

**Origin & function**

Activity 1: Human cytomegalovirus, laboratory and clinical strains, complete infectious genome. Intended to allow mutagenesis in bacteria, followed by reconstitution by transfection of permissive human cells in culture.
Activity 2: Selectable marker genes gpt (from Escherichia coli), puromycin acetyl transferase (from Streptomyces alboniger) and Green fluorescent protein (from Aequorea victoria). Intended to facilitate the selection and isolation of human cytomegalovirus strains, where insertion of the selectable marker gene is coupled to genetic change, usually deletion of cytomegalovirus gene regulator genes.
Activity 3: Individual regulatory protein genes from human cytomegalovirus, to be expressed in long term retroviral vector producer cell lines based on third generation amphotropic packaging cell line 0NX-A. Individual regulatory protein genes from human cytomegalovirus, to be expressed over the long term in human cell lines, intended for the complementation and growth of human cytomegalovirus strains unable to synthesise these proteins.
Activity 4: Human cellular proto-oncogenes and known/suspected viral oncogenes from Adenovirus, Human papilloma virus, and Human cytomegalovirus. Intended to generate human fibroblast cell lines which are immortalised or resistant to apoptosis.

**Evaluation of foreseeable effects**

Activity 1: Human cytomegalovirus BACs are infectious DNAs, able to regenerate human cytomegalovirus when introduced into permissive human cells. Foreseeable effects are limited to the accidental introduction of BAC DNA into the tissue of a human handler, either by exposure of damaged skin, or direct injury. The consequences of such an event are indistinguishable from activity 2 below. Survival outside the laboratory of bacteria containing HMCV BACs is not expected, due to the defective host strains used. DNA transfer to a human host via colonisation by BAC-copntaining strains is likewise not expected, as strains used are non-replicating and non-colonising in the human host.
Activity 2: The genetic material to be added to recombinant cytomegalovirus strains is limited to genes involved in the drug selection and tagging of recombinant viruses. All of the proteins concerned have been used as marker genes for recombinant HCMV, and none are known to modify viability or pathogenicity of the virus. Further genetic changes will involve the modification of viral gene regulatory genes, either by deletion or smaller scale modification. The majority of these changes are expected to result in reduced viability of the recombinant strains. None of the changes proposed are expected to increase viability or pathogenicity, but as the whole purpose of the modification is for experiment, such events cannot be 100% excluded. All alterations will initially be made in cell culture adapter strains AD169 and Towne. These strains are known to have significant genomic deletions relative to clinical strains, and are believed to be clinically. The Towne strain has been used as a candidate vaccine strain without any associated problems. Changes will not be introduced into clinical strains of HCMV until the effects of these changes has carefully monitored in laboratory strains, and found not to result in changes which could modify viability or pathogenicity. Therefore, in all cases, the consequences of infection by the recombinant strains generated are expected to equivalently or less severe than infection by wild-type cytomegalovirus strains. Foreseeable effects would result from accidental infection of a human handler in the laboratory, and could extend to secondary human contacts. Infection of a handler would require contaminated tissue injury, or application of infectious material to mucous membranes. Infection by aerosol is considered unlikely, due to the low levels of replication achieved with human cytomegalovirus in cell culture.
Activity 3: For this activity, the vector, rather than the modified target, constitutes the main hazard. Transduction of cells in human handler by vectors designed to express human cytomegalovirus gene regulatory proteins is not expected to be harmful, and defective retroviral vectors cannot replicate once they insert into the host cell. Infection of handlers is nevertheless undesirable. Contaminated tissue injury or application to mucous membranes are the most likely routes of transmission of vector material to human handlers. This hazard will be limited by not using sharps, and the use of appropriate protective clothing, especially gloves.

A secondary hazard is the potential of packaging cell systems to regenerate replication competent retroviruses. These might resemble wild-type retrovirus, or could conceivably incorporate other genetic material, e.g., cytomegalovirus genes. Although the cytomegalovirus gene products in question are not known to be damaging to human health, this situation is nevertheless undesirable from the point of view of potential release of uncharacterised genetically modified viruses. The generation of replication competent retrovirus will be avoided by the adoption of the following procedures.

i) The use of third generation packaging cell lines, using heterologous promoters to drive separate gag-pol and env expression cassettes.
ii) Where possible, the use of transient packaging procedures, which allow only 3 days contact between vector and packaging line, thus greatly reducing the risk of the multiple recombination events required to yield replication competent retrovirus.
iii) Regular screening of retroviral producer cell lines, once established, for the production of replication competent retrovirus on feline FL3 cells.

Activity 4: For this activity, the vector, rather than the modified target, constitutes the main hazard. Transduction of cells in human handler by vectors designed to express oncogenes could result in long-term harm to the handler, although defective retroviral vectors cannot replicate once they insert into the host cell. The oncogenes in question do not act alone to transform human cells - rather they would participate in a multiple stage process. The vectors are therefore not expected to be acutely transforming after accidental infection, but could pre-dispose to longer term carcinogenesis in any cells affected. Contaminated tissue injury or application to mucous membranes are the most likely routes of transmission of vector material to human handlers. This hazard will be limited by not using sharps, and use of appropriate protective clothing, especially gloves.

A secondary hazard is the potential of packaging cell systems to regenerate replication competent retroviruses. These might resemble wild-type retrovirus, or could conceivably incorporate other genetic material, e.g., oncogenes initially retrovirus will be prevented by the adoption of the following procedures:

i) The use of third generation packaging cell lines, using heterologous promoters to drive separate gap-pol and env expression cassettes.
ii) Limitation of the work to the use of transient packaging procedures, which allow only 3 days contact between vector and packaging line, thus greatly reducing the likelihood of the multiple recombination events required to yield replication competent retrovirus.
iii) Screening of packaged vector for replication competent retrovirus on feline FL3 cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Activity 1: Liquid waste - 30 minutes treatment with 5% v/v chloros (freshly diluted), followed by disposal to drains. Solid waste - 20 minutes autoclaving of dry waste at 121 degrees C. Waste transferred to yellow clinical waste bags, and disposed by microwaving and shredding. Both procedures give effectively 100% kill. Chloros disinfectant used according to manufacturer's instructions. Thermologe strips used in autoclave, together with regular performance testing and servicing.

Activities 2, 3 and 4: Liquid waste - 30 minutes treatment with 5% v/v chloros (freshly diluted) inside microbiological safety cabinet, followed by disposal to drains. Solid waste - 30 minutes soaking in 5% chloros solution inside microbiological safety cabinet, followed by 20 minutes autoclaving of dry waste at 121 degrees C. Waste transferred to yellow clinical waste bags, and disposed by microwaving and shredding. Both procedures give effectively 100% kill. Chloros disinfectant used according to manufacturer's instructions. Thermologe strips used in autoclave, together with regular performance testing and servicing.
Proposed containment levels and procedures approved.

### Project Additional Information

#### Purposes of the contained use

The aim of this project is to 1) construct strains of these bacteria lacking specific genes, 2) establish whether gene inactivation has affected their ability to cause disease, and 3) further characterise the proteins encoded by these virulence genes.

#### Recipient or parental organism

Escherichia coli, Shigella spp., Neisseria meningitidis, Neisseria gonorrhoeae and Haemophilus influenzae are ACDP Hazard Group 2, as they are human pathogens. The organisms will have the equivalent or less potential to cause human disease as the wild-type bacterium. The insertions will interrupt gene function and are likely to attenuate the host.

The disabled E. coli hosts are ACDP Hazard Group 1, as they do not cause human disease.

#### Host/vector system

- **Neisseria meningitidis, Neisseria gonorrhoeae, Haemophilus influenzae (Hosts)**/pMID216 and derivatives (vector)
- **Shigella and E. coli (Host)/pCR2.1, pUC and pET derivatives, pACYC184, pSTM115, pYH204, pMID216 (vectors)**

All these are plasmids which have been used previously with the corresponding microbes. They carry antibiotic resistance markers for agents not usually used to treat human infections with these bacteria.

#### Origin & function

- **Source of genetic material (inserts):** transposons and antibiotic resistance markers.
- **Source of genetic material (vectors):**
  - pCR 2.1 topo, pACYC184, pUC and pET derivatives: commercially available
  - pMID216 from collaborator
  - pYH204, pSTM115: generated in own laboratory

#### Evaluation of foreseeable effects

All the GMMs are ACDP Hazard Group 2 except the disabled E. coli strain.

The modification of the host bacteria is in the form of insertions into the chromosome that inactivate gene function. The insertions carry antibiotic resistance markers that encode for resistance against antibiotics not used for treatment of infections caused by these micro-organisms. These modifications should not pose any increased risk to human health. The environmental survivability of the GMM will be similar to the parental wild-type strains.

For disabled E. coli, the modifications is in the form of a self replicating plasmid which may contain cloned genes from the pathogenic bacteria. The plasmids confer resistance to ampicillin, kanamycin, and erythromycin. There is a wide variety of alternative agents that can be used to treat successfully infections cause by E. coli. The environmental survivability of the GMM will be similar to the parental strain.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
Chemical disinfection of GMM waste except N. meningitidis:
1% virkon as per manufacturers instructions, at least 1 hour exposure. Plates and plastic are sterilised by autoclaving. Discard cycle 134 degrees C for 30 min. 100% kill. Machine and cycle validated after each cycle by thermograph; autoclaves thermocouple tested regularly (6 monthly) qualified engineer.

Autoclaving of waste contaminated by Neisseria meningitidis: Discard cycle 134 degrees C for 30 min. 100% kill. Machine and cycle validated after each cycle by thermograph; autoclaves tested regularly qualified engineer.

Please enter comments on the GM safety committee on the risk assessment:

It was considered that work with disabled E. coli strains could be conducted in Containment Level 1 facilities. However, this work will be done in a Containment Level 2 laboratory along with the work on Neisseria gonorrhoeae, Haemophilus influenzae, Shigella flexneri, and E. coli K1. The importance of prompt reporting any incidents and episodes of diarrhoeal disease among researchers working with Shigella spp. was highlighted.

People working with N. meningitidis must complete a health questionnaire; any persons with suspected immunodeficiency must be seen by the Occupational Health doctor before working with the bacterium. It was recommended that work with N. meningitidis is carried out in a dedicated (Containment Level 3) room. Only individuals who have undergone a locally approved training programme would be allowed to work with live N. meningitidis. All person must be aware of the signs and symptoms of meningococcal infection, and should seek early medical advice should they become unwell, informing medical staff of their potential exposure to N. meningitidis at the work place. All accidents/spillages to be reported promptly to the Occupational Health Department and Department Safety Officer. A list of individuals allowed to work with the meningococcus, details of the clinical presentation of N. meningitidis infection, and guidelines for safe working is to be kept at the entrance to the designated facility at all times.

**Project Additional Information**

**Purposes of the contained use**

It is intended that this cell line will be used as a cell model to investigate some of the possible effects of virus replication on host gene expression.

**Recipient or parental organism**

The Acs cell line produces infectious HBV virions. However the absence of the correct receptor(s) on the surface of Acs cells means that there is no cycle of re-infection. The HBV DNA is covalently linked to cellular DNA therefore there is little or no chance that it could be mobilised. The HBV genome contained in the Acs cell is an unmodified ‘wild type’ HBV sequence, consequently the virions produced by this cell line are unmodified ‘wild type’ HBV.

**Host/vector system**

Recipient or parental organism

| Acs cell line (HepG2.2.15) |

**Origin & function**

The Acs cell line (Sells, M A., M-L. Chen, and G. Acs. 1987. Proc. Natl. Acad. Sci. USA 84:1005-1009) was made by transfecting HepG2 cells (a stable human hepatoblastoma cell line) with a head-to-tail double stranded DNA dimeric construct of the hepatitis B virus (HBV) genome. The HBV genome is stably integrated into the cellular DNA in Acs cells and the RNAs required for HBV replication are transcribed from this integrated HBV DNA.

**Evaluation of foreseeable effects**

The HBV virions produced by Acs cells could infect unvaccinated humans. HBV can cause liver damage in infected humans and chronic infection with HBV is associated with a significant increase in the risk of liver cancer (probably as a consequence of chronic liver damage and an increase in the turnover of hepatocytes). All procedures involved in the propagation of the Acs cells and the subsequent extraction of RNA will take place in a Class III safety cabinet which is tested every 6 months.
experimenter will wear the appropriate protective gowns and gloves at all times, while handling these cells. The experimenter has been vaccinated against HBV and has been shown to have good antibody levels against HBV (next testing for antibodies should take place in 5 years ie 2007). Since the HBV genome used in Acs cells is an unmodified 'wild type’ sequence it is susceptible to anti-HBV therapies.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste produced during the culturing of the Acs cells will be treated with Virkon to inactivate HBV virions. At least 1 hour in a 1% Virkon solution (ie final concentration of waste liquid plus 10% stock solution of Virkon). The manufacturer of Virkon have demonstrated that it will rapidly inactivate HBV if used under the conditions described above effectively giving 100% killing of HBV.

Plasticware used in the propagation of Acs cells and any cells that remain associated with them will be placed in plastic autoclave bags and subjected to one cycle of autoclaving in the autoclave present in the laboratory which will give 100% kill. Chart recordings will indicate that the correct autoclave cycle has taken place and the autoclave will be maintained and tested as required by the local safety rules. After autoclaving solid waste will be removed by the approved waste disposal contractor for final disposal (clinical waste will not be generated in these experiments).

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment
Comments were made on the risk assessment which was submitted to the Genetic Modification Committee (GMC). The risk form was subsequently modified to incorporate these comments. Several typographic errors and absence of ticks in the appropriate boxes were pointed out. Other comment corresponding to particular sections of the completed form were:

3.1.5 (GMC comment) "Possibly should be yes as the cell now expresses a pathogen". (MMcG response) However, the modified cell line (Acs) itself is not pathogenic.

3.1.18 (GMC comment) "Does not explain why his response is no." (MMcG response) The HBV genome used is an unmodified wild type sequence and is susceptible to anti-HBV therapies.

7. (GMC comment) "It should be stated that those working with HBV are vaccinated and that the antibody titre is checked." (MMcG response) This has been added to the risk assessment.

9.2 (GMC comment) "This sharing is not ideal under COSHH as HBV poses a greater threat of persistent contamination an infection risk than HIV." (MMcG response) The agreed protocol for HBV decontamination, stated in the risk assessment (Section 5) should minimise any potential contamination. All personnel using this facility have been successfully vaccinated against HBV.

(GMC comment) "The classification of Class II is appropriate on the basis of the information provided." (MMcG comment) The appropriate entry in the risk assessment form has been made to show this classification.

### Project Additional Information

#### Purposes of the contained use

The Haemophilus, Actinobacillus and pasturella (HAP) group contains bacteria that are commensals and/or cause disease in animals or man. Those that cause disease include H. influenzae, H. ducreyi, A. actinomycetemcomitans (man) A. pleuropneumoniae, A.suis, H. parasuis (pigs) A. ligneresei (sheep), H. paragallinarum (chickens) and H. somnus (cattle). With the exception of H. influenzae comparatively little is known about the molecular basis of their pathogenicity and there is an urgent need for safe effective vaccines that, for those that exist, currently compromise bacterins and are of limited use. The genome sequences are available for some of the human pathogens, and selected species of the animal pathogens are in progress. However, it will not be possible to maximally capitalise on the availability of these genomes because of (1) the lack of suitable genetic systems for the construction of defined and random knockout mutants for comparison in surrogate models of infection and (2) the lack of reporter gene technology to facilitate the identification of promoters suitable for use in heterologous expression systems and (3) the need for suitable heterologous expression systems for novel and known vaccine antigens, as these are crucial in extending the range of live vaccines to protect against multiple pathogens. A successful outcome to the project will contribute towards the development of live and sub-unit vaccines for the prevention of the disease caused by HAP bacteria. Thus the aims of this project are to develop (1) genetic systems (2) reporter gene technology and (3) heterologous expression systems for vaccine antigens for the HAP bacteria.

</table>

#### Origin & function

The source of the host cells will be bacterial culture collections (St Mary's, NCTC, ATCC and individual). The source of the vectors (including those containing non-toxic reporter genes) will be departmental and individual collections, commercial sources or from investigators describing natural HAP vectors. The aims of this project are to develop (1) genetic systems (2) reporter gene technology and (3) heterologous expression systems for vaccine antigens for the HAP bacteria.
The host cells are pathogens or commensals of man or animal. For pathogens gene inactivation is likely to make the strains less virulent or have no effect on their capacity to cause disease. The expression of non-toxic reporter genes or vaccine antigens is unlikely to alter the pathogenicity of the host.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Chemical disinfection of liquid GM waste - a minimum final concentration of 2% Hycolin would be used for all infectious liquid waste. The degree of 'kill' achieved has been determined empirically to be 100%. It will also be monitored on an ongoing basis by plating out random samples to establish whether any viable cells are present. Solid GM waste will be autoclaved at 134°C for 30 min. The degree of 'kill' achieved has been determined empirically to be 100%. It will also be monitored on an ongoing basis by plating out random samples to establish whether any viable cells are present.

Laboratory equipment will be monitored on a regular basis:
1. Safety cabinets are under a regular, 6 monthly, servicing and validation contract
2. Autoclaves are under a 6 monthly servicing and validation contract
3. Equipment in the laboratory is regularly serviced, and staff in the laboratories will monitor whether equipment needs further testing and repairing
4. Safety inspections will be carried out by the Departmental safety office and random external checks will also take place.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The was concern about the centrifugation of organisms, aerosols spread and spill procedures. Assurances were given that the organisms would be centrifuged in appropriate sealed containers and that spills would be decontaminated by standard laboratory procedures. Confirmation that the autoclave was on a six monthly service contract was also given.

**Project Additional Information**

**Purposes of the contained use**
We intend to define the influence of dendritic cells on RSV disease and to explore approaches to immune modulation of disease using dendritic cells. The aim of this project is to transfect murine CD11c+ cells with genes for murine IL-12, IL-10 and IL-4 in vitro to induce overexpression.

**Recipient or parental organism**
An HIV based 2nd generation lentivirus vector with viral genes deleted containing a SFFV promoter driving expression of GFP, murine IL-12, murine IL-10 or murine IL-4 will be generated. Separate batches of E. coli cells will be transformed to express one of the following 3 split plasmids: - vector plasmid (pHR-SIN-CSGW); - packaging plasmid (pCMVR8.91) encoding gag/pol, tat and rev but with deletions of the virulence genes vif, vpu and nef; and - envelope VSV-G plasmid (pMD-G). Plasmids isolated from the respective E. coli cultures will be used to infect 293T human foetal kidney cells, which will assemble the lentiviral vector which is infective, but replication defective. Such replication deficient viruses are not pathogenic in mice (Zuifferery et al. Nat. Biotechnol. 15:871-875). Following isolation of this vector from cell culture supernatant it will be used to transfect isolated murine CD11c+ cells with GFP, murine IL-12, murine IL-10 or murine IL-4. These mouse cells will not produce new virions. The split plasmids which are used in E. coli cannot cause harm to humans. The complete lentiviral vector is able to infect human cells but it cannot replicate. Spread from cell to cell or from individual to individual is not possible! There is a theoretical risk of insertional mutagenesis/overexpression of cellular genes by random integration of the vector and from expression of the inserted murine genes. The main risk is to laboratory personal directly handling the lentivirus. The risk attached to using these modified lentiviruses is minimised by the following measures: protective clothing, gloves, glasses and filter masks will be used, no use of sharps or needles.

**Host/vector system**

02/03/2022
Gene transfer by HIV-based lentiviral vectors will be used. In these vectors viral virulence genes have been deleted and split plasmids are used. The genes of interest will be cloned in our lab and inserted into the vector plasmid. The vector plasmids, a packaging plasmid and an envelope plasmid will then be introduced separately into different E. coli cells each using calcium chloride based transformation techniques. These transformed cells will be used as plasmid stocks. Plasmids will then be extracted by growing transformed E. coli in culture, and then harvested using a commercially available kit (Qiagen). DNA from these separately purified plasmids will then be used to infect 293T human foetal kidney cells, which will produce the lentivirus vector. The vector will then be purified from the culture supernatant and used to transfect CD11c+ murine dendritic cells.

We intend to use the 2nd generation lentiviral vector for the following reasons:

- The vector has been shown to transfect murine DC successfully (pers. communication by M. Collins). Whether a 3rd generation vector would be just as suitable has not been shown.

- 3rd generation lentiviral vectors which split the rev gene onto a separate plasmid tend to have lower titers following assembly in human cell lines. Lower vector titers will result in reduced infection of target cells and will diminish the chance of successful transfection of DC.

This 2nd generation vector never given replication competent recombinant (RCR) virus in Prof. M. Collins laboratory in 3 years of use. In these non-clinical studies extra safety at the risk of poor infection does not seem justified.

Both 2nd and 3rd generation lentiviral vectors are capable of infecting human cells. There are no efficient pseudotypes of HIV with envelopes that infect only mouse cells.

Origin & function

Common disabled E. coli K-12 or B derivatives (Stratagene), modified and attenuated for laboratory use including XL-1blue will be used for transformation experiments.

Inserts (murine IL-4, IL-10 and IL-12) will be generated by PCR in our lab. These DNA fragments will be cloned into a transfer vector (pHL-SIN-CSGW). Replication-defective lentiviral vectors are generated by transient transfection of 293T human foetal kidney cells with three plasmids (the transfer plasmid, a packaging plasmid and an envelope plasmid).

The plasmids pCMVR8.91, pMD-G and pH-SIN-CSGW will be obtained from Professor M. Collins, Immunology and Molecular Pathology, Windeyer Institute, University College London.

293T human foetal kidney cells will be obtained from ATCC.

Evaluation of foreseeable effects

The host strains of E. coli used are laboratory adapted and do not infect humans or propagate in humans. Laboratory adapted E. coli need the optimised conditions of a laboratory to survive. In addition, antibiotic resistance and the recombinant plasmid would quickly be lost in the outside environment if bacteria were to survive. The used strains of E. coli are commonly used for molecular cloning of a range of foreign genes. As far as is known, cloning does not affect the growth or normal physiology of the host. The inserted genes which do not code for a pathogen or a pathogenic determinant (murine interleukins IL-4, IL-10 and IL-12) will not be expressed in E. coli.

Neither lentiviral genes nor murine cytokine genes will overcome disabling mutations in bacteria.

The inserted DNA fragments encode for the murine cytokines IL-4, IL-10 and IL-12. MiL-4 and mL-10 are not active in humans, whereas mL-12 is active in human cells. No adverse effects to human health are to be expected since the murine cytokine genes will not be used in humans or human cells. Only IL-12 could be active in human cells and might stimulate an increased local immune response with inflammation following accidental inoculation. No toxic responses are to be expected and allergic reactions are highly unlikely although theoretically possible. The recombinant murine cytokines could theoretically cause harm if transformed E. coli were to infect wild populations of mice. This event is extremely unlikely since the work involving transformed bacteria is carried out in a modern category 2 laboratory in the absence of mice. Transfer of recombinant genes between mice following adoptive transfer of transfected dendritic cells is not conceivable.
The lentiviral vectors used are mobilisation defective so that even in the event of a wild-type HIV infection (which would provide tat and other deleted genes which are required for infection) the vector and its inserted gene would not be packaged into infective virus. There is therefore no risk of mobilisation of the vectors.

To keep working procedures as safe as possible, safety rules will be maintained. Sealed buckets will be used to prevent aerosol release, and these buckets will be opened in a Microbiological Safety Cabinet only. In addition, protective clothing, gloves, glasses and filter masks will be used as a protection from aerosols. In addition to that, no sharps (needles, blades, surgical instruments etc.) will be used.

Notes not apply.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Contains and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For the disinfection on solid GM waste autoclaving will be used. Quality assurance will be monitored by the use of sterilisation indicator tubes (Fisher), which indicate that the autoclave has reached required temperature. Solid waste is autoclaved, placed into yellow bags, sealed, tagged and taken out of the laboratory as clinical waste.

Virkon (2%) will be used as a chemical disinfectant for liquid GM waste. Therefore, materials will be soaked in Virkon overnight. Liquid disinfected with 2% Virkon is washed with water in excess to drains. Both these methods will lead to 100% killing of any GM organisms.

Autoclaves and safety cabinets are services every 6 months, lab coats are autoclaved before being given to St. Mary's laundry. Surfaces are cleaned by daily swabbing after use by user, centrifuges are cleaned with 5% Decon & Mikrozid on a monthly rotation list together with hoods, incubators, and water baths and solid waste is autoclaved on a daily basis by a laboratory assistant.

At the end of each experiment mouse carcasses will be placed into biohazard bags in CBS. These bags will be sealed and incinerated.

Project Containment
**Project Ref** 77/03.3

**Date Ackn'd** 28/07/2003

**CU2 Project Title** TRANSFECTION OF VARIOUS CELL LINES WITH FULL-LENGTH HEPATITIS B VIRUS PLASMID CONSTRUCTS.

**Class** Class 3

**CultureVolClass2** 10-20ml

**Non-GMM** yes

**Consent Granted**

**Withdrawn** N

**Tick if notifying a connected programme of work** N

**Project notified under transitional arrangements** N

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

Hepatitis B virus (HBV) does not normally infect cells in culture. Transfection of cloned DNA is therefore used to study the biology of the virus at the molecular level. This however is not a very efficient process. Nevertheless, shedding of virus particles is expected in the tissue culture fluid. This shedding does not reach the levels of virus one sees in patient sera.

**Recipient or parental organism**

The plasmid constructs to be used in the transfection experiments will contain a common genetic background of HBV, consisting of longer than genome length HBV sequences. This is necessary as the genome of the virus is circular, and when linearised, some of the open reading frames are disrupted, necessitating duplication of part of the genome. Point mutations seen in patients with chronic infection, after treatment with antiviral agents and following immunisation will be introduced by site directed mutagenesis into the construct, one at a time, or in combination.

**Host/vector system**

The plasmid vector to be used in pBluescript KS 11+. Transcription will be under the control of endogenous HBV promoters. Host cells to be used will include cell-lines of...
hepatocyte or lymphoid origin. All of these are long established laboratory cell-lines.

Origin & function

The HBV DNA cloned in the above vector was obtained from a chronically infected patient. This construct was given to us by Dr Jinlin Hou, China. Following introduction of the necessary point mutations, transfected cells will be used to establish the effect of these mutations on the replication capacity of the resulting viruses, and level of expression of viral proteins. Constructs containing mutations relating to antiviral resistance will be used to compare their replication efficiency to that of the wild-type construct, and to assess efficacy of other antiviral compounds. Finally, vaccine escape constructs will again be used to assess their replication capacity, since the surface antigen encoding region where the observed mutations occur, overlaps with the polymerase gene of the virus, and may have a knock-on effect on its function.

Evaluation of foreseeable effects

HBV infects humans and chimpanzees. Immunised individuals are protected from infection following vaccination and development of antibodies. The use of vaccine escape constructs, may pose a threat if an individual is exposed. The risk is minimised however since HBV is not transmitted by aerosols, and sharps will not be used at all. Six well plates of transfected cell cultures will be transferred from the cabinet to the incubator one at a time.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste will be autoclaved within the laboratory, before removal. This will be re-bagged and placed in the ante-room to the lab. From there, laboratory staff will transport it to the contractor collection point in sealed bins. The autoclave run will be monitored by means of a chart recorder, and indicator strips attached to the bags.

For disinfection of liquids, solid surfaces and spillages, Virkon at a final concentration of 1% will be used. Contact time will be as detailed in the local rules. Liquid waste will then be poured down the sink. Solid waste will be autoclaved. HBV does not grow in tissue culture and therefore cannot be monitored for its viability. However, Virkon activity against the virus has been assessed by the manufacturer.

Please enter comments on the GM safety committee on the risk assessment

The committee agreed that appropriate training for personnel involved with this project, local rules and SOPs to be drawn up with consulation from the relevant Divisional Safety Officers prior to the commencement of this work. The committee agreed with the control measures and classification given for this work: Class 3 containment level 3.
Deregulation of cell controls affecting proliferation and apoptosis is a common event in cancer development. This programme of work will use amphotropic retrovirus and adenovirus vectors to help study the functions of cellular and viral genes that affect the regulation of cell proliferation and cell survival. These viral vectors will enable the efficient transduction of human and other mammalian cells grown in tissue culture with either cDNAs or siRNA genes.

The viral vectors to be used in this work are disabled derivatives of human adenovirus type 5 or severely disabled derivatives of animal retroviruses which are packaged in helper lines that enable the vector to infect human cells. The virus vectors are initially propagated as plasmids in E.coli. Packaged virus able to infect human and other mammalian species are produced by transfection of the vectors containing inserts into cell lines which provide functions in trans necessary for replication and/or packaging of the virus. Packaged vectors are able to transduce the inserted genes into a wide range of human and other mammalian cells in tissue culture, however, the vectors are unable to replicate in these transduced cells.
### Host/vector system

Adenoviruses will be packaged in cell lines which complement the E1a and E1B defects in the vectors. One example of the packaging lines to be used is QBI-HEK-293A cells, provided by Q-BIOgene (see www.qbiogen.com). The adenovirus vectors lack both the E1 and E3 early regions. Examples of the adenovirus vectors to be used are AdenoVator and AdEasy obtained from Q-BIOgene.

Retroviruses will be packaged in highly transfectable cell lines such as HEK293T cells and NIH3T3 cells. These cells will express gag-pol genes to provide replication and packaging functions. In addition the cells will express amphotropic or polytropic envelope proteins or the VSV-G glycoprotein. These viral receptors will enable the packaged retroviruses to infect humand and other mammalian cells. Examples of the packaging lines to be used are AmoPack-293 and RetroPack PT67 provided by BD BioSciences/Clontech and the Retrovirus Packaging Kit Amphi provided by TaKaRa Biomedicals. A number of animal retrovirus vector systems will be used including MSCV, BD Retro-X Q, LXSN, MMT, pBabe, pZIP (all based on murine Mo-MuLV) and RCAS (based on avian ALV).

### Origin & function

The cDNAs carried down by the adenovirus vectors will represent cellular and viral genes that promote cell proliferation and/or decrease apoptosis - such genes are generally, but not exclusively, oncogenes. These cDNA will also be inserted into the amphotropic retrovirus vectors. Only single growth-promoting (for example EBN-A-2, EBNA-3C, LMP1, RUNX1, RUNX3, Id2 and B-myb) and anti-apoptotic genes (for example Bcl-2) will be transduced in this programme of work. As cancer development is a multistep process, transduction with such genes will not transform the infected cells. This programme of work will not include viral oncogenes that have multiple oncogenic activities such as the SV40 T antigen, nor will it include clusters of oncogenes such as HPV16 E6-E7. Genes encoding toxins will not be included in this work. These vectors will enable efficient transduction of these genes into human and other mammalian cells grown in culture, with the aim of studying their effects on cell growth and survival. In addition, genes encoding tumour suppressor genes and siRNA genes will be inserted into retrovirus vectors. Tumour suppressor genes (for example p53, ASPP, RB, p130) and pro-apoptotic genes (for example Bax, Bik and Bad), are expected to inhibit cell growth. Short interfering RNAs (siRNA) are designed to ablate expression of a specific gene target. The siRNA genes used in this work will be directed against regulators of cell growth and survival (e.g. oncogenes, tumour suppressor genes and pro- and anti-apoptotic genes). siRNA's directed to tumour suppressor genes would be expected to promote cell growth, while those directed to oncogenes would be expected to inhibit cell growth. However, it is extremely unlikely that ablation of a single gene, as proposed in this project, would have major effects on cell growth and/or survival.

### Evaluation of foreseeable effects

Adenovirus and amphotropic vectors are designed to infect efficiently cells of many different species and lineages. The two major foreseeable effects are accidental transduction with the packaged vector. The consequences for animal species are therefore negligible, since even in the extremely unlikely event that mice were exposed to the packaged vector, the virus could not propagate. It is noted that replication-competent retroviruses can be generated at low frequencies in packaging cell lines, albeit it seems likely that acquisition of viral replication functions by the vector would be at the expense of the inserted transgene. The use of these vectors will be restricted to transduction into cells in tissue culture, and the risk that infectious virus will be transmitted to animal species is minimal under Containment Level 2 conditions proposed for this project.

Exposure of laboratory personnel to packaged vectors containing growth promoting genes such as oncogenes or anti-apoptotic genes could result in some growth advantage of transduced cells. Similarly, transduction with retroviruses encoding siRNAs directed to growth inhibitory genes could also result in a growth advantage. It should be noted, however, that the single genes targeted in these studies can not by themselves result in cell transformation, even in highly responsive rodent cells. Targeting of combinations of genes with the potential to caluse cell transformation has been specifically excluded from this programme of work. It should also be noted that with the scale of production to be used, it is extremely unlikely that accidental transduction will occur in stem cells at risk of carcinogenic development. Because of the very slight risk involved, it is proposed to carry out this activity under Containment Level 2 conditions.

It is noted that insertion of certain viral oncogenes (such as HPV 16 and E7 and some EBV genes) into E1a/E1B-deficient adenovirus vectors can complement their growth defect. Experimental observations show that rescue is incomplete (Steinwaerder et al, Mol Ther. 4:211-216, 2001) and replication of the recombinant is significantly less that of wild-type virus. The recombinant virus would therefore be debilitated in its ability to spread in an infected human host. The risk associated with such recombinants is therefore no greater than that of the wild-type virus. It is therefore proposed to carry out this activity under Containment Level 2 conditions.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

---

02/03/2022
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be collected in double autoclave waste bags and subjected to autoclaving under approved conditions. 100% kill is achieved with this procedure. Liquid waste will be collected in polythene containers and treated for 24 hours with 1% Chloros. This achieves 100% kill. Small laboratory spills will be treated with 2% Virkon (retroviruses can also be effectively treated with 70% ethanol. Studies by the manufacturer have shown that this concentration of Virkon effectively kills a wide range of viruses. Larger spills will be cleaned with 1% Chloros. Contaminated paper towels are treated as solid waste. Extracts will be made from tissue culture cells transduced by adenovirus and retrovirus vectors for biochemical and cell biological procedures (e.g. microscopy). The simple act of infection inactivates much of the input virus as it becomes uncoated upon entry into the cell. When making cell extracts, residual virus will be inactivated by detergent treatment (i.e. 1% SDS or 0.5% NP40). The effectiveness of the detergent treatments will be validated by plating transduced cell extracts on indicator cells and selecting for antibiotic resistance carried by the vector or GFP expression. For flow cytometry and microscopy techniques, the transduced cells will be fixed with 70% ethanol or 4% paraformaldehyde. As this explained, there will be little or no packaged virus in these infected cells, and any remaining virus should be inactivated by these treatments.

Is an emergency plan required according to regulation 20?  N

Please enter comments on the GM safety committee on the risk assessment

It was agreed by the GM Safety Committee that Containment Level 2 was appropriate in view of the slight theoretical risk to human health of transducing genes designed to alter cellular growth controls. It was noted that ACGM Compendium of Guidance (Part 2B - Annex III recommends Class 2 for these activities with these vectors.

Project Ref  77/07.1
**Project Additional Information**

**Purposes of the contained use**

This project will use a newly established cell culture system to investigate the replication of Hepatitis C Virus (HCV). HCV presents a large and growing health burden with an urgent medical need. At least 70% of infections lead to chronic hepatitis, resulting in severe liver disease including cirrhosis and hepatocellular carcinoma. Current estimates are that 170 million people worldwide are infected with HCV. For patients, the only therapy for HCV is treatment with a combination of interferon-α and ribavirin, which has unpleasant side-effects and is at best effective in only 40-50% of patients.

The development of HCV RNA replicons has allowed major advances to be made in understanding the replication mechanisms of HCV and has aided the discovery of potential new anti-viral drugs. However, as the structural genes are missing, the full virus replication cycle cannot be studied using these replicons. A second important development has been the description, in 2005, of a full-length HCV sequence termed JFH1, which can undergo replication, in Huh7 cells without adaptive mutations. This was important for establishing a complete virus replication cycle system as the presence of cell culture adaptive mutations in other HCV replicons has been shown to interfere with virus particle production. Consequently, transfection of full genome length JFH1 RNA into Huh7 cells leads to the production of virus particles which are then capable themselves of infecting untreated Huh7 cells.

The new HCV cell culture system is based on the JFH1 sequence, which has a 2a genotype background, whereas most other replicons have been based on genotypes 1a or 1b. In addition, replacing the JFH1 2a structural proteins with genotype 1a or 1b structural proteins results in efficient genome replication and virus particle production. These findings raise many important questions about the replication of HCV which will be addressed in this project. For example, what are the properties of the JFH1 non-structural proteins which allows it to replicate much more efficiently than any replicon previously studied? Why is it that this virus can replicate much more efficiently in 1FN cured Huh7 cells compared to untreated Huh7 cells? Is this greater level of virus replication due to increased levels of (co) receptor molecules, or to ineffective dsRNA antiviral responses in these cells (e.g. Huh 7.5 or Huh7- Lunet) or is the JFH1 virus particularly adept at replicating and or evading the cells defenses?

**Recipient or parental organism**

Plasmid DNAs that contain a copy of the HCV genome will be grown in E.Coli DH-5 alpha which does not contain T7 polymerase that is necessary for the transcription of the plasmid insert. There will therefore be no expression of the inserts in E.coli DH5-alpha.
Human hepatoma 7 (Huh7) cells, a cell line derived from human liver, will be used to propagate HCV. Additional cell lines which have been developed from Huh7 derivative cells e.g. Huh7.5 cells (which has a mutation in the RIG-1 protein) and Huh7-Lunet cells (which express increased levels of CD81) will also be used to propagate HCV. These human hepatoma cells can only be grown under standard cell culture conditions e.g. at 37°C in DMEM medium in a CO2 incubator.

Host/vector system

Purified plasmid DNAs (pJFH1, pJFH1/GND, pJFH1/DE1-E2JFHQ, pFK-Luc-JFH1 and pFK-Luc-JFH1/E1-E2) that contain a copy of the HCV genome will be transcribed with T7 polymerase in a cell free to synthesise HCV RNA transcripts. These genome length HCV RNA molecules will be used to transfect tissue culture cells (Huh7, Huh7.5 and Huh7-Lunet cells) to produce HCV virus.

Origin & function

The genomic sequence in pJFH1 was isolated and cloned from HCV virions obtained from an infected Japanese patient i.e it is the same sequence as the virus in the natural infection (Wakita T et al (2005). "Production of infectious hepatitis C virus in tissue culture from a cloned viral genome." Nature Medicine; 11:791-796). Using standard cloning and PCR methods, intergenotypic chimaeric virus sequences will be generated which combine the coding sequences of proteins and sub-domains of proteins from different HCV genotypes in a reciprocal fashion. The HCV genome is expressed as a polyprotein. This is the process to produce the functional HCV proteins. These are: C - virus capsid protein, E1 and E2 - virus membrane glycoproteins, p7 - putative ion channel proteins, NS2 - autoprotease cofactor, NS3 - serine protease/RNA helicase, NS4A - serine protease cofactor, NS4B - membranous web inducing protein, NS5A - interferon response suppression protein and NS5B - RNA dependent RNA polymerase. In the JFH1 2a genome, which produces virus particles, proteins or domains of proteins will be replaced with those from 1a or 1b genotypes. Similarly, in the 1a and 1b genomes, which don't produce virus particles. JFH1 protein sequences will be substituted. These chimaeric HCV viruses will be assessed and compared for their replication efficiency which will identify virus sequences that are important for virus production. Site directed mutagenesis of viral sequences will also be undertaken to further pinpoint regions of interest.

Evaluation of foreseeable effects

HCV will be propagated in Huh7 cell lines and could cause hepatitis if it infected human liver. The levels of HCV replication will be monitored by quantitative PCR as part of the investigation and the PI will receive this information (and all other experimental data generated by this work) immediately after it is available. There will be a re-assessment of the risks by the local GM Safety Committee if, although unlikely, any significant increases (10-20 times the level of JFH1) in HCV replication are found. Changes may alter (probably reduce) the ability of HCV to replicate in Huh7 cells. Changes to host range or tissue tropism of HCV are very unlikely. No alterations will be made to the bacterial hosts (no expression of the HCV insert occurs in these cells). If any changes to the Huh7 cells leads to significant increase in the levels of HCV replication the risks will be also re-assessed.

None of the proteins encoded by HCV are toxins, allergens or carcinogenic. There is no risk of an exchange of genetic material between HCV and other microorganisms as there is no likelihood of recombination.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste (HCV cell culture Media) will be treated by the addition of Virkon (an anti-microbial disinfectant), to a final concentration of 1% and then left for 30 mins. According to manufacturers data (http://reylon.dupont.com/mainframe2.htm) this treatment results in 100% killing of HCV. Treated liquid waste will then be disposed of via a sink.

Solid waste in plastic bags (tissue culture flasks, plastic pipettes, pipette tips and eppendorf tubes) will be autoclaved at 134C, for 30 mins. This will result in 100% killing of HCV. A chart record will indicate the successful completion of the autoclave cycle and the autoclave is tested annually by 12 point thermocouple testing. The bagged
The Committee approved the classification. The project is subject to re-assessment as the work changes. The Committee advised the PI to update the risk assessment to include a proviso in the event that a virus is created that replicates much more efficiently, and to state that the project will be re-assessed if such an event occurs. The Committee queried the varying percentages of Virkon specified in the risk assessment and Code of Practice (CoP), explained that the percentage is dependent upon the specific use. The Committee requested that prior to completion, the CoP is read through and matches the risk assessment e.g. personnel list. Recommended that personnel be listed on the laboratory door rather than the CoP. Revised CoP to be sent to Safety Dept and Chair for final approval.

Withdrawn N

Tick if notifying a connected programme of work N
The goal of our project is to understand host-parasite interactions and to dissect the immune mechanisms resulting in resistance or susceptibility to infection with protozan parasites of the species Leishmania.

Parental parasite strains: Leishmania major and Leishmania mexicana.

Modified parasites: L. major DsRed, L. mexicanaDsRed
L. major GFP, L. mexicana GFP
L. major LPG1-/-, L. mexicana LPG1-/- and L. major LPG2-/-, L. mexicana LPG2-/-
L.major lmcDN16-/-

All the transfected or gene deleted Leishmania parasites fall in the hazard group 2 safety category. There are no additional harmful properties associated with the inserted fluorescent labels and the gene deletions do also not represent increased risks.

For parasite modification the following vectors were used:
2) pSSUint: to introduce fluorescent label eGFP (Mol.Bio.Par. 107:271,200)
4) plmcDNA16: to delete HASP proteins (Cell.Microbiol. 3:511,2001)

One aspect of our work focuses on host-parasite interactions and for this we will use genetically modified Leishmania parasites for in vitro experiments. The modified Leishmania we will use fall into 2 groups: One group of Leishmania parasites will be modified by the introduction of fluorescent red or green labels to facilitate the tracking of the parasites in cells. In the other group of Leishmania parasites, genes are be deleted to investigate their role in the parasite life cycle or in virulance as well as in...
host-parasite interactions. All transfected or gene-deleted parasites have already been generated by other groups.

**Evaluation of foreseeable effects**

The products of the inserted genes are fluorescent labels and they are not known to have an impact on the virulance of the parasites for humans. In all likelihood the deletions will attenuate the parasites. In the unlikely event that evidence would be obtained indicating the opposite, the work would be halted pending reassessment. Gene transfer between Leishmania parasites and other microorganisms is unlikely to occur, the parasites are not free living in nature, they only survive in their sandfly vectors, infected mammalian cells or in special culture in vitro. The parasites are not transmitted by aerosols and establishment of infection can only occur as a result of direct introduction of the parasites in the skin and the bloodstream.

The hazard to the environment is low, Leishmania parasites will not survive outside the laboratory. The alterations reduce parasite development and transmission by their vectors and in all likelihood they will attenuate the parasites.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste (parasite cell culture liquid) will be collected and treated for at least 10 min with 1 % Virkon before disposal. All solid waste is collected in autoclave bags. When the bags are full they will be put in solid boxes, closed and autoclaved at 134 degree Celcius for a minimum of 30 min. The autoclaved material will be placed in yellow clinical waste bags. An internal thermocouple monitors the chamber temperature on every run and in addition, indicator strips are used. A 12pt thermocouple test is conducted every 12 months to establish that an effective and validated sterilised temperature and time is achieved in all areas of the load.

Please enter comments on the GM safety committee on the risk assessment

02/03/2022
Reviewer 1:

I felt that there were essentially two distinct GM components to this project. The class 1 cell line modification that had been carried out by other groups, (but still needed to be included as storage and use is covered by the GMO contained use regs), and the Leishmania parasite modifications which formed the class 2 component. My feeling is that for clarity that should be on two separate assessments.

2.3.3.2. - Room number and type of room e.g. lab, equipment room etc
2.3.3.3d If a tube breakage is suspected before opening the centrifuge lid wait at least 30 mins for any aerosol to settle
2.3.4.2 The COP dates look a bit old, have they been reviewed recently?
2.3.6 CL2 and class 2 for the Leishmania - CL1 and class one for the cell lines.
3.1b - check if the 12 pt TC test is actually carried out every 6 months. If this is Estates maintained the records I yhave seen indicate it is usually every 12 months - which is fine
3.2b - is the autoclave in the lab?

Reviewer 2:
The categorisation is correct.

Reviewer 3:
My only comment is a suggestion. In part 2, the deletions do not increase virulence, they decrease it. It would be a good idea to cite the evidence for that. Had this only been supposition, I would have suggested a statement something like: "In all likelihood the deletions will attenuate the parasites. In the unlikely event that evidence was obtained indicating the opposite, the work would be halted pending reassessment".

Agreed: Class 2, Containment level 2

</table>
The overall aim of the project is to understand the molecular mechanism of human norovirus and sapovirus genome translation and replication. Noroviruses and sapoviruses are members of the Caliciviridae family of positive stranded RNA viruses and the major cause of viral gastroenteritis in humans. Until very recently, methods for growing human noro- and sapoviruses in tissue culture were unavailable. A recent advance in the field now suggests that noroviruses replicate in a differentiated small intestinal cell line and that cell lines containing norovirus replicons can be generated at low frequency. We now wish to use these systems to characterise cellular and viral factors required for virus translation and replication.

Specifically we aim to:
1) Generate an efficient reverse genetics system to allow the recovery of genetically defined human noroviruses and sapoviruses in tissue culture
2) Examine the effect of specific mutations in viral RNA structures and viral proteins on virus replication in tissue culture
3) Generate genetically tagged human norovirus and sapoviruses containing innocuous biochemical markers such as green fluorescent protein, luciferase, antibiotic selection markers as well as affinity purification tags such as biotin acceptor sequences, TAP, HA, FLAG etc
4) Examine the effect of small interfering RNAs (siRNAs), short hairpin RNAs (shRNAs) and RNA aptamers on human norovirus and sapovirus replication

Recipient or parental organism

- Human noroviruses & sapoviruses
e.g. MD 145 and sapovirus, as well as various other strains which may be amplified from norovirus or sapovirus positive stool samples. Human noroviruses and sapoviruses are a major cause of viral acute gastroenteritis, the symptoms of which include nausea, vomiting and diarrhoea. Virus infection is usually self limiting and readily resolves within 24-72 hours after the onset of symptoms, however approximately 25% of infected people can continue to shed virus for up to 3 weeks. Infection is rarely fatal (<0.1% fatality rate) and generally only occurs in the elderly or individuals with underlying medical conditions. Immunity to infection is short lived (<12 months). Infection is highly contagious but acute and self-limiting. The most hazardous GMM to be generated will be a wild type norovims or sapovirus. None of the additional sequences to be inserted are considered hazardous and are unlikely to impart any additional pathogenic properties to the virus. This risk assessment excludes the generation of viruses in which the tropism or virulence is likely to be greater than that of the wild type virus
- E.coli strains:
DHSalpha (and derivatives), JM1 09, NEB Turbo, BL2 1 (and derivatives), XL 10, Mach 1
- Mammalian Cells
TNT 407, 293, CHO, HT29, Caco, HeLa (and derivatives), BEK, CRFK, Cos, RAW264.7
- MVA-T7
MVA is a highly attenuated form of VACV that was used during the latter stages of the smallpox eradication campaign without adverse reaction. MVA replicates well in some avian cell lines such as chick embryo fibroblasts but is unable to replicate in most mammalian cell types and consequently is severely attenuated in mammals.
- FPV-T7
FPV-T7 is a highly species restricted avian pox virus, replicating only in primary chick embryo fibroblasts and incapable of replicating in mammalian cells and consequently is severely attenuated in mammals.
All plasmid vectors to be utilised are considered non-mobilisable:
Expression in mammalian cells: pCDNA3, pTriEXl.l, pSportl, The following plasmids will be used for episomal maintenance of RNA and protein expression constructs:
pHebo:Super - On P containing plasniid containing Pol lit promoter pMep & pCEP — Ori P containing plasmids also expressing the EBV EBNA 1 protein

Origin & function

1) Green fluorescent protein, including all derivatives will be used to monitor virus infection and localisation
2) Luciferase and derivatives will be used to monitor virus replication
3) Norovirus and sapovirus non-structural proteins. Individual regions coding for noro and sapovirus analogues of the picomavirus proteins (Norovirus nomenclature in brackets): 2A (NS1), 2B (NS2), 2C (NS3), 3A (NS4), 3B (NS5), 3C (NS6) and 3D (NS7). Possible biological properties:
a.2A (NS 1): no biological activity ascribed as yet,
b. 2B (NS2): no biological activity ascribed as yet, probably membrane bound protein involved in virus replication c.2C (NS3): Probable NTPase/Helicase, membrane anchored;
d.3A (NS4): no biological activity ascribed yet, probably membrane anchored.
e.3B (NS5): Also known as VPg. Covalently linked to the 5' end of the viral RNA. Interacts with translation initiation factors and the viral polymerase 3D. Likely to function as a peptide primer for genome replication.
3C (NS6): Chymotrypsin-like serine protease
3D (NS7): RNA-dependent RNA polymerase
4) Norovirus and sapovirus structural proteins. The major and minor capsid proteins of human noroviruses and sapoviruses. a, VP1: Major capsid protein involved in receptor binding - no other biological activity ascribed as yet
b. VP2: Minor capsid protein. Highly basic protein, probably involved in RNA binding but no biological role ascribed as yet
5) Antibiotic selection markers for puramycin, G418, Zeocin, blasticidin and hygromycin
6) shENA sequences to host cell nucleic acid binding proteins such as PCBP, NFAR, PABP, ILF3, PTB, ITAF45 will be used to inhibit the expression levels of the relevant proteins and examine their role in the virus life cycle.
7) RNA aptamer sequences directed towards various norovirus and sapovirus proteins will be used as potential method of inhibiting virus replication.
8) Affinity purification and epitope tags such as HA, FLAG, biotin acceptor motif, TAP etc. will be used to piirifS’ viral proteins and any associated factors from infected or transfected cells.

Evaluation of foreseeable effects

None of the genetic alterations to be generated are likely to increase the pathogenicity of the viruses. In cases where point mutations will be introduced into the viral genome, the majority of these will be designed to disrupt RNA:protein or protein:protein interactions required for virus replication, effectively attenuating the virus.
None of the additional biochemical tags or genetic markers to be introduced into the viral genome will increase the pathogenicity of the virus in the natural host.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid Waste e.g. liquids containing GM viruses or E.coli cultures:
Treated with >1% final concentration of Virkon S0minutes at room temperature. 100% effective kill rate as specified by manufacturer (http://www.antechh.com/virkonpd.html). Treated waste will then be disposed of via the sink.
Solids e.g. contaminated plastics, sharps and glassware:
Waste will be autoclaved using a cycle of 121 deg C, 2 bar, 20 minutes. Treatment is monitored via a chart recorder attached to the autoclave and validated by an annual 12 point thermocouple test. Once autoclaved the waste will join the hospital clinical waste.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

Following the discussion of your proposals entitled "Characterisation and intervention of human noro- and sapovirus translation and replication", (GMIC —01599.1) via virtual Committee, they request that the following amendments are made to the proposals prior to approval:

- Section 1.25. The Norvirus and sapovirus structural proteins should be listed.
- 3.1.1. The chemical inactivation with Virkon should state 1% final concentration.
- Correct few spelling errors.

Agreed: Class 2, Containment Level 2. This project is notifiable to the HSE.

Purposes of the contained use

This programme of work will use lentivirus vectors to aid analyses of the functions of viral proteins involved in poxvirus entry, morphogenesis and immune modulation as well as human orthologues of these proteins. The lentivirus vector system will enable the efficient infection of cells grown in tissue culture with lentiviruses expressing cellular and viral proteins.

Recipient or parental organism

Lentiviruses will be produced by transfection of the SV40 transformed human embryonic kidney cell line HEK 293T. Human and rodent cells grown in tissue culture will be the recipients of the lentivirus GMOs. These cells will include (but are not restricted to) BSC-i, HeLa, and TK-143 cells and other human or rodent (e.g. NIH 3T3) cell lines supplied by ATCC. In addition, some primary cells will be used including rat embryo fibroblasts. After trypsinisation these cells will express the transgene but will not produce or contain any lentiviruses and so are uninfectious.

Host/vector system

The vectors are based on mutated lentivirus genomes, pseudotyped with a vesicular stomatitis virus (VSV) envelope glycoprotein (VSV-G) allowing infection of a broad range of cell types and containing a gene for puromycin resistance to allow the selection of expressing cells. The vectors are pCMVR8.91 (encodes the lentivirus genes), pMD (encodes VSV-G), pdlNotl'MCS'R'Pk and pdlNotl'nPk'MCSR, (each contain a multiple cloning site to allow cloning of gene of interest fused to a N- or C-terminal V5 epitope tag respectively, and a puromycin resistance gene).

Origin & function

1. Poxvirus proteins involved in entry and or morphogenesis
   A33, A34, A36, A56, 85, F12, F13, E2 and K2 each have a role in the entry or exit of vaccinia virus. Each will be cloned into the lentiviral vector.
2. Poxvirus immunomodulators
   K7, B14, Ni, A46, A52, A49, C6, A41, A44, B15, B18, and v-GAAP are all non-essential for virus replication in vitro but have roles in altering the host response to infection in vivo. Each of these will be cloned separately into the lentivirus vector. In addition, uncharacterised poxvirus proteins, which have a putative immunomodulatory role, may be expressed in this way in the future.
3. Cellular orthologues of poxvirus proteins
   Many poxvirus proteins have cellular orthologues, the function of some of which is not yet fully understood, and each of these may be cloned into the lentivirus vector. This includes the newly characterised human Golgi anti-apoptotic protein (h-GAAP), which shows 73% amino acid identity to the vaccinia virus v-GAAP (Gubser et al., 2007. PLoS Pathogens 3:e17).

Evaluation of foreseeable effects

Each lentivirus vector produced will be able to infect cells, but is not able to replicate in those cells and so cannot spread to new cells. These vectors are therefore classified as replication-defective. The nature of the foreign proteins expressed by these vectors is not likely to affect the hazard group of the parent vector and will only be expressed from the infected cell.
Lentivirus vectors provide an efficient means to transduce genes into human cells. In theory, these genes can be transduced into laboratory personnel working with the packaged viruses, however, the virus is replication-defective, and so an ongoing infection with these viruses is not possible. The ability of h-GAAP to block apoptosis means that any cells transduced with h-GAP? would be resistant to cell death, which would in theory increase the chance of those cells becoming cancerous. Because the lentivirus is replication-defective, there is a very low probability that infection will occur in stem cells with the potential to become cancerous. This programme of work will not include viral oncogenes which have multiple oncogenic activities such as the SV40 T antigen, nor will it include clusters of genes such as HPV1 6 E6-E7. Genes encoding toxins will not be included in this work.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The use of lentiviral vectors to study poxvirus proteins and their cellular orthologues, Virology, Investigative Sciences, St Mary’s-
Following the discussion of your proposal the following amendments are requested prior to approval:
1-25: Remove the sentence; “Any other viral gene subsequently implicated in morphogenesis may also be included.” The Committee recommend that further genes be considered on a case by case basis in new (Form C, if appropriate) submissions - - .
1.3: The sentence; The ability of h-GMP to block apoptosis indicates that is may be a proto-oncogene and contribute to cancer” is too broad and needs clarification.
3.8: Tick declaration box.
Agreed: Class 2, Containment Level I IC reference number: GMIC-01698.1

Project Containment
The aim of the project is to identify the molecular mechanisms that contribute to the pathogenicity of the human T-lymphotropic virus type 1 (HTLV-1), in particular during the formation of the virological synapse (VS), and the mechanisms by which HTLV-1 spreads between T-cells. The objective of the present experiments is to test the effects of certain HTLV-1 genes on the formation and function of the VS by examining the consequences of mutations in the HTLV-1 genome.

We plan to use an infections molecular clone of HTLV-1, designated ACH, that is easily manipulated in vitro and ex vitro, and deletion mutants of this clone. The biological activity of clone ACH has been characterized in various cell lines (Kimata JT, Virology, 1994; 204(2): 656-64). The purpose of these experiments is to express the HTLV-1 molecular clone, full length or deleted of certain regions coding for specific viral proteins, to test their effect on the formation of the virological synapse and on transmission of the virions between T-cells. The altered HTLV-1 genes encode small regulatory proteins of the virus. In some cases we may include a reporter gene such as GFP, luciferase, or a short antigen tag (“flag”), or similar additional mutations which are unlikely to increase the risk to human health or the environment.

We are also planning to introduce a biarsenical labelling system in the HTLV-1 full length molecular clone. This system is based on the insertion of a small tetracysteine
(TC) motif into a protein of interest. Cells expressing the TC-tagged protein are treated with a membrane-permeable biarsenical dye [e.g. green (FIAsH) or red (ReAsH)] that fluoresces upon binding to the TC tag (Gousset K., PLoS Pathog. 2008 Mar;4(3):e1000015). This will allow us to visualise by real time fluorescence the newly formed virions without altering their intrinsic properties (virulence and infectivity).

The precise molecular effects of each of the HTLV-1 genes to be deleted or mutated are partially characterised; all the available evidence suggests that the genetic changes in HTLV-1 will severely impair or abrogate the replication and/or transmission of HTLV-1. This will be kept under continual review: if any unanticipated effects are noted from the published data, work will be halted until an assessment has been made of the risk and approval obtained from the GM committee.

Recipient or parental organism

The plasmids will be grown in E. coli K12. We will be using the following six types of construct:

1-Full length proviral clone of HTLV-1, designed ACH (Kimata DT, Virology. 1994; 204(2): 656-64).

2-The mutant Delta p30 protein is a small accessory protein. There is some evidence that it regulates the transcription of HTLV-1 Tax protein at the post-transcriptional level, but its complete actions and its main physiological role are unknown (Nicot C. et al., Nat Med. 2004; 10(2): 197-201).

3-The mutant Delta p12. HTLV-1 pt12 protein down-regulates MHC class 1 on the surface of the HTLV-1 infected cell, and so may contribute to immune escape by the virus (Fukumoto R. et al., Blood, 2008; Epub ahead of print).

4-The mutant Delta HBZ. HBZ appears to act both at the RNA level and the protein level. There is evidence that it promotes HTLV-1 persistence by driving proliferation of the HTLV-1 infected T-Cell; it may also inhibit HTLV-1 proviral expression (Barbeau B. and Mesnard JM. Int Rev Immunol. 2007; 26(5-6):283-304).

5-The mutant Delta p13. The small regulatory protein of HLV-1, p13, is targeted to mitochondria and disrupts mitochondrial morphology. As in the case of other regulatory proteins, the main physiological role of this protein is still under investigation Silic-Benussi M. et al., Proc Natl Acad Sci U S A. 2004 April 27;101(17):6629-34).

6-Insertion of a small tetracysteine motif (TC) in the HTLV-1 full length molecular clone. Cells expressing the TC-tagged protein are treated with a membrane-permeable biarsenical dye [e.g. green (FIAsH) or red (ReAsH)] that fluoresces upon binding to the TC tag (Gousset K, PLoS Pathog. 2008 Mar 7;4(3):e1000015). This will allow us to visualize by real time fluorescence the newly formed virions without altering their intrinsic properties (virulence and infectivity).

Host/vector system

The vector system is full length proviral clone of HTLV-1, designated ACH. The E. coli K12 competent cells will be used to amplify the plasmids.

Only in vitro cell lines (Jurkat, BHK21, HeLa, 293T) will be used as hosts for these constructs; no other intact organism.

Origin & function

The precise molecular effects of each of the HTLV-1 genes to be deleted or mutated are partially characterized; all the available evidence suggests that the genetic changes in HTLV-1 will severely impair or abrogate the replication and/or transmission of HTLV-1.

Evaluation of foreseeable effects

The precise molecular effects of each of the HTLV-1 genes to be deleted or mutated are partially characterized; all the available evidence suggests that the genetic changes in HTLV-1 will severely impair or abrogate the replication and/or transmission of HTLV-1. This will be kept under continual review: if any unanticipated effects are noted from the published data, work will be halted until an assessment has been made of the risk, and approval obtained from the GM committee.

Please enter comments on the GM safety committee on the risk assessment
Following the discussion of the proposal at the GM Safety Committee meeting, the committee requested that the following amendments be made to the proposals prior to approval:

Comments: CB gave a brief summary of the project.
PK queried if the plasmids would be grown in Containment Level 1 and this was confirmed by CB.
PF asked how the mutations would be handled. CB informed the committee that they expected the mutations to result in attenuation, this would be viewed continually and additional changes made via a Form C if necessary. The Committee suggested that a statement to this effect should be added to the current risk assessment rather since the HSE would most likely request this if it was not stated.
PK requested to know what type of proteins had been altered in the Delta mutants. CB stated that some were thought to be accessory proteins but the function and roles of others were unknown.
PL suggested that this information be stated on the form.

The following amendments were requested prior to approval:

Part 1: Title Type: T-cells
1.1: Add more information about the scientific goals of the project. HTLV-1 should appear in full at the first use and thereafter in abbreviated form.
1.21: Indicate what is known about the proteins of interest (delta mutants) or state that their functions/role is unknown. Add in any reporter genes e.g. GFP that may be used.
- Typo: Properties
- Change hypochlorite to Virkon.
1.22: Specify what cell lines will be used.
1.3: Make statement indicated that any mutation would be expected to result in attenuation, that this would be reviewed continually and any committee would be informed of any unexpected phenotype and any additional charges necessary to be submitted to the committee for approval via a Form C.
1.4: Tick box: containment level 3.
2.1.1.2: Type: carring.
2.2.1.1.: Rephrase this sentence ensuring that both plasmids and bacteria are considered.
2.3.2.2: Clarify rooms
2.3.5.: Advice form occupational health is required.
2.3.6: Tick box: containment level 3.
3.1.1a: Split the liquid waste section in two parts to include the specific information for CL2 and CL3 rooms. CL3 waste should specify that tissue culture media be disposed of via autoclaving and that an annual 12 point thermocouple testing of the autoclave be used for validation.
3.1.1b: State print out is used to monitor autoclave runs and give details of the type of strips used.
3.5a: Add wipe up contact time.
- Change 1% Virkon to 2%.
- Specify aluminium box will be opened in a microbiological safety cabinet in the event of a spillage.
3.5b: Remove: Eye protection is worn for use of vaccinia virus.
3.6: Clarify rooms.
Ensure that any of the above changes and the Code of Practice (which will need to be submitted to the HSE) are consistent.

Agreed: Class 3, Containment Level 3, HSE notification and written consent required prior to commencement.

Project Containment
Purposes of the contained use

Penicillium spp. and their related sexual species, Talaromyces, in particular Penicillium marneffei and Talaromyces stipitatus, are saprophytic ascomycetous fungi. In the context of a severely debilitated host Penicillium marneffei can cause a fatal disease. Healthy individuals are at negligible risk of Penicillium marneffei infection, and this is reflected in Penicillium marneffei being listed as an ACDP category 2 pathogen in countries other than the UK. In the UK Penicillium marneffei is listed as ACDP category 3a.

The aim of this work is to identify, sequence, disrupt and analyse the expression of fungal genes involved in virulence e.g. STE12 (transcriptional regulator), STE11 (MAP kinase), RIM101 (Transcriptional regulator), RAC (polarized growth regulator) and other genes as yet unidentified. To achieve this, genes will be isolated from genomic DNA by PCR, heterologous hybridisation, mutant complementation and related techniques. This will require construction of Penicillium and Talaromyces libraries in Saccharomyces cerevisiae/Escherichia coli shuttle vectors e.g. YEp24. Genes of interest will be sequenced and characterised further. Phenotypic assays e.g. the ability to grow in the presence of 0.1% SDS, low/high pH, reduced glucose and 500mM KCl, will be used to characterise the effect of inactivation of each gene. As part of this further
analysis gene disruption and replacement experiments will be performed in the modified *P. marneffei* KU70 deletion strain. This strain has a high rate of homologous gene replacement. In addition these lesions will be complemented using the *P. marneffei* homologous gene. This will be done by DNA mediated transformation of viable fungal cells (KU70 and/or wild-type) using non-mobilisable vectors carrying appropriate nutritional (for complementation of auxotrophy) or antibiotic (eg hygromycin and phleomycin) markers. Where appropriate, ablation of virulence will be assayed in a murine model.

**Recipient or parental organism**

*Penicillium marneffei* FRR2161, FRR2161 KU70 gene-deletion strain. These strains have a long prior history of safe use in Dr. Alex Andrianopoulos' laboratory ([http://www.genetics.unimelb.edu.au/Research/andr/index.html](http://www.genetics.unimelb.edu.au/Research/andr/index.html)) in Melbourne, Australia, where the fungus is classified at a ACDP category 2 pathogen according to Australian and USA legislation.

We also seek permission to use other wild-type clinical strains that have essentially the same characteristics as those described for use as controls.

**Host/vector system**

Saccharomyces cerevisiae: the majority of laboratory strains are derived from three major wild type lineages S288Cand W303. Most contain multiple auxotrophies and would not survive outside the laboratory.

*Escherichia coli*: strains in common laboratory use eg DH5alpha, XL-10 will be used as cloning tools. These strains, which are generally derivatives of the K12 strain, have a widespread and long history of safe use. They also contain numerous mutations eg thi-1 which render the strains auxotrophic and therefore unlikely to survive outside the laboratory environment.

**Origin & function**

The origins of the GM material will be from:

1. *Penicillium marneffei* will be the donor organism and will constitute 'self-cloning' as we will reinsert genes to complement genes that have been intentionally ablated to investigate loss-of-pathogenicity mutations.

2. We will also add selected tags eg GFP, TAP, HA, etc to selected genes *Penicillium marneffei* genes (full gene-set to be determined)

3. We will use heterologous antibiotic genes eg. ampR, bleR, hygR as markers of transformation.

**Evaluation of foreseeable effects**

The GMMs and gene knock-outs are disabled or are expected to result in loss-of-virulence: they are unlikely to be able to survive in the environment and the modifications proposed (gene inactivation) would not confer a selective advantage even if they were to be transferred to a wild type organism. The likelihood of hazard is therefore considered to be no greater than that of the parental strains. We will assay phenotypes in both cell-culture (macrophage cell line THP-1) and in-vivo models (mouse) and record whether genetically-modified *P. marneffei* occur that show unusual or aggressive phenotypes.

To summarise: the most hazardous GMM organism is likely to be the re-constituted wild-type organism.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
SOLID WASTE

All pipettes, loops, and pasteur pipettes used in the facility will be of the disposable type.

Solid culture media will be in plastic Petri dishes, plastic universals, or plastic bijoux bottles.

The main disinfectants to be used will be 1% Trigene liquid in liquid-contained: this disinfectant is effective against a wide range of fungal pathogens as well as P. marneffei. However, we will validate its ability to kill P. marneffei prior to the commencement of our experiments.

All solid waste will be autoclaved post-disinfection and prior to disposal.

SPECIFIC DETAILS ON HANDLING SOLID WASTE

a) Disposafe jars are placed in the safety cabinet. These will be used to contain plastics such as tips, pastettes, microscrew tubes, loops, graduated pipettes, 96well plates, 24 well plates and any plastics that won’t hold liquid/Trigene detergent very well and therefore needs containing. 24-well tissue culture plates and 96-well tissue culture plates can be disinfected with 1% Trigene and then placed in the disposafe jar. There should be NO MORE THAN 0.5L of liquid volume in the bottom of the disposafe jar otherwise the jar will not reach the desired sterilisation temperature. The Disposafe jar can then be placed into an autoclave bag and sprayed with 70% ethanol before being removed from the MSC and then autoclaved. This is classed as Disposafe jar waste.

b) Petri dishes containing agar cultures should be sealed with tape inside a Petri dish bag and then discarded into a double Sterilin bag for autoclaving. This is classed as mixed discard.

c) Used gloves, tissues and other material that has not been in direct contact with fungi should be discarded into a double Sterilin bag suspended in the white bin liner holder and then autoclaved. This is classed as mixed discard.

All solid waste materials from the laboratory must be autoclaved before final disposal. Autoclave bags must not be more than 2/3rds full. An autoclave for routine disposal is located within the laboratory. The desired temperature is 121 degrees C for 15 minutes. All waste to be autoclaved must be discarded into a thermolabile bag sitting within a thermostable Sterilin one, both securely held by the bag holder.

Disposafe jars should be placed in double Sterilin bags. In all cases the bags must not be overfilled with jars and must not be closed (hold the bag around the neck on the way to the autoclave). Once placed in the autoclave ensure that the bag neck is open before running the autoclave.

All autoclaved material will be placed in yellow clinical waste bags, tagged with the appropriate recorded tag and transported to the yellow clinical waste bins for disposal. The print out receipt for each autoclave run and tag number of each yellow waste bag will be recorded in the diary on the day of autoclave completion.

The liquid waste in the Tundish vessel from the autoclave will be disinfected with 1% Trigene for 24 hrs before being disposed of in the sink.

All autoclaves will receive annual 12 point thermocouple testing, 6 monthly servicing and annual insurance inspection.

LIQUID WASTE

Small volumes of liquid culture (10 - 20ml) will normally be grown in plastic universals/50ml falcon tubes. Larger volumes of liquid culture (up to 100ml) will be grown in 250ml plastic Erhrlenmeyer flasks that do not have vented caps.
The main disinfectants to be used will be 1% Trigene liquid or spray.

All liquid waste will be autoclaved post-disinfection and prior to disposal.

SPECIFIC DETAILS ON HANDLING LIQUID WASTE

a) Enclosed vessels such as flasks, falcons and bijoux tubes will have 1% Trigene disinfectant added to them, re-lidded and then left overnight for 24h in the cabinet (but without causing overcrowding within the cabinet). All paper waste, contaminated gloves and paper towels together with the enclosed vessels will then be placed straight into a double autoclave bag, sprayed with ethanol and then removed from the MSC and placed directly into the autoclave. This is classed as mixed discard.

All liquid waste materials from the laboratory must be autoclaved before final disposal. Autoclave bags must not be more than 2/3rds full. An autoclave for routine disposal is located within the laboratory. The desired temperature is 121 degrees C for 15 minutes. All waste to be autoclaved must be discarded into a thermolabile bag sitting within a thermostable Sterilin one, both securely held by the bag holder.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The following comments were made by the GM Safety Committee:

State GM Centre No: GM77

1.1: Name the cell lines here.
1.2: Specify the gene deletions and list the strains for which you request permission. Remove the references to E.coli and S.cerevisiae and fill in a separate GM form A for the class 1 aspect of the work.
1.3: Add ‘GMM organism will most likely be the…’
2.1.1.1: Remove: Aspergillus fumigatus ACDP 2 and Talaromyces stipitatus ACDP 1.
2.1.1.2: Remove reference to E.coli.
2.1.1.3: ‘The majority of genes inserted will be from the same organism…’ clarify this.
2.3.3.1.a: Include PRC testing.
2.3.3.3.b: Correct/reword this sentence i.e. will the buckets be sealed?
2.3.3.3.d: The tissues used to clear up any spill should be autoclaved. State that this will be the case.
2.3.4.1: Is it 1 or 2% Trigene? Please be consistent throughout the Forms and COP.

Part 3: Fill in tick box.
3.2.a: Remove ‘drop-proof’ to ‘robust’ boxes.
3.31.b: Remove reference to A. fumigatus.
3.42: Answer the question re use of sharps.

3.5.a: Rearrange sentence order in first paragraph to reflect correct order of activities; point out that spills will be disinfected, then autoclaved. Remove reference to E.coli and S.cerevisiae.

Agreed: Class 3, Containment level 3. HSE notification and written consent required prior to start of work.

Remove the references to E.coli and S.cerevisiae and complete a new GM Form A, Class 1, for this part of the work. It was decided that MF should submit the application with the animal work included despite the fact that this work is to be done at a much later point in order to prevent later complications. An explanatory note will be included in the risk assessment and in the letter to the HSE. A code of practice for the animal work will be submitted to the Safety Dept and the HSE at a later date once home office approvals have been granted. No work will start before submitting the Codes of Practice and gaining HSE approval.

IC reference number: GMIC-01888.1

All of the comments have been addressed and the required changes incorporated into the risk assessment attached to this form.

---

**Project Additional Information**

**Purposes of the contained use**

To study the interaction between influenza viruses and their hosts in order to understand virus pathogenesis, factors that determine the biological outcome of infection and factors that restrict or expand the virus host range. In addition to develop suitable in vivo and in vitro models for testing interventions and therapies to enable better control of influenza disease.

**Recipient or parental organism**

Influenza A viruses that are reconstructed from cDNAs representing the entire genome of the virus. The parental organism for work with swine origin H1N1 influenza virus will be A/England/195/09, an isolate from a UK patient who suffered a mild upper respiratory tract infection. In addition recombinant influenza viruses containing internal genes from the vaccine strains A/PR/8/34 and surface antigens HA and NA from the swine virus will be generated and the activity of infection of ferrets with these viruses is considered to be of higher risk than their recovery which will take place under our existing class II project.

**Host/vector system**

The influenza viruses will be rescued in vitro in cell culture systems using plasmid DNAs propagated in E. Coli bacteria.

**Origin & function**

The recombinant influenza viruses will be used to infect cell cultures to study the replication capacity, host responses induced and susceptibility to antiviral drugs. In addition the viruses will be used to infect animal models including mice and ferrets to study their pathogenesis and transmission in vivo.

As described in the attached risk assessment, point mutations will be introduced into genes of swine origin H1N1
Influenza that are linked with the acquisition of resistance to antiviral drugs. The H274Y mutation in the NA gene will be introduced to England/195/09 virus. This virus will be tested for susceptibility to Tamiflu, Relenza and Peramivir. In addition this virus will be used to infect ferret to assess pathogenesis and transmissibility. A single gene reassortant virus will be generated with 7 RNA segments from England/195/09 and the NA segment from a recent human H1N1 virus that already carries the Tamiflu resistance mutation H274Y. This virus will be tested for antiviral susceptibility, virulence and transmissibility in ferrets.

### Evaluation of foreseeable effects

Infection of workers or swine is possible. Viruses in which mutations are engineered that may confer resistance to Tamiflu are expected to remain susceptible to other antiviral drugs including Relenza. Nevertheless these viruses constitute a significant health hazard and their release is undesirable. Aerosols are controlled so that infection of workers is, so far as is reasonably possible, prevented. In the unlikely event that a worker were to be infected (or exposed and potentially infected) with such a mutant, they would be treated with Relenza and isolated at home.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| Liquid waste: liquid waste containing infectious virus will be treated with 1% Virkon for minimum 30 minutes inside the MSC then in 50 ml maximum volumes in plastic flasks will be autoclaved within the room. Flasks will be placed in double autoclave bags and autoclaved for 20 minutes at 135°C 3 bar. After removal from the autoclave bags will be placed inside metal tins that will sprayed out of the room with 70% methanol and disposed of a solid waste through the usual hospital clinical waste route. |
| Solid waste: solid waste contaminated with infectious virus (plastic tips, flasks) will be immersed in 1% Virkon for minimum of 30 minutes inside the MSC. After this it will be placed inside a double autoclave bag, and autoclaved within the laboratory at 135°C 3 bars for 20 minutes. Conditions of each autoclave run are stored in printed form. The autoclave undergoes a 12 point thermocouple test annually. After autoclaving the solid waste joins the usual hospital clinical waste route. |

In room B44 CBS facility there is no autoclave within the room. In this case liquid waste and solid waste will be Virkon treated as above by immersion in 1% Virkon for 30 minutes in the MSC hood, placed inside a double autoclave bag and then the whole placed in a plastic Ultima bin. The bin will be sprayed out of the room with 70% methanol and autoclaved in the CBS autoclave at 135°C, 3 bar for 20 minutes.

Animal waste from room B44 will be placed in double autoclave bag, inside an ultima bin and sprayed out of the room with 70% methanol and autoclaved in CBS autoclave as above.

Y
The following comments were made by the GM Safety Committee:

Comments: WB gave a summary talk on the background to the project. MS stated that it was important to contain exposure at the primary level when performing the ferret nasal washes. AdP responded by reporting that all relevant control measures would be put into place; the experiments will be conducted with a replication of conditions utilised at Porton Down for the handling of Highly Pathogenic Avian Influenza. This will involve the use of modified downflow benches, supplemented with positive pressure respiratory protective equipment. PF asked whether a microbiological safety cabinet (MSC) would be employed. WB replied that the use of an MSC would be difficult especially as two people were required for handling of the ferrets. PK queried the means of disinfection of the RPE in order to prevent crosscontamination and spread of the viruses. AdP replied that the CoP had yet to be written but it would involve two people spraying each other's other masks in turn with 70% EtOH; RPE would be located inside the lobby and only 'clean' reagents, people, and equipment would enter the facility. PK queried contact time with 70% EtOH. AdP and WB answered that validation experiments with EtOH addressing questions such as contact time etc. had been performed by WB’s lab and would go in the CoP. PF raised concerns over the unpredictable nature of nasal washes and asked about alternative methods for virus rescue. The alternatives were discussed and the use of a MSC discounted. AdP reiterated that the downflow benches would be tested under conditions of use to check that they offered equivalent levels of aerosol containment as an MSC and that the RPE would then provide an extra level of protection against splashes. WB also commented that the use of anaesthetised animals would probably aid in safety but that the quality of data would be severely compromised in that the amount of virus rescued may be less and that it would be very difficult to anaesthetise the animals on a daily basis.

The following amendments are requested prior to approval:

1.3. Typo: 'PUC'

2.1.3. Expound the last sentence so that management controls, e.g. logging use of viruses, obligatory (& logged) UV of hoods, etc. are mentioned; the sum of these controls should “prevent” and not just "minimize the risk". It is important to be able to demonstrate should the need arise that work on incompatible viruses is not, or has not been, conducted.

2.1.1.6. If there is an increase in titre of more than 3 logs, what is the threshold above which the novel virus will be destroyed? Does this refer to the wild one? If yes, what is the normally expected titre?

2.2.1.3 & 2.2.1.4. Reword these sections as not desirable to have Tamiflu-resistance circulating in the pig population.

2.3.1.1. Are the SOPs for microscope examination of cultures the same as for Cat II work, or will there be additional precautions?

2.3.2.1. Wherever transfer of live viruses from Cat 3 labs is mentioned, a statement should be added clarifying that these transfers are only made to other approved Cat 3 labs, or unless approval is gained from the local GM Safety Committee that a particular virus(es) is free of other contaminating Cat 3 viruses and does not require category 3 containment.
Agreed: Class 3, Containment level 3. GMSC members have been asked to forward any further specific comments on the forms to YH at the earliest opportunity. HSE notification and written consent are required prior to start of work.

A Code of Practice for the laboratory as well as the animal (ferret) work is to be devised. PL suggested, unanimously agreed, that the relevant codes of practice and pertinent testing information be forwarded to the GMSC for review in order to ensure that all effective control measures have been put in place. Additionally, AdP has asked GMSC members decide and report back on the extent to which they wish to inspect and monitor this work at the aforementioned facilities.

All of the comments have been addressed and the required changes incorporated into the risk assessments attached to this form.

Project notified under transitional arrangements [N]
Toxoplasma gondii is a single-celled protozoan that is an obligate intracellular ubiquitous parasite that can infect any animal and is currently found in ranges of 22-84% in human populations across the world. The most infectious stage is the extracellular sporozoite stage found in cat feces and infections are minor and self-limiting but is classified as a Class 2 pathogen in the ACDP because it can be serious for a developing fetus whose mother first contracts the disease during pregnancy or an immunocompromised person. In the laboratory we only maintain the intracellular stages.

Recipient or parental organism

Toxoplasma gondii is a single-celled protozoan that is an obligate intracellular ubiquitous parasite that can infect any animal and is currently found in ranges of 22-84% in human populations across the world. The most infectious stage is the extracellular sporozoite stage found in cat feces and infections are minor and self-limiting but is classified as a Class 2 pathogen in the ACDP because it can be serious for a developing fetus whose mother first contracts the disease during pregnancy or an immunocompromised person. In the laboratory we only maintain the intracellular stages.

Host/vector system

The vector is based on the standard non-mobilizable cloning vector pKS+ with T. gondii sequences for expression in parasites and chloramphenicol acetyl transferase as a selectable marker. There are now several hundred publications using these vectors for T. gondii transfections including ones from UK institutions. It does not contain elements for propagation in T. gondii (e.g. origins of replication, retrotransposons) and is not expected to be mobilizable.

Origin & function

Initial gene disruptions will target an enzyme in amino acid conversion (GenBank No. ACB99414 and ACB99413). There are no known hazards associated with these classes of enzymes and the products (tyrosine and L-DOPA) are normal metabolites in animals and humans. Most experiments will only utilise a gene fragment so that the chromosomal copy of the targeted gene is inactivated whilst overexpression may increase the likelihood that the infected rat is attracted to cat odour. The intended function is to alter expression levels of metabolic genes so that the effect on the parasites ability to subtly modify rat behaviour can be monitored.

Evaluation of foreseeable effects

The final GMM is likely to be of the same risk of harm as the un-modified host. It is possible that the genetic lesions in metabolic pathways will lower fitness. It is unlikely to escape the laboratory conditions due to this intracellular parasite’s requirement of a host cell and specific nutrients. In the event of escape, there is no increase in virulence and hence no increase in harm from normal exposure to these pathogens in the environment. Indeed as this parasite is common in animals and humans and
approximately 30% of the UK population have antibodies to Toxoplasma, the GMM would find it difficult to compete for a niche. Hence, there is no foreseeable harmful effect of escape from containment. This parasite can only survive as an intracellular parasite in animal cells. It has a very short lifespan outside the culture dish. Hence possible exposure is only to lab workers and, due to high exposure rate in the environment and high levels of antisera in the population, there is negligible risk to lab workers, the environment, or community at large. This project does not use the stable sporozoite form excreted by cats that is the only form that can survive outside host cells. The ecological consequences on escape are minimal to nil as this parasite in its more competent wildtype form is prevalent in the environment. It would require 10,000-100,000 viable parasites to infect a cat. If this did occur, the resulting sporozoites in the cat feces would present no greater harm than the un-modified host.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

| Liquid waste from culture media obtained during initial inoculation only (GMM produced and provided from Leeds University) – will be decontaminated using an equal volume of 2% Virkon and left overnight (following manufactures literature and following assays confirming killed cultures for regrowth on fresh culture media performed at Leeds university prior to commencement of study) before disposal in drains with 100 volumes of water. Any solid waste from initial culture material will be autoclaved on programme 2 (1260 for 1 hour), before being destroyed as clinical waste. Animal bedding following initial inoculation (rats do not shed T. gondii) will be autoclaved, before being destroyed as clinical waste. Animal carcasses at the end of the study will be autoclaved and destroyed as clinical waste as above. Emergency spill procedure: Liquid spill – treat with Virkon granules until deep pink, or add an equivalent volume of 2% Virkon – will be left for at least half an hour before being mopped up with plenty of water. Wearing strong gloves of the "Marigold" or similar type, solid spills will be gathered into an autoclave bag, the area affected will be wiped liberally with 2% Virkon. The treated area will be left for half an hour for the disinfectant to have time to act and the area will then be mopped up with plenty of water. Immediately after it has been collected and the affected area has been treated with Virkon, the solid waste will be taken for autoclaving, as above. For spills inside centrifuges the local Standard Operating Procedure as indicated on the equipment will be followed. All spills of genetically modified microorganisms (GMM) will be reported immediately to the local Biological Safety Officer, or local Safety Supervisor in the absence of the BSO; all spills and their mode of treatment will be recorded. Any personal injury where an infection by a GMM may be involved will be reported immediately to one of the local BSO’s or Safety superiors and the immediate advice of Occupational Health will be sought. |

| Is an emergency plan required according to regulation 20? | N |
| If yes, tick to confirm that it is attached to this form | N |
Dear Professor

Following the discussion of your proposal entitled “The role of L-DOPA synthesis in Toxoplasma-altered host behaviour”, GMIC-01953.1 at the last GM Safety Committee meeting, the Committee request that the following amendments are made to the proposal prior to approval:

Comments: PL gave brief summary of the proposal. The Committee had a few queries about the methods used:
- JC explained the gavage method and JW described further how the GMM was prepared in Leeds before it will be transported to the College.
- PK queried if there will be shedding and JW confirmed there will not, this is to be clarified on the proposal.
- PK also questioned who would be doing the animal exposure work, JW answered that the CBS technicians at the College would be carrying out this work.
- MS pointed out that the risk to pregnant workers needed to be addressed.
- PL suggested that all reference to latex gloves are replaced by the use of Nitrile gloves.
- JW was also asked to confirm is centrifugation will be used and to add this to the proposal if so.
- Finally a Code of Practice needs to be completed.

The following amendments are requested prior to approval:

1.1: Describe further the link between urine attraction and behavioural changes in the mice.
1.22: Please quote references.

Part 2: GMIC reference number is: GMIC-01953.1
2.1.1.2: State the hazards of the host organism, the toxoplasma wildtype; risk to humans, and pregnant workers.
2.1.1.5: Typo: „lielihood“ and double full stop at the end of the sentence.
2.2.1.1: Typo: „avrirulent“ and „hereare
2.2.1.3: Clarify this answer.
2.2.1.4: Clarify this answer.
2.3.1.1: Space between “…10ml/kg).IP infections…”
- Change from latex gloves to Nitrile
- Typo: „personell“ and „afterwhich“
- State that there is no shedding and that all bedding will be autoclaved.
2.3.3.1.c: Typo: „personal”, should be „personnel"
2.3.3.2.a: Typo: „Transportion”
2.3.3.3: Determine if centrifugation will be used and then answer the questions in the section appropriately.
2.3.3.5: Typo: „withinthe”, „personell”, „GMOS” and „afterwhich”.
2.3.3.8.c: Typo: „consumaption”
2.3.5: AS to complete this section.

Part 3: GMIC reference number is: GMIC-01953.1

Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N
3.31.a: Typo: "GMM", should be "GMO"
3.31.c: Point out that this is unlikely.
3.41: "X" mark the "yes" box and remove the "X" in the "no" box. Clarify that face mask will not be worn all the time.
3.5.a: If centrifuging will be used, add details here.
   - Remove: "(Parasite maintaining?)"
3.5.b: Typo: "sterilized"
3.7.1: Remove JC and add to 3.7.2

Agreed: Class 2, Containment level 2. HSE notification and written consent are required prior to start of work. The Code of Practice will be sent with the HSE notification.

Could you please ensure that the risk assessment is revised (add GMIC number) and the amendments above addressed, the Occupational Health information should be attached. The form should then be emailed to me. Please see http://www3.imperial.ac.uk/safety/guidanceandadvice/biosafety/gmprocedures for further information.

The HSE notification form is attached to this email.

**Project Ref 77/11.1**

- **Date Ackn'd**: 16/06/2011
- **CU2 Project Title**: Characterisation of acute HIV-1, SIV AND SHIV strains
- **Class**: Class 3
- **CultureVolClass2**: < 1 Litre
- **Non-GMM Consent Granted**: Yes
- **Project notified under transitional arrangements**: N

---

**Historical Significant Changes**
During acute infection, HIV-1 crosses mucosal barriers and infects primary target cells e.g. CD4 T cells, macrophages and Dendritic cells. The way in which viruses responsible for transmission interact with primary target cells and tissues is not fully understood and may differ substantially from the behaviour of chronic or lab-adapted viruses. The aims of this project are

Aim 1. To define the sequence of events required for establishment of HIV-1 infection in mucosal tissue explants and primary target cells.
Aim 2. To define the viral determinants of mucosal HIV-1 transmission using in vitro models.
Aim 3. To define the earliest genomic and proteomic responses following infection of cellular and mucosal tissue models in vitro.
Aim 4. To examine possible intervention strategies that may prevent HIV transmission via mucosal routes e.g. use of microbicides.

Our Collaborators within the Centre for HIV/AIDS Vaccine Immunology (CHAVI) consortium have cloned HIV envelope genes and full length HIV-1 provirus from acutely infected patients in order to conduct these studies. Envelope genes and full length proviral clones isolated from chronically infected patients and lab-adapted viruses will be used as controls. Some constructs also contain reporter genes such as GFP or Luciferase. These viruses will be used to infect primary cells such as dendritic cells, macrophages and CD4 T cells, established immortalised cell lines, and primary tissues of vaginal, penile, rectal and tonsil origin.

As SIV infection in macaques is used as a model of HIV in humans to examine early events in infection, SIV and SHIV (HIV/SIV chimeras) strains will also be used to study transmission, pathogenesis and to test potential anti-viral compounds. Direct comparison of these related retroviruses in human tissue models will be conducted. The effect of mutations that confer resistance to antiretroviral drugs will also be studied by inducing such mutations into proviral clones, and expanding these in established cell lines. Our collaborators will conduct in vivo infection experiments in non-human primates. Our laboratory will receive blood serum and tissue samples from these experiments for analysis and storage. We will also need to culture SIV and SHIV strains in our laboratory for infection assays.

Competent E. coli strains TOP10, DH5a, STBL2, STBL3 will be used to prepare plasmid DNA. These are recognised as non-colonising and disabled, and may be considered to be equivalent ACDP hazard group 1. They are not considered pathogenic to humans or animals. They are expected to have limited survivability in the environment and often have auxotrophic requirements, which are unlikely to be satisfied outside of laboratory culture. In the event of transfer of the plasmid to other bacterial strains, HIV genes would not be expressed as HIV requires numerous human proteins to complete its lifecycle, and these genes are absent from prokaryotic organisms, thus the plasmid provide no selective advantage. The virus generated would not differ from other HIV-1 strains already present within the laboratory, and so recombination would not be expected to result in a strain that would pose any higher risk than those already in use. Outside the specialised laboratory environment and

Recipient or parental organism

Competent E. coli strains TOP10, DH5a, STBL2, STBL3 will be used to prepare plasmid DNA. These are recognised as non-colonising and disabled, and may be considered to be equivalent ACDP hazard group 1. They are not considered pathogenic to humans or animals. They are expected to have limited survivability in the environment and often have auxotrophic requirements, which are unlikely to be satisfied outside of laboratory culture. In the event of transfer of the plasmid to other bacterial strains, HIV genes would not be expressed as HIV requires numerous human proteins to complete its lifecycle, and these genes are absent from prokaryotic organisms, thus the plasmid provide no selective advantage. The virus generated would not differ from other HIV-1 strains already present within the laboratory, and so recombination would not be expected to result in a strain that would pose any higher risk than those already in use. Outside the specialised laboratory environment and
without cellular support HIV is unlikely to survive and thus is unlikely to be a significant environmental threat.

Constructs will be transiently expressed in human embryonic kidney (HEK) 293T cells and virus stocks produced by transfection may be expanded in primary human HIV SIV and SHIV susceptible cells (primary CD4 T cells, macrophages and DC) and immortalised T-cell lines (Jurkat, MT-4, C8166, PM-1, CEMx174-R5). Virus stocks produced in this way will be infectious, however, as the envelope genes and full length proviral clones are derived from HIV infected patients, the virus generated is not expected to differ from known HIV-1 strains in terms of tropism, pathogenicity or infectivity. Cell lines used to generate virus stocks require specialised culture conditions and will not survive outside a specialised tissue culture environment, and so would present minimal risk to the environment.

Host/vector system

Full-length proviral clones are provided in plasmids pCR-XL-Topo, pBR322, pUC18, pTZ19R, pNLFPB, and pBluescript II. Envelope genes from acutely infected patients are cloned into a pUC18-based vectors containing the HIV-1 strain NL4-3, these constitute full-length proviral clones. Single round replication incompetent (env deleted) clones will also be used, in conjunction with HIV-derived envs, and VSV-G. Note that VSV-G will only be used in conjunction with env-deleted vectors, never with full-length virus.

Origin & function

Plasmids will contain either full-length or near full-length (env-deleted) HIV genomes derived from HIV-infected patients. Some provirus clones will contain env genes from HIV positive patients inserted into the backbone of a lab-adapted HIV-1 provirus (NL4-3). The HIV genome consists of the following genes:-

- Gag - Group-specific Antigen, codes the structural HIV-1 proteins (Capsid, Matrix Nucleocapsid, and p6)
- Pol - Codes the viral enzymes reverse transcriptase, protease, and integrase
- Tat - Transactivator protein, increases efficiency virus transcription
- Rev - regulates traffic of virus RNA species out of the nucleus
- Nef - down regulates CD4
- Vif - counteracts antiviral effect of cellular APOBEC proteins.
- Vpr - Contains nuclear localisation sequence
- Vpu - Down-regulates CD4, transports Env proteins to cell surface, counteracts antiviral effect of cellular tetherin proteins.
- Env - encodes the viral envelope proteins gp120 and gp41, theses proteins mediate virus entry into target cells. The viruses received from our collaborators will contain envelope genes derived from primary HIV-1 strains.
- Env-deleted viruses will be pseudotyped with Vesicular stomatitis virus glycoprotein (VSV-G) this allows virus entry by endocytosis, thus by-passing normal entry requirements for HIV.

Evaluation of foreseeable effects

Expression of plasmids encoding a full-length HIV genome in human cells will lead to release of infectious HIV into the culture supernatant. The virus generated would not differ from other HIV-1 strains already present within the laboratory, and so recombination would not be expected to result in a strain that would pose any higher risk than those already in use. Outside the specialised laboratory environment and without cellular support HIV is unlikely to survive and thus is unlikely to be a significant environmental threat.

Expression of SIV and SHIV strains will also lead to expression of infectious virus capable of infecting human and selected non-human primate cells. As there is no vaccination available against HIV infection and no cure, this poses a significant risk to human health, and as such will be handled at containment level 3. Adherence to containment level 3 procedures with regards to PPE, no sharps policy, and adequate training by experienced staff should substantially reduce the risk of self-inoculation to effectively zero.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste - Bacterial culture supernatant will be treated with a 2% (final concentration) Virkon solution for 30 minutes. Efficiency data is available from http://www2.dupont.com/RelyOn/en_US/assets/downloads/europe/Virkon_efficacy_data.pdf

Virus containing supernatant - High volumes (>250ml) of low titre liquid waste such as PBS used to wash infectious virus from cells or tissue samples will be treated with 1% (final concentration) Trigene solution for 30 minutes then disposed of via the sink. Efficiency data available from http://www.medi-mark.co.uk

High virus titre or high protein waste e.g. cells used to grow virus - Will be collected in a sealable, hard-plastic, leak-proof container, when full this will be autoclaved at 134°C for 20 minutes (cycle 3 mixed waste) total running time 1hr 30mins.

Solid waste - disposable plasticware including flasks, pipettes, tips and centrifuge tubes that had come into contact with infectious virus will be autoclaved at 134°C for 20 minutes (total running time 1hr 30mins). Re-usable plasticware e.g. flasks for growing bacterial supernatant, will be soaked in 2% Virkon solution for 30 minutes, rinsed and autoclaved. Autoclave treatment cycles are monitored and recorded with a printout, that is stored by the laboratory manager. Autoclaves are serviced every three months and have an annual 12-point thermocouple test.

After autoclaving on site, waste is sent via the clinical waste route by the specialist waste contractor SRCL (formerly White Rose Environmental Ltd) for alternative treatment to landfill. This process involves shredding of waste and autoclaving in an industrial autoclave, and resultant waste is sent to landfill.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The following amendments are requested prior to approval:

Part 1: Please provide CID numbers when available and Faculty
GM Centre number is: GM77
1.1: Amend sentence, "During acute HIV infection, the HIV-1 virus crosses..."
1.2: Remove references 'such as' and specify strains or cell lines. Also provide the extent to which it is disabled.
1.4: 'X' mark the Containment and Class 3 boxes only.
2.1.1.2: Clarify or list by containment level.
2.1.1.3: Change the term 'should' or 'would' to 'will'.
2.2.1.4: "HIV genes would not be expressed..." please explain why.
2.3.2.2.a: Amend sentence, "would take place in a containment lab..."
2.3.2.2.c: Typo: 'Conatinament'. Remove, 'the' all labs...
2.3.3.1.a: Add: "containers and rotors..."Remove the last sentence.
2.3.3.2.a: Please provide a room numbers, discuss with Roberta Perelli.
2.3.3.2.b and c: Change the term 'should' or 'would' to 'will'
2.3.3.3.c: A bit confusing. Does this section mean that class 1 work can be opened on the bench in containment level 2, class 3 work will be opened in an MSC in containment level 3. Please clarify.
2.3.3.4.a: Change the term 'should' or 'would' or 'maybe' to 'will'.
2.3.3.4.b: State if the microbiological lab coats are the Howie type or another.
2.3.5: Medical Issues to be completed by Occupational Health
2.3.6: 'X' mark the Containment and Class 3 boxes only.
3.1.1.a: Change the term 'should' or 'would' to 'will'. - Remove 'overnight' change to '30 minutes'- Autoclaves can be serviced every 6 months.
- Route of disposal is through clinical waste.
3.1.1.b: Autoclaves serviced every 3 month? Seems to be very frequent please confirm that this is correct.
- Route of disposal is through on site clinical waste.
- Please provide details of the location of the autoclaves.
3.2.b: Please explain under what conditions you would use the 50ml tube.
3.5.a: Change the term 'should' or 'maybe' to 'will'.
- Adding liquid virkon to an already substantial spill make sit bigger and dilutes the virkon. The committee recommended the following method.
Inside the cabinet: Leave the cabinet on.
Absorb the spill in absorbent material e.g. paper towels or blue roll.
Spray the site of the spill liberally with 2% virkon, and leave for 20-30mins to inactivate the spill.
Mop up with additional absorbent material and disposed of all material as solid waste after use.
Lift the grill and check under the cabinet work surface for any signs of contamination/spill. If present, contain and decontaminate as described previously.

3.5.b: For any exposure incident:
1. Encourage bleeding, but do not scrub the wound: this may increase tissue damage.
2. Wash any wound or contaminated skin with soap and clean water. Cover with a sterile dressing.
3. If blood is splashed into the eye or mouth, stop & wash out immediately with tap water or saline.
4. For any exposure during normal working hours contact the duty occ health nurse for the Trust via Trust telephone extension 33063. The nurse will assess the risk over the phone and if emergency treatment for a possible HIV exposure was indicated would arrange for HIVPEP to be dispensed locally. Outside of normal working hours follow the hospitals out-of-hours procedure for sharps accidents and go straight to A&E, and inform them of the possible exposure to HIV.

- Reporting of incident: include, Safety Coordinator, and completing an accident form to be sent to the Safety Dept.

3.6: Please list building.

3.7: Please provide CID Numbers.

3.8: Declarations Tick box to be completed once amendments have been made
Agreed: Class 3 Containment level 3. This project is notifiable to the HSE

Further comments from the committee after addition of the SIV / SHIV components
1.24: Typo: should say ‘Bluescript’
1.3: Drug resistance mutations – some clarification required as to what mutations they will be working with and any implications for treatment should be stated.
Please also include a statement in Part 2 of the Form saying “that should any of the SHIV chimeras (with or without mutations associated with drug resistance) have greater replicative fitness than the wild-type strains, then GM77 will be informed and a further risk assessment undertaken”.
2.1.1.3, Typo 1st para, last line non-human primate lines

**Project Additional Information**

**Purposes of the contained use**

- Scientific research

**Recipient or parental organism**

- Human respiratory syncytial virus (RSV), A2 strain

**Host/vector system**

- RSV A2 clone containing cDNA of all RSV genes (pSynkRSVline19F)
- Helper plasmids containing L, N, P and M2 genes (names of the plasmids are not available yet)
- Vector containing T7 polymerase (name not available yet)

**Origin & function**

The WT and two Matrix mutants are originally made at Monash University, Australia (Prof J lab). The origin of the viral vectors is Emory University and Vanderbilt University, USA. I will use the WT and Matrix mutant virus to study the role of Matrix gene in viral assembly and budding process. The viral vectors will be used to generate recombinant virus with additional mutations in Matrix or other structural genes to study the interaction of virus with cellular proteins during assembly and budding.

The RSV clone used to generate recombinant virus contains Green Flourescent Protein (GFP) tag.

**Evaluation of foreseeable effects**

The RSV mutant carrying mutation in the Matrix gene that I have already been working on in the past is attenuated compared to the WT strain. The mutations cause reduced virus titer since the virus can not assemble or bud efficiently from the cell. My future mutagenesis of the RSV will be based on my viral-cellular protein interaction screen and will hopefully result in even more dramatically attenuated virus that is stucked inside the host cell. All experiments will be carried out in tissue culture, and there is no intention to generate a GM animal.

n/a

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

n/a
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste (e.g. tissue culture supernatent) will be inactivated by chemical disinfection. A solution of 1% Virkon disinfectant (final concentration) will be used for a minimum contact time of 30 minutes. This will achieve effectively 100% degree of kill as validated by the disinfectant manufacturer. The inactivated liquid waste will be discarded to drain.

Solid waste (e.g. disposable laboratory plasticware, paper towels etc) will be inactivated by autoclave. Cycle conditions of a minimum of 121 degrees centigrade for a minimum duration of 20 minutes will be used to achieve effectively 100% degree of kill. Each cycle will be monitored using a chart recorder attached to the autoclave. The autoclave treatment will be validated by annual multi-point thermocouple testing. Autoclaved solid waste is then discarded as clinical waste via the ‘orange’ stream.

Please enter comments on the GM safety committee on the risk assessment

Reviewer 1
1.24: Do the plasmids and vectors listed have names? Please give them if available and any information about the characteristics of the plasmids/vectors, e.g. from where they are derived, whether they are self mobilise-able or non mobilise-able or mobilisation defective.
1.25: Isn't the GFP tag an inserted gene? Even though the modification may not have been made by this group it should be noted.
2.3.4.1: The College Policy on MSC's requires that where MSC's are used for operator protection at containment level 2 that in addition to the engineers 6 monthly checks the air flow rates are tested monthly by the operators using a 100mm vane anemometer.

Reviewer 2
1.22: RSV2 strain is this wild type and fully virulent?
1.3: Attenuated - in what way? Just budding?
-Add statement saying that if any mutations lead to more virulence then GM77 will be informed and another risk assessment submitted.
2.2.13: because....the statement should be supported

2.3.3.2: What rooms
2.3.3.3: state nature of topical disinfection (also 3.5)
Agreed: Class 2, Containment Level 2. This project is notifiable to the HSE.

Project Containment
Single-round retro-and-lenti viral VsV-G pseudotyped particles will be produced to transduce mammalian cell lines in order to express or ablate the expression of a gene of interest.

Many cellular processes are regulated by the addition and removal of Ubiquitin (Ub) either as single or multiple units in various types of linkage. The mono ubiquitination of histone 2A (H2A) is a key facet of DNA damage and repair and transcriptional repression by Polycomb Repressive complex 1 (PRC1). PRC1 is itself subject to ubiquitin mediated turnover by USP11. USP11 is implicated in the regulation of senescence via the effects of PRC1 on the CDKN2A tumour suppressor locus and in DNA damage response.

The major goals of this project are to gain further understanding of the interactions between USP11 and components of PRC1 and the DNA repair machinery by a variety of approaches including the production of recombinant proteins described in this CU2 and the associated risk assessment. The genes expressed or knocked down may be oncogenic.

This is not intended to be the submission of a broad assessment to cover a multitude of different projects but relates only to the work described above by Dr Maertens and her group.

Mammalian cell lines such as HeLa, 293T, U2OS, human diploid fibroblasts, mouse embryonic fibroblasts, obtained from ATCC.
Host/vector system

Single round retro- and lentiviral vectors based on the pQCXIP, pLVX-tight-puro (Clontech) vectors and the Mission shRNA lentiviral vectors (Sigma). The envelope will be provided by the pCG-VsVG plasmid and the GagPol for retroviral vectors from pCG-GagPol, for lentiviral expression, pCMVdelta8.2 (described first in Naldini L. et al, PNAS 1996).

For transient expression in mammalian cells, the following vectors will be used pHcRed1, pEGFP (clontech), pcDNA6V5Hisb (Invitrogen)

Origin & function

Origins: shRNA plasmids to make lentiviral particles will be purchased from Sigma. The genes that will be over-expressed in mammalian cells are amplified and cloned from cDNA made from RNA isolated from HeLa cells.

Intended functions of the GM involved: the genes of interest are ablated and/or overexpressed in order to study their role in tumourigenesis and the repair of DNA damage.

Inserted genes:
USP 11 ubiquitin specific protease 11, involved in removing ubiquitin from ubiquitinated proteins
Polycomb Group Proteins (PcG): Involved in regulating transcription of housekeeping and INK4a tumour suppressor locus. They exist in two distinct complexes. Polycomb Repressive Complex 2, PCR2, which initiates the repression by marking Histone H3 with a trimethyl mark on Lys27. PRC1 is then recruited and ubiquitinates histone H2A at Lys2A and Lys119, thus maintaining the repression.

Any other protein that will be identified during the course of the project to be a binding partner/substrate of USP11 and PRC1 involved in DNA damage repair and regulation of the CDKN2A tumour suppressor locus and other PRC1 target genes.

Evaluation of foreseeable effects

The vectors produced can only be used for single round infections - thus cell lines will be produced and selected that stably express a gene of interest, or an shRNA to ablate the expression of a gene of interest. These cell lines do not present any hazard and will, after selection, be cultured like any other mammalian cell lines used in the lab. There are SOPs in place to minimalise the risk of contamination during the production and use of the small scale single-round vectors. In addition the procedure involved a very limited number of technical steps, which are all contained within a class 2 MSC cabinet, the risks involved are thus minimal.

Control measures in place are sufficient to minimise risk. The final GMMs are not hazardous to humans or the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

liquid waste
*supernatant of cells:
2% Virkon for minimum 30 minutes. Virkon is provided by Antech inc, their website provides validation data. The Virkon treated liquid is disposed of via the sink.
*supernatant containing viral particles:
2% Virkon for a minimum of 30 minutes. Virkon treated liquid is disposed of via the sink.
solid waste
serological pipettes and flasks are rinsed with 2% virkon prior to autoclaving.
Tips, tubes, rinsed serological pipettes and flasks are autoclaved using a solid or mixed cycle, 134C, holding time 20 min, cycle time 1.5h. Each run is validated via a printout, stored as a record are kept by the lab manager. Autoclaves are serviced quarterly and tested quarterly, annual 12 point thermocouple test and calibration. The final route of disposal is as clinical waste.
Following the discussion of your proposal entitled "Structural and functional characterization of USP11, a ubiquitin specific protease implicated in cancer", GMIC-1380 at the last GM Safety Committee meeting, the Committee request that the following amendments are made to the proposal prior to approval:

1.2.1: Include where the E.coli and fungal work will take place, their procedures and risk level.
2.1.1.4: Answer n/a
2.1.1.5: Answer n/a
2.1.1.6: Answer n/a
2.2.1.1: Viral vectors are „Stable”
2.2.1.2: Answer n/a
2.3.4.1: "...stored as a record and are..."

Part 3: Hatch the tick box
3.7.2: Please answer.

Comments: GM gave a brief description of the work to be carried out.
PL queried what was considered the most hazardous aspect of the work.
GM answered that producing the single vectors or an eye splash would be, however, all the safety measures were in place for this work to be carried out with care. The work would be done in class 2 microbiological safety cabinets and when transported it will be contained.

Agreed: Class 2, Containment Level 2. This project is notifiable to the HSE.

Patient blood cells (primarily PBMCs) and 3mm skin biopsy samples, as well as primary and immortalized fibroblasts and B cells will be received from our collaborator in Paris (Dr. Casanova lab). These samples will be used for DNA/RNA extraction as well as cell stimulation experiments. Infecting primary and immortalized patient cells with viruses and assessing cytokine/protein levels (by ELISA, western blot, expression arrays, qPCR, viral load determinations, cell mortality experiments etc). Retroviral transduction of cells to genetically rescue phenotypes in patient cells.

Human fibroblasts or blood cells.

HSV-1 GFP strain (Desai, P., and S. Person. 1998. J Virol 72:7563-7568) will be used to assess viral replication in various cell types (Guo et al. 2011. J Exp Med 208(10): 2083-98). Human retroviral particles will be used to transduce patient fibroblasts. The generation of these particles will be carried out in a collaborator's lab, Dr Sylvie Fabrega in Paris INREM. Briefly, retroviral vectors pseudotyped with the vesicular stomatitis G protein (VSV-G) will be generated as previously described (Barde et al. 2006. Mol Ther 13(2):382-90) by calcium phosphate transfection into 293T cells of a packaging construct, pMNold gag-pol ; a plasmid producing the VSV-G envelope (pMD.G); and each of the pLINX vectors carrying an empty, wild type or mutated form of TRIF (our particular gene of interest). As other genes are identified in this study, we may wish to generate cells retrovirally transduced with that particular gene of interest. Once this gene has been identified in the future, we will submit an amendment of risk assessment for its approval.

Human gene TRIF will be inserted into pLINX: an adaptor protein involved in the production of types I and III interferons following viral infection or double stranded RNA stimulation. May induce...
apoptosis when overexpressed.

### Origin & function

Human gene TRIF will be inserted into pLINX: an adaptor protein involved in the production of types I and III interferons following viral infection or double stranded RNA stimulation. May induce apoptosis when overexpressed.

### Evaluation of foreseeable effects

The most hazardous GMM to be constructed are the fibroblasts retrovirally transduced with wild type TRIF as there may be higher expression of this gene that may induce apoptosis. This is the reason we have opted to use a conditional promoter which will shut off transcription in the presence of doxycycline. The cells will be allowed to express TRIF only for specific assays which will occur for no longer than 48hrs. In addition these cells have been retrovirally transduced by replication incompetent retroviral particles, are stably transduced cells, and no longer produce infectious particles thus presenting no danger to the user or to the environment. HSV-GFP, similar to the wild type KOS strain, can cause herpes labialis, whitlow, zoster, keratitis and on very rare occasions encephalitis.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Please enter comments on the GM safety committee on the risk assessment
Following the discussion of your proposal entitled “Genetic investigations of pediatric infectious diseases”, GMIC - 1402 at the last GM Safety Committee meeting, the Committee request that the following amendments are made to the proposal prior to approval:

Comments: V.SS gave a brief description of the work to be carried out. MS queried the use of the plasma and VSS confirmed she would include the UCL reference to validate this. PF inquired what the plasma did. VSS told the Committee is was used to insert the TRIF gene. MS further queried if there were possible gene mutations. VSS confirmed there were not. IH asked what the bacteria mentioned in 1.2 were. VSS explained this would be meningococcal, however, this was not part of the current work and she would remove this from the risk assessment.

The following amendments are requested prior to approval:

Principal Investigator: Please provide CID number

1.2: Remove reference to ‘bacteria’. Typo: ‘immortalized’

5.7: Typo: ‘transferred’ and ‘spil’

5.8: Typo: ‘consulation’ and ‘distrubance’

6.4: Typo: ‘autocalving’

10.1: Typo: ‘muntes’, ‘transferred’ and ‘spil’

10.2: Typo: ‘Satnford’

Agreed: Class 2, Containment Level 2. This project is notifiable to the HSE.

Project Additional Information

Purposes of the contained use

GMMS will only include recombinant influenza virus requested from Professor Wendy Barclay's laboratory. The strains that will be grown will be generated by reverse genetics and limited to GM constructs that will share sequences with the circulating influenza strains, e.g. H1N1 2009 A/England/195/09 virus and similar strains that are circulating in the population not exceeding GMM class II containment level 2. The strains to be generated are essentially wild type strains circulating in the human population with no novel genetic introductions and therefore is similar to the currently circulating wild type strains. There is no additional risk of our GMM undergoing recombination with circulating strains than in the general environment.

Recipient or parental organism

Circulating influenza viral strains including the H1N1 2009 A/England/195/09 virus and similar strains that are circulating in the population not exceeding GMM class 2 containment level 2.

Host/vector system

The vector system is the PR8/34 influenza virus. This is a laboratory strain that has been in use for over 50 years.

Origin & function

- Segment 1. polymerase basic subunit 2, PB2. Involved in viral replication.
- Segment 2. polymerase basic subunit 1, PB1. Involved in viral replication.
- Segment 3. polymerase acidic subunit, PA. Involved in viral replication.
- Segment 4. haemagglutinin, HA. Involved in viral entry and immune signalling.
- Segment 5. nucleoprotein, NP. Involved in viral replication.
- Segment 6. neuraminidase, NA. Involved in viral entry and release from cells.
- Segment 7. matrix M1 and ion channel protein M2. Involved in viral structure and uncoating respectively.
- Segment 8, non-structural protein NS1 and nuclear export protein NEP. Involved in the modulation of immune signalling and viral replication, respectively.

Evaluation of foreseeable effects

Influenza is primarily a respiratory tract infection that affects millions of people every year worldwide, mainly infecting the elderly and the young. The GM influenza virus described here is no different to currently circulating strains and consists of surface coat proteins (haemagglutinin (HA) and Neuraminidase (NA)) that enable it to bind and enter the human host cells and other core proteins such as the Matrix proteins (M1 & M2), Nucleoprotein (NP), Polymerases (PB1, PB2, PB3) and non-structural proteins (NS1, NS2 & PB1-F2) that are essential for viral replication.

There are no foreseeable effects beyond those exhibited by the wild type virus.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste material will be treated prior to disposal with Virkon (2% w/v final) and left for 30mins. This will kill the GMM. The waste material is then disposed as per guidelines in the Institute with liquid waste left to drain away and any solid waste subject to sterilisation and autoclave and then disposed as clinical waste. Sharps will be disposed in sharp bins and also autoclaved before disposal.

Autoclave parameters are 121 degrees for a holding time of 15 minutes (minimum).

13. * Is an emergency plan required according to regulation 20? Yes No

Please enter comments on the GM safety committee on the risk assessment

Comments: SS gave a brief description of the work to be carried out.
The Committee has no amendments for this risk assessment.
Agreed: Class 2, Containment level 2. This project is notifiable to the HSE.

## Project Additional Information

### Purposes of the contained use

Induction of highly neutralizing antibodies requires correct presentation of HIV Env glycoproteins, and important epitopes for virus neutralization may not be presented using recombinant forms of Env. In order to present conformationally correct forms of Env, we wish to generate non-infectious HIV-based Virus-Like Particles (VLPs) and use these to vaccinate small animals models and characterize the vaccine-induced immune responses.

### Recipient or parental organism

Vector stocks will be prepared in competent cells STBL2, STBL3 and related strains. Plasmids will be transfected into mammalian cells to produce VLP stocks. Mammalian cell lines HEK293 and derivatives, CHO, SIRC, RK13,

### Host/vector system

Our Collaborator, Prof. Eric Arts, has constructed an expression vector to generate non-infectious VLPs (pRECnflHIV-1). This plasmid contains the near full length (nfl) HIV-1 genome from which the 5’ long terminal repeat has been deleted. This sequence is critical for the initiation of reverse transcription required to generate infectious progeny. The CMV promoter has been inserted in pRECnfl HIV-1 up-stream of the pbs site and transcribes nfl HIV-1 RNA, which cannot support the production of infectious virus due to the deletion of 5’ LTR but can still be spliced and translated into the full set of HIV-1 proteins and assembly of virus like particles. The nfl HIV-1 RNA cannot support virus replication due to an inability to complete reverse transcription, therefore the virus like particles produced pRECnfl HIV-1 transfected cells are completely non-infectious and there is no possibility for recombination or reversion leading...
infectious viral production (Dudley DM et al, Biotechniques. 2009;46(6):458-67, Moore DM et al, Methods Mol Biol. 2005;304:369-85, Marozsan AJ et al, J Virol Methods. 2003;111(2):111-20). DNA stocks of the vector will be prepared in competent bacterial cells. The vector will be transfected into mammalian cell lines to produce Virus-like particles, and cells may also be selected using Zeocin to establish stably producing cells. VLP stocks will be used in vaccination experiments in small animal models by mucosal and parenteral routes. Vaccinations will require use of sharps.

The cloning vector is pcDNA3.1 Zeo, which expresses the inserted sequence from a CMV promoter. The insert also contains yeast centromere sequence (CEN6), the autonomously replicating sequence (ARSH4), and the betaisopropylmalate dehydrogenase (LEU2) for the maintenance of this plasmid in yeast in the absence of leucine. However yeast expression studies will not be undertaken in this project. This vector also contains an ampicillin resistance marker for selection in bacterial cells, a zeocin marker for maintenance in mammalian cells as an expression vector.

Origin & function

Inserted material contains near-full-length HIV genome, but with the 5' LTR deleted preventing replication of this vector as it is unable to reverse transcribe.

Evaluation of foreseeable effects

The most hazardous GMMs will be the VLPs themselves produced by transfection of plasmid pRECnflHIV into susceptible cells, as they will be able to enter human cells, however, as the particles are not replication competent, due to the deletion of the LTR, no spreading infection can be established, and there is no risk posed from insertional mutagenesis, as no nucleic acid will be produced. These particles would not pose an infection hazard to non-humans, and would not be able to survive outside of a specialised tissue culture environment, and thus would pose minimal environmental hazard.

Expression of the VLP plasmid will produce HIV-1 -based Virus Like Particles (VLPs), which are structurally and antigenically identical to live HIV particles. However as they lack the 5'LTR sequence that forms the promoter in eukaryotic cells, particles are unable to reverse transcribe, and will thus be non-infectious, and proteins cannot be expressed in target cells. The plasmid will only be expressed in cell lines that do not contain LTR elements, and are not capable of supporting HIV replication, so that in the highly unlikely event of complementation of the LTR deletion, there will be not expansion of infectious virus.

In the event of transfer of the plasmid to other bacterial strains, retroviral genes would not be expressed as retroviruses require numerous cellular proteins to complete their lifecycle, and these genes are absent from prokaryotic organisms, thus the plasmid provide no selective advantage. The plasmid also contains sequences CEN6, ARSH4 and LEU2 for maintenance in yeast, however, no yeast work is carried out in the areas where this plasmid would be stored and used.

The VLPs would be structurally similar to other lentiviral particles already present within the laboratory, and nucleic acids will have significant homology with full length lentiviral plasmids, and thus there is a possibility of recombination if these plasmids were co-transfected into the same cells. However, as transfection of full-length lentiviral plasmids is only permitted in CL3, and we propose production of nfl-HIV VLPs in our CL2 laboratory, there should be minimal risk of this event occurring. In the unlikely event that the wrong DNA sample is used in culture or that VLP have acquired 5'LTR form the environment this will be detected by applying a 5'LTR targeted PCR based test to both DNA stocks and any VLP culture before it is used more widely in the laboratory. Any culture giving a positive result will be immediately disposed of in the CL 3 facility following the CL3 COP.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- Liquid waste: Tissue culture waste will be soaked in 2% (final concentration) Virkon solution for 30 minutes or 1% Trigene Advance before disposal down the sink.
- Solid Waste: Tips and pipettes used to handle biological samples are placed in biobins and then into autoclave bags.
- All other plasticware used to culture biological material (flasks, plates, tubes) are placed directly into autoclave bags.
- All solid waste in contact with cells/tissue will be autoclaved at 121°C for 30 minutes (cycle 3 mixed waste) total running time 1hr 45mins.
- Virkon and Trigene have been validated for use against HIV by the manufacturers and are proven to be effective at reducing the biological viable activity by at least 10^5 under the conditions specified.
- The Autoclave is serviced quarterly.
- Annually a worst case scenario mock load is prepared and placed in the autoclave. An engineer using a 12pt thermocoule load temperature NAMAS test apparatus ensures that every test point within the load achieves a temperature known to be effective at inactivating pathogenic microorganisms. At the same time the autoclaves load and chamber sensors are calibrated against the test rig.
- In all cases a minimum of a 10^5 reduction in microbiological viable activity is expected.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Following the discussion of your proposal entitled “Generation of non-infectious Virus-Like Particles for use HIV vaccine immunogens”, (GMIC-1431) at the last GM Safety Committee meeting, the Committee request that the following amendments are made to the proposal prior to approval:

4.18 or 4.19: In the unlikely event that the wrong DNA sample has been used in culture or that VLP have acquired 5?LTR form the environment this will be detected by applying a 5?LTR targeted PCR based test to the VLP culture before it is used more widely in the laboratory. Any viral culture giving a positive result will be immediately disposed of in the CL 3 facility following the CL3 COP.

Comments: RS gave a brief description of the work.

KG asked how would the protein be quantified?
RS explained he used a Light Scattering quantitation device to do this.

PF queried the transport method to the centrifuge

PL pointed out that section 5.3 has sufficiently answered this.

IH checked that the buckets would be used and if they were biosealed. IH also wanted to know how RS would get the particles out of the centrifuge tube.
RS answered the particles are pelleted, not layered and needles were not involved.

MM questioned if the committee knew of anyone else handling Virus-Like Particles (VLPs) in CL2 laboratories.
RS stated the U.S. handled them in containment level 2 laboratories.
IH pointed out 5 litres of cultures grown is quite a lot.
RS explained that this is the maximum volume he could state on the form, but they would not be growing this much.
IH asked if the wave bag was leak-proof?
RS informed IH the cells would set up for 24 hours prior to infection in the wave bags in order to test for leaks.
PF queried if during the characterisation step of producing the VLPs, would you know if you had inadvertently created Replication Competent Viruses (RCV).
RS suggested putting them on susceptible cells to check. He had not included this in the risk assessment as they were not anticipating this to occur.
PF suggested starting with a check of the DNA stocks
RS confirmed that the DNA was quality controlled before transfection.

MM asked if others in the lab worked with 5?LTR sequence

PF stated that this DNA existed in the lab but there was complete separation between the VLP DNA stocks and anything that might cross contaminate or lead to the generation of RCV.

PF stated that DNA stocks were checked prior to use. PF agreed that a culture end point check would be introduced before the VLP?ss were used elsewhere to ensure that RCV had not been inadvertently generated. They would use a 5?LTR targeted Polymerase Chain Reaction (PCR) test to look for the presence of LTR in the culture. If this was detected the culture would be disposed in the CL3 facility without opening the bag.
The Committee agreed that this should be added to the risk assessment, perhaps in section 4.18 or 4.19
IH questioned if there was a risk of shedding with the animals.
RS answered that rabbits would be the animals used and the dilution factor so large that shedding of detectable VLP would be unlikely. The doses of virus are insufficient to sero convert a human even if they inoculated the entire animal dose into themselves. Additionally the particles are replication incompetent and could increase in number, the animals used were not natural hosts to HIV and did not support replication even if the virus was RCV.

Agreed: Class 2, Containment Level 2. This project is notifiable to the HSE.

Project Additional Information

Purposes of the contained use

Bacterial lung infections are a significant cause of morbidity and mortality. Particularly in individuals with underlying co-morbidities e.g. Cystic fibrosis, COPD, asthma and diabetes are more susceptible to bacterial lung infections. We are interested in the interactions between the bacteria and the host, looking at how the host tries to control the bacterial infection and how the bacteria tries to evade this. Using both in vitro and in vivo systems, we wish to define differences between healthy individuals and those with underlying co-morbidities that leads to greater disease susceptibility to bacterial lung infection. We will look at 4 bacterial pathogens. Staphylococcus aureus, Pseudomonas aeruginosa, Klebsiella pneumoniae and non-typeable Haemophilus influenzae ntHi (hazard group 2 pathogens). All of these bacteria can be carried as part of the normal nasal/host bacterial flora. We will also look at mouse pathogen Citrobacter rodentium (ACDP hazard group 1).

Staphylococcus aureus is a major cause of hospital acquired infection, particularly bacterial pneumonia and wound infection. Bacterial pneumonia is a significant cause of morbidity and mortality. Attention has focused in particular on hospital-acquired, antibiotic-resistant, bacterial infections, a government health priority. However, there is a lack of good in vivo models of bacterial infection in the lung. This project will develop in vivo models of S. aureus infection and then investigate the immune responses to it and approaches to control it using vaccines or antimicrobial therapies. Both Methicillin Sensitive S. aureus (MSSA) and Methicillin Resistant S. aureus (MRSA) will be used.
Pseudomonas aeruginosa is able to infect a wide variety of hosts and tissues and is an excellent model for studying infection by gram-negative bacteria. It is particularly prevalent in cystic fibrosis patients. We will be using in vitro models of infection using airway epithelial cells and differentiated airway epithelia to assess the effect of altering physiological conditions on bacterial growth. We will then assess these conditions and drugs that can alter them using in vivo mouse models.

Haemophilus influenzae is serotyped according to the capsular antigens. Strains without a capsule are described as the non-typeable (ntHi). In general the non-capsulated strains are less virulent than the capsulated strains. Non-capsulated H. Influenzae is often observed in the airways of patients with chronic obstructive pulmonary disease (COPD). We are interested in extending Haemophilus influenzae vaccination to ntHi strains. We will then assess protection of vaccines using in vivo mouse models. We will also assess ntHi as an agent of co-infection with other pathogens.

Klebsiella pneumoniae is primarily a hospital-acquired bacterial pathogen that causes pneumonia, urinary tract infections and septicemia. Its success is related to its ability to form biofilms on medical devices, such as catheters. We will investigate how Klebsiella biofilm formation affects virulence and how the metabolic profile changes.

Citrobacter rodentium is a murine pathogen that belongs to a family of enteric pathogens, including enteropathogenic E. coli (EPEC) and enterohaemorrhagic E. coli (EHEC), which utilize attaching and effacing (A/E) lesions to colonize the gastrointestinal tract of the host.

Deletion mutants will be made, but genes will not be deleted if known to increase pathogenicity. Deletion mutants will be screened for the effect on pathogenicity in mouse models and if the mutants are more pathogenic than wild type they will be destroyed.

### Recipient or parental organism

Both long term lab strains and clinically isolated strains of bacteria will be used in this project. The strains below are those most commonly used for this study, but others may be used:

- **S. aureus**  
  MSSA Lab Strains including: 8325-4 (NARSA NRS135) and derivatives, Newman  
  MRSA lab strains including Sanger 252 (NARSA NRS71), no toxin producing MRSA strain will be used.

- **P. aeruginosa**  
  PAO1, PA14, PAK, PA103, TB, SG17 (Clone C)

- **ntHi Strains**  
  12. 2019, 1479, 76, 3198, 5557, 7502, 162, 176, R2868 and 9274

- **K. pneumoniae**  
  AJ218, B5055, B5055nm

- **C. rodentium**  
  ICC168, ICC180, ICC306, ICC169

### Host/vector system

The vectors used will be non mobilizable and replication incompetent and include:

1. Gene targeting by DNA plasmid complementation and homologous recombination in a non-replicative vector
2. Clean gene deletion by suicide vectors (e.g. pKNG101 or pEX series of plasmids)
3. Random transposon mutagenesis will be performed using Mariner based transposon system or Tn5 or Tn7 derivative plasmids

### Origin & function

1. Deletion mutants. Mutants will be generated or acquired with deletions of genes in areas including, but not limited to those involved in modulation of the host immune response e.g. Pseudomonas PilA, S. aureus IEC, Chp, Sak, Sc; virulence factors e.g. Pseudomonas AprA, Cif, K. pneumoniae MrkH; normal metabolic function, e.g.
**Pseudomonas gltK, Edd, Opr; or antigenicity e.g. ntHi protein D. Complementation studies may be performed to recover function.**

2. Reporter gene expression. Mutants will be generated or acquired expressing reporter genes, for example (but not limited to) luciferase or fluorescent proteins.

### Evaluation of foreseeable effects

The mutants generated will either be loss of function mutants or carry non-toxic reporter genes. It is not anticipated that bacterial strains produced in the laboratory are more virulent than strains that already exist in the environment. Indeed, many strains produced will have deletions in genes, which are required for optimal growth and virulence of the organism. Also, antibiotic resistance markers (carbenicillin, gentamycin, chloramphenicol, tetracycline, kanamycin and streptomycin markers) used in the laboratory do already exist in the host strains found in the environment and hence there is no risk of introducing new resistance genes to environmental strains.

Non GM Citrobacter rodentium is a murine pathogen and hazard group 1 in terms of pathogenicity to humans but once genetically modified it is included in this submission as a class 2 GMO under the terms of the GM contained use regulations because of the risk of infection to wild murine populations in the event of an accidental release. However it is not anticipated that any of the modified organisms will be more hazardous than wild type and as explained above many will be less virulent.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

**Liquid Waste:** Tissue culture waste will be soaked in 1% (final concentration) Trigene/Distel solution for 30 minutes before disposal down the sink. Alternatively Virkon (minimum 1% final concentration) can be used.

**Solid Waste:** Plasticware including all tips, flasks, plates and pipettes used to handle biological samples are placed either in biobins, or directly into autoclave bags. All solid waste in contact with cells/tissues will be autoclaved at 121°C for 30 minutes (cycle 3 mixed waste) total running time 1hr 30 mins.

**Tick if you are claiming exemption from disclosure for section of the risk assessment**

N
Following the discussion of your proposal entitled "Immunology of bacterial infection of the lungs", GMIC-2393 at the last GM Safety Committee meeting, the Committee request that the following amendments are made to the proposal prior to approval:

1.3 Room numbers for the 4th floor labs? These will need to be inspected by Safety Dept before work starts.

Done.

2.2 First line states Animal tissues. The rest of the statement list human cell lines. Please make it more clear what tissues and cell lines are in use. It is important that the risk assessment sets the limits of the work. While some statements might be generic about types of cell line (especially where there are too many to list) it must be clear that they are all of the same type or risk group.

Have increased information about the cells/tissues. Have also included PBMC. Have stated that the cells/tissues will not be greater than CL2.

2.15 It is important that the risk assessment sets the limits for the work. It may be acceptable to have generic statements about the host strains but the limits must be clearly stated for example regarding MRSA you might want to mention that no strain used will be toxin producing, if this is the case then this must be stated in the risk assessment in this section. Will you be using clinical isolates or long term lab strains? It is worth stating which early on in the risk assessment.

See response to comments below, have put both and said they are well characterised rather than lab adapted strains. Have stated that the Staph are not toxin producing/community acquired strains

Please state the ACDP bio Hazard group for each organism (2 by the look of it) done

2.16 vector and plasmid names please, if the list is too long please give some examples and set the limits of the work, e.g. Stating that they are non mobilizable, replication incompetent etc.

Done.

2.17 Please give some examples of the types of genes you will be deleting. Also make sure that you mention all the types of genes you will be altering. Your current statement just says "including" and then lists some genetic areas of functionality.

Have put in a few examples, but still would like it to be broad. Also put a statement in 2.14 to the effect that if increased pathogenicity observed strains will be destroyed and that known increases will not be made.

Again it is important that the limits are set. For example you may wish to state that no genes will be targeted whose deletion might lead to an increase in virulence, host range or pathogenicity.

Done in 2.14 and stated we will not overexpress toxins

5.1 Will use an MSC at any stage other than cleaning up in the event of a rotor spill? Yes

You identify several aerosol risk.

Item 1. Substitute should for must. Done.

Item 2 Why use flip flop tubes? If it is practical to do so, why not remove the hazard and use screw top with an O ring seal? This also reduces the risk of aerosol from flasks during centrifugation. Done.

Item 3 How will you tell if there is a leak? Have put after an imbalance

After discussion all the above will be performed in an MSC

5.2 So material is always transported in the lab in concial screw cap flasks? Never in multi well plates, eppendorfs, or petri dishes? This looks like the answer to a different question.

It was, have changed it to say: When moved within the lab, material with a liquid component will be moved in falcon tubes with sealed screw caps in tube racks or in flasks.
with screw cap lids.
Cultured biological material will be transferred from incubators to MSC in sealed vented flasks or plates with lids in secondary containers in the same laboratory. Petri
dishes will be sealed with parafilm after incubation.

5.2 - how will this be contained in transport. See above
5.3 - add the term double contained? Done
5.6 Room number for the -80 lab. Done 463
- Volume of stocks and storage containers (both primary/secondary containers)? Biological agents may be stored as glycerol stocks at -80 in lab 463. 2 aliquots of 1ml
stored in cryovials will be stored per strain. The cryovials are stored in plastic lidded boxes.

5.7 Will rotors always be opened in the MSC? Is this practical for the fixed angle rotors? For swing out rotors with larger volumes (e.g. 50ml or 15ml falcons) the buckets will
be opened in MSC. For fixed angled rotors, these will be opened on the bench or in the centrifuge.
Remove the term tissue culture cabinet and replace with microbiological safety cabinet or MSC. This applies to all uses of the term tissue culture cabinet.
Why 2% is this diluted to 1% final concentration with waste liquid? Yes
8.1 MSC - KL once per year, airflow checks using a 11mm vane anemometer twice per year be an engineer and monthly by the operators where the MSC is used to provide
operator protection Added
- shaking incubator maintenance? Annual
9.1 - is competency assessed? Yes, put by me
10. Remove the term tissue culture cabinet and replace with microbiological safety cabinet or MSC. This applies to all uses of the term tissue culture cabinet
Why 2% virkon but only 1% Trigene? Any spill will dilute this to less than 1% and below the manufacturers recommended minimum effective concentration. Changed
throughout
13 Is all the work only carried out in one lab? Section 1.3 seems to indicate more labs are in use but does not list them. Done
14 Please complete this section. It is Class 2 Done

Comments JT gave a brief description of the work. MS suggested building in a proviso to the risk assesment that no knockouts will be conducted that will knowingly
increase virulence.Added
PF advised giving a few examples of the altered genes in 2.17. Added : 1. Deletion mutants. Mutants will be generated or acquired with deletions of genes in areas
including those involved in modulation of the host immune response e.g. Pseudomonas PilA, S. aureus IEC; Chp, Sak, Sc, virulence facoters including Pseudomonas AprA,
Cif, and normal metabolic function, these include Pseudomonas gltK, Edd", Opr or antigenicity e.g. ntHi protein D. Complementation studies may be performed to recover
function.
PF increased pathogenicity…. Have mentioned this will not be done
PL suggested adding that Toxins will not be over-expressed, this should be mentioned in the form to set boundaries. He also recommended that mariner based transposon
system for future collaborations with his group. Done
MS asked if the consequences of co-infections had been addressed and to give this some thought. Co-infections unlikely due to viral work occurring in MSC and bacterial
work on bench.
PL Remove the term 'Lab adapted' and change to 'widely used' or 'well characterised' Done in 2.10 and 2.11.
IH advised adding the current room numbers to the form and when moved to new location; a Form C can be completed to update. Done
PL pointed out that the statement about markers used for making mutants, should state "genes conferring resistance to antibiotics used to treat clinical infections will not be
used as markers". Done
IH recommended adding the phrase to the hosts * not using toxin producing strains 2. Also, to provide some examples for the vectors.
TN to check the formulations of distell. Trigene highly effective against strains described .log5 reduction at 1:200
IH suggested defining at what point in the experiment would the work be carried out in the MSC. I have put in 5.1 that work will be performed on the bench.
PL queried if JT had worked with the MRSA strain on the bench
JT confirmed he had in the past, but not at ICL.
PL advised change the word 'should' to 'must' in 5.1. Done.
Agreed: Class 2, Containment Level 2. This project is notifiable to the HSE

Project Ref 77/14.2

In vitro passage of HIV-1 (NL4-3 strain) to determine resistance mutations associated with the use of C34-PEG4-Chol.

Date Ackn’d: 05/03/2014

CU2 Project Title

Tick if notifying a connected programme of work: No

Date Project Ceased

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use

The project is a laboratory based study of the resistance mutations associated with a novel antiretroviral (ARV) drug, C34-PEG4-Chol, which is due to enter a phase 1 first in human study in late 2014. C34 is a polypeptide homologue of a section of the gp41 protein of HIV-1 and therefore acts as a virus fusion inhibitor; the C34 peptide has been pegylated with four oxalythene molecules to make it more aqueous soluble (PEG4) and a cholesterol moiety added to enhance the half-life of the drug. Preliminary data suggest that C34-PEG4-Chol has very low toxicity in comparison with current ARVs. As with all other ARVs it is anticipated that the virus will be select resistance mutations which confer reduced susceptibility to the drug (characterised by signature mutations in the viral genome).

The laboratory-based aspects of this project involve induction of resistance to C34-PEG4-Chol in laboratory virus strains and characterisation of the resistance associated mutations.
Aim: The aim of the proposed laboratory project is to select resistance mutations in vitro associated with the use of C34-PEG4-Chol. 50mg of C34-PEG4-Chol product has been procured for experimentation. It is aimed to select resistance mutations in vitro by culturing HIV-1 in the presence of sublimiting concentrations of C34-PEG4-Chol. A set of 6 overlapping oligonucleotide primers have been developed to reverse transcribe, amplify and sequence the entire sequence of gp41 to elicit which mutations emerge as a result of drug exposure during culture. Having identified mutations associated with C34-PEG4-Chol, it is planned to introduce these mutant genes into a construct of the plasmid pNL4-3 through a process of chimeric virus technology (described by Fikkert et al) to generate an infectious molecular clone of HIV-1 NL4-3; this clone can then be used to determine the effect the mutations have on the susceptibility of HIV-1 to the drug.

Selection of mutations by passage in the presence of C34-PEG4-Chol are likely to confer reduced susceptibility of the NL4-3 strain of HIV-1 to the fusion inhibitor class of antiretroviral drugs; as such, should there be accidental infection of a chimeric viral construct into human, resistance to this class of drugs would ensue. These agents however, are used exceptionally rarely in clinical practice and these mutations would not have any effect on susceptibility of the virus to the other classes of antiretroviral drugs which form the cornerstone of therapy. There are not any anticipated environmental effects by in vitro passage and creating an infectious molecular clone with mutations associated with C34-PEG4-Chol.

Permissive T-cell lines (H9 cells) will be used for cultivation of infectious virus. H9 cells can also be used for transfection. TZM-bl cells will be used as a reporter cell line to measure infection of chimeric virus into these cells when cultured in the presence of the C34-PEG4-Chol drug. Note: TZM-bl, previously designated JC53-bl (clone 13) is a HeLa cell line. The parental cell line (JC.53) stably expresses large amounts of CD4 and CCR5. The TZM-bl cell line was generated from JC.53 cells by introducing separate integrated copies of the luciferase and β-galactosidase genes under control of the HIV-1 promoter. The TZM-bl cell line is highly sensitive to infection with diverse isolates of HIV-1. This was commercially purchased and not generated by this lab. Reference: Wei X, Decker JM, Liu H, Zhang Z, Arani RB, Kilby JM, et al. Emergence of resistant human immunodeficiency virus type 1 in patients receiving fusion inhibitor (T-20) monotherapy. Antimicrobial agents and chemotherapy. 2002;46(6):1896-905.

Host/vector system

Retroviral based vector plasmid, pNL4-3 will be used. The original construction of pNL4-3 involved blunt end cloning of the 5’ SmaI-EcoRI fragment of proviral NY5 (5’ SmaI in flanking sequences to 3’ EcoRI) and the 3’ fragment of proviral LAV (5’ EcoRI to 3’ NruI in flanking sequences) into pUC18 at the PvuII site after removal of polylinker sites.

Origin & function

Origins: pNL4-3 plasmids will be purchased from the AIDS reagents program. HIV-1 NL4-3 is a molecularly cloned laboratory strain of HIV-1 differing from HIV-1 HXB2, the prototypical laboratory strain of HIV-1 in that the latter is defective of three nonessential auxiliary genes: vpr, vpu and nef. NL4-3 has a low ability to generate chronic virus producers and encode all HIV-1 gene products. By creating an infectious molecular clone of NL4-3 with mutations within gp41 associated with use of fusion inhibitor drugs, this will create a chimeric virus stock with resistance to C34-PEG4-Chol and probable cross resistance to other fusion inhibitor drugs however these drugs are used only exceptionally rarely to treat HIV-1 and this alteration will not change susceptibility of the virus to other classes of antiretroviral drugs.

Evaluation of foreseeable effects

NL4-3 viral stocks represent the most hazardous GMM to be constructed; whilst this is laboratory strain virus, it retains potential to cause HIV infection in human hosts. Viral titres are likely to reach levels > 1x10^6 copies/mL. The infectious molecular clone is also likely to be hazardous however may be less replication competent.
Introduction of mutations into the gp41 (Viral envelope fusion peptide) region of the HIV-1 viral genome are likely to reduce viral fitness and infectivity.

C34-resistant NL4-3 HIV will be generated during experimentation; if accidental exposure via mucosa or transcutaneous injury were to occur, the recipient would likely have a HIV infection which is resistant to fusion inhibitor drugs. This class of antiretrovirals are used extremely uncommonly in clinical practice therefore this is unlikely to have any additional clinical consequence in terms of managing such an infection.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste
High viral load waste will be contained in falcons/flasks, placed in sweet jars and then autoclaved.

Solid waste
Tips and pipettes used to handle biological samples are placed in sweet jars and then into autoclave bags. Other plasticware used to culture biological material are placed directly into autoclave bags (double bags). All Solid waste in contact with cells/tissue will be autoclaved at 121°C for 30 minutes (cycle 3 mixed waste) total running time 1hr 45mins.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Dear Dr Quinn,

Following the discussion of your proposal entitled "In vitro passage experiment of HIV-1 (NL4-3 strain) to determine resistance mutations associated with the use of C34, a novel fusion inhibitor for treatment of HIV-1", GMIC-2479 at the last GM Safety Committee meeting, the Committee request that the following amendments are made to the proposal prior to approval:

COP still mentions Roberta Perelli and Tracey Norris who have both left Imperial College. This should be updated as soon as replacements are appointed.

PI – The PI is the grant holder. Please specify who this is.

Title of the activity - Please provide something shorter e.g. In vitro passage of HIV-1 to determine resistance mutations associated with C34.

- Throughout the form amend CAT3 to Containment Level 3.

1.2: Amend temperatures to -15℃, -80℃ and 95℃.

-In point 3, amend 10 passages to 20 passages.

2.16: Is pNL4-3 the Vector? It is possible to be both a vector and a host.

2.18: Mentions viral titres of 1x10^6, section 4.21 states titres of 1x10^9. Please rectify the apparent conflict.

4.6: Sentence does not make sense "Full personal protective equipment will be used and procedures will be supervised by Dr Steve Kaye until the principal investigator is fully 'completent' (amend to Operate independently) with procedures involved and the category 3 facility and the standard operating procedures for this lab." Please amend.

4.16: Same as 2.16. Please clarify, even if it is considered to be both vector and insert or vector and host.

5.3: Please reference the inactivation of the HIV by Triton x-100 and heating in the SOP’s. Please provide this information and the validation data or other evidence that this is effective at giving at least a Log 5 reduction in biological activity.

5.7: A 30 minute waiting time is a bit short to allow settling of aerosols. It is recommend at least an hour. This will also need changing in the suite manual.

Spraying a spill with any disinfectant will dilute that disinfectant. Either apply an equal volume of twice the recommended concentration of disinfectant or absorb the spill treat the dry but contaminated surface with 1% virkon or Trigene and dispose of the absorbent material as solid waste for autoclaving. This is described in 10.1. Please make sure that the two descriptions of how to deal with a spill are the same.

- Remove Roberta Perelli's name.

5.8: as above

5.12: Please provide an SOP reference for this technique and the validation data as per 5.3

Section 11: Please provide an SOP/COP reference

Section 12: We will let the OH physician know that you have completed this section in your capacity as a Clinician with expertise in HIV.

Comments: KQ gave a brief description of the work.

PL asked if the virus was 'fitter' is it more likely to invade human cells?

KQ explained that this unlikely. HIV-1 NL4-3 would be no more virulent than wild type virus, and as a lab strain may be less virulent.

PL questioned if it would remain susceptible to conventional ART?

KQ answered yes, there would be no impact on the front line antiretroviral viral drug resistance.

KQ added that there were no sharps used and precautions were taken to create a low risk of splashes therefore the risks of accidental infection was reduced.

PL asked if any of the altered genes would make HIV-1 NL4-3 more virulent?
KQ confirmed it would not be more virulent than wild type and quite likely to be less virulent.
IH queried if C34 has been used in any other clinical setting.
KQ explained it had not been used like this before.
KG suggested increasing the 10 passages to 20 passages.
IH checked if the plasmid pNL4-3 could cause infections.
KQ informed the committee that it could start up an infection if introduced into the cell.

**Agreed:** Class 3, Containment Level 3. This project is notifiable to the HSE.

Could you please ensure that the risk assessment is revised (add GMIC number) and the amendments above addressed. I will then forward the form onto Occupational Health to complete. The completed HSE CU2 form (attached to this email) needs to be updated to include the comments from the committee, and copy of the Purchase Order (for BACs Payment) made payable to the HSE should be sent to me (s.joomun@imperial.ac.uk), I will then send it all to the HSE. Please ensure the information given in HSE Form relates to that provided in your risk assessment.

For further information, please see http://www3.imperial.ac.uk/safety/subjects/biosafety/gmprocedures

Please note that this work must be notified to the HSE and an acknowledgement receipt received prior to this work commencing.

If you have any queries, please contact me.

Kind regards,

Sarah Joomun
Administrator for Radiological and Biological Safety
Safety Department
Imperial College London
Level 4 Sherfield Building

### Project Additional Information

**Purposes of the contained use**

Streptococcus pneumoniae is a common human nasopharyngeal commensal and pathogen. The species is genetically highly variable, and these differences underlie variation in antibiotic resistance, susceptibility to vaccine-induced immunity and interaction with the host. Exchange of sequence within S. pneumoniae, and with members of related species of the viridans group streptococci, has shaped its recent evolution in response to clinical interventions. Hence this project is designed to understand the importance of differences between S. pneumoniae strains, and how sequences are transferred between cells as part of the mechanisms that generate this diversity.

**Recipient or parental organism**

- Streptococcus pneumoniae strains TIGR4, ATCC 700669, R6 and other clinical isolates (class 2)
- Other viridans group streptococci (class 2)

**Host/vector system**

S. pneumoniae and viridans group streptococci may be modified with streptococcal mobile genetic elements. Streptococcal mobile genetic elements, typically integrative and conjugative elements - known to carry antibiotic resistance genes, only transmissible through direct contact with a live donor cell. Some elements can be transferred to other streptococci. These will not be modified by the addition of any genes not commonly found on naturally occurring examples of such elements. Other streptococcal mobile genetic elements do not readily transfer between species.

Streptococcal phage - only transmissible between closely-related species; not known to carry any genes hazardous to human health

**Origin & function**

Inserted genes:
- **cat** - encodes chloramphenicol acetyltransferase, which causes chloramphenicol resistance
- **tetM** - encodes a protein causing resistance to tetracycline.
- **ermB** - encodes a protein causing resistance to macrolides, lincosamides and streptogramins
mefE - encodes a protein causing resistance to macrolides
aph3' - encodes a protein causing resistance to aminoglycosides
Genes from mobile genetic elements - these may include one, or more, of the antibiotic resistance genes listed above. All mobile genetic elements used would be native to viridans group streptococci, and would not include any genes known to be hazardous to human health (e.g. toxin-encoding genes)
Altered/disrupted genes:
Genes involved in competence - these genes are required for the acquisition of DNA through transformation, and therefore their alteration and disruption will likely impair the ability of the mutant to acquire novel DNA
Bacteriocin synthesising operons - these genes are required for the synthesis of bacteriocins, which play a role in inter-strain competition. Therefore knocking out these genes would be expected to impair the strain's fitness
Restriction-modification systems - these genes protect S. pneumoniae against infection by phage, and therefore their elimination through knock-out would be expected to impair the strain's fitness
Signalling systems - genes potentially involved in cell-cell communication within S. pneumoniae populations
Other similar genes that are likely to be involved in affecting the pneumococcal population structure.

Evaluation of foreseeable effects

The most hazardous GMMs to be constructed would be those generated through exchange of DNA between cells through transformation, as this process can affect any locus in the recipient genome. Wherever possible, the recipient would be an unencapsulated S. pneumoniae strain such as R6. Only donors of the same species, or a less pathogenic one, would be used in these experiments. Donors would also be selected to have as few antibiotic resistance genes as feasible for the experiment. Experiments of this type have been safely conducted by the principle investigator previously. Other construction of GMMs would target genes for knockout, and therefore likely impair the fitness of the strain.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]
NC gave a description of the changes to the work.
AH wanted to know if the natural competence contributed towards resistance?
NC answered that the transformation was the biggest problem.
PL asked for more information on the restriction modification systems and how they contributed towards impaired Strep pneumoniae fitness mentioned in section 2.17.
NC explained that published research has demonstrated that increased susceptibility to phage infection has led to reduced fitness.
IH asked if the encapsulated strains are more dangerous? How do identify which are encapsulated and unencapsulated? Also, what are the dangers of being exposed?
NC confirmed the strain R6, unencapsulated, is the strain they plan to use most and has been extensively sequenced. It is not known to cause serious disease.
IH asked if the other strains were encapsulated?
NC answered, yes.
IH questioned if they should be separated in the laboratory?
NC pointed out that it was unnecessary as it is difficult to transfer all of the genes required for encapsulation from one strain to another.
IH asked if they will both be in the same Microbiological Safety Cabinet at the same time?
NC confirmed they will work with both encapsulated and unencapsulated strains.
PL inquired about invasive serotypes? Were they more transmissible?
NC informed the Committee that the Serotype 1 was most invasive. Serotype 1, and other higher virulence serotypes, would be avoided as far as possible especially in experiments involving the movement of antibiotic resistance genes between strains most frequently identified in asymptomatic carriage. There are some experiments where the choice of strains is constrained (e.g. due to the presence of genes of interest or need for high-quality sequence data), and serotype 1 strains are the least drug-resistant candidate isolates. Serotype 1 does not warrant extra control measures. Where possible, non-encapsulated isolates would be used to minimise risk.
PF pointed out that the elements stated were very specific and is NC considered other ones for the future?
The Committee suggested adding the words, ‘and other similar…’ after the list in section 2.17 and to the Standard Operating Procedure to broaden three elements.
AH queried if 10 minutes for liquid waste was enough.
IH pointed out the Safety Department recommends 30 minutes.
2.17: adding the words, ‘and other similar…’ after the list in section 2.17 (altered/disrupted genes) and to the Standard Operating Procedure to broaden the application.
5.1: Can vortexing take place in the MSC?
5.1: Cultures left for 30s to settle. I have not seen this before, is it effective or necessary? If not, please remove.
7.2 and 8.1: Please let the Safety Dept know when the autoclave in VA11b is re-commissioned.
10.1: Centrifuges: The HSE has previously mentioned that centrifuges should be left for at least an hour before opening if an infectious aerosol is suspected. Now would be a good time to make this relatively minor amendment to both the Bio1 and the SOP/COP
11.2: Remove individual names to keep this section generic. Please complete the Biopersonnel Form and return to biosafety@imperial.ac.uk
Agreed: Class 2, Containment Level 2. This project is notifiable to the HSE.

## Project Containment

02/03/2022
Mycobacterial diseases are the result of a complex series of interactions between pathogen and host, and there is an urgent need for new drugs, diagnostic tools and better vaccines to combat tuberculosis and other non-tuberculous infections.

In order to understand the molecular basis of the host-pathogen interactions in mycobacterial disease we will use genetic manipulation to generate strains of Mycobacterium tuberculosis, Mycobacterium bovis BCG and non tuberculous strains (e.g. Mycobacterium abscessus and kansaii) carrying defined genetic defects and/or reporter genes.

We will also work with the live attenuated defined M. tuberculosis auxotrophic mutants (Sampson et al, Infection & Immunity (2004) 72:3031–3037; Sambandamurthy et al, (2005) Infection & Immunity 73:1196-1203; Sambandamurthy et al, Vaccine (2006) 24: 6309-6320; Roy et al., Immunology Letters (2006) 103: 196-199) with targeted mutations which render them highly attenuated and suitable for use under containment level 2 conditions. The use of these strains under CL2 rather than CL3 containment will result in increased operator safety, time and cost savings and allow experiments which are otherwise not logistically feasible under CL3 conditions.
All these strains will be characterised in a range of in vitro models with the aim of identifying new drugs and drug targets, vaccine targets, diagnostic biomarkers of infection and disease and of improving our understanding of the host immune response and host-pathogen interactions of these important pathogens.

GM will be undertaken to insert plasmids (to insert/knock down genes of interest) into competent class 2 mycobacterial species including *Mycobacterium bovis* BCG, *M. abscessus, M. kansaii, M. avium, M. intracellulare, M. chelonae* by electroporation.

No additional modifications will be undertaken on the attenuated *M. tuberculosis* strains (class 2).

Inserting genes may be self-cloning of mycobacterial genes either in the sense orientation to allow overexpression, or in the antisense orientation to allow downregulation, under the control of either an inducible or constitutive promoter e.g. down-regulation and also overexpression of the 19kDa lipoprotein gene (Rv3762, involved in immune subversion), Acr2 gene (Rv0251c involved in bacillary defense against oxidant stress). Mycobacteria do not express any toxins and there is little risk of altering pathogenicity by this method.

Selectable markers are usually hygromycin (not clinically used as toxic to humans), kanamycin, spectinomycin, zeocin (not part of first line therapy), sometimes in combination with the sucrose and the SacB enzyme as a counterselectable marker.

Reporter genes include a range of fluorescent reporters such as GFP or mCherry, luminescent reporters such as the lux operon from Phorhabdus luminescens or Vibrio harveyi, or the luciferase genes from Firefly or Gaussia princeps.

Genes will also be inserted into Mycobacterium tuberculosis clinical isolates that are present in the reference strain H37Rv but naturally deleted in the clinical isolate. The pSMT3 vector will be used that encode the open reading frames for genes including Rv 0180 (Function unknown, probable conserved transmembrane protein), 1519 (probable conserved hypothetical protein), 3019 (Function unknown - Secreted ESAT-6 like protein EsxR, 3020 (function unknown - ESAT-6 like protein EsxS), 3516 (Could possibly oxidize fatty acids using specific components), 3517 (Function unknown - conserved hypothetical protein), 3738 (Function unknown - PPE family protein PPE66), 3739 (Function unknown - PPE family protein PPE67).

We will also use live attenuated M. tuberculosis auxotrophic mutants which are already genetically modified and have the following gene deletions and antibiotic resistance genes (no further modifications will be made in these strains):

Evaluation of foreseeable effects

Most GM Mycobacterium strains will be obtained from Dr Brian Robertson's lab, Imperial College London, in addition to constructing some other GM strains. Genetic manipulation will be undertaken to generate strains of mycobacteria including Mycobacterium tuberculosis, Mycobacterium bovis BCG and non-tuberculous mycobacteria carrying defined genetic defects and/or reporter genes.

Previous genetic manipulation will be undertaken to generate strains of mycobacteria carrying defined genetic defects and/or reporter genes. Mutants will be created by either the deletion of all or part of target genes and the introduction of a selectable marker, by double cross overs and homologous recombination. This can be done using mycobacteriophage or suicide plasmids, usually with a two-step selection procedure such as sucrose plus selection for an antibiotic marker such as kanamycin or hygromycin.

Reporters, such as genes for luminescence or fluorescence, will be introduced by electroporation of plasmid DNA which will be either maintained episomally by a mycobacterial origin of replication or will integrate into the attB phage attachment site. Reporters and mycobacterial genes may be over-expressed, or knocked down using antisense and inducible systems such as tetracycline or acetamide.

Genetic deletions in defined Mycobacterium tuberculosis clinical isolates will also be complemented by introducing the intact genes present in the reference strain Mycobacterium tuberculosis H37RV.
There is no evidence that any of the recombinant mycobacteria made in this project will be any more hazardous than parental strains.

In order to set the boundaries of the work we confirm that we will not be doing any genetic modification that involves i) the complementation of the RD1 deletion in Mycobacterium tuberculosis BCG, ii) the over expression of efflux pumps associated with drug resistance or iii) the cloning of large DNA fragments such as large insert Mycobacterium tuberculosis libraries in mycobacteria.

There is published evidence that disrupting some two-component regulators in M. tuberculosis alters virulence in immunocompromised animals; no such experiments are currently planned for mycobacteria.

If there is any increase in pathogenicity traits observed in in vitro models, then a further application will be submitted to GM77 committee at Imperial College London.

We will also use genetically modified live attenuated Mycobacterium tuberculosis auxotrophic mutants under containment Level 2. These defined M. tuberculosis strains with already targeted mutations render them highly attenuated and suitable for use under containment level 2 conditions. No further modification will be undertaken. All four of the strains carry two independent mutations, rendering them all auxotrophic for pantothenate, in combination with either leucine or lysine auxotrophy, or the deletion of the RD1 region responsible for the major attenuation of M. bovis BCG. The auxotrophic strains are well characterised and highly attenuated. Extensive safety testing has been performed on all the 4 strains: attenuated Mycobacterium tuberculosis leuD ΔpanCD hygR, attenuated Mycobacterium tuberculosis mc2 6020 ΔlysA ΔpanCD hygR, attenuated Mycobacterium tuberculosis mc2 6030 ΔRD1 ΔpanCD hygR, attenuated Mycobacterium tuberculosis mc2 7000 ΔRD1 ΔpanCD unmarked. (references Sampson et al, Infection & Immunity 2004 72:3031–3037; Sambandamurthy et al, Nature Medicine 2002 1171-1174; Sambandamurthy et al, 2005 Infection & Immunity 73:1196-1203.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste infected with mycobacteria (e.g. unwanted mycobacterial cultures or preparations originating from live mycobacterial cultures such as supernatants from infected eukaryotic cells) are discarded by adding 10% surfanios disinfectant (minimum final concentration) and leaving overnight before placing in a clear aurtoclave bag for autoclaving to achieve the desired sterilisation temperature for killing of 121 degrees Celsius for 15 minutes. This disinfection policy has been extensively validated in house at Imperial College London and data is available upon request. Autoclaved waste is then bagged in orange bags before being disposed of via clinical waste which is transported for microwaving and landfill.

All solid waste infected with mycobacteria (e.g. bacterial plates), will be placed in autoclave bags and autoclaved to achieve the desired sterilisation temperature for killing of 121 degrees Celsius for 15 minutes. Autoclaved waste is then bagged in orange bags before being disposed of via clinical waste which is transported for microwaving and landfill.

Autoclaves are serviced twice per year, and validated and insurance inspection once per year in accordance with Imperial College London regulations.

Any liquid waste which is not infected with mycobacteria (e.g. unwanted eukaryotic cells, whole blood) and is to be discarded, is treated with 2% virkon final concentration and left for 30mins-1hr before disposing via the drain.

Any solid waste items not infected with mycobacteria or blood/cells will be discarded into orange bags for disposal via clinical waste.
Following the discussion of your proposal GMIC-01147.1 and GMIC-01148.1, the committee request that the following amendments are made to the proposal prior to approval.

No comments received.

Comments from the BSO made prior to the consultation with the GM committee.

Title We will submit both Bio1’s under the same CU2 notification but what I will do is change the Title’s to “Host and bacillary correlates of pathology in human tuberculosis - class 3” and “Host and bacillary correlates of pathology in human tuberculosis - class 2” as it is two different aspects of the same project.

GMIC 1147.1

2.14 and 4.28 Crispr/Cas9 Ther is the potential for “gene drive” occurring as a result of the use of this system. I doubt this would be the case here as I think you are pretty much just using it to knock out genes and down regulate systems but it may be as well to add a line explaining why it could not happen.

2.16 Add the word “further” to the sentence “no modifications of the live attenuated M. tuberculosis ……… “

How were the M.tb deletion mutants created? Was this a GM technique or is the only genetic modification the addition of the antibiotic markers?

I don’t see reference to the use of the Crispr/Cas9 system mentioned in 2.14. You should describe it here.

2.18 and 4.18 How likely are the increases in virulence you mention here to occur and how would you notice or monitor for an increase in virulence? Basically we need to robustly justify use at CL2, the HSE will probably ask this question.

Does the fact that you are not introducing large fragment libraries into BCG reduce the likelihood of increased virulence to negligible?

Please enter comments on the GM safety committee on the risk assessment

Human T lymphotropic virus type 1 (HTLV-1) remains asymptomatic in over 90% of infected individuals. Approximately 5% of infected individuals develop an aggressive malignancy known as adult T cell leukaemia/lymphoma (ATLL). A smaller proportion (1% to 4% of infected individuals) develop a chronic inflammatory disease, of which the best recognized is HTLV-1-associated myelopathy/tropical spastic paraparesis (HAM/TSP). Certain experiments will be carried out on cells infected with HIV-1 and compared with the results from experiments on HTLV-1 and HTLV-2. The laboratory will focus on the understanding of virus infections. The main aims of the project are i) establish an in vitro reporter system for HTLV-1 and -2 infection (=deltaretroviruses) ii) dissect the role of host factors in viral infectivity and integration site targeting; iii) investigate the efficacy of (lentiviral) integrase strand transfer inhibitors (INSTIs) to inhibit HTLV infection; iv) investigate host receptor contribution to infection efficacy; v) investigate mechanism of cell-to-cell versus cell-free infection. To investigate the efficacy of integrase inhibitors, experiments to determine IC50s will also be performed with HIV to compare the data. The laboratory will focus on the understanding of virus infections and more specifically integration. Gene delivery by retrovirus pseudoparticles: The lab produces pseudoparticles for cellular or reporter gene transduction to create stable transgene-expressing cell lines or to study heterologous viral entry in cells lines. Production of pseudoparticles is achieved by transfecting a producer cell line (e.g., 293T cells) with plasmids encoding 1) the gene of interest flanked by 5’ and 3’ retroviral long terminal repeats (LTRs) as part of a minimal packagable proviral genome 2) a plasmid encoding the retroviral gag-pol genes 3) a plasmid encoding the envelope proteins of a broadly tropic virus such as vesicular stomatitis virus (VSV). Pseudoparticles can then be used to infect cells of interest, in which LTRs mediate integration of the transgene. In addition, pseudoparticles are used to express a library of gene fragments, to express interfering small RNAs (shRNA, siRNA) as well as microRNAs (miRNA) and other non-protein coding sequences. Efficiency and biological function of the manipulated cells will be assessed following inactivation of any residual infectious particles via flow cytometry, imaging, luciferase assays, p24 ELISA and western blot analysis. Virus stocks (e.g. HTLV-1 and -2, HIV and MLV) will be produced by using recombinant plasmid based
transfection/electroporation methods using 293T or Jurkat T cell lines to produce high-titer, wild-type or recombinant viruses encoding reporter genes allowing easy identification of infected cells (e.g. fluorescent proteins). We will furthermore generate recombinant HTLV-1 and -2 with suspected drug resistance mutations (based on the homology with HIV) to determine their viral fitness in cells. Sequencing will be performed by isolating viral or cellular nucleic acid post inactivation of any residual infectious virus. Cell-free infection by HTLV occurs with extremely low efficiency (<0.001%), thus cell-to-cell transductions are performed by co-culture of the producer cell (either made by transient transfection of recombinant plasmid or by using the stably infected and producing HTLV cell lines MT-2 or C91PL) with a suitable target cell (such as HEK293T or Jurkat T cells). Co-culture of the target cells with MT-2 or C91PL will take place following gamma-irradiation of the producer cell lines following established protocols. Viral titers will be determined by qPCR (HIV and MLV) or ELISA (HTLV-1 and 2) following inactivation of infectious particles.

Recipient or parental organism

HIV (ACDP HG3) Human T-cell lymphotropic Virus type 1 and 2 (ACDP HG 3),
Disabled Lentiviral gene transfer vectors (ACDP classification 1),
disabled retroviral (MLV) gene transfer (ACDP classification 1),
disabled retroviral (HTLV) gene transfer (ACDP classification 1)
non-pathogenic E. coli, including DH5alpha, TOP10, XL1-blue and Mach1 (ACDP classification 1),
non-pathogenic insect cells (Sf9, HiFive) for protein expression (ACDP classification 1),
HEK293T (ACDP classification 2) and Jurkat T cell lines (ACDP classification 1) (and similar) for the production of retro/lenti-viral particles and infection/transduction.

Host/vector system

Lentiviral (3rd generation attenuated gene transfer vectors relying on a three-plasmid transfection system, cotransfection of pCG-VsVG (envelope), pCMVdelta8.2 (Naldini et al PNAS 1996) and commercially available pLKO (shRNA), pLentiLox3.7 and pDEST (for gene expression), pCHW-GFP (GFP reporter)), retroviral (attenuated gene transfer vectors relying on a three-plasmid transfection system; pCG-VsVG, pCG-GagPol (Ulm JW, et al Virology 2007) and commercially available pQCXIP, or pMarx-GFP), plasmids encoding infectious cDNA/DNA clones of HTLV-1 and -2. We are generating a triple plasmid based HTLV-1 and -2 vector system to produce non-replicating virus. The three plasmids will contain the following features:
1) Envelope gene expressed from CAG promoter (either VsVG or HTLV-1 and -2 specific envelope genes)
2) packaging plasmid encoding for gag-pol-pX region (NOT ENV); here no functionalLTRs are present AND the psipackaging signal has been mutated; these genes are under the regulation of the CAG promoter
3) transfer plasmid: contains: psi packaging signal, functional LTRs and transfer gene (such as EGFP, or luciferase reporter gene).

Only the RNA from the transfer plasmid will be packaged into the viral like particles, therefore these viral particles do not contain the information to produce new particles since the essential genes are absent from the genetic information packaged in the particles.

Above described mutations will be introduced into the packaging plasmid.
Plasmids for bacterial expression: commercially available pCDF-Duet1, pET28aSUMO, pGEX, pMalc2, pET20
Plasmids for eukaryotic expression: for retroviral expression pQCXIP derived, for lentiviral shRNA expression: pLKO (Sigma), gene expression: pLentiLox3.7 or pDEST system, for transient expression we use pcDNA6 plasmids.
Plasmids for baculovirus expression: pBacPackHis-StrepTEV

Origin & function
Integrase: viral gene essential for insertion of cDNA copy of viral genome into host DNA
HTLV binding partners such as protein phosphatase 2A (PP2A),
Proteins involved in DNA damage repair, chromatin segregation and others, see list in Supplementary Table of
Guide RNAs to target genes for knock-out using the CRISPR/Cas9 system (e.g. targeting the scaffold subunit of
PP2A) will be produced in vitro and transfected (nucleofected) into Jurkat cells together with commercially available
Cas9

**Evaluation of foreseeable effects**

Genetically modified microorganisms based on HTLV-1 and -2; These recombinants encode fluorescent proteins,
antibiotic resistance cassettes or luciferase reporter cassettes, used to identify infected cells in vitro or in vivo. All GM
viruses exhibit growth properties similar to or lower than the parental virus and none of the inserts are increasing
virulence. A standard read out of our experiments is the viral titre and infection efficiency, thus any change in
virulence/growth properties will be noticed. Should any GMM exhibit enhanced growth properties/virulence, GM safety
committee approval will be sought prior to any further experiments with said GMM.
HTLV GMMs encoding drug resistance mutations conferring them with resistance to INSTIs can result in drug
resistant virus infection. However, only drug-resistance mutations for integrase will be used.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

**Liquid waste**
Low titre liquid waste e.g. wash solutions and Class 1 GM culture will be inactivated with 1% Virkon (final
concentration after dilution with the waste) for 30 minutes prior to disposal.
High viral titre class 2 and 3 and all HG3 and Class 3 virus culture waste in the CL3 suite will additionally be
autoclaved.

**Solid waste**
Solid infectious waste will be put into a sweetie jar in the MSC cabinet, which when full will be closed in the MSC
cabinet, sprayed with 70% ethanol and put into an autoclave waste biohazard bin for autoclaving. Plastic ware that is
too big for the sweetie jars, will be put into an autoclave bag inside of the MSC cabinet, this bag will be closed with
autoclave tape and transferred to autoclavable biohazard bin.

**Is an emergency plan required according to regulation 20?**

N

If yes, tick to confirm that it is attached to this form

N

**Tick to confirm that you have attached a risk assessment to this form**

Y

**Tick if you are claiming exemption from disclosure for section of the risk assessment**

N
Following the discussion of your proposal entitled “Study of host factors that aid or restrict delta-retrovirus infection” GMIC-6945 at the last GM Safety Committee meeting, the Committee request that the following amendments are made to the proposal prior to approval:
