OAV623 is a recombinant adenovirus, which contains the full viral genome and a transgene containing a human tissue-specific promoter and a gene encoding an enzyme that can act on a pro-drug to produce a toxic agent. OAV is capable of infecting human cells, but it has been shown to be unable to complete its full replication cycle (Khatri, A et al [1997]: Virology 239 p.226-237), resulting in an abortive infection. OAV has also been shown to replicate abortively in human cells, which are co-infected with human adenoviruses. The abortive replication cycle of these viruses suggests that there is minimal risk to the worker when propagating these viruses. However, due to the lack of pre-existing immunity of the worker to OAV, there will be limited immunity on first exposure to the virus. Subsequent exposure would result in an unknown immune response to the virus.

The plasmid DNA containing the full genome of OAV623 will be used to rescue the virus under segregated conditions. As the plasmid contains the same genetic material as the intact virus, it is highly unlikely that the plasmid would be of greater risk to the worker than the virus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
The virus will only be handled in class II microbiological safety cabinets that will be swabbed with a viricide (e.g. Virkon or Klearcide) after use. All contaminated materials will be treated by chemical means (e.g. 1% Virkon solution, which is proven to destroy both Mastadenoviruses and Aviadenoviruses) and/or autoclaving at 121°C for a minimum of 15 minutes prior to removal by a contractor for incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMSC agree that class 1 would normally have been appropriate for the protection of human health, but as this virus can cause mild infection in sheep it becomes a class 2 activity to ensure protection of sheep in the environment.

### Project Additional Information

#### Purposes of the contained use

The aim of this project is to evaluate the immune-therapeutic benefit of expressing immune-stimulating proteins in murine tumour cells killed in vivo by enzyme/prodrug combinations, namely NTR/CB1954 or Cyp1A2/acetaminophen. Immun-therapeutic effects will be studied using the mouse 4T1 breast cancer cell line in the host BALB/c mice in the first instance. The mouse TRAMP spontaneous prostate tumour model will subsequently be used.

#### Recipient or parental organism

The parental organism is a replication-defective, human Adenovirus (Ad) type 5. Human Ad are found worldwide, and over 40 different serotypes have been isolated. Ad5 is associated with mild upper respiratory tract infections in young children. Immunity to Ad infection is thought to be life-long following primary infection. Although some serotypes are closely related they nevertheless remain distinct entities suggesting that the potential for recombination in vivo is not high. Human serotypes do not naturally infect other animal species and there are relatively few reports of virus replication following inoculation of Ad into experimental animals. There is no evidence that human Ad cross species and so a replication defective virus could not be maintained in non-human host. The replication-defective vector is not expected to be harmful. The potential hazard to the environment, from inadvertent release of the quantities of virus expected to be handled, is extremely low. The recipient cell line used to produce the virus is the human PER.C6 cell line (Fallaux et al., Human Gene Therapy, 1998, 9: 1910-1917). This E1-containing cell line is engineered to avoid recombination between the vector genome and the viral sequences present in the genome of the producer cells and thereby RCAs (Replication-Component Adenviruses) should not be generated at significant levels.

#### Host/vector system

The vector system is a replication-defective human adenovirus type 5 (E1 and E3 deleted). The host cell line is PER.C6 (Fallaux et al., Human Gene Therapy, 1998, 9: 1910-1917).

#### Origin & function

Murine immune stimulatory genes will be generated by RT-PCR from mouse splenocytes or from commercially available sources with immune modulating activity in humans.

#### Evaluation of foreseeable effects

Ad expressing xenogeneic proteins such as a bacterial nitroreductase or a mouse cytokine that is inactive in humans may be immunogenic. It is possible that the Ads expressing a mouse cytokine that is active in man (ie that can bind the equivalent human cytokine receptor) could give additional immunogenicity, eg a local inflammatory response. However, this would be very limited and cleared rapidly in most humans, since the great majority of people have antibodies to Ad coat proteins through exposure to the virus in early childhood. Human cytokines have been evaluated in clinical studies and only show toxicity with systemic administration at high levels.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Local contamination of the safety cabinets and other control and containment equipment and devices will be carried out by swabbing with 1% Virkon (as recommended by the manufacturer to achieve most effective killing) followed by 70% ethanol. Cell culture media will be immediately treated with Virkon as recommended by the manufacturer.

All waste materials will be treated with Virkon or autoclaved and/or incinerated.

In the case of an accidental puncture of the skin by a contaminated sharp, the procedure is to wipe the wound with 70% ethanol and report immediately to the Medical Centre.

Standard operating procedure for injection of GM adenoviruses into tumours.
1. All viral vectors have to be handled within class II containment cabinets.
2. Viruses must be carried in a tube enclosed within a sealed container (e.g. cyrovial inside a 50 ml Falcon tube)
3. Operator must wear suitable protective clothing (gown) and latex gloves.
4. If virus leaks from the injection site, the site is wiped with paper tissue soaked in 1% Virkon. Any spillages are wiped up with tissues soaked in Virkon, all tissues must be discarded into an autoclave bag.
5. Contaminated syringes and tips must be soaked in 1% Virkon for at least 30 minutes before being discarded into the sharps bin.
6. Following all work, all surfaces must be decontaminated by wiping with 1% Virkon followed by 70% ethanol, tissues solid waste, gloves etc must be discarded into an autoclave bag.

Standard operating procedure for husbandry of mice injected with recombinant adenoviral vectors.
1. Wear a dedicated lab coat/gown and gloves for handling the animals.
2. Keep a supply of 1% Virkon solution in the room for decontamination purposes.
3. After transferring the animals to clean cages, dirty cages must be put in bags and autoclaved with their contents.
4. The box used for weighing the animals must be disinfected at the end of each session.
5. Routine cleaning of cage racks and filters should be preceded by spraying with 1% Virkon and allowing to stand for 1 hour.
6. All animal carcases etc. are disposed of by incineration off site.
7. All protective clothing is to be autoclaved prior to laundering.
8. All solid waste, disposable gloves etc. is to be autoclaved prior to incineration.

Project Additional Information

Purposes of the contained use

Contained manufacture for human clinical trials.
HSV1 vectors deleted for the neurovirulence factor ICP34.5 have been engineered to express human and mouse forms of GM-CSF and other immune modulators such as RANTES, B7.1, and CD40L. These viruses are designed to replicate in tumours but not surrounding tissue (considerable literature demonstrates such a phenotype for HSV1 and 2 ICP34.5 deleted viruses) with the additional delivery of immuno-stimulatory factors. Some viruses will be additionally modified such as HSV genes that usually minimise immune responses to HSV infection are also deleted. Such genes are UL43, vhs and ICP47. Each of the deletions in ICP34.5, vhs or ICP47 has been shown individually to generate a non-pathogenic, though still replication competent virus. Deletion of UL43 alone probably does not significantly reduce pathogenicity, but this deletion will only be included in viruses already deleted for the other gene(s) above.

### Host/vector system

Vero cells/Herpes Simplex Virus 1 or 2.

### Origin & function

Inserted genetic material is of either human or rodent origin and has been cloned by PCR or obtained from collaborators in plasmid form. Genes to be inserted include GM-CSF, RANTES, B7.1, and CD40L.

### Evaluation of foreseeable effects

None of the genes to be inserted are anticipated to result in harmful effects.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Derogation re: autoclave on site.**

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste generated during the activity that has been in contact with the GMM will be treated with a Virkon solution. This broad-spectrum disinfectant is effective against herpes simplex virus at a 0.5% (w/v) concentration giving terminal disinfection after 10 minutes of contact. Normal contact time is about 16 hr (overnight) prior to disposal to drain.

Solid (mainly plastic disposables) waste will be double bagged and placed in Weaver bins then transported as clinical waste by a registered carrier for incineration offsite.

Prevention of class 2 GMOs being a hazard to workers

#### Recipient or parental organism

#### The HSV2 vectors are deleted for the neurovirulence factor ICP34.5 as well as vhs, ICP47 and UL43. These viruses are modified so that the HSV genes that usually minimise immune responses to HSV infection are deleted. No transgenes are present.

#### Host/vector system

02/03/2022 Page 9965 of 15326
Herpes simplex virus 2.

Origin & function
No genes are being inserted. Only deletions of the HSV genes are being carried out.

Evaluation of foreseeable effects
No harmful effects are anticipated due to the increased immuno-stimulatory status of the virus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not required.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All waste generated during the activity that has been in contact with the GMO will be treated with a 1% Virkon solution. This broad spectrum disinfectant is effective against herpes simplex virus at a 0.5% (w/v) concentration giving terminal disinfection after 10 minutes of contact.

All disposable items will be placed into Weaver bins and sealed within the cleanrooms. These are then sprayed with Biocide B, with a contact time of 5 minutes before leaving the room. These are then removed to an external compound where they are placed in clinical waste bins. A registered contractor (White Rose Environmental) then removes the bins for incineration.

Animal Units | Large Scale Activities | Human Clinical Applications

02/03/2022
Deletion of two genes from the chromosome of a Gram-positive bacterium.

Purposes of the contained use
To create a strain of a Gram-positive bacterium that does not produce two proteins which have therapeutic applications. This will be used as a control strain in assays allowing all the other proteins produced by the bacterium to be detected.

Recipient or parental organism
A Gram-positive bacterium.

Host/vector system
A plasmid possessing the pMB1 origin of replication and an antibiotic resistance gene flanked by dif sites, flanked by regions homologous to the target genetic loci. This will replicate in E. coli only, not in the target organism. The vector system is for gene deletion only, not gene expression.

Origin & function
A gene cassette will be synthesised (de novo and in E. coli) consisting of an antibiotic resistance gene flanked by the recognition sites for the native Xer site-specific recombinases (dif sites). This will in turn be flanked by regions of chromosomal homology upstream and downstream of the gene to be deleted. Competent cells of the target Gram-positive bacterium will be made and transformed with the linearised gene cassette, with deletion mutants identified by survival on the selective antibiotic. The deletion mutant will be cultured in the absence of the antibiotic, allowing cells to undergo site-specific recombination to delete the antibiotic resistance gene. These recombinants will be identified by antibiotic sensitivity and by PCR. The process will then be repeated for the second gene to be deleted. To determine transformation efficiencies, plasmids possessing the pMB1 and pUB110 origins of replication will be transformed into the Gram-positive bacterium and colony counts performed, but these...
will not be used for further culture.

Evaluation of foreseeable effects

The deletion of two genes is not predicted to have any adverse effects on the biosafety of this organism. Indeed, the proposed modifications are likely to reduce the fitness and potential pathogenicity of this organism.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste generated will be inactivated by disinfection overnight with 2.5 % (v/v) Chloros (hypochlorite). Solid waste (mainly plastic disposables) will be double-bagged and placed in Weaver bins, then transported as clinical waste by a registered carrier to incineration off-site.

Tick if you are claiming exemption from disclosure for section of the risk assessment: Y

Tick if you are claiming exemption from disclosure for section of the risk assessment: N
Production of a hybrid AAV2/AAV1 vector expressing human alpha1-antitrypsin (hAAT) by the infection of human HEK-293 cells with two recombinant HSV-1 helper vectors.

Overview: A recombinant AAV1-hAAT (hybrid) vector is produced by co-infection of HEK-293 cells with two HSV-1 based vectors: rHSV-rep2/cap1 and rHSV-rAAV2-AAT. rHSV-rep2/cap1 expresses the AAV Rep and Cap proteins. Rep proteins are derived from serotype AAV-2 and Cap proteins from serotype AAV-1. rHSV-AAV2-AAT contains the recombinant AAV-2 vector, comprising the ITRs (Inverted Terminal Repeats) from serotype AAV-2 and the expression cassette for human alpha1-antitrypsin (hAAT). This is the AAV genome, which will be packaged into the AAV virions. The producer cell line 293 is an embryonic human kidney cell line that has been transformed by human Ad5 E1 gene sequences (Cobra BRA0015) and it is a well characterised cell line that has been used for many years for the production of biopharmaceuticals.

The recombinant AAV is produced after co-infection of HEK-293 cells with both HSV helper viruses. GMO evaluations: 1. Recombinant HSV vectors: The two HSV vectors in question are deleted for the viral gene ICP27 thereby, in theory, disabling the replication capacity of the virus. In both vectors the TK gene is disrupted by insertion of either the Rep2/Cap1 expression cassette (rHSV-rep2/cap1) or the recombinant AAV2-hAAT cassette (rHSV-AAV2-AAT). The potential for recombination with wild-type HSV-1 in already infected humans is very low. The inserted gene sequences could potentially recombine with wild-type HSV-1 if the vectors are present within the same cell. The vectors would then be converted to wt HSV-1 by acquiring the TK and ICP27 genes, vice versa, the wt HSV-1 would be inactivated by deletion of ICP27 and TK genes. The two HSV helper viruses are produced on the complementing cell line V27 (containing the ICP27 gene to allow amplification of the two HSV vectors), and the virus preparations are contaminated with recombinant, replication-competent HSV vector (rHSV). Contamination is normally in the range of <10pfu rHSV/1xE+08 pfu of rHSV. Also, some amplification of the contaminating rHSV is expected after infection of the HEK-293 cells with the two recombinant HSV vectors (the ratio of rHSV/recombinant HSV increases up to 1000-fold). The replication-competent vectors will be wild-type for ICP27 and will have either the Rep/Cap cassette or the AAV genome with the hAAT expression cassette at the TK gene position, respectively. They will not contain the TK gene, as this gene is not present in the V27 producer cell line and cannot be acquired by recombination (TK is not needed for in-vitro cell culture replication). Therefore the rHSV viruses would still be resistant to antiviral drugs like acyclovir. Also, the rHSV viruses would be still sensitive to other anti-HSV drugs like vidarabine and foscarnet (Martuza RL et al., Science 1991: 252, 854-856). The TKminus rHSV viruses are attenuated in-vivo especially for the neurovirulent phenotype (Martuza RL et al., Science 1991: 252: 854-856). Also, this Tkminus virus can replicate in dividing cells but is severely impaired for replication in non-dividing cells. Recombination of these replication-competent HSV-1 contaminations (rHSV) with wild-type HSV-1 present in the same cell could cause the exchange of the TK gene and the recombinant cassette present in the rHSV vectors (either the AAV2-AAT cassette or the Rep2/Cap1 expression cassette). This would not change the type of vectors being present in the cell. Interaction of the two recombinant HSV vectors or the contaminating rHSV with
the HEK-293 cell host or subsequent processing media should not change/increase the hazard and/or classification. 2. Recombinant AAV

Adeno-Associated Virus (AAV) belongs to the Parvoviridae family and here to the subfamily Parvovirinae and here to the Genus Dependovirus. The name Dependovirus represents the fact that this virus cannot induce a lytic cycle after infection if a Helper Virus is not present. Helper Virus can be Adenovirus, HSV, Vaccinia Virus, CMV or HPV. In case of the production the recombinant rAAV-AAT, the helper functions are supplied by the HSV vectors. AAV is normally transmitted via respiratory and fecal/oral routes. AAV particles are very robust and can survive outside the host for several weeks. Generally AAV is not associated with human disease. Recombinant AAV vectors are not pathogenic, have comparatively low intrinsic immunogenicity, can transduce non-proliferating cells and are capable of long-term transgene expression. Serotype AAV-1 is most effective in infecting skeletal muscle cells. The AAV virus produced within this procedure is completely defective for Rep and Cap genes and is therefore not able to replicate even in the presence of an Helper Virus in the target cell. After infection of HEK-293 cells with the two rHSV, the HEK-293 cells will produce recombinant AAV particles containing the hAAT expression cassette. The tropism of this rAAV is identical to that of AAV1 as Capsid proteins are derived from serotype AAV-1. Rep proteins are derived from AAV-2 but do not influence the tropism of the virus particle. It is not thought that the recombinant AAV would pose any serious risk to the environment. It might survive at maximum a few weeks outside the host cell. Infection is restricted to humans. Interaction of the recombinant AAV virus with the HEK-293 cell host or subsequent processing media should not change/increase the hazard and/or classification.

Host/vector system

Host: The producer cell line HEK-293 is an embryonic human kidney cell line that has been transformed by human Ad5 E1 gene sequences (Cobra Biological Risk Assessment 0015). The recombinant AAV will be produced after co-infection of HEK-293 cells with both rHSV vectors. Vector: Recombinant HSV-1 and recombinant, hybrid AAV1/AAV2 with AAV-1 tropism.

Origin & function

The expression cassette comprises the human CMV enhancer in combination with the chicken C-actin promoter, an intron, the cDNA for human alpha1-antitrypsin and the SV40 poly(A) signal. Therefore expression is constitutively switched on in mammalian cells. Alpha 1-antitrypsin (AAT) is a 52 kDa serine proteinase inhibitor that is normally secreted from hepatocytes and circulates in the plasma, protecting lung elastin from degradation by neutrophil elastase and related proteases. Neutrophil elastase is released from white blood cells to fight infection but if not properly controlled can attack normal cells and lead to e.g. emphysema in lung alveoli. For therapeutic applications expression of 800 mg/ml AAT seems necessary to avoid the development of clinically significant lung disease, much higher levels (8 mg/ml or more) are observed without obvious side effect. Earlier studies of protein replacement indicated that no adverse effects were seen with serum hAAT levels greater than 100-fold above the therapeutic threshold (i.e. > 80 mg/ml).

Evaluation of foreseeable effects

1. Vectors Both recombinant HSV vectors are based on the parental virus HSV-1 (strain Kos). Wild-type HSV-1 is classified as ACDP 2 biological material. HSV-1 belongs to the Alphaherpesvirinae subfamily. HSV-1 has got a wide host range, multiplies efficiently and rapidly destroys the infected host cell. HSV-1 is more frequently associated with non-genital infection (infection above the belt, e.g. skin lesions: Herpes labialis, Keratoconjunctivitis). Within Europe, about 70-80% of the human population are sero-positive for HSV-1. HSV-1 is a universally prevalent virus, which, even in its wild-type form, rarely causes severe problems unless the virus somehow manages to get to the brain or the eye where it could cause encephalitis and retinopathy, respectively. HSV-1 typically exists in a latent form (for life time; primarily but not exclusively in sensory ganglia) after primary infection, and outbreaks of subsequent active viral replication ("cold sores") are associated with episodes of lowered host cell immunity allowing low levels of virus to evade the immune system and re-infect. Reactivation of latent HSV is mainly caused by UV light, stress and fever. Transmission between human hosts requires contact, and transmission by aerosols is not thought to occur. Infection would require direct contact between culture or process media containing virus and process operators via oral, eye or broken skin routes. The contaminating ICP27plus/Tkminus replication-competent viruses (rHSV) would still be significantly attenuated in vivo especially for neurovirulence. Also, it can replicate in dividing cells but is severely impaired for replication in non-dividing cells. The rHSV viruses would be resistant to acyclovir but are still sensitive (like wild-type HSV-1) to alternative drugs like vidarabine and foscarnet (Martuza RL et al., Science 1991: 252, 854-856). HSV-1 causes mainly infection above the belt (skin and eye). In more severe cases HSV-1 infects the brain or the eye and leads to encephalitis and retinopathy, respectively. About 70-80% of people (Europe) are expected to be sero-positive for HSV-1. For those people, the presence of neutralising antibodies should protect against infection with HSV-1. Immunosuppressed persons are at higher risk. We conclude that accidental infection with the low contaminant replication-deficient viruses (ICP+/TK-) should result in a significantly attenuated infection compared to infection with wild-type HSV-1 infection especially for neuropsychogenicity. 2. Transgene Because excess levels of hAAT in serum (100-fold) do not indicate any adverse effects, no harmful consequences after accidental inoculation of the recombinant AAV virus or the recombinant rHSV-Rep2/Cap1 vector by an operator are expected.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Derogation re: autoclave on site.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Environmental evaluation: HSV-1 is species-specific in its infectivity, and thus there is negligible potential for harm to non-human species in the environment. The virus/vector is fragile and rapidly inactivated by desiccation, lipids solvents and mild detergents. The fact that contact is required for transmission attests to the instability of the virus outside the host. Operational evaluation: - All operations will be performed under GMO class II containment levels. - A detailed inactivation protocol for inactivation of HSV and AAV has been supplied by the Client (see inactivation data as performed by the client attached with the GM Risk Assessment). Small volume spills will be treated with excess volume of 0.525% (v/v) Sodium Hypochlorite (1:20 dilution of 10-11% Sodium Hypochlorite stock giving a final conc. of 0.525%) for at least 10 minutes, which should give complete inactivation. The contaminated surface area will then be wiped with tissues wetted with 0.525% Sodium Hypochlorite solution. Larger volume spills of up to 5L will be treated with the emergency procedure for virus or animal cells (addition of equal volume of 1.05% Sodium Hypochlorite stock solution: 1:10 dilution of 10-11% Sodium Hypochlorite stock to give the same final concentration of 0.525%; incubation for at least 10 minutes). Once chemical inactivation is complete liquids will be mopped up with spill granules (Spill-kit available for the Lab where the work will take place) and disposed of in weaver bins by approved disposal route for GMO class II only. - Access to the facility is restricted and appropriate disinfection and waste management procedures for class II waste are in place (e.g. weaver bins for solid waste (double bagged); contaminated consumables will be removed from site by accredited sub-contractor and destroyed by incineration). - Handling will be done by trained operators wearing appropriate PPE (labcoat, gloves and safety goggles). - Arm wrists should be covered at all times when working with virus: this must be done either by coverage with gloves or by the usage of disposable arm sleeves. - If clothing is wet call for immediate assistance and change of clothing. - If accidental contact with gloves happened, these should be changed immediately.

Project Containment

Please enter comments on the GM safety committee on the risk assessment

The GMBSC opinion is that because of the contamination of the culture with replication-competent HSV-1 vector the recombinant HSV viruses to be used are Class 2 GMOs requiring Containment level 2.
**Project Ref:** 566/08.1

**Date Ackn'd:** 05/03/2008

Production of an investigational drug for use in clinical trials.

**Recipient or parental organism:**

The work that will be performed using this GMO covers the technical transfer of a 20L manufacturing process of the biologic TNFerade and the scale up of this process to 100L manufacture. TNFerade is a replication incompetent human Adenovirus (serotype 5) Vector containing a Tumour Necrosis Factor-a (TNF-a) transgene. The virus will be propagated in the 293-ORF6 human cell line which was generated by stably transfecting 293 cells with an inducible E4-ORF6 expression cassette (Brough D, Lizonova A, Hsu C, Kulesa V, and Kovesdi I, J. Virol Sept 1996. 70(9): 6497-6501). The cells will be grown up in a combination of shaker flasks, disposable bag cell culture systems and stainless steel fermentors to a volume of between 20-100L. When an optimal cell density is achieved the cells will be infected with the seed virus. Subsequently the propagated virus will be harvested and purified using column chromatography.

The modified virus is replication incompetent due to the complete deletions of the E1 and E4 regions. There is also a partial deletion of the E3 region. The virus therefore needs a genetically modified cell line that can supply E1 and E4 elements in trans in order to replicate. The inserted TNF-a expression cassette replaces the deleted E1 region. Tumour necrosis factor-alpha(TNF-a) is a pleiotrophic inflammatory cytokine with biological activity that includes immunomodulation, oncostatic, osteolytic proinflammatory amongst other effects.

The virus described is replication incompetent and alone would not therefore be able to replicate in the environment if it were to be accidentally released. There is a theoretical possibility that the vector could become replication competent via recombination or complementation events. Because the TNF-a cassette replaces the deleted E1 region in the viral genome recombination with a wild type Ad5 at this site would result in a disabled virus with no overall gain in pathogenicity.
Host/vector system

The host cell line is 293-ORF6, which was produced from 293HEK cells by stably transfecting them with an inducible E4-ORF6 expression cassette.

Origin & function

The modified adenovirus is replication incompetent due to the complete deletions of the E1 and E2 regions. There is also a partial deletion of the E3 region. The inserted TNF-a expression cassette replaces the deleted E1 region, this is controlled by a chemoradiation sensitive promoter. The purified GM virus produced will be used as a commercial treatment for pancreatic cancer. The virus will be administered to the patient via intramoral injection. Targeted radiotherapy will then be used to switch on the TNF-a gene where it will have multiple anti-tumour effects.

Evaluation of foreseeable effects

Vector: The virus may be transmitted by inhalation, ingestion, skin adsorption or via needle stick injury. The health effects in humans are not well characterised but based on the limited clinical trial data available administration of TNFerade via intramoral injection in combination with radiation or chemoradiation therapy caused side effects of flu-like symptoms, abdominal pain, anaemia, anorexia, dehydration, diarrhoea, esophagitis, hypotension, headache and tachycardia.

Transgene: Any GM that were to enter a human cell has the potential to express biologically active TNF-a, however the virus cannot replicate in human cells and therefore the transient expression of the TNF-a should not pose a hazard to human health. Furthermore the transgene is controlled by a promoter that is switched on by radiotherapy lessening the expression levels that would be achieved in a person who was accidently inoculated.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Part II, Table 1a, Containment Measures, Equipment:

8. Autoclave required on site.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All product contacting disposable materials (solid waste) will be handled as class 2 GMO waste and disposed of in weaver bins, this waste will be removed from site for incineration by an approved contractor. In house studies have shown that cultures of liquid human adenovirus type 5 can be effectively inactivated by 1% (final concentration) Sodium Hypochlorite solution for a contact time of 5 minutes (refer to attached risk assessment) this can be applied to either spillages of Adenovirus or unwanted cultures, any spill lit materials that are used to mop up a treated adenovirus spill will be disposed of as solid waste as described above. The virus will only be handled by appropriately trained personnel.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

**Project Ref** 566/09.1

- **Date Ackn’d**: 04/03/2009
- **CU2 Project Title**: Deletion of combinations of the genes guaBA, thyA, dapD, set and sen from the Shigella flexneri chromosome.
- **Class**: Class 2
- **CultureVolClass2**: < 1 Litre
- **Consent Granted**: Not Applicable

---

**Project Additional Information**

- **Purposes of the contained use**: To create an attenuated strain of Shigella flexneri suitable for plasmid maintenance that is free of antibiotic resistance genes.
- **Recipient or parental organism**: Shigella flexneri 2a.
- **Host/vector system**
The host is Shigella flexneri 2a. There is no associated expression vector system.

Origin & function

Gene cassettes will be synthesised consisting of an antibiotic resistance gene flanked by the recognition sites for the native Xer site-specific recombinases (dif sites). This will in turn be flanked by regions of chromosomal homology upstream and downstream of the gene to be deleted. Competent S.flexneri cells will be prepared that contain a helper plasmid transiently expressing the lambda Red recombination functions from genes bet, exo and gam. These will be transformed with the linearised gene cassette, with deletion mutants identified by survival on the selective antibiotic. The deletion mutant will be cultured in the absence of the antibiotic, allowing cells to undergo site-specific recombination to delete the antibiotic resistance gene, in addition to the loss of the helper plasmid. These recombinants will be identified by antibiotic sensitivity and by PCR. The process will then be repeated for the other genes to be deleted. A maximum of three genes will be deleted per strain: set, sen and one of the following: guaBA thyA or dapD.

Evaluation of foreseeable effects

The proposed modifications are designed to significantly reduce the pathogenicity of Shigella flexneri. These mutations have been carried out by others and have resulted in strains that are safe and well-tolerated in mice and humans following oral or mucosal inoculation (see Risk Assessment).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste generated will be inactivated by disinfection overnight with a solution of sodium hypochlorite shown to reduce viability by greater than five orders of magnitude (S.flexneri is known to be sensitive to 1% sodium hypochlorite). Solid waste (mainly plastic disposables) will be double-bagged and placed in Wiva bins, then transported as clinical waste by a registered carrier for incineration off-site.

Is an emergency plan required according to regulation 20? N

Project Additional Information

Purposes of the contained use
To create a strain of BCG suitable for plasmid maintenance that is free of antibiotic resistance genes.

Recipient or parental organism
BCG.

Host/vector system
The host is BCG, with the vector system consisting of plasmids possessing the pAL5000 origin of replication for secreted expression of recombinant antigens.

Origin & function
Gene cassettes will be synthesised consisting of a hygromycin resistance gene flanked by the recognition sites for the native Xer site-specific recombinases (dif sites). Adjacent to this will be the tetracycline (tet) repressor gene, and the tet operator/promoter region. This will in turn be flanked by regions of chromosomal homology upstream and downstream of the essential chromosomesal genes to be targeted. Competent BCG cells will be prepared that contain a helper plasmid transiently expressing bacteriophage recombination functions. These will be transformed with the linearised gene cassette, with ORT strains identified by growth dependant on a sub-lethal
Evaluation of foreseeable effects

BCG has been used to safely immunise over three billion people worldwide. The proposed modifications will reduce the already minimal pathogenic effects of BCG through the metabolic burden of plasmid maintenance and recombinant protein expression. Additionally, the ORT strains will have expression of an essential gene made conditional on the presence of a sub-lethal concentration of tetracycline or of a plasmid possessing the tet operator sequence, thus increasing their biosafety. The HIVCONSV gene is a synthetic construct with no biochemical activity.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Project notified under transitional arrangements N

Historical Significant Changes

Project Additional Information

Purpose of the contained use
Production of an investigational drug for use in clinical trials (solid tumors).

Recipient or parental organism
This risk assessment covers the assay/process development and cGMP manufacturing process of a biological oncolytic virus up to a scale of 20L. The oncolytic virus is a CRAd (serotype 5) vector containing three distinct mutations in the adenovirus genome, through which infection of and replication in tumour cells is enhanced.

Host/vector system
The virus is based on human Adenovirus serotype 5 (Ad5 is transmissible via the mouth, nasopharynx or ocular conjunctiva and uniquely via the airborne route in a military setting. Ad5 is most commonly spread in children by the faecal/oral route although other strains may largely spread via contaminated water (Fields, Virology (1996): page 2153). Whilst adenoviruses can transform rodent cells numerous screens have failed to correlate the presence of adenoviruses with oncogenesis in humans. Willd-type Ad5 is classified as ACDP class 2 biologic according to UK HSE standards. The infection with Ad5 is very common within populations and within the Western world over
90% of individuals are sero-positive for Ad5 resulting in lifelong immunity.

The aim of Conditionally-Replicating Adenoviruses (CRAds) is to destroy tumour cells by selective virus replication and associated oncolysis and to spare healthy, non-tumour cells. The CRAd will be produced on A549 human lung cancer cells, which are well characterised and have been used in the laboratory since 1972. A549 cells do not contain adenoviral sequences excluding the possibility of homologous recombination between virus and host genome but they do support the replication and progeny production of the CRAd, thus identifying the producer cell line also as a permissive tumour cell type.

**Evaluation of foreseeable effects**

The virus will be propagated on human lung cancer cells A549. Uncontaminated cell lines serving as host for virus propagation pose little hazard to healthy individuals. Even if direct dermal inoculation were to occur it would likely result only in localised inflammation.

The virus may be transmitted by inhalation, ingestion, skin absorption or via needle stick injury. The determination of toxicity of replicating adenovirus in animal models is difficult as human Ad5 does not replicate in mice. Semi-permissive animal models for replication of human Ads are the syrian hamster and the cotton rat.

In case of accidental inoculation of an operator with the CRAd, it is expected that the infection is cleared efficiently in sero-positive individuals. Additionally, the capacity to replicate in normal, non-dividing tissue should be decreased compared to wild-type Ad5. However, it is expected that the level of cancer-specific virus replication is not complete and some leaky, residual replication in normal cells might be present. The level of residual replication in normal cells seems to be dependent on the cell type used. Virus replication/propagation could happen if the CRAd does infect cells that are actively dividing. However, again this event should be controlled by the operator's immunity against Ad5.

Further, several clinical studies with comparable oncolytic viruses have been done or are being conducted at the moment.

**Consideration of recombination events:**

As the production host A549 does not contain any adenoviral DNA sequence, homologous recombination can not happen. In case of infecting HEK293 or HER911 cells with the CRAd for assay purposs (small scale work only), recombination between adenoviral DNA within the host genome and DNA sequences within the CRAd can theoretically happen. However, this recombination happens at low frequency and several rounds of amplification are normally required to achieve detectable amounts of recombinant virus. As the virus will not be propagated for more than one round of infection on HEK293 or HER911 cells for assay purposes, the risk of accumulation of any reasonable amount of such a recombinant virus is very low.

**Consideration of interaction with other organisms and GMOs:**

When performing infectivity and titre assays the virus might be handled with other adenoviral vectors including E1-deleted, replication defective vectors. Even theoretical recombination between such vectors e.g. within a host cell or within an operator after accidental inoculation should not generate any more hazardous recombinant than already discussed above. The parallel handling with other viruses is not planned or expected. Working with the CRAd will be performed uner segregated conditions (spatiotemporal)

In summary, it is expected that the CRAd is less cytotoxic after accidental inoculation than wild-type Ad5.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1. Treatment where cell line only is present
Where the cell line alone is being handled small scale spills and liquid waste can be treated with 1% solution (final concentration) of sodium hypochlorite solution (0.12% available chlorine) for at least 5 minutes or 1% Virkon for least an hour. Large spills may also be treated with 1% (final concentration) Sodium Hypochlorite solution for 5 minutes or 1% Virkon for at least 1 hour. Inactivated spills may be mopped up with spill kits and disposed of as solid clinical waste. Contaminated cultures in bioreactors will be killed by heat sterilisation or via the following disinfectants: 2% TEGO, 0.5M NaOH or 10% sodium hypochlorite (1.2% final active chloride). The usage of 1% Virkon is also possible in non-cGMP labs. All these methods will result in a greater than 5-log kill.

2. Treatment of virus and infected cell cultures

a. Fluids of virus and/or infected cells

Virus containing fluids can be inactivated with either 0.5M NaOH or 10% sodium hypochlorite (1.2% active chloride) for a minimum of 1 hour to give a minimum 5-log kill.

B. Routine surface cleaning of stainless steel, bench surface and vinyl

Routine surface cleaning should be carried out with Biocide B spray for a minimum of 30 min contact time followed by wipe over with 70% IPA wpes. Stainless steel and bench surfaces are easily cleaned by this method whereby vinyl surface is more resistant to cleaning. Accordingly, surfaces in class II MSCs should be cleaned after each usage with Biocide B spray followed by a final wipe over with 70% IPA impregnated wipes. A full MSC clean (trays to be taken out) is performed according to a cleaning rota every month using Biocide B followed by 70% IPA cleaning. Theses methods will result in a greater than 5-log kill.

C. Fresh virus/infected cell spills (small and large)

Small-scale spills of the GMO (up to 50ml) will be inactivated by treatment with 10% sodium hypochlorite solution (1.2% available chloride) for a minimum of 5 minutes, the inactivated spill may then be absorbed with spill kits and disposed of as class II solid waste. Where the work performed presents the potential for a large spillage to occur spill kits should be kept in the immediate vicinity of the work such that they could be employed to stem the flow of virus as the room is vacated. Sufficient time should be allowed before re-entering the room to ensure there is no risk of inhaling any aerosols generated. The spill should then be treated with 10% (1.2% active chloride) sodium hypochlorite solution for 5 minutes, after which time the spill should be mopped up and any solid waste disposed of as Class II waste via wiva bins.

General handling:

All product contacting disposable materials (solid waste) will be handled as class II GMO waste and disposed of in wiva bins according to the local rules, waste will be removed from site for incineration by an approved contractor. Non-disposable product contacting items will be kept to an absolute minimum; glassware and any stainless steel items will be disinfected with 1% Sodium hypochlorite solution for 5 minutes prior to washing.

Storage:

The purified virus product and any associated samples will be double contained and stored at -80°C using a biotainer or other suitable, sealable, 'unbreakable' container as the secondary containment vessel. These containers will be labelled with a class 2 GMO label accordingly.

| Is an emergency plan required according to regulation 20? | N |

**Date Ackn’d** 03/06/2015

**CU2 Project Title** The production and purification of 3rd generation lentiviral vector at a scale of 2L using 4 plasmid transient

**Class** Class 2

**Culture Vol** 1-50 Litres

**Non-GMM** Consent Granted

**Project notified under transitional arrangements** N

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

Production of a modellentivirus to assess Cobras’ ability to produce high quality lentiviral vector.

**Recipient or parental organism**

The production process will utilise a four plasmid vector system to generate a third generation lentiviral vector. By splitting the vector system into 4 plasmids (3 helper plasm ids and 1 containing the vector genome plus transgene), the
The number of recombination events required to form a complete replication-competent vector increases, thereby reducing the possibility of making a replication-competent vector particle. The system is designed to produce 'self inactivating' lentiviral vector.

Replication-defective lentiviral vectors are not known to cause any diseases in humans or animals. The risks associated with working with lentiviral vectors are:

1) Lentiviral vectors produce 2 proteins common to HIV: If the lentiviral vector accidentally enters the human body there is a possibility that seroconversion towards HIV-1 viral proteins could result. The antibodies raised to the lentiviral vector proteins could result in a partially positive HIV test result.

2) Possibility of recombination event producing a replication competent lentiviral vector (RCL): If there was an extremely unlikely recombination event a replication competent vector could result which could infect and replicate in humans (Cancer/AIDS may result). Recombination would only pose a significant risk if the operator was HIV positive.

3) Possibility of oncogenesis via random chromosomal integration: Lentiviral vector transgene could integrate into chromosomal DNA. If the vector enters the body the transgene could integrate into the cells chromosome. If it were to integrate by an active gene, it could cause cancer.

Host/vector system

Transient transfection of HEK293T cells will be performed. HEK293T cells are a well characterised producer cell line for the production of lentiviral vector and are considered to be non-hazardous to humans.

Origin & function

The lentiviral vector will be produced using 4 separate plasmids co-transfected. The plasmids were produced in E.coli and purified by column chromatography. The lentiviral vector produced will be assessed for titre and quality by the customer to assess Cobra's ability to produce lentiviral vector. Successful completion of this task would lead to larger scale production which would be addressed in a future risk assessment and CU2 form.

Evaluation of foreseeable effects

The risks associated with working with lentiviral vector are:

1) Lentiviral vector produces 2 proteins common to HIV: If the lentiviral vector accidentally enters the human body there is a possibility that seroconversion towards HIV-1 viral proteins could result. The antibodies raised to the lentiviral vector proteins could result in a partially positive HIV test result. All open manipulations will be performed inside a class II microbial safety cabinet, (MSC); the 2L production upstream processing will be performed within the MSC as a closed system.

2) Possibility of recombination event producing a replication competent lentiviral vector (RCL): If there was an extremely unlikely recombination event a replication competent vector could result which could infect and replicate in humans (Cancer/AIDS may result). Recombination would only pose a significant risk if the operator was HIV positive. The 3rd generation 4 plasmid split gene transfection process has been proposed to perform this work, which is designed to prevent the formation of replicational competent lentiviral vector and offers the maximal biosafety.

3) Possibility of oncogenesis via random chromosomal integration: Lentiviral vector transgene could integrate into chromosomal DNA. If the vector enters the body the transgene could integrate into the cells chromosome. If it were to integrate by an active gene, it could cause cancer.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The most probable route of exposure for this work would be dermal via sharps (needle-sticks), absorption through exposed scratches or abrasions on the skin, or mucous membrane exposure of the eyes, nose and mouth. Another route would be inhalation via aerosols. Given the containment measures that will be used whilst handling the lentiviral
The likelihood of accidental inoculation is low. The following measures must be adhered to whilst handling lentiviral vector:

1. Physical Containment: All work will be performed in a room with negative pressure (not essential), a dedicated Class II MSC (left on continuously) and a dedicated tissue culture incubator. A warning sign must be posted on the door alerting personnel of the presence of lentiviral vector particles.

2. Personal Protective Equipment (PPE): A disposable non-sterile Tyvex suit or lab coat should be worn at all times. A fresh suit must be worn for each processing session. A full face shield will be worn. Double gloves and disposable oversleeves must be worn paying particular attention to cover bare skin at the wrists. Potentially contaminated gloves must be removed and replaced with new gloves before touching anything outside the MSC, such as the incubator.

3. Spill kit: The lab must have a spill kit comprising easy-to-read outline spill response procedures, gloves, masks, goggles, clean lab coat, paper towels to absorb contaminated liquids; disinfectant and a biohazardous waste bag.

4. Sharps: Sharps and glassware cannot be used.

5. Solid Waste: Everything that contacts lentiviral vector-containing solutions or vessels must be decontaminated or contained before leaving the MSC. Solid waste can be collected in a biohazard bag inside the MSC. Pipette tips must be collected in a dedicated, labelled sharps bin.

6. Liquid Waste: Must be decontaminated using the sodium hyperchlorite at > 5000ppm free chlorine for 1 hour before drain disposal.

7. Centrifugation: Centrifuge tubes must be prepared and sealed in the MSC. The centrifuge tubes must then be sealed into lidded centrifuge rotor buckets prior to removal from the MSC. Once centrifugation is complete the sealed centrifuge buckets must be returned to the MSC prior to opening.

8. Filtration: Ensure the filter is vented away from the MSC opening I operator.

With all of these precautions the possibility that an operator will be exposed to the organism is extremely unlikely. Dehydration alone reduces the titre by 90% within several hours, which means that with the prescribed cleaning procedures of 70%IPA and hyperchlorite (Biocide E), the possibility of any organisms escaping the class II containment is highly unlikely.

---

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid Waste: Everything that contacts lentiviral vector-containing solutions or vessels must be decontaminated or contained before leaving the MSC. Solid waste can be collected in a biohazard bag inside the MSC. Pipette tips must be collected in a dedicated, labelled sharps bin.

Liquid Waste: Must be decontaminated using the sodium hyperchlorite at > 5000ppm free chlorine for 1 hour before drain disposal.

Inactivation protocols:

1) Small spills in the MSC (<25mL) can be decontaminated by covering the spill with a dry wipe and applying Biocide E. The dry wipes should be removed to a biohazard bag/container within the MSC. Residual Biocide E can be removed by spraying with IPA and wiped using sterile IPA wipes. Replace any contaminated PPE.

2) Large spills (>25mL) in the MSC. The MSC must be left running and personnel removed from the room. A warning sign must be placed on the door advising personnel not to enter. Allow 30mins for possible aerosols to settle. Cover the spill with dry wipes, apply Biocide E and allow 20 minutes to inactivate the virus. Deposit soaked wipes in a biohazard bag in the MSC. Decontaminate the interior of the MSC by wiping down with IPA. Replace any contaminated PPE.

3) Spills outside the MSC: Spills generate aerosols therefore alert all personnel present in the area. Remove...
contaminated PPE. Exit the room and place a warning sign advising personnel not to enter. Allow 30 minutes for aerosols to settle. On re-entry to the room, wear fresh PPE and cover the spill with dry wipes. Soak with Biocide E and allow 20 minutes for the virus to be inactivated. Transfer soaked wipes to a biohazard bag. Wipe up any residual spill with dry wipes and then wipe-down with IPA. These inactivation methods will result in a minimum of a 5-log kill. All product-contacting disposable material (solid waste), will be treated as class II GMO waste and disposed of using WIVA bins.

Project Ref 566/15.2

Date Ackn'd 04/11/2015

CU2 Project Title The production and purification of 3rd generation lentiviral vector to a scale up to 10L using 4 plasmid transient transfection

Class 2

CultureVolClass2 < 1 Litre

Consent Granted

Project notified under transitional arrangements
Project Additional Information

Purposes of the contained use

To develop a production and purification process for the supply of Lentiviral Vector for client's clinical needs.

Recipient or parental organism

The production process will utilise a four plasmid vector system to generate a third generation lentiviral vector. By splitting the vector system into 4 plasmids (3 helper plasmids and 1 containing the vector genome plus transgene), the number of recombination events required to form a complete replication-competent vector increases, thereby reducing the possibility of making a replication-competent vector particle. The system is designed to produce 'self inactivating' lentiviral vector.

Additionally a commercial GFP lentiviral vector will be used as reference material for lentiviral titre assays. This virus has been produced using the third generation plasmid system and contains an inactivated 3' L TR.

Replication-defective lentiviral vectors are not known to cause any diseases in humans or animals.

The risks associated with working with lentiviral vectors are:
1) Lentiviral vectors produce 2 proteins common to HIV: If the lentiviral vector accidentally enters the human body there is a possibility that seroconversion towards HIV-1 viral proteins could result. The antibodies raised to the lentiviral vector proteins could result in a partially positive HIV test result.
2) Possibility of recombination event producing a replication competent lentiviral vector (RCL): If there was an extremely unlikely recombination event a replication competent vector could result which could infect and replicate in humans (Cancer/AIDS may result). Recombination would only pose a significant risk if the operator was HIV positive.
3) Possibility of oncogenesis via random chromosomal integration: Lentiviral vector transgene could integrate into chromosomal DNA. If the vector enters the body the transgene could integrate into the cells chromosome. If it were to integrate by an active gene, it could cause cancer.

Host/vector system

Transient transfection of HEK293FT cells will be performed. HEK293FT cells are a well characterised producer cell line for the production of lentiviral vector and are considered to be non-hazardous to humans.

Origin & function

The lentiviral vector will be produced using 4 separate plasmids co-transfected. The plasmids were produced in E.coli and purified by column chromatography. The final purified Lenti vector material will be delivered to the client to enable them to perform clinical trials.
### Evaluation of foreseeable effects

The risks associated with working with lentiviral vector are:

1. **Lentiviral vector produces 2 proteins common to HIV**: If the lentiviral vector accidentally enters the human body there is a possibility that seroconversion towards HIV-1 viral proteins could result. The antibodies raised to the lentiviral vector proteins could result in a partially positive HIV test result.

   All open manipulations will be performed inside a class 2 microbial safety cabinet, (MSC); the 2 x 3.9L production upstream processing will be performed within the MSC as a closed system.

2. **Possibility of recombination event producing a replication competent lentiviral vector (RCL)**: If there was an extremely unlikely recombination event a replication competent vector could result which could infect and replicate in humans (Cancer/AIDS may result). Recombination would only pose a significant risk if the operator was HIV positive. The 3rd generation 4 plasmid split gene transfection process has been proposed to perform this work, which is designed to prevent the formation of replicational competent lentiviral vector and offers the maximal biosafety.

3. **Possibility of oncogenesis via random chromosomal integration**: Lentiviral vector transgene could integrate into chromosomal DNA. If the vector enters the body the transgene could integrate into the cells chromosome. If it were to integrate by an active gene, it could cause cancer.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The most probable route of exposure for this work would be dermal via sharps (needle-sticks), absorption through exposed scratches or abrasions on the skin, or mucous membrane exposure of the eyes, nose and mouth. Another route would be inhalation via aerosols. Given the containment measures that will be used whilst handling the lentiviral vector the likelihood of accidental inoculation is low. The following measures must be adhered to whilst handling lentiviral vector:

1. **Physical Containment**: All open work will be performed in Class 2 MSCs (left on continuously). A warning sign must be posted on the door to the laboratory alerting personnel of the presence of lentiviral vector particles.

2. **Personal Protective Equipment (PPE)**: A disposable non-sterile Tyvex suit or lab coat should be worn at all times. A fresh suit must be worn for each processing session. A full face shield will be worn during operations that could result in aerosols if there was a system failure ie the use of peristaltic pumps. Double gloves and disposable oversleeves must be worn paying particular attention to cover bare skin at the wrists. Potentially contaminated gloves must be removed and replaced with new gloves before touching anything outside the MSC, such as the incubator.

3. **Spill kit**: The lab must have a spill kit comprising easy-to-read outline spill response procedures, gloves, masks, goggles, clean lab coat, paper towels to absorb contaminated liquids; disinfectant and a biohazardous waste bag.

4. **Sharps**: Sharps i.e. needles cannot be used.

5. **Solid Waste**: Everything that contacts lentiviral vector-containing solutions or vessels must be decontaminated or contained before leaving the MSC. Solid waste can be collected in a biohazard bag inside the MSC. Pipette tips must be collected in a dedicated, labelled container.

6. **Liquid Waste**: Must be decontaminated using sodium hypochlorite (> 5000ppm free chlorine) for 1 hour or 0.5M sodium hydroxide before drain disposal.

7. **Centrifugation**: Centrifuge tubes must be prepared and sealed in the MSC. The centrifuge tubes must then be sealed into lidded centrifuge rotor buckets prior to removal from the MSC. Once centrifugation is complete the sealed centrifuge buckets must be returned to the MSC prior to opening.

8. **Filtration**: Ensure the filter is vented away from the MSC opening I operator.

With all of these precautions the possibility that an operator will be exposed to the organism is extremely unlikely. Dehydration alone reduces the titre by 90% within several hours, which means that with the prescribed cleaning procedures of 70%IPA and hypochlorite (Biocide E), the possibility of any organisms escaping the class 2 containment is highly unlikely.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid Waste: Everything that contacts lentiviral vector-containing solutions or vessels must be decontaminated or contained before leaving the MSC. Solid waste can be collected in a biohazard bag inside the MSC. Pipette tips must be collected in a dedicated, labelled container.

All waste is treated with disinfectants for the stipulated period of time and solid waste is disposed in WIVA bins which are then bagged. Bags are then stored in a designated Class 2 storage container on the premises, this container is then taken by the contractor off site for incineration of the contents.

Liquid Waste: Must be decontaminated using sodium hypochlorite (> 2000 ppm free chlorine) or 0.5M sodium hydroxide before drain disposal.

Inactivation protocols:

1. Small spills in the MSC (< 2SmL) can be decontaminated by covering the spill with a dry wipe and applying Biocide E. The dry wipes should be removed to a biohazard bag/container within the MSC. Residual Biocide E can be removed by spraying with IPA and wiped using sterile IPA wipes. Replace any contaminated PPE.

2. Large spills (> 2SmL) in the MSC. The MSC must be left running and personnel removed from the room. A warning sign must be placed on the door advising personnel not to enter. Allow 30 mins for possible aerosols to settle. Cover the spill with dry wipes, apply Biocide E and allow 20 minutes to inactivate the virus. Deposit soaked wipes in a biohazard bag in the MSC. Decontaminate the interior of the MSC by wiping down with IPA. Replace any contaminated PPE.

3. Spills outside the MSC: Spills generate aerosols therefore alert all personnel present in the area. Remove contaminated PPE. Exit the room and place a warning sign advising personnel not to enter. Allow 30 minutes for aerosols to settle. On re-entry to the room, wear fresh PPE and cover the spill with dry wipes. Soak with Biocide E and allow 20 minutes for the virus to be inactivated. Transfer soaked wipes to a biohazard bag. Wipe up any residual spill with dry wipes and then wipe-down with IPA.

These inactivation methods will result in a minimum of a 5-log kill.

All product-contacting disposable material (solid waste), will be treated as class 2 GMO waste and disposed of using WIVA bins.

Is an emergency plan required according to regulation 20? N

The GMBSC have agreed that this organism should be handled as a class 2 GMO and therefore requires level 2 containment measures.
### Project Additional Information

**Purposes of the contained use**

To develop a production and purification process for the supply of Lentiviral Vector for client's clinical needs.

**Recipient or parental organism**

The production process will utilise a four plasmid vector system to generate a third generation lentiviral vector. By splitting the vector system into 4 plasmids (3 helper plasmids and 1 containing the vector genome plus transgene), the number of recombination events required to form a complete replication-competent vector increases, thereby reducing the possibility of making a replication-competent vector particle. The system is designed to produce 'self inactivating'
lentiviral vector. Additionally a commercial GFP lentiviral vector will be used as reference material for lentiviral titre assays. This virus has been produced using the third generation plasmid system and contains an inactivated 3’ L TR. Replication-defective lentiviral vectors are not known to cause any diseases in humans or animals.

The risks associated with working with lentiviral vectors are:
1) Lentiviral vectors produce 2 proteins common to HIV: If the lentiviral vector accidentally enters the human body there is a possibility that seroconversion towards HIV-1 viral proteins could result. The antibodies raised to the lentiviral vector proteins could result in a partially positive HIV test result.
2) Possibility of recombination event producing a replication competent lentiviral vector (RCL): If there was an extremely unlikely recombination event a replication competent vector could result which could infect and replicate in humans (Cancer/AIDS may result). Recombination would only pose a significant risk if the operator was HIV positive.
3) Possibility of oncogenesis via random chromosomal integration: Lentiviral vector transgene could integrate into chromosomal DNA. If the vector enters the body the transgene could integrate into the cells chromosome. If it were to integrate by an active gene, it could cause cancer.

Host/vector system

Transient transfection of HEK293FT cells will be performed. HEK293FT cells are a well characterised producer cell line for the production of lentiviral vector and are considered to be non-hazardous to humans.

Origin & function

The lentiviral vector will be produced using 4 separate plasmids co-transfected. The plasmids were produced in E.coli and purified by column chromatography. The final purified lentiviral vector material will be used for process development or delivered to the client for their own purposes.

Evaluation of foreseeable effects

The risks associated with working with lentiviral vector are:
1) Lentiviral vector produces 2 proteins common to HIV: If the lentiviral vector accidentally enters the human body there is a possibility that seroconversion towards HIV-1 viral proteins could result. The antibodies raised to the lentiviral vector proteins could result in a partially positive HIV test result.
2) Possibility of recombination event producing a replication competent lentiviral vector (RCL): If there was an extremely unlikely recombination event a replication competent vector could result which could infect and replicate in humans (Cancer/AIDS may result). Recombination would only pose a significant risk if the operator was HIV positive.
3) Possibility of oncogenesis via random chromosomal integration: Lentiviral vector transgene could integrate into chromosomal DNA. If the vector enters the body the transgene could integrate into the cells chromosome. If it were to integrate by an active gene, it could cause cancer.

Possible Effects of Infection of a Person with, or Exposure of a Person to, the Recombinant Vector:
The lentiviral vector transgene is intended for use in a CAR T cell treatment of Multiple Myeloma.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
The most probable route of exposure for this work would be dermal via sharps (needle-sticks), absorption through exposed scratches or abrasions on the skin, or mucous membrane exposure of the eyes, nose and mouth. Another
route would be inhalation via aerosols. Given the containment measures that will be used whilst handling the lentiviral vector the likelihood of accidental inoculation is low. The following measures must be adhered to whilst handling lentiviral vector:

Purposes of the contained use

To develop a production and purification process for the supply of Lentiviral Vector for client's clinical needs.

Recipient or parental organism

The production process will utilise a four plasmid vector system to generate a third generation lentiviral vector. By splitting the vector system into 4 plasmids (3 helper plasmids and 1 containing the vector genome plus transgene), the number of recombination events required to form a complete replication-competent vector increases, thereby reducing the possibility of making a replication-competent vector particle. The system is designed to produce 'self inactivating' lentiviral vector.

Additionally a commercial GFP lentiviral vector will be used as reference material for lentiviral titre assays. This virus has been produced using the third generation plasmid system and contains an inactivated 3' LTR.

Replication-defective lentiviral vectors are not known to cause any diseases in humans or animals. The risks associated with working with lentiviral vectors are:

1} Lentiviral vectors produce 2 proteins common to HIV: If the lentiviral vector accidentally enters the human body there is a possibility that seroconversion towards HIV-1 viral proteins could result. The antibodies raised to the lentiviral vector proteins could result in a partially positive HIV test result.

2} Possibility of recombination event producing a replication competent lentiviral vector (RCL): If there was an extremely unlikely recombination event a replication competent vector could result which could infect and replicate in humans (Cancer/AIDS may result). Recombination would only pose a significant risk if the operator was HIV positive.

3} Possibility of oncogenesis via random chromosomal integration: Lentiviral vector transgene could integrate into chromosomal DNA. If the vector enters the body the transgene could integrate into the cells chromosome. If it were to integrate by an active gene, it could cause cancer.

Host/vector system

Transient transfection of HEK293FT cells will be performed. HEK293FT cells are a well characterised producer cell
Origin & function

The lentiviral vector will be produced using 4 separate plasmids co-transfected. The plasmids were produced in E.coli and purified by column chromatography. The final purified Lentiviral vector material will be delivered to the client to enable them to perform clinical trials.

Evaluation of foreseeable effects

The risks associated with working with lentiviral vector are:
1) Lentiviral vector produces 2 proteins common to HIV: If the lentiviral vector accidentally enters the human body there is a possibility that seroconversion towards HIV-1 viral proteins could result. The antibodies raised to the lentiviral vector proteins could result in a partially positive HIV test result.
   All open manipulations will be performed inside a class 2 microbial safety cabinet, (MSC); the 5 x 3.9L production upstream processing as a closed system. Down stream processing will be performed as a closed system.
2) Possibility of recombination event producing a replication competent lentiviral vector (RCL): If there was an extremely unlikely recombination event a replication competent vector could result which could infect and replicate in humans (Cancer/AIDS may result). Recombination would only pose a significant risk if the operator was HIV positive.
   The 3rd generation 4 plasmid split gene transfection process has been proposed to perform this work, which is designed to prevent the formation of replicational competent lentiviral vector and offers the maximal biosafety.
3) Possibility of oncogenesis via random chromosomal integration: Lentiviral vector transgene could integrate into chromosomal DNA. If the vector enters the body the transgene could integrate into the cells chromosome. If it were to integrate by an active gene, it could cause cancer.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The most probable route of exposure for this work would be dermal via sharps (needle-sticks), absorption through exposed scratches or abrasions on the skin, or mucous membrane exposure of the eyes, nose and mouth. Another route would be inhalation via aerosols. Given the containment measures that will be used whilst handling the lentiviral vector the likelihood of accidental inoculation is low. The following measures must be adhered to whilst handling lentiviral vector:
1. Physical Containment: All open work will be performed in Class 2 MSCs (left on continuously). A warning sign must be posted on the; door to the laboratory alerting personnel of the presence of lentiviral vector particles.
2. Personal protective Equipment (PPE): Operators must change into appropriate PPE consisting of sterile Tyvek, overboots, facemask, safety glasses and double gloves. When working in the MSC, operators must wear two pairs of gloves and over-sleeves. Potentially contaminated gloves (outer-layer) must be removed to a Dispo-Safe container or waste bag inside the MSC and replaced before touching anything outside the MSC.
   Operators will wear a full face shield during pumping operations and safety glasses at all other times.
3. Spill Kit: The processing room must have a spill kit available. Procedures for dealing with spills must be displayed in the processing room. In addition all operators must undergo training including a mock spill event prior to the commencement of any work with LV.
4. Sharps: The use of sharps is forbidden when working with LV.
5. Solid Waste Disposal: Pipettes must be re sheathed post use and placed into a outer bag, the outer bag must be sealed using a cable tie, wiped with 70% IPA and immediately placed into a Wiva Bin. Waste bags must be sealed using cable ties and Dispo-Safe containers closed tightly prior to removal from the MSC. Dispo-Safe containers and yellow waste bags must be transferred to a Wiva Bin after sealing. When the Wiva Bins are full of processing has ended, bins must be sealed using the lids provided. Wiva Bins must be sprayed with Biocide E, left for 20 minutes and
then wiped with 70% IPA so that it can be transferred from the processing room. The bins are then handed over to Technical Support Services for disposal by incineration using external contractors.  

6. Liquid Waste Disposal: Liquid waste containing LV must be decontaminated either inside the MSC or by welding on a bag containing Sodium Hypochlorite to a final concentration of ≥ 1%. The waste must be decontaminated for at least 1 hour prior to disposal to the drain. Hypochlorite can cause a thermal reaction, care must be taken at all times.  

7. Centrifugation: Centrifuge tubes must be prepared and sealed in the MSC. The centrifuge tubes must then be sealed into lidded centrifuge rotor buckets prior to removal from the MSC. Once centrifugation is complete the sealed centrifuge buckets must be returned to the MSC prior to opening  

9. Filtration: Ensure the filter is vented away from the MSC opening / operator.  

With all of these precautions the possibility that an operator will be exposed to the organism is extremely unlikely. Dehydration alone reduces the titre by 90% within several hours, which means that with the prescribed cleaning procedures of 70%IPA and hypochlorite (Biocide E), the possibility of any organisms escaping the class 2 containment is highly unlikely.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Application for a derogation regarding the treatment of Class 2 waste:  
All waste is treated with disinfectants for the stipulated period of time and solid waste is disposed in red plastic bags or WIVA bins which are then bagged. Bags are then stored in a designated Class 2 storage container on the premises, this container is then taken by the contractor off site for incineration of the contents. Red

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1. Solid Waste: Everything that contacts lentiviral vector-containing solutions or vessels must be decontaminated or contained before leaving the MSC. Solid waste can be collected in a biohazard bag inside the MSC. Pipette tips must be collected in a dedicated, labelled container.  

All waste is treated with disinfectants for the stipulated period of time and solid waste is disposed in WIVA bins which are then bagged. Bags are then stored in a designated Class 2 storage container on the premises, this container is then taken by the contractor off site for incineration of the contents.  

2. Liquid Waste: Must be decontaminated using sodium hypochlorite (> 5000 ppm free chlorine) or 0.5M sodium hydroxide before drain disposal.  

3. General handling of HyperStacks. During incubation (post seeding) HyperStack vessels must be removed from the incubator by two operators and placed into a container suitable to hold the vessel and the capacity to hold up to 4L liquid volume in the event of spillages from the HyperStack. The vessel must be transported inside the aforementioned secondary container using a trolley. This applies to transport between the bench and incubator and rooms within the same building. These will be disposed of into the Class II waste disposal bags.  

HyperStack Decontamination and Disposal: Following harvest of the cells from the HyperStack, the vessel must be decontaminated by filling with Sodium Hypochlorite solution (1% final concentration) and leaving for >1 hour. This is to be drained into a sink and the vessel disposed of in a yellow biohazardous waste bag which are sealed with cable ties, sprayed with Biocide E, left for 20 minutes and then wiped with 70% IPA so that it can be transferred from the processing room. The bags are then handed over to Technical Support Services for disposal by incineration using external contractors.  

4. Storage of LV: LV product is stored at ≤-70°C in a controlled storage area with restricted personnel access. The material must be double contained and enclosed in a labelled, sealable GMO Class II storage bag.  

5. Use of peristaltic pumps. The operators must inspect all pump tubing to ensure integrity and that all connections are properly secured with cable ties. Once the tubing has been connected, the operator must ensure that no clamps are closed that will prevent pumping or cause a build up of pressure.

02/03/2022 Page 9994 of 15326
When pumping, the operators must initially run the pump at a low setting (-10% of maximum) and observe to ensure the tubing is running correctly through the pump head. The pump speed can then be gradually increased.

6. Use of Biowelder. Post welding, discarded tubing must be removed from the welder carefully so as not to open the sealed tubing and transferred immediately to the MSC where the tubing will be decontaminated in sodium hypochlorite to 1% for v/v ≥ 1 hour.

7. Seeding cells in HyperStacks: Pumping media containing HEK293T cells. Pumping: Refer to activity: Use of peristaltic pumps. Handling of HyperStacks: Refer to Activity: General handling of HyperStacks.

Decontamination of liquid waste: Waste medium, assumed to contain HEK293T (but no LV), will be pumped into a flexboy bag. Liquid waste containing LV must be decontaminated inside the MSC with 0.5M NaOH for a minimum of one hour prior to disposal to the drain. Spillages: All spillages of HEK293T cells (BRA 0136[2]) inside the MSC must be mopped up using helapets and decontaminated

8. Transfection of cells in HyperStacks: Pumping media containing DNA:PEI complexes.

Pumping: Refer to activity: Use of peristaltic pumps.
Welding: Refer to activity: Use of Biowelders.

• Handling of HyperStacks: Refer to Activity: General handling of HyperStacks.

Spillages: All spillages of medium containing DNA:PEI complexes must be mopped up using helapets and the area cleaned using 70% IPA spray (5 minutes contact), followed by a final wipe using dry wipes.

9. Media exchange post-transfection/ final harvest of supernatant containing LV: Pumping media containing LV.

Pumping: Refer to activity: Use of peristaltic pumps.
Welding: Refer to activity: Use of Biowelders.

• Handling of HyperStacks: Refer to Activity: General handling of HyperStacks.

Decontamination of liquid waste: Waste medium, assumed to contain LV particles, will be pumped into a flexboy bag. This must, be decontaminated in the MSC by pumping into the bag a volume of 12% sodium hypochlorite sufficient to make a final concentration of 1% v/v sodium hypochlorite. Decontamination of LV-containing solutions must be performed for ≥ 1 hour prior to disposal.

Spillages: Decontamination of spillages of materials containing LV must be performed by addition of sodium hypochlorite to 1% v/v for ≥ 1 hour.

10. Harvest of HYPERStack vessels. Welding: Refer to activity: Use of Biowelders. HYPERStacks shall be welded onto recovery line(s) of the first closed system assembly. HYPERStacks will be tilted so that supernatant drains into central pooling bag. Two HYPERStacks can be drained at the same time before being sealed and replaced with next vessel.

11. Clarification of Lentiviral vector containing Culture Supernatant.

• Welding: Refer to activity: Use of Biowelders

Inspect tubing to be used for signs of damage prior to use. Perform a finger trace of the filtration flow path prior to filtration to ensure that no blockages exist and that all valves are opened/closed as appropriate. Full face visors must be worn during all pumping activities. Start pumping at a low speed, observing for signs of high pressure build up prior to increasing pump speed. Filtration pressure shall be monitored throughout filtration and shall be terminated if the inlet pressure exceeds 14psi. When venting filters, the vent port shall be directed away from the operator/ working hatch. The vent port shall be opened/closed using an ethanol soaked wipe. Should PPE become soiled during venting process, this should be replaced with clean PPE (i.e. gloves/oversleeves).

Sampling shall be performed using appropriate sized pipettes. Pipettes must be re sheathed post use and placed into a second labelled bag inside the MSC, the outer bag must be sealed using a cable tie, sprayed with Biocide E, left for 20 minutes and then wiped with 70% IPA transferred out of the MSC and immediately placed into a Wiva Bin.
12. Benzoase® digestion of Lentiviral vector containing cell culture supernatant.
Welding: Refer to activity: Use of Biowelders
Sampling shall be performed using appropriate sized pipettes. Pipettes must be re sheathed post use and placed into a outer bag, the outer bag must be sealed using a cable tie, wiped with 70% IPA and immediately placed into a Wiva Bin. Prior to removal from the MSC for temperature controlled incubation, all vessels containing Lentiviral vector material must be sealed. Vessels must remain sealed throughout any period of time that the vessel is outside of the MSC environment.
During temperature controlled incubation the collection bag will be placed onto the WAVE rocking platform, this will be heated to 37°C, care must be taken to avoid burns and prevent crush events from moving parts during mixing.
13. TFF of Lentiviral vector containing cell culture supernatant.
Welding: Refer to activity: Use of Biowelders
Inspect tubing to be used for signs of damage prior to use. Perform a finger trace of the TFF flow path prior to filtration to ensure that no blockages exist and that all valves are opened/ closed as appropriate. Pressure sensors shall be used throughout processing to monitor for signs of system over pressure. Filter leak test will be performed prior to TFF this involves monitoring a higher pressure over the Filter and observing for any reduction in pressure over time. Clamps must be securely in place on the tubing post filter and formlation buffer used for priming pumped at low speeds to increase the pressure to a maximum of 14psi (1 bar), clamps will then be securely closed pre filter to maintain pressure. Pressure monitors will be used to see any reduction in pressure over time. Start pumping at a low speed, observing for signs of high pressure buildup prior to increasing pump speed. Decontamination of LV-containing tubing rig must be performed for ≥ 1 hour prior to disposal. This must be decontaminated by pumping into the TFF rig a volume of 12% sodium hypochlorite sufficient to make a final concentration of 1 % v/v sodium hypochlorite.
14. Final fill of Lentiviral vector. Sampling will performed using a appropriate sized pipette.
Pipettes must be re sheathed post use and placed into a outer bag, the outer bag must be sealed using a cable tie, wiped with 70% IPA and immediately placed into a Wiva Bin ..
All pipetting into appropriately sized containers must be performed within the MSC.
15. Transfer and Storage. All samples shall be labelled with preprinted labels detailing that the product is a Class II organism and transferred out of the MSC prior to any decontamination methods. All sample containment vessels must be suitable for storage ≤-650C. All sample containment must be stored within a secondary containment vessel, ideally a plastic box with lid. All samples will be stored in controlled storage with restricted personnel access.
16. Cleaning of spillages. Full details regarding spillage handling are found in GMO Risk assessment GM/2015/04. Spill procedure: Procedures for dealing with spills must be displayed in the room. In addition all operators should undergo training including a mock spill event prior to the commencement of any work with LV.
Inactivation protocols: Lentiviral Vector Spill procedures
Lentiviral Vector Spill Procedures
1. Small spills (<2ML) in the MSC.
Cover spill with a fresh Helapet.
Once aliquotting complete remove Helapet to a biohazard bag
Spray the MSC with IPA and wipe with a sterile IPA wipes
2. Small spills (<25ML)) in the MSC
Cover spill with a dry wipe and apply Biocide E (20 mins contact time)
Remove to a biohazard bag/ container within the MSC
Remove residual Biocide E by spraying with IPA and wiping with sterile IPA wipes

Replace and contaminated PPE
3. Large spills (>25mL) in the MSC
Ensure MSC is running and remove personnel from the room.

For very large spills which may spread beneath the metal of the MSC (200mL), use barriers to contain the liquid

Place a warning sign on the door advising personnel not to enter

Allow 30 minutes for possible aerosols to settle

Cover the spill with dry wipes, apply Biocide E and allow 20 minutes to inactivate the virus

Deposit soaked wipes in a biohazard bag/container within the MSC and seal
Decontaminate the interior of the MSC by wiping down with IPA

Replace any contaminated PPE
4. Spills outside the MSC
Spills generate aerosols therefore alert all personnel present in the area

For very large spills (>100mL), use absorbent barriers to contain the spill

Exit the room and place a warning sign on the door advising personnel not to enter

Allow 30 minutes for the aerosols to settle

On re-entry to the room, wear fresh PPE and cover the spill with dry wipes or absorbent mats in a large spill

Soak with Biocide E and allow 20 minutes for the virus to be inactivated

Transfer soaked wipes to a biohazard bag/container and seal
Wipe up any residual spill with dry wipes
Wipe down with IPA

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The GMSSC have agreed that this organism should be handled as a class 2 GMO and therefore requires level 2 containment measures.

Purposes of the contained use

To develop a platform production and purification method as a part of the process and research development activities; to use the established method and/or transferred method of production for the supply of the lentiviral vector for client's clinical requirements.
The production process will utilise a four plasmid vector system to generate a third generation lentiviral vector. By splitting the vector system into 4 plasmids (3 helper plasmids and 1 containing the vector genome plus transgene), the number of recombination events required to form a complete replication-competent vector increases, thereby reducing the possibility of making a replication-competent vector particle. The system is designed to produce 'self inactivating' lentiviral vector.

The components encoded by the plasmids are:
- Plasmid 1 - encodes gag (matrix and core proteins) and pol (polymerase, encoding protease, integrase and reverse transcriptase) proteins required for viral vector assembly;
- Plasmid 2 - encodes the Rev protein under a ubiquitous promoter (e.g. RSV, CMV), which acts on the rev responsive element (RRE) sequence to assist in the transportation of the viral mRNA into the cytoplasm;
- Plasmid 3 - provides the envelope function. Commonly, a broad-specificity VSV-G (vesicular stomatitis virus glycoprotein G) is used as the envelope. Any other common envelope whether with broad specificity or tissue-specific tropism can be used in this system, provided it is non-toxic and has been separately evaluated in a risk-assessment;
- Plasmid 4 - transgene encoded between 2 LTRs under control of any tissue-specific mammalian or any other non-specific promoter, depending on the disease indication for LV use. LTRs in 3rd generation lentivirus system are self-inactivating (SIN) and transcription is regulated by a mammalian promoter at the 5’ LTR.

Any common reporter transgene constructs, likely to be green fluorescent protein (GFP), Luciferase or LacZ will be used as a transgene. These transgenes are not known to be associated with any hazards for human health. Other transgenes will be determined by the client’s indication/target and will be non-oncogenic.

Recipient or parental organism

The production process will utilise a four plasmid vector system to generate a third generation lentiviral vector. By splitting the vector system into 4 plasmids (3 helper plasmids and 1 containing the vector genome plus transgene), the number of recombination events required to form a complete replication-competent vector increases, thereby reducing the possibility of making a replication-competent vector particle. Any common reporter transgene constructs, likely to be green fluorescent protein (GFP), Luciferase or LacZ will be used as a transgene. These transgenes are not known to be associated with any hazards for human health. Other transgenes will be determined by the client’s indication/target and will be non-oncogenic.

Origin & function

The lentiviral vector will be produced using 4 separate plasmids co-transfected into mammalian packaging cell line using PEI or Calcium phosphate reagents. The plasmids encode for the essential structural and genome components of the lentivirus including gene of interest to be delivered to the target cells. The plasmids are produced in E.coli, under appropriate antibiotic selection.

Intended uses of the final purified Lentiviral vector material will include: process development work, assay development work for internal use at Cobra Biologics as a part of platform process development; material supply to client and research collaborators as research or GMP grade material.

Evaluation of foreseeable effects

The risks associated with working with lentiviral vector are:
1) Lentiviral vector produces 2 proteins common to HIV: If the lentiviral vector accidentally enters the human body there is a possibility that seroconversion towards HIV-1 viral proteins could result. The antibodies raised to the lentiviral vector proteins could result in a partially positive HIV test result.

All open manipulations will be performed inside a class 2 microbial safety cabinet, (MSC); otherwise all processes will be performed within a closed system. This will virtually eliminate the risk of exposure to any lentivirus containing aerosols. PPE worn by the operator will protect from accidental dermal exposure.

2) Possibility of recombination event producing a replication competent lentiviral vector (RCL). If there was an
extremely unlikely recombination event a replication competent vector could result which could infect and replicate in humans (Cancer/AIDS may result). Recombination would only pose a significant risk if the operator was HIV positive.

The 3rd generation lentiviral vector system only will be used. This system relies on the use of 4 plasmids split gene transfection process, which is designed to prevent the formation of replication competent lentiviral vector and offers the maximal biosafety.

3) Possibility of oncogenesis via random chromosomal integration: Lentiviral vector transgene could integrate into chromosomal DNA. If the vector enters the body the transgene could integrate into the cell's chromosome. If it were to integrate within an active gene, it could cause cancer. The risk of introducing sufficient amount of lentivirus vector via accidental exposure route (e.g. inhalation of aerosols, skin exposure) is extremely low.

The most probable route of exposure for this work would be dermal via sharps (needle-sticks), absorption through exposed scratches or abrasions on the skin, or mucous membrane exposure of the eyes, nose and mouth. Another route would be inhalation via aerosols. Given the containment measures that will be used whilst handling the lentiviral vector the likelihood of accidental inoculation is low. The following measures will be adhered to by the trained operator whilst handling lentiviral vector:

1. Physical Containment: All open work will be performed in Class 2 MSCs (left in continuously). A warning sign must be posted on the door to the laboratory alerting personnel of the presence of lentiviral vector particles.
2. Personal Protective Equipment (PPE): A disposable non-sterile Tyvex suit or lab coat should be worn at all times. A fresh suit must be worn for each processing session. A full face shield will be available to be worn during operations that could result in aerosols if there was a system failure i.e. the use of peristaltic pumps. Double gloves and disposable oversleeves must be worn paying particular attention to cover bare skin at the wrists. Potentially contaminated gloves must be removed and replaced with new gloves before touching anything outside the MSC, such as the incubator.
3. Spill kit: The lab must have a spill kit comprising easy-to-read outline spill response procedures, gloves, masks, goggles, clean lab coat, paper towels to absorb contaminated liquids; disinfectant and a biohazardous waste bag.
4. Sharps: Sharps i.e. needles cannot be used.
5. Solid Waste: Everything that contacts lentiviral vector-containing solutions or vessels must be decontaminated or contained before leaving the MSC. Solid waste can be collected in a biohazard bag inside the MSC. Pipette tips must be collected in a dedicated, labelled container.
6. Liquid Waste: Must be decontaminated using sodium hypochlorite (> 5000ppm free chlorine) for 1 hour or 0.5M sodium hydroxide before drain disposal.
7. Centrifugation: Centrifuge tubes must be prepared and sealed in the MSC. The centrifuge tubes must then be sealed into lidded centrifuge rotor buckets prior to removal from the MSC. Once centrifugation is complete the sealed centrifuge buckets must be returned to the MSC prior to opening.
8. Filtration: The filter must be vented away from the MSC opening / operator.
9. All tangential flow filtration (TFF) operations will be performed within a MSC.

With all of these precautions the possibility that an operator will be exposed to the organism is extremely unlikely. Dehydration alone reduces the titre by 90% within several hours, which means that with the prescribed cleaning procedures of 70% IPA and hypochlorite (Biocide E), the possibility of any organisms escaping the class 2 containment is highly unlikely.

Risks to the environment: The lentiviral vector will only be manipulated inside an MSC. Transfer of the lentiviral vector from the MSC to storage will be performed in sealed containers with secondary containment in place. Lentiviral vectors are fragile and would not survive long in the environment; therefore the risk to the environment is negligible and classed as Class 1. All waste will be inactivated following an approved appropriate procedure.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

| None |

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

| Solid Waste: Everything that contacts lentiviral vector-containing solutions or vessels must be decontaminated or contained before leaving the MSC. Solid waste can be collected in a biohazard bag inside the MSC. Pipette tips must be collected in a dedicated, labelled container. All waste is treated with disinfectants for the stipulated period of time and solid waste is disposed in WIVA bins which are then bagged. Bags are then stored in a designated Class 2 storage container on the premises, this container is then taken by the contractor off site for incineration of the contents. Liquid Waste: Must be decontaminated using sodium hypochlorite (> 5000ppm free chlorine) or 0.5M sodium hydroxide before drain disposal. Inactivation protocols: 1) Small spills in the MSC (525mL) can be decontaminated by covering the spill with a dry wipe and applying Biocide E. The dry wipes should be removed to a biohazard bag/container within the MSC. Residual Biocide E can be removed by spraying with IPA and wiped using sterile IPA wipes. Replace any contaminated PPE. 2) Large spills (>25mL) in the MSC. The MSC must be left running and personnel removed from the room. A warning sign must be placed on the door advising personnel not to enter. At least 30 mins will be allowed for possible aerosols to settle. The spills will be covered with dry wipes, Biocide E will be applied and allowed to work for at least 20 minutes in order to inactivate the virus. Soaked wipes will be disposed off into a biohazard bag in the MSC. The interior of the MSC will be decontaminated by wiping down with IPA. Any contaminated PPE will be immediately replaced. 3) Spills outside the MSC: Spills generate aerosols therefore all personnel present in the area will be alerted of any spills. The following steps for managing spills will be adopted: 1. Remove contaminated PPE; 2. Exit the room and place a warning sign advising personnel not to enter; 3. Allow 30 minutes for aerosols to settle; 4. On re-entry to the room, wear fresh PPE and cover the spill with dry wipes; 5. Soak with Biocide E and allow 20 minutes for the virus to be inactivated; 6. Transfer soaked wipes to a biohazard bag; 7. Wipe up any residual spill with dry wipes and then wipe-down with IPA. These inactivation methods will result in a minimum of a 5-log kill. All product-contacting disposable material (solid waste), will be treated as Class 2 GMO waste and disposed of using clearly labelled WIVA bins. |

**Project Ref 566/19.2**

- **Date Ackn'd**: 31/01/2019
- **CU2 Project Title**: This risk assessment covers the storage and handling of stable cell lines generated for the production of retroviral vectors. The cell lines express Retroviral vector Moloney murine leukemia virus (MoMLV)
- **Class**: Class 2
- **Culture Volume Class 2**: ≤ 1 Litre
- **Non-GMM**: Not Applicable
- **Consent Granted**: Project notified under transitional arrangements

**Project Additional Information**

- **Purposes of the contained use**: Generation of HEK293 stable producer Master Cell Bank.
- **Recipient or parental organism**: The cell lines express one or more of retroviral vector plasmids (MLV gagpol under heterologous promoter, lacking...
full packaging signal, RD114 heterologous envelope under heterologous promoter and MLV genome plasmid containing CAR proteins and/or suicide genes and/or selection markers and/or surface tags) These risk assessment will cover two CAR's targeting two different target molecules I receptors.

Host/vector system

Transient transfection of immortalised human embryonic kidney (HEK)293-related cells including but not limited to HEK293T) will be performed. HEK293 cells are a well characterised producer cell line for the production of lentivirus and other gene therapy vectors and are considered to be non-hazardous to humans. The stable producer cells are based on the HEK293 standard human cell line; cells have been genetically modified to produce retroviral vectors. The cells are unable to exist for long periods of time outside the body and are extremely sensitive to temperature, pH, osmolality and radiation. They will not replicate under normal environmental conditions and therefore do not represent an adverse risk to the environment. The retroviral vector could theoretically transduce a broad range of cell types of multiple species and theoretically express the CAR and/or suicide gene within those cells. Expression of these proteins is unlikely to cause harm if accidentally transferred to humans. Due to the inherent instability of the retroviral vector outside of the cell, the risk of this is extremely low.

The retroviral vector contains only the minimal elements required for genome packaging, integration and transgene expression and is replication deficient, in the unlikely event of accidental transfer to human, it will not propagate. The separation of the 3 components and the absence of significant regions of homology between components (gagpol, envelope and genome) minimises the chance of production of replication-competent virus due to recombination events. Retroviral transduced cells are not expected to be of any greater hazard than the original unmodified cells.

Origin & function

Evaluation of foreseeable effects

1) There are only two theoretical scenarios for in which the cells could pose a risk to human health; accidental release during transport or transfer via needle stick injury. Thus the risk to human health takes precedence.
2) There are only two theoretical scenarios for AUTO2, AUTO3 and AUTO4 transmission; namely accidental release during transport or transfer via needle stick injury. Accidental release would result in environmental exposure, but with no adverse effects expected due to the nonpersistence or replication of cells.
   Needle stick injury could introduce modified cells into the exposed person. Under these circumstances, the cells would be recognised as non-self cells (allo-reaction) and be eliminated through the individual's innate and adaptive immune system. Given the small magnitude of possible dose, adverse event would likely be limited to a normal immune reaction to non-self cells.
3) The retroviral vectors produced will be replication deficient vectors derived from either MoMLV or HIV. The vectors are replication deficient by design since the viral proteins that confer infectivity and replication are not present within the viral RNA packaged into vector particles. The vector can thus undergo one round of transduction only. The only way for the retroviral vector to become replication competent would be by a series of recombination events. In order to minimise this possibility, the genes encoding viral proteins have been separated onto different plasmids using the so-called split packaging design. Furthermore, the plasmids used in the production of vectors do not contain homology with each other and thus the generation of replication competent retroviral vectors by homologous recombination is extremely unlikely.
Accidental insertion of the vector genome into human cells could theoretically lead to insertional mutagenesis in the transduced cells; the likelihood of the latter is extremely low. Any vector that may enter the body, either by needle stick injury or other means, would be inactivated by human serum. RD114 pseudotyped retroviral vectors have a half-life of 4-8 hours at 37°C, and although no conclusive data is available on the half-life of RD114 envelope in the presence of sera, VSV-G pseudotyped retroviral vectors have an in vivo half-life in the order of a few minutes (DePolo et al. 2000). Furthermore, cell transduction by retroviral vectors in the absence of facilitating agents, such as RetroNectin®️, is very inefficient. It is unlikely a clinical event would be detected.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The following measures detailed in points 1–5 must be adhered to whilst handling the stable producer cell line.

Inactivation protocols:
1) Solid Waste: Everything that contacts the stable producer cell line must be decontaminated or contained before leaving the Class II MSC. Solid waste must be collected in a biohazard bag inside the Class II MSC. Pipette tips must be collected in a dedicated labelled container.
2) Liquid Waste: Liquid waste must be decontaminated using 1% final concentration sodium hypochlorite (>5000ppm free chlorine) for 1 hour before drain disposal.
3) Small spills in the Class II MSC <25mL can be decontaminated by covering the spill with a dry wipe and applying Klercide Sporicidal Active Chlorine. The dry wipes must be removed to a biohazard waste bag within the Class II MSC. Residual Klercide Sporicidal Active Chlorine can be removed by spraying with IPA and wiping using a sterile IPA wipe. Replace any contaminated PPE.
4) Large spills in the MSC >25mL. The MSC must be left running and personnel evacuated from the room. A warning sign must be placed on the door instructing personnel not to enter. Allow 30 minutes for any possible aerosols to settle. Return to the spill and cover with dry wipes, apply Klercide Sporicidal Active Chlorine and allow 20 minutes to inactivate the retroviral vector. Deposit soaked wipes in a biohazard bag within the Class II MSC. Decontaminate the interior of the Class II MSC by wiping with a sterile IPA wipe. Replace any contaminated PPE.
5) Spill outside the MSC generate aerosols therefore alert all personnel present in the area. Remove contaminated PPE and exit the room, place a warning sign instructing personnel not to enter. Allow 30 minutes for any potential aerosols to settle. On re-entry to the room wear fresh PPE and cover the spill with dry wipes. Soak with Klercide Sporicidal Active Chlorine and allow 20 minutes for the retroviral vector to be inactivated. Transfer soaked wipes to a biohazard bag. Wipe any residual spill with sterile IPA wipes.

All product contacting disposable material (solid waste), will be treated as Class 2 GMO waste and disposed of using WIVA bins or red plastic hazardous waste bags as appropriate.

Project Ref 566/20.1

This risk assessment covers the receipt, storage, and handling of stable cell lines generated for the production of retroviral vectors. The cell lines express retroviral vector Moloney murine leukemia virus (MoMLV).
Purposes of the contained use

Generation of H EK293T stable producer Master Cell Bank.

Recipient or parental organism

The cell line expresses one or more of retroviral vector plasmids (MLV gagpol under heterologous promoter, lacking full packaging signal, RD114 heterologous envelope under heterologous promoter and MLV genome plasmid containing CAR proteins and/or suicide genes and/or selection markers and/or surface tags).

Host/vector system

HEK293T cells are a well characterised producer cell line for the production of lentivirus and other gene therapy vectors. These cell lines are considered to be non-hazardous to humans. The stable producer cells are based on the HEK293T standard human cell line; cells have been genetically modified to produce retroviral vectors. The cells are unable to exist for long periods of time outside the body and are extremely sensitive to temperature, pH, osmolality and radiation. They will not replicate under normal environmental conditions and therefore do not represent an adverse risk to the environment. The retroviral vector could theoretically transduce a broad range of cell types of multiple species and theoretically express the CAR, co-receptors, and/or suicide gene within those cells. Expression of these proteins is unlikely to cause harm if accidentally transferred to humans. Due to the inherent instability of the retroviral vector outside of the cell, the risk of this is extremely low. The retroviral vector contains only the minimal elements required for genome packaging, integration and transgene expression and is replication deficient, in the unlikely event of accidental transfer to human, it will not propagate. The separation of the 3 components and the absence of significant regions of homology between components (gagpol, envelope and genome) minimises the chance of production of replication-competent virus due to recombination events. Retroviral transduced cells are not expected to be of any greater hazard than the original unmodified cells.

Origin & function

Evaluation of foreseeable effects

1) There are only two theoretical scenarios in which unmodified HEK293T cells could pose a risk to human health; accidental release during transport or transfer via needle stick injury. Thus the risk to human health takes precedence.
2) There are only two theoretical scenarios for transmission; namely accidental release during transport or transfer via needle stick injury. Accidental release would result in environmental exposure, but with no adverse effects expected due to the nonpersistence or replication of cells.
   Needle stick injury could introduce modified cells into the exposed person. Under these circumstances, the cells would be recognised as non-self cells (allo-reaction) and be eliminated through the individual's innate and adaptive immune system. Given the small magnitude of possible dose, adverse event would likely be limited to a normal immune reaction to non-self cells.
3) The retroviral vector is spontaneously expressed into supernatant by the cell line during growth. The MoM LV-derived vector is replication deficient by design since the viral proteins that confer infectivity and replication are not present within the viral RNA packaged into vector particles. The vector can thus undergo one round of transduction only. The only way for the retroviral vector to become replication competent would be by a series of
recombination events. In order to minimise this possibility, the genes encoding viral proteins have been separated onto different plasmids using the so-called split packaging design. Furthermore, the plasmids used in the production of vectors do not contain homology with each other and thus the generation of replication competent retroviral vectors by homologous recombination is extremely unlikely.

Accidental insertion of the vector genome into human cells could theoretically lead to insertional mutagenesis in the transduced cells; the likelihood of the latter is extremely low.

Any vector that may enter the body, either by needle stick injury or other means, would be inactivated by human serum. RD114 pseudotyped retroviral vectors have a half-life of 4-8 hours at 3°C, and although no conclusive data is available on the half-life of RD114 envelope in the presence of sera, VSV-G pseudotyped retroviral vectors have an in vivo half-life in the order of a few minutes (DePolo et al. 2000). Furthermore, cell transduction by retroviral vectors in the absence of facilitating agents, such as RetroNectin®, is very inefficient. It is unlikely a clinical event would be detected.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not Applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

The following measures detailed in points 1-5 must be adhered to whilst handling the stable producer cell line.

**Inactivation protocols:**

1) **Solid Waste:** Everything that contacts the stable producer cell line must be contained before leaving the Class II MSC. Solid waste, such as cell culture flasks, media bottles, and reagent or waste vessels must have lids tightly secured inside the Class II MSC, ready to be collected in a biohazard bag immediately upon removal. Stripettes must be re-sheathed, and pipette tips must be collected in a dedicated labelled container.

2) **Liquid Waste:** Liquid waste must be decontaminated using 1% final concentration sodium hypochlorite (>5000ppm free chlorine) or sodium hydroxide (1 M) for a minimum of 1 hour before drain disposal.

3) **Small spills in the Class II MSC <25mL** can be decontaminated by covering the spill with a dry wipe and applying an appropriate volume of Klercide Sporicidal Active Chlorine. Cell culture flasks and/or vessels containing cell suspension must be wiped with 70/130 IPA and removed from the Class II MSC before application of Klercide Sporicidal Active Chlorine. The contaminated dry wipes must be removed to a biohazard waste bag within the Class II MSC. Residual Klercide Sporicidal Active Chlorine can be removed by spraying with IPA and wiping using a sterile IPA wipe. Replace any contaminated PPE.

4) **Large spills in the MSC >25mL.** The MSC must be left running and personnel evacuated from the room. A warning sign must be placed on the door instructing personnel not to enter. Allow 30 minutes for any possible aerosols to settle. Return to the spill and cover with dry wipes, apply Klercide Sporicidal Active Chlorine and allow 20 minutes to inactivate the retroviral vector. Deposit soaked wipes in a biohazard bag within the Class II MSC. Decontaminate the interior of the Class II MSC by wiping with a sterile IPA wipe. Replace any contaminated PPE.

5) **Spill outside the MSC generate aerosols therefore alert all personnel present in the area.** Remove contaminated PPE and exit the room, place a warning sign instructing personnel not to enter. Allow 30 minutes for any potential aerosols to settle. On re-entry to the room wear fresh PPE and cover the spill with dry wipes. Soak with Klercide Sporicidal Active Chlorine and allow 20 minutes for the retroviral vector to be inactivated. Transfer soaked wipes to a biohazard bag. Wipe any residual spill with sterile IPA wipes.
All product contacting disposable material (solid waste), will be treated as Class 2 GMO waste and disposed of using WIVA bins or red plastic hazardous waste bags as appropriate.

The Genetically Modified Biological Safety Committee at Cobra Biologics have agreed that this organism should be handled as Class 2 GMO and therefore requires level 2 containment measures.

#### Purposes of the contained use

| Generation of HEK293T stable producer Master Cell Bank |

#### Recipient or parental organism

| HEK293T cells are a well characterised producer cell line for the production of lentivirus and other gene therapy vectors. These celllinse are considered to be non-hazardous to humans. The stable producer cells are based on the HEK293T standard human cell line; cells have been genetically modified to produce retroviral vectors. The cells are unable to exist for long periods of time outside the body and are extremely sensitive to temperature, pH, osmolality and radiation. They will not replicate under normal environmental conditions and therefore do not represent an adverse risk to the environment. The retroviral vector could theoretically transduce a broad range of cell types of multiple species and theoretically express the CAR, co-receptors, and/or suicide gene within those cells. Expression of these proteins is unlikely to cause harm if accidentally transferred to humans. Due to the inherent instability of the retroviral vector outside of the cell, the risk of this is extremely low. The retroviral vector contains only the minimal elements required for genome packaging, integration and transgene expression and is replication deficient, in the unlikely event of accidental transfer to human, it will not propagate. The separation of the 3 components and the absence of significant regions of homology between components (gagpol, envelope and genome) minimises the chance of production of replication-competent virus due to recombination events. Retroviral transduced cells are not expected to be of any greater hazard than the original unmodified cells. |

#### Host/vector system

| Origin & function |

---

02/03/2022
Evaluation of foreseeable effects

1) There are only two theoretical scenarios in which unmodified HEK293T cells could pose a risk to human health; accidental release during transport or transfer via needle stick injury. Thus the risk to human health takes precedence.
2) There are only two theoretical scenarios for AUT04 transmission; namely accidental release during transport or transfer via needle stick injury.

Accidental release would result in environmental exposure, but with no adverse effects expected due to the nonpersistence or replication of cells.

Needle stick injury could introduce modified cells into the exposed person. Under these circumstances, the cells would be recognised as non-self cells (allo-reaction) and be eliminated through the individual’s innate and adaptive immune system. Given the small magnitude of possible dose, adverse event would likely be limited to a normal immune reaction to non-self cells.

3) The retroviral vector is spontaneously expressed into supernatant by the AUT04 cell line during growth. The MoM LV-derived vector is replication deficient by design since the viral proteins that confer infectivity and replication are not present within the viral RNA packaged into vector particles. The vector can thus undergo one round of transduction only. The only way for the retroviral vector to become replication competent would be by a series of recombination events. In order to minimise this possibility, the genes encoding viral proteins have been separated onto different plasmids using the so-called split packaging design. Furthermore, the plasmids used in the production of vectors do not contain homology with each other and thus the generation of replication competent retroviral vectors by homologous recombination is extremely unlikely.

Accidental insertion of the vector genome into human cells could theoretically lead to insertional mutagenesis in the transduced cells; the likelihood of the latter is extremely low.

Any vector that may enter the body, either by needle stick injury or other means, would be inactivated by human serum. RD114 pseudotyped retroviral vectors have a half-life of 4-8 hours at 3rC, and although no conclusive data is available on the half-life of RD114 envelope in the presence of sera, VSV-G pseudotyped retroviral vectors have an in vivo half-life in the order of a few minutes (DePolo et al. 2000). Furthermore, cell transduction by retroviral vectors in the absence of facilitating agents, such as RetroNectin®, is very inefficient. It is unlikely a clinical event would be detected.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The following measures detailed in points 1-5 must be adhered to whilst handling the stable producer cell line.

Inactivation protocols:

1) Solid Waste: Everything that contacts the stable producer cell line must be contained before leaving the Class II MSC. Solid waste, such as cell culture flasks, media bottles, and reagent or waste vessels must have lids tightly secured inside the Class II MSC, ready to be collected in a biohazard bag immediately upon removal. Stripettes must be re-sheathed, and pipette tips must be collected in a dedicated labelled container.

2) Liquid Waste: Liquid waste must be decontaminated using 1 % final concentration sodium hypochlorite (>5000ppm free chlorine) or sodium hydroxide (1 M) for a minimum of 1 hour before drain disposal.

3) Small spills in the Class II MSC <25mL can be decontaminated by covering the spill with a dry wipe and applying...
an appropriate volume of Klercide Sporicidal Active Chlorine. Cell culture flasks and/or vessels containing cell suspension must be wiped with 70/30 IPA and removed from the Class II MSC before application of Klercide Sporicidal Active Chlorine. The contaminated dry wipes must be removed to a biohazard waste bag within the Class II MSC. Residual Klercide Sporicidal Active Chlorine can be removed by spraying with IPA and wiping using a sterile IPA wipe. Replace any contaminated PPE.

4) Large spills in the MSC >25mL. The MSC must be left running and personnel evacuated from the room. A warning sign must be placed on the door instructing personnel not to enter. Allow 30 minutes for any possible aerosols to settle. Return to the spill and cover with dry wipes, apply Klercide Sporicidal Active Chlorine and allow 20 minutes to inactivate the retroviral vector. Deposit soaked wipes in a biohazard bag within the Class II MSC. Decontaminate the interior of the Class II MSC by wiping with a sterile IPA wipe. Replace any contaminated PPE.

5) Spill outside the MSC generate aerosols therefore alert all personnel present in the area. Remove contaminated PPE and exit the room, place a warning sign instructing personnel not to enter. Allow 30 minutes for any potential aerosols to settle. On re-entry to the room wear fresh PPE and cover the spill with dry wipes. Soak with Klercide Sporicidal Active Chlorine and allow 20 minutes for the retroviral vector to be inactivated. Transfer soaked wipes to a biohazard bag. Wipe any residual spill with sterile IPA wipes.

All product contacting disposable material (solid waste), will be treated as Class 2 GMO waste and disposed of using WIVA bins or red plastic hazardous waste bags as appropriate.

The Genetically Modified Biological Safety Committee at Cobra Biologics have agreed that this organism should be handled as Class 2 GMO and therefore requires level 2 containment measures.

The Genetically Modified Biological Safety Committee at Cobra Biologics have agreed that this organism should be handled as Class 2 GMO and therefore requires level 2 containment measures. Previous HEK293T stable producer cell lines authorised for use related to this Connected Program of Work have been classified as Class II GMOs. This Connected Program of Work will cover prospective HEK293T cell lines, which are stable producers of Moloney murine leukemia virus (MoMLV). Assessment will be made by the Cobra Biologics GMBSC on a case-by-case basis to determine whether this Connected Program of Work is applicable.

Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

The committee consists of 8 members:

- GMO is a senior lecturer with over 15 yrs experience in cloning at the Max-Planck Institute and Newcastle University, GMO is a senior lecturer with over 15 years experience in cloning at the Max-Planck Institute and Newcastle University, involving various cell systems and constructs.
- Head technician of the 1st & 3rd floor research labs who has prior experience in GM at Manchester University.
- Head technician of the teaching labs on the 4th floor who has experience in cloning and microbiology.
- Health and Safety trade union representative.
- Professor with prior experience as a GMO and BSO at Manchester University. Also has experience with lenti-viruses.
- Senior research fellow with experience in cloning and lenti-viruses and being part of a GMO committee at Manchester University.
- Postdoctoral Research fellow with experience in GM work at Christies.
- Senior lecturer with experience in yeast mutagenesis.
- Head of division of Biology & Conservation Ecology with expertise in microbial ecology and bacterial transformation.

The committee intends to meet 4 times a year. Appraisals will be assessed in the form of an internal document detailing the project, vectors and cells being used and possible hazards - these will be reviewed by the committee to determine which class the project will fall under. Modifications will also be reviewed.

Training will also be given and reviewed and signed documentations gathered

Waste Disposal
Solid waste (plastics): 2% Virkon overnight. The manufacturer specifies that this will give 99.9999% kill. The decontaminated waste will be then autoclaved prior to disposal. After autoclaving solid waste is disposed of as normal refuse.

Liquid waste: will be autoclaved, 134 degrees centigrade applied including air extraction, heating and steaming for 30 minutes. The manufacturer specifies that this will give 100% kill. After autoclaving liquid waste will be disposed down a designated sink in a GM area with copious amounts of water.

Monitoring
Disinfection: The disinfectant of choice (Virkon) is used in strict accordance with the manufacturer's (Antec's) guidelines.

Autoclaving: To ensure 100% efficacy, testing of the autoclave is carried out annually, by the manufacturer, to demonstrate, using a 12 point test with independent thermocouples, that the correct temperature and pressure have been reached for the required time. On subsequent runs verification that the correct conditions were reached is obtained through use of a temperature probe in the centre of the load. Testing is arranged and test reports are kept by the Health and Safety Co-ordinator.

Inspections: Safety inspections are carried out annually to ensure Local Rules are adhered to and that risk assessments and training records are in order. Inspection reports are kept by the Health & Safety Co-ordinator. Microbiological Safety Cabinets: Services and KI tested on annual basis. Certificates of conformity are displayed on each cabinet and copies kept by the Health and Safety Information Officer.
The GMC have in place an "acknowledgement of training" form that those listed in the risk assessment must sign. Those listed in the risk assessment must add their names to the list of GMO workers kept by the GMC.

The risk assessment is valid for 5 years. Any use of organisms and genetic material and work spaces not covered in the risk assessment is valid for 5 years. Any use of organisms and genetic material and work spaces not covered in the risk assessment must be notified to the GMC through filling in the modifications section.

Any Class II activities are not covered by this form and a separate CU2 must be prepared and submitted (the GMC can advise and support completion and submission).

**Purposes of the contained use**

Development of vectors (viral and plasmid) and molecules for the study of cellular signaling processes in normal development and disease. This will involve transgene over-expression, gene knockdown, cellular reprogramming and directed differentiation. All gene modifier vectors are disabled and lack essential genes which prevent their autonomous replication. All require specific packaging cell types to produce a viral particle which is replication deficient and cannot multiply or produce progeny. All vectors will have no effect to the environment as they will be maintained and contained under strict laboratory conditions.

**Recipient or parental organism**

**Recipient Cells**

Mammalian cell lines (for example 293T, 3T3, CHO, HepG2, Huh7, U2OS, HeLa, PC3, DU145).

Primary human and mammalian cells (for example fetal and adult fibroblasts, blood cells, and vascular endothelial cells).
Human and mouse embryonic stem cells and adult stem cells either obtained commercially or from collaborators and repositories or from biopsy material (for example; mesenchymal stem cells, cardiac and vascular stem cells, pancreatic/hepatobiliary progenitors).

Human embryonic cells and primary cells or tissues are obtained by donation after pathogen screening (HIV, Hepb/c). Human primary cells are donated from unscreened patients and are quaranteened pending the pathogen screening as described prior to genetic modification.

Viral Vectors
Retroviral vectors used are derived from Moloney murine leukaemia virus (MMLV), a mouse virus therefore chances of mobilisation by recombination with endogenous viruses in a human are practically impossible. Furthermore, the vectors contain no MMLV protein coding sequences and so are completely replication disabled and the chances of recombination are minimised.

Lentiviral vectors derived from HIV1, SIV, EIAV and FIV are based on genome integrating viruses. Like retroviruses, the severely deleted genomes contain no endogenous protein coding sequences and the 3'-Long Terminal Repeat (LTR) contains a self-inactivating mutation that prevents the replication cycle initiating after reverse transcription of the RNA viral genome.

Adenoviral vectors (serotypes Ad2/5) are disabled by mutations to the E1a and E3 genes that are fundamental to the early stages of viral replication. Although adenoviruses are human pathogens infection does not result in serious illness and as such are a low risk to humans. The viral genome is transient in infected cells (does not naturally integrate into the host genome) and so there is minimal risk of insertional mutagenesis.

Adeno-associated Viral vectors (AAV) are disabled by mutations to the Rep gene which is necessary and fundamental to replication. Furthermore, AAV requires the expression of adenoviral genes to facilitate its replication. Recombinant forms of AAV will integrate into the host cell genome at very low frequency and so the chances of insertional mutagenesis are low.

Host/vector system

Origin & function
Transgenic material - Human and mammalian cDNAs of transcribed genes involved in aspects of cellular transformation, self-renewal, differentiation, proliferation, senescence, apoptosis and metabolism will be expressed from pol II promoters. These genes would include transcription factors, signaling molecules, enzymes, growth factors and cytokines.

Such genes would include but are not limited to:
- Transformation; hTERT, BMI-1, C-MYC
- Self-renewal; OCT4, Nanog, SOX2, LIN28, KLF4, STAT3
- Differentiation: Wnt, PI3K, Notch, Hedgehog, TGFbeta, BMP, MAPK, ERK, JNK, RAS, NFkB
- Cell adhesion, migration & communication: ICAM-1, VCAM-1, Selectins, RhoGTPases, Ezrin, PDK1, Cadherins, B-Catenin, HGF, eNOS.
- Hypoxic Responses: HIF, ARNT, C-MET
- Innate Immunity: TLRs, RLRs, TBK, NFkB, IRF3, IRF7

The above gene targets will also be subject to gene knockdown with siRNA and miRNA expressed from pol II/III promoters.

Bacterial Cre-recombinase for removal of LoxP flanked gene sequences.

Reporter genes will also be expressed from endogenous and viral promoters with or without additional enhancer elements either constitutively or conditionally to mark cells or quantify surrogate gene expression. These will include;
Flourescent- e.g. GFP, YFP, CFP, dsRed, mCherry.
Luminescent- e.g. firefly and renilla, gaussia, vargula luciferases.
Biochemical marker genes e.g. CAT, AFP.

**Evaluation of foreseeable effects**

The recombinant viral vectors are all highly disabled vectors.

**Lentivirus/retrovirus:** These self-inactivating vectors have had regulatory and accessory genes deleted ensuring that viral particles produced in the packaging cells are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication/ infection cycles. Whilst the envelope pseudotyping extends the cellular tropism and confers greater stability the viral vector will always be contained within a class II safety cabinet thus user exposure to liquid aerosol is minimised.

The exposure of non-human hosts to pseudotyped vector could result in initial infection but, again seroconversion is highly unlikely.

Adenoviral vectors are deleted of essential replication/packaging genes that are supplemented by an established packaging cell line (293T).

Adeno-associated Virus is defective by nature and has a replication disabled genome and is incapable of replication without the presence of helper adenovirus proteins. In this instance the vectors used would require the provision of cap and rep genes in trans in order to replicate and disseminate. There is no significant chance of reversion to the wild-type. Furthermore, the AAV8 & 5 subtypes derived from humans are not able to replicate or cause disease in any animal species therefore it highly unlikely that such a virus, if released into the environment, would represent a significant risk. Furthermore, most AAVs proposed for use constitute AAV5 genomes pseudotyped with other AAV envelopes so would never occur in nature and thus would be incapable of reversion.

The majority of the gene products expressed are expected to affect cellular properties such as proliferation, apoptosis, migration, adhesion and fate. Also, some have known or suspected oncogenic or tumour suppressor properties.

Gene products in plasmid form exist in non-mobilisable constructs and are therefore of minimal environmental risk. Viral vector expressing potential oncogenes are a potential environmental risk as host infection could elicit a transformation event. All work is carried out in a class II cabinet and all liquid waste inactivated by virkon treatment and solid waste autoclaved.

Primary cells infected with viral vector containing potential oncogene would pose minimal threat as expression would most likely be restricted to the infected cell, which in itself would be rejected by the host immune system.

Sharps will not be used in the production or handling of any of the viral vectors described in this project.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not Applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not Applicable.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All viral production, handling and experimental procedures will occur in containment level 2 laboratories (designated cell culture and tissue culture on the 1st and 3rd Floor John Dalton Building). The laboratories have restricted access, through a card key and number pad only accessible by staff and authorised personnel trained in containment level 2 GM use.

Non-viral work will occur in Class 1 conditions.
Liquid waste will be treated with freshly prepared 1% Virkon or 10% hypochlorite solution for at least one hour prior to disposal via the sink. Solid waste will be autoclaved at 134°C on a destruct cycle prior to be placed in Tiger striped bags for disposal. Sharps will be placed in yellow sharps boxes that will be first autoclaved then removed by the waste contractor for incineration. Cryovials containing virus will be stored in specified cryofreezer and opened only in Class II microbiological safety cabinets. Spillages and working surfaces will be cleaned with 2% Distel or 1% Virkon and with 70% ethanol.

Solid waste that has not been autoclaved will be placed in clearly labelled biohazard double bags will be incinerated as clinical waste.

Hazard conditions consist of possible spillages, aerosol spray when opening cryovials.

Work is restricted to determined areas (containment level 2 laboratories), disinfecting solutions will always be available, working guidelines are clearly posted, unauthorised personnel is not permitted. Strict adherence to Category II working practices. Reporting in case of accident is according to College procedures using the online or paper accident / incident forms or by contacting the Safety, Health and Environment Office directly on extn. 5365.

Training to work with class II GMM's will include Instruction of the guidelines regarding dressing code, how to treat spillages and disinfection with 2% Distel, 1% Virkon and 70% ethanol.

Documented spillage procedures are clearly established. In case of accident with sharps, College procedure with blood borne viruses will be followed.

Autoclaves are regularly serviced and checked. Autoclaved material is checked using autoclaving tape and spore strips to assess has reached appropriate temperature for disinfection.

Please enter comments on the GM safety committee on the risk assessment

The Genetic Modification and Biological Agents Committee at the School of Healthcare Science, Manchester Metropolitan University met on the 17th December 2015 and have considered the risk assessment for this project and consider it to be suitable and appropriate and agree with the allocation of the final containment level 2.

The committee agreed the following:
Brief reports will be made and documented of GM2 agents produced and disposed of will be made.
Acknowledgement of training for all individuals engaged in GM2 activities.
All staff are made aware of GM2 activities within the School and their location within specific units.
All GM2 activities will be carried out in designated tissue culture facilities.

Measurement of survival of Pseudomonas aeruginosa following bacteriophage infection.

Pseudomonas aeruginosa expressing green fluorescent protein will be co-cultured with an established and well characterised human bronchial epithelial cell line to mimic an infection. Wild-type Pseudomonas-specific bacteriophage will be introduced and their ability to kill the bacteria determined. The eventual aim of this project is to determine if such bacteriophage could be useful as a novel treatment for chest infections in patients with cystic fibrosis.

PAO1 is an ACDP Hazard Group 2 organism which only presents a risk to cystic fibrosis patients, immunocompromised individuals or those with severe burns. Thus the containment level for the GMO can be no lower than Category 2.

Recipient or parental organism

PAO1 is an ACDP Hazard Group 2 organism which only presents a risk to cystic fibrosis patients, immunocompromised individuals or those with severe burns. Thus the containment level for the GMO can be no lower than Category 2.

Host/vector system

The core construct is a standard pUCP18 vector incorporating a fragment of the lacZ gene for blue-white selection. pUCP18 is an E. coli-P. aeruginosa shuttle vector carrying a 1.8kb fragment of pRO1614 which confers stability in Pseudomonas and is inserted into a non-essential region of pUC1 8. The gene coding for green fluorescent protein was inserted into the MCS as a 700bp HindIII/BamHI fragment to form vector pLS10. This vector would be assigned to Class 1 if it were carried in a species with a lower ACDP hazard categorisation.
Both construction of the recombinant plasmid and transformation of host bacteria were performed by others (Feldman et al. 1998, Cormack et al., 1996). pLS1 0 does not carry sequences which are predicted to alter the pathogenic traits of P. aeruginosa with respect to virulence, infectivity, immunogenicity, or host range (SACGM compendium of Guidance Part 2, page 15). pLS1O carries an ampicillin resistance gene (bla) as a selectable marker in E. coli. However as P. aeruginosa possesses its own endogenous beta-lactamases, treatment with most beta-lactam antibiotics would not be attempted, thus prophylactic options are unaffected. This additional bla gene increases the MIC (minimum inhibitory concentration) of beta-lactam antibiotics for P. aeruginosa e.g. the MIC of Carbenicillin for wild type PAO1 is 64 microg/ml (Kwon etal., 2006) ,with the addition of the bla gene on pLS1O this increases to >300 microg/mL The gene for green fluorescent protein is expressed from this construct allowing visualisation of the GMM under ultraviolet light.

References

Evaluation of foreseeable effects
Pseudomonas aeruginosa is widespread throughout the environment and poses a low risk to animals (Rhame, 1980). The primary risk is therefore to human health. P.aeruginosa is an ACDP Hazard Group 2 organism which only presents a risk to cystic fibrosis patients, immunocompromised individuals or those with severe burns (Hatchette et al., 2000, Driscoll et al., 2007). Thus with proper control measures the risk of the GMM to human health is negligible. Transfer of the antibiotic resistance gene to other micro-organisms is unlikely as the plasmid is only suitable for P. aeruginosa and E. coli and cannot be mobilised between micro-organisms (Schweizer, 1991).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The waste generated will consist of limited numbers of agar petri dishes with the GMM growing on them as colonies, spent liquid bacterial cultures & broths (less then 2L at any one time) and a small number of 6 well tissue culture dishes. All solid waste is autoclaved using an autoclave in the building. Solid waste is autoclaved at 121 degrees centigrade for 1 hour at 20 p.s.i.. This gives a chance of 1 in 1 to the power 34 of an individual organism surviving and represents the highest level of killing currently possible for any organism. Thus there is an utterly negligible chance of organismal survival. All liquid waste is subjected to the same autoclave treatment cycle. The autoclave killing is validated on each run by multiple independent thermocouples producing a print out which is archived for reference purposes.
The risk assessment associated with this notice of intent has been read and approved by the BSC/GMO, the microbiological safety representative and the Chair of the Safety Committee.

**Project Additional Information**

**Purposes of the contained use**

The aim of the project is to utilise molecular genetic approaches to investigate the genetic basis of virulence, biofilm formation and antimicrobial resistance in three bacterial opportunistic pathogens (two Gram-negative and one Gram-positive). The interaction of these organisms with bacteriophage (viruses who infect and kill host bacteria) will also be studied on a genetic level, with the view to generating novel bacteriophage based antimicrobials. A greater understanding of the virulence and antimicrobial resistance will lead to novel strategies to treat these infections.

**Recipient or parental organism**

E. coli hosts: Standard, disabled E. coli cloning strains such as EPI300, JM109, S17.1, SM10, HB101, DH5alpha, XL1-Blue etc. All strains to be used are non-hazardous and non-pathogenic. Hazard group 1. L. Lactic hosts: L. lactis cloning strains as used by other researchers, such as NZ9000, H61 etc. L. lactic is non-hazardous, non-colonising, non-invasive, and non-pathogenic. Hazard group 1. Self cloning strategies will also be employed with P. Mirabilis, Ps. Aeruginosa and S. aureus (all Hazard group 2).

**Host/vector system**

No vectors capable of self-transfer between bacterial species will be used. All vectors to be used require introduction through laboratory manipulation. The vector systems to be used include standard narrow host range E. coli and L. lactis cloning vectors, broad host range vectors for self cloning strategies, and E. coli or L. lactis expression vectors. All selectable markers present are naturally occurring, and already present in the wider environment. The majority of vectors to be used are commercially available and all have a history of safe use. For full details see risk assessment.

**Origin & function**

Genetic material will originate from P. mirabilis, Ps. aeruginosa or S. aureus, which are all opportunistic pathogens capable of causing disease in susceptible, compromised individuals, and do not normally constitute a risk for health individuals. Effective treatment exists for healthy individuals and as such the overall level of risk to human health and the environment associated with these pathogens is low. Ps. Aeruginosa may also cause opportunistic infections in plants, but no species or strain known to be pathogenic to plants will be used in these studies. P. mirabilis and S. aureus have no known ability to cause infection in plants. All GMMs created will be the result of mutagenesis procedures, self-cloning or transfer of DNA from hazard group 2 pathogens (P. mirabilis, Ps. Aeruginosa and S. aureus) into hazard group 1 disabled cloning strains (E. coli and L. lactis). The primary molecular genetic approaches employed will be the generation of attenuated mutants and identification of disrupted genes. Genes identified in this way will subsequently be cloned and maintained in standard E. coli or L. lactis disabled cloning host for further study and characterisation. Clones derived from P. mirabilis, Ps. Aeruginosa or S. aureus will encode genes related to virulence attributes, biofilm formation and antimicrobial resistance.

**Evaluation of foreseeable effects**

The primary approach used to study these organisms will be the generation of mutants attenuated in virulence mechanisms, biofilm formation, general growth in laboratory media, or antimicrobial resistance, using site-directed gene knockouts or random transposon mutagenesis. As mutants will be attenuated in comparison to the wild type organisms, no additional risk is associated with this procedure above that of the original hazard group assigned to P. mirabilis, Ps. Aeruginosa and S. aureus (Hazard group 2). Cloned DNA derived from P. mirabilis, Ps. Aeruginosa and S. aureus may contain virulence or antimicrobial resistance genes that are expressed in the E. coli or L. lactis hosts, and as such there is potential to increase the pathogenicity and resistance of these organisms. However these genes will be cloned in disabled level 1 receipt organisms (E. coli and L. lactis standard cloning strains), which are unlikely to survive outside the laboratory, and are sensitive to a wide range of antimicrobial agents. As such the risk associated with expression of virulence genes and antimicrobial resistance genes in the disabled E. coli or L. lactis cloning strains is negligible. The resulting GMMs will not possess an ability to displace environmental strains or survive in the environment above that of the original parental species, which are all Hazard Group 2 organisms, and already widely distributed in the environment, and th risk to the environment is low.
Complementation studies which involve the transfer of DNA between E. coli cloning strains and the bacterial species from which cloned DNA originated (self-cloning) will also be undertaken. As this is a self-cloning only procedure (e.g. P. mirabilis DNA cloned in P. mirabilis host only) there is no additional risk above that originally assigned to donor organisms (P. mirabilis, P. aeruginosa and S. aureus), and the overall risk is negligible. Overall inserted and donated genetic material is highly unlikely to increase the pathogenicity or environmental impact of recipient organisms when using the proposed molecular genetic approaches, and the resulting GMMs will not constitute a hazard above that of the original parental species, which are all Hazard Group 2 organisms. The overall risk to the environment and human health is low, and all GMMs will be handled at containment level 2 to reduce any associated risk to effectively zero.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste will be sterilised by autoclaving including GMMs. Liquid waste will be collected in robust, sealed vessels in leak proof secondary containers, and all other waste collected in robust leak proof autoclavable boxes or containers with lids. Waste will then be sterilised by autoclaving. Decontamination of laboratory surfaces will be carried out with broad spectrum disinfectants. In accordance with advice offered in the SACGM compendium for guidance (Part 3, section 3.5, clauses 8-22) hypochlorite (bleach) disinfectants will be used for standard decontamination of laboratory surfaces.

Project Additional Information

Purposes of the contained use

The aim of this project is to employ replication defective retroviral vectors harbouring inserts coding for proteins that ablate or modify replicative senescence in mammalian cells (typically primary human strains). The objective of this project is to gain a fundamental understanding of the mechanisms underlying cellular ageing. This risk assessment relates to an existing class 2 notification (Ref No: 570/00.1) covering producer cell lines generating amphotrophic retroviral vectors carrying telomerase (hTERT), and Dominant Negative-hTERT.

Recipient or parental organism

E. coli hosts: The standard, disabled E. coli cloning strain TOP10 will be used. These are non-hazardous and non-pathogenic with a long history of safe use. Hazard Group 1.

Mammalian cells: NIH3T3 and other primary cell types to be used in this project are Hazard Group 1. Primary human cell lines which are not fully characterised but low risk for endogenous biological agents will also be used, which are Hazard Group 2. Under no circumstances will operator derived cells be used.

Host/vector system

The vector systems to be employed are third generation retroviral vectors from the pBABE family of retroviral vector systems (e.g. pBABEpuro, pBABEneo, pBABEhygrom, pBABEpuro(LOX)). These are derived from the Moloney Murine Leukemia Virus which is classified as Hazard Group 1. These will be used to maintain the genetic material specified below in E. coli TOP10 (Hazard Group 1), and primary mammalian cells, including those of human origin. Hazard group 1, and Hazard Group 2 primary cells will be used.

Origin & function

The psiCRIP producer cell lines contain 2 mutant Moloney murine leukemia virus-derived proviral genomes with frame shift mutations in the gag-pol or env regions. In both
viral genomes the "psi" sequence has been deleted, which is required for the efficient packaging of retroviral genomes.

The pBABE series of vectors are derived from Moloney murine leukemia virus (Hazard Group 1). These are designed to express an inserted gene and a selectable marker. Viral particles are produced in disabled packaging systems which render the production of replication competent virus highly statistically improbable.

The genetic material to be cloned into pBABE vectors and transferred to E. coli TOP10 or primary mammalian cells. Includes sequences encoding for proteins considered to be oncogenes, originating from human papilloma virus (HPV E6 and E7) and SV40 virus (Large T antigen). This also subsumes telomerase (hTERT), and an inactive form of telomerase (DN-hTERT). Telomerase is a specialised reverse transcriptase which acts to balance the attrition of chromosomal ends and is not generally considered oncogenic HPV E6 and E7 target the p53 and pRB tumour suppressor genes respectively and can immortalise a wide variety of celltypes. SV40 Large T antigen binds both p53 and pRB and thus produces extended lifespan and spontaneous immortalisation at low frequency (1 per million per cell generation). The selectable marker to be used encodes resistance to the antibiotic puromycin.

**Evaluation of foreseeable effects**

E. coli TOP10 harbouring pBABE with cloned genetic material: Genes of human or mammalian origin are not properly expressed or translated into functional proteins by prokaryotic cells, which lack the cellular machinery required to process mammalian genes. E. coli TOP10 strains are hazard group 1 and it is highly unlikely that inserts cloned on pBABE vectors harboured by E. coli TOP10 will increase the hazard above this level. E. coli TOP10 is unlikely to survive outside the laboratory and cloned genes will not provide any survival advantage in the environment, and the resulting GMMs will thus pose no risk to the environment, and no risk to human health beyond the original hazard classification assigned to the parental strain (Hazard Group 1).

The mammalian cells to be used are either Hazard group 1 or Hazard group 2. The most probable foreseeable effect of transduction of the specified sequences growth requirements and no operator derived cells will be used there will be no increased risk to human health or the environment from these above that assigned to untransduced cells.

Forseeable hazards posed by amphotrophic vectors include: i) Generation of wild type viruses, ii) Insertional mutagenesis and iii) any hazard arising from transgenes carried by the vector. pBABE vectors are replication defective and it is highly unlikely that the psiCRIP producer cell lines will generate wild-type virus because the required viral genes (gag-pol and env) are encoded on two distinct viral genomes (which contain mutations in other key viral genes). The insertional mutagenesis and immortalisation hazards (ii and iii) are low because retroviruses can only infect cells which are traversing the cell cycle (an event which occurs - once 2-5 years in human fibroblasts). Nonetheless, possible routes of infection by inhalation of aerosols and direct inoculation will be blocked by avoidance necessary, and barring operators from work if they have open skin lesions. The overall risk to human health is thus low, and all work will be conducted at containment level 2 to further reduce the risk to effective zero. Liquid waste will be decontaminated at point of use using 5%-10% (w/v) Virkon and all solid waste will be sterilised by autoclaving. P

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste will be sterilised by autoclaving including GMMs. Wastes containing GMMs will be double bagged, and transported to adjacent autoclaves in leak proof secondary containers with lids. Waste will then be sterilised by autoclaving. The autoclaves used achieve terminal sterilisation (i.e complete killing) by steam heating above 121 degrees centigrade for 15 minutes. Temperature and run times are automatically recorded using thermocouples which actively monitor in-chamber temperature. Sterilised waste is then disposed of as standard clinical waste by our contractors.

Liquid waste arising from cell culture experiments (small volumes) will be sterilised by 5-10% (w/v) Virkon for 12 hours. This is an extremely robust killing schedule (typically 0.5% Virkon achieves full bacterial killing within 5 minutes and the potency of adenovirus types 5 and 6 can be reduced by greater risk than six logs when subjected to 0.9% Virkon for 12 hours).
Virkon for five minutes under tissue culture conditions). Liquid waste can then be disposed of by standard routes. Validation of Virkon kill is technically impractical on a routine basis (due to the difficulty of removal of the agent to conduct viability screening). However the SACGM compendium of guidance recognises this and considers it an acceptable means of inactivation for this class of procedure.

Decontamination of laboratory surfaces will be carried out with broad spectrum disinfectants (typically 5% virkon). In accordance with advice offered in the SACGM compendium (Part 3, section 3, 5, clauses 8-22). 70% industrial methylated spirits will be used for routine surface sterilisation and 5% (w/v) Virkon for decontamination in the event of spillage.

The Study of diseases of the brain and nervous system, neurodegeneration and repair, using GM microorganisms

**Project Additional Information**

**Purposes of the contained use**

Human and rodent primary and cell line cultures will be transfected by various viral vectors (incl. lenti-, adeno- & adeno-associated virus), to introduce genes or RNA species associated with neurodegenerative disease and/or repair processes. Patient-specific iPSCs will be generated using lentiviral vectors. Viral transduction will be used in vivo to create or repair models of neurodegenerative disease. Containment will be required during the transduction phase of cell culture until stable cell lines are generated, and these will normally be considered class 1 GMOs unless the risk assessment states otherwise.

**Recipient or parental organism**

Well characterised commercial bacteria, e.g. AADH1alpha or One Shot Top 10 Chemically Competent E. coli - disabled, non colonising, non-pathogenic.

Well characterised viral expression systems, e.g. HIV-1 derived 3rd and 4th generation replication defective, lentiviral vectors, and replication defective AAV vectors.

Adenoviral vectors AdEasy and Adtrack, replication defective, deleted E1 and E3 genes.

Commercial packaging cell lines, e.g. HEK293T human cell line, a highly transfectable derivative of human embryonic kidney 293 cells, containing the SV40 T-antigen. This cell line is competent to replicate vectors carrying the SV40 region of replication. It gives high titers when used to produce retroviruses. It has been widely used for retroviral production, gene expression and protein production.

Human and rodent primary neural cultures, somatic neural stem/precursor cells (NPCs), embryonic stem cells, skin fibroblasts and induced pluripotent stem cells.

Characteristics of cell cultures are never totally understood, so primary human cultures will be handled at containment level 2 considering the possibility of adventitious blood borne viruses, rodent cultures will normally be handled at containment level 1 unless the risk assessment advises.

**Host/vector system**

Only well characterised, replication deficient viral vector systems with a history of safe use will be used, for example:

1) Dh1alpha or One Shot Top 10 E. coli/pLVX-EF1a-IRES-Puro or /pLVX-TRE3G plasmids, introduced by heat-shock transformation.

2) HEK-293T/pLVX-EF1a-IRES-Puro or /pLVX-TRE3G plasmids, transient co-transfection of viral gene and insert expression (4th generation system/5 plasmids) production of amphotropic replication deficient HIV-1 derived lentiviral particles using calcium phosphate precipitation.

3) Human and rodent cells/HIV-1 vectors - replication defective lentiviruses, with stable genomic integration.
Inserts are arbitrarily grouped as follows:

Type 1. DNA expression constructs, for example: Human cDNA (+/-TAG sequences) inserts will code for transcription factors, Ascl1, Brn2, Myt11, NeuroD, ngn2, lmx1a, lmx1b, foxA2, Nurr1 and Otx2. These genes are expected to influence cell fate decision and differentiation of fibroblast cells, iPSCs, neural/precursor stem cells, or hES cells towards a neuronal lineage, but are not expected to have an effect on cell proliferation. Other genes may code for growth factors, disease associate proteins such as mutant tau, huntingtin or alpha synuclein, or regrowth-enhancing agents such as chondroitinase.

Type 2. RNA constructs, for example: miRNA sequences and miRNA target sequences (miR-124) will produce non-coding miRNA sequences targeting cell endogenous mRNA or exogenous miRNA target sequences on miRNA regulated vectors -miRNA-124 is thought to affect the differentiation of cells to a neuronal lineage.

Type 3. Reporter genes: (enhanced GFP (eGFP) and destabilized GFP (dGFP) at different cellular locations, firefly luciferase (fLuc) and mCherry, will code for proteins with fluorescent or enzymatic properties to allow identification of genetically modified cells.

Type 4. Selection genes: (bacterial resistance - Ampicillin, untransduced fibroblasts - Puromycin), will express proteins with enzymatic activity to allow selection of bacterial or GM cell cultures.

Type 5. Functional non-coding sequences will act as promoters of transcription (promoter, enhancer), local chromatin structure modifiers (enhancers, insulators), transcription regulators (IRES), or RNA transcript stabilizers (WPRE), of mammalian or viral origin). They will be used individually or in combination as required in viral expression cassettes to achieve best control of transgene expression according to the target cell type.

**Evaluation of foreseeable effects**

- **Human health considerations** -
  1. The most obvious risk to human health is from the recombinant viral particles, via accidental infection of the researcher.
  2. The cells from human samples also carry the possibility of adventitious agents as they are uncharacterised, they will be processed at Containment Level 2 from collection. Because only replication defective viral particles (non-infectious) will be used throughout this project, and inserts will not produce compounds with acute toxicity (such as bacterial toxins), no additional risk will arise from the final genetically modified cells, compared to the initial cell source.

  1. The risk associated with the nature and design of recombinant viral particles - lentiviral recombinant particles (HIV-1 derived) will be packaged in protein G from the vesicular stomatitis virus (VSV-G) to alter the tropism of the retroviral particles, as it only requires interaction with the plasma membrane of cells rather than a specific receptor, allowing increased stability of the viral particles associated with the VSV-G envelope which may add to the aerosol risk in addition to the percutaneous risk. Retroviruses stably integrate into the host cell genome, and there may be a risk of insertional mutagenesis, with subsequent ectopic inhibition/activation of host gene expression. Subsequent de-regulation of endogene expression could theoretically lead to transduction associated detrimental effects such as initiation of oncogenic processes. Moreover the addition of the Woodchuck hepatitis Post transcriptional Regulatory Element (WPRE) to the expression cassette in several retroviral backbones could also enhance the oncogenic potential of such vectors (SACGM 2004). However, the use of a lentiviral backbones is thought to be safer, as the genomic integration profile of lentiviral derived vectors do not show an integration bias towards the transcriptional start site region of host cell genes.
  Risk is also associated with inserted coding sequences. cDNA or shRNA/miRNA inserts carried by viral vectors will direct ectopic expression or inhibition of transcription factors, and strong promoter/enhancer effects from non-coding sequences could lead to ectopic activation of neighbour endogene expression.
  2. Risks are theoretically higher where multiple genes are expressed in the same experiment - researchers will be informed of the additional risk if using polycistronic vectors.
  The risks described above will be moderated by the fact that we will use the strictly replication defective viral vectors such as the Clontech Lenti-X HTX Lentiviral Expression System, a 4th generation 4 plasmid system by separating the gag from the gag-pro-pol sequences normally found on 3rd generation vectors making the production of recombinant lentivirus (RCL) evenmore unlikely, as extra recombination events would be needed. In fact, the emergence of RCL is undetectable from
systems using this approach. (Wu, X. et al (2000) Mol. Ther. 2(1): 47-55). AAVs have no known link to human illness and are commonly used as vectors for the introduction of genes. In most cases Containment Level 1 will be sufficient, unless there are any additional risks due to the biological activity of the insert, identified by risk assessment. For all viral vector types, in the event of an accidental contamination, (percutaneous or inhalation) the amount of viral vector able to effectively contaminate a worker's cell will be minimal, the transduction for cells in vitro needing a specialized protocol for efficient uptake. The VSV-G pseudotyping results in complement sensitivity, increasing the likelihood of immunological neutralization in human hosts. Cells of the cornea, and lung, are terminally differentiated cells with a limited lifespan and high turnover, which greatly diminishes the chance of effective transformation.

- Environmental considerations -
VSV-G pseudotyping makes the recombinant viral particles amphotropic, able to infect a larger range of animal and cell types, however the viral particles are still sensitive to air, temperature and pH, and will have a short lifespan in the open environment. Importantly, they will be replication defective and so will not produce progeny able to spread from an infected host.

Transgene mobilization is theoretically possible if infection occurs in a host cell which is also infected by a wild-type retrovirus - if the wild-type virus is compatible with the recombinant lentivirus, it may provide encapsidation to allow production of a replication competent viral particle carrying the transgene. The likelihood of this mobilization is very low, and replacement of the VSV-G envelope would remove the amphotropism of the resulting viral particle. Generation of replication competent viral particles (RCV) is associated with the highest risk factor for human health and the environment, therefore production steps will be carried out under Containment level 2 conditions. This involves packaging of the separate constructs, concentration of the resultant viral supernatant, transduction of the target cells, and culture/analysis of the resultant GM cell populations. All researchers will be trained in the use of hazards involved in working with recombinant viruses. To decrease the likelihood of infection, standard measures to decrease percutaneous as well as aerolised transmission of viral particles will be adopted, such as no use of sharps and all work to be carried out within a Class II microbiological safety cabinet. All waste will be sterilised by validated means via immediate immersion disinfection and local autoclaving.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMNs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All highly contaminated waste solid material, such as pipette tips, petri dishes, will be immersed in 2% Virkon solution for 24 hours, within the microbiological safety cabinet, effectively 100% kill.

All solid waste will be discarded to autoclave bags and autoclaved locally, at 121 degrees C for at least 45 minutes, before discard in clinical waste bag for incineration, 100% kill.

Small surface spills will be immediately soaked with Distel, followed by wiping with 70% Ethanol, effectively 100% kill.

Large spills will be sprinkled with Virkon powder before cleaning as above, effectively 100% kill.

Safety cabinet surfaces will be wiped down with Distel before and after working, effectively 100% kill.

All discarded GM modified cell cultures will be destroyed by soaking in 2% Virkon solution or 24 hours followed by autoclaving at 121 degrees C for at least 45 minutes and subsequent discard in clinical waste bag for incineration 100% kill.

Autoclave is temperature validated annually.

All mammalian tissue which has been infected with virus will either be fixed with 4% paraformaldehyde or 2% glutaraldehyde, or if fresh will be subject to risk assessment of the possibility of infectious virus still being present, and handled accordingly.
This work was discussed on 30th September 2013 at the Brain repair Centre Biological and Genetic Modification Safety committee meeting. It was agreed that the work could go ahead subject to appropriate controls and conditions. Some Class 1 work was approved and the whole project was written into this notification and the attached risk assessment over the intervening months.

The risk assessment was revised and reviewed after a meeting of the committee on 14th August 2014

For activities involving GMMs, describe the waste management measures which will apply to the activity

All liquid waste from GM work is treated with Chloros in accordance with college policy and then disposed of by flushing down the sinks. Maximum culture volumes are 250 mls for a maxiprep at any one time. Solid waste is placed in designated containers in the prokaryotic room and then the bags removed and autoclaved prior to disposal. When autoclaving, monitoring tape is always used and in addition our autoclave is regularly serviced and tested.

Historical Significant Changes
Viral haemorrhagic septicaemia (VHS) is generally considered to be a disease of farmed salmonid fish, and as such poses a serious threat to the farmed rainbow trout (Oncorhynchus mykiss) populations in the UK which have not been exposed to it. In recent years however, the VHS virus (VHSV) has been isolated from an increasing number of marine fish species, including Atlantic herring (Clupea harengus harengus), cod (Gadus morhua), haddock (Melanogrammus aeglefinus), sprat (Sprattus sprattus), and rockling species, which suggests that a natural reservoir of the VHSV exists among marine species. Having already determined the complete genome sequence of pathogenic and non-pathogenic strains, the gene(s) involved in conferring virulence to VHSV will be identified by generating recombinant viruses using sequences amplified from both the marine and fresh water isolates. Virulence data on the recombinant virus, obtained by challenging rainbow trout with the recombinant and non-modified viruses under controlled conditions, will be used to predict the likelihood that, under the selective pressures attributed to the farming practices, more pathogenic strains would be generated following the introduction of marine isolates on to a farm site.

Plasmids containing the VHSV/IHNV cDNAs will be replicated in E.coli strain JM 109. The reporter gene, green fluorescent protein (GFP) from Aequorea victoria will be inserted into the full length cDNA of the fish pathogen VHSV. Recovery of recombinant VHSV and/or IHNV will require the use of either a T7 RNA polymerase expression system based on the Modified Virus Ankora (MVA), a multiply attenuated vaccinia virus, or a fowlpox T7 RNA expression system. VHSV, the MVA and the FP expression vectors will be grown in established fish cell lines (CHSE-214, BF-2- and EPC-cells).

VHSV and IHNV derived cDNA will be inserted into pcDNA3.1 and pCI which are pUC-based vectors considered to be non-mobilisable. These will be used in conjunction with E.coli JM109 which is disabled. They are non-pathogenic to humans and animals and are unable to survive in the environment. The MVA expression vector is a multiply attenuate variant of the vaccinia virus which is unable to produce infectious virus in humans. Fowlpox virus is also unable to replicate in mammalian cells.
The N, P, M, G, Nv and L genes and the 5' and 3' non-coding sequences from VHSV and IHNV will be inserted into the eukaryotic expression vector pCI (Promega) to create a positive sense (antigenome) copy of the complete virus genome under the control of a T7 promoter. A T7 terminator sequence will be inserted downstream of the virus sequences and hepatitis delta virus (HDV) ribozyme sequence will be inserted between the terminator and the 3' trailer to ensure that virus transcripts have the authentic terminal ends required for replication.

The N, P and L genes of VHSV and IHNV will be inserted into the expression vector pcDNA3.1 under the control of a T7 promoter. Infectious virus will be recovered by co-transfection of fish cell lines (EPC, BF-2 or CHSE-214 cells) with the full length cDNA and the N, P and L gene constructs following infection with either the MVA-T7 expression vector (Sutter et al., 1995) or the FP-T7 expression vector (Britton et al., 1996). As a positive control for the expression system, the full length cDNA will be replaced with a minigenome in which the N, P, M, G, Nv and L gene sequences are exchanged for the reporter gene, chloramphenicol acetyl-transferase (CAT).

Single and multiple nucleotide substitutions will be introduced into the VHSV and IHNV cDNA clones at positions thought to play a role in virulence of VHSV and IHNV for rainbow trout. Changes in the replication and tissue tropism of site-directed mutants will be monitored by inserting the gene for Green fluorescent protein (GFP) upstream of the first open reading frame.

HAZARDS TO HUMAN HEALTH
Recombinant DNA will be grown in JM109, a strain of E.coli which is disabled and unable to survive in the environment and is non-pathogenic to humans. The fish rhabdovirus genes, the reporter genes CAT and GFP, and the T7RNA polymerase are considered to be non-toxic and these are unlikely to alter the pathogenicity of the cloning host.

The viral proteins will be expressed using the mammalian expression vectors pcDNA3.1 and pCI which are pUC based and when used in conjunction with the fish cell lines are considered to be non-mobilised.

HAZARDS TO THE ENVIRONMENT
VHSV and IHNV are list II fish viral pathogens and are notifiable both to the Office International des Epizooties (OIE) and under local Fish Health Regulations. Monitoring for VHSV and IHNV currently involves the isolation of the VHS or IHN viruses. In the future surveillance for VHSV could rely more heavily on an assessment of antibody or the presence of virus nucleic acid. Since the proposed work uses disabled hosts and mobilised defective vectors which will not survive in the environment the risk of interference to future diagnostic tests is negligible.

The MVA is a multiply attenuated vaccinia virus containing six major deletions and will not replicate in human cells.

The FP will also not replicate in humans.

Although expression is sought in the fish cells the VHSV and IHNV genes, CAT, GFP and T7RNA polymerase are all considered to be non-toxic.

Insertion of GFP in to the VHSV and/or the IHNV genome is unlikely to alter the pathogenic traits of the recipient viruses.

Both VHSV and IHNV are highly pathogenic for farmed salmonid fish species and the consequences of their release are severe; particularly the potential loss of the "approved zone" status afforded to the UK by the European Union under Council Directive 91/67/EEC.

Therefore, in line with the Department of Environment Food and Rural Affairs (DEFRA) recommendations all work on VHSV and IHNV will be performed at containment level 2.

Evaluation of foreseeable effects

n/a
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

INACTIVATION AND DISPOSAL
All material for disposal (pipette tips, microcentrifuge tubes, Petri dishes, pipettes etc) is placed in biohazard autoclave bags and transported to the autoclave by authorised personnel in robust metal bins. Recyclable items (glassware etc.) are transported to the autoclave in robust metal bins; the latter is done on a daily basis. Clinical waste (infected fish) will only be generated on one or two occasions per year. It will be placed in biohazard autoclave bags, transported to the autoclave by authorised personnel in robust metal bins and autoclaved immediately.

Inactivation of GMMs is performed by autoclaving at 126 degrees C for 30 minutes using an LTE Scientific series 400 autoclave. Autoclaved recyclable items are washed and returned to the clean store. Autoclaved disposable material is discarded with normal laboratory waste. The degree of kill by autoclaving is effectively 100%.

Inactivation of GMMs in water by ozone treatment. The water is saturated with ozone for 30 minutes and the residual ozone above saturation point is always >0.02 ppm. The degree of kill is effectively 100%. Some disinfection of equipment, surfaces etc is by treatment with sodium hypochlorite (200 ppm for 24 hours). The waste liquids generated are further treated with ozone before discharge from the site. The degree of kill is effectively 100%.

VALIDATION AND MONITORING OF CONTROL METHODS
The autoclaves are serviced every three months, and at the annual service independent thermocouples are used to demonstrate that the correct temperature and pressure have been reached for the required time. On subsequent runs, a chart recorder is used to verify that the correct conditions were reached. Should those conditions not be reached, the load will be retained until the autoclave has been serviced/mended.

Validation tests on the ozone disinfection system using spores of Bacillus cereus have shown complete inactivation is effected when the water is saturated with ozone.
Saturation can be demonstrated by measurement of residual ozone; any residual detected is indicative of water saturation by ozone. The ozone plant runs with an ozone residual of greater than 0.02 ppm, which is continuously monitored, and should the residual fall below that level, there are automatic systems in place to prevent discharge of untreated water. The water is not discharged until a residual of >0.02 ppm ozone is obtained, or the water has been treated with sodium hypochlorite.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form Y
Tick to confirm that you have attached a risk assessment to this form N
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The proposal was reviewed by the CEFAS Weymouth Laboratory Genetic Modification Safety Committee and approval given for the work to proceed subject to endorsement by the HSE.

Prion Proteins in Fish

The presence of the normal cellular isoform of the prion protein is an absolute requirement for prion replication. Recently the first data on homologues to tetrapod prion proteins (PrP) were reported in fish (Oidtmann et al. 2003, Rivera-Milla et al. 2003). Therefore fish fill the basic precondition to contract a TSE (Transmissible Spongiform Encephalopathy).

The aims of this work are to
1. Identify further PrP gene sequences in various fish species.
2. Develop diagnostic tools to detect PrP expression.
3. Develop diagnostic tools to detect possible formation of PrP-res (the protease resistant form of the prion protein). These are required for our planned experiments infecting fish with BSE or Scrapie agent and in vitro conversion to detect fish PrPres formation.
4. Further characterisation of the fish prion protein (e.g. 3D structure).
5. Investigate, using in vitro conversion, whether recombinant fish PrP can be converted into a PrP res form.

For sequencing purposes DNA and cDNA of the fish prion protein gene will be cloned into non-mobilisable plasmid vectors. The fish prion protein cDNAs/DNAs will be replicated in a disabled E.coli strain for production of sequencing quality DNA.

For fish prion protein expression in prokaryotic hosts, cDNAs of full or partial length of the translated region of the fish PrP gene will be cloned into a vector host system expressing the inserted sequence only after induction, and in which expression is otherwise suppressed. The hosts used for expression are E.coli K12 strains or strains derived from E.coli BL21, which are disabled. Alternatively, E.coli BL21 strains or strains derived from E. coli BL21, will be used, BL21 strains being considered broadly...
equivalent to E. coli K12 strains.

For prion protein expression in eukaryotic expression systems, cDNAs of full or partial length of the translated region of the fish PrP gene will be cloned into Pichia pastoris, which is disabled. Vectors that will be used in combination with Pichia pastoris are pUC or pBR322 derived vectors.

Constructs that will be generated for sequencing purposes:
are for example:
non-mobilisable plasmid vectors containing fish PrP DNA or cDNAs replicated in the E. coli K12 strain JM109 for production of sequencing quality DNA.
Examples of constructs that will be generated for expression in prokaryotic hosts:

1. Using pET vectors
For fish prion protein expression, cDNAs of full or partial length of the translated region of the PrP gene will first be established in a non-expression host (some E. coli K12 strain, e.g. JM109). Thereafter, they will be transformed into a host bearing the polymerase genes required for expression of the target protein inserted in the retrospective vector. For this purpose cDNAs of full or partial length of translated region of the PrP gene will be cloned into vector pET15b or another vector from the pET system (Novagen). Inserts cloned into vectors of the pET series will only be expressed when the vector is transferred into a host cell supplying the T7 RNA polymerase gene for expression. The hosts that are intended to be used for this purpose are: E. coli BL21, Rosetta series (derived from Tuner, which are BL21 lacZY derivates), Rosetta Blue (derived from Nova Blue, which is a K12 strain), Rosetta gami (derived from Origami, which is a K12 derivate). In the mentioned hosts, DE3 strains will be used, which means that the host is a lysogen of ADE3, and therefore carries a chromosomal copy of the T7 RNA Polymerase gene under control of the lacUV5 promoter, making this strain suitable for protein expression using vectors containing the T7 or T7 lac promoter.

2. Using pGEX vectors
Fish Prion protein expression will also be attempted using pGEX vectors. Expression of the inserted sequence is induced by IPTG, thus expression of the insert is tightly controlled. We would intend to use the same strains as mentioned above, which are either E. coli K12 or BL21 derivates.

Examples of constructs that will be generated for expression in eukaryotic hosts:
For Prion protein expression in eukaryotic expression systems, cDNAs will be cloned into vector pPIC 3.5 K or pPIC 9 (which are pBR322 derived) for expression in Pichia pastoris GS115 and KM 71 or an equivalent Pichia pastoris strain.

Example of a construct that will be generated for sequencing purposes:
DNA/cDNA of the complete or partial fish prion protein genes from various fish species will be inserted into vector pGEM-T-easy, pCR (latter being a pUC based vector), or an equivalent non-mobilisable vector. These will be used in conjunction with E. coli JM109, or another disabled E. coli K12 strain. Plasmids will be replicated in E. coli K12 JM109 (or another disabled E. coli K12 strain) for production of sequencing quality DNA.

Examples of constructs that will be generated for expression in prokaryotic hosts:

1. Using pET vectors
For fish Prion protein expression, cDNAs of full or partial length of the translated region of the PrP gene will first be established in a non-expression host (some E. coli K12 strain, e.g JM109). Thereafter, they will be transformed into a host bearing the polymerase genes required for expression of the target protein inserted in the respective vector. For this purpose cDNAs of full or partial length of translated region of the PrP gene will be cloned into vector pET15b or another vector from the pET system (Novagen). Inserts cloned into vectors of the pET series will only be expressed when the vector is transferred into a host cell supplying the T7 RNA polymerase gene for expression. The hosts that are intended to be used for this purpose are: E. coli BL21, Rosetta series (derived from Tuner, which are BL21 lacZY derivates), Rosetta Blue (derived from Nova Blue, which is a K12 strain), Rosetta gami (derived from Origami, which is a K12 derivate). In the mentioned hosts, DE3 strains will be used, which means that the host is a lysogen of ADE3, and therefore carries a chromosomal copy of the T7 RNA Polymerase gene under control of the lacUV5 promoter, making this strain suitable for protein expression using vectors containing the T7 or T7 lac promoter.
expression. The hosts that are intended to be used for this purpose are E. coli BL21, Rosetta series (derived from Tuner, which are BL21 lacZY derivates), Rosetta Blue (derived from Nova Blue, which is a K12 strain), Rosetta gami (derived from Origami, which is a K12 derivate). In the mentioned hosts, DE3 strains will be used, which means that the host is a lysogen of DE3, and therefore carries a chromosomal copy of the T7 RNA Polymerase gene under control of the lacUV5 promoter, making this strain suitable for protein expression using vectors containing the T7 or T7/lac promoter.

2. Using pGEX vectors

Expression of inserts cloned into a pGEX vector (which is a pBR322 derived vector) is under the control of the IPTG-inducible tac promoter. All pGEX vectors are also engineered with an internal LacIq gene. The lacIq gene product is a repressor protein that binds to the operator region of the tac promoter preventing expression until induction by IPTG, thus maintaining tight control over expression of the insert. Expression can be achieved in any E. coli strain. We intend to use the same strains as mentioned above, which are either E. coli K12 or BL21 derivatives.

Examples of constructs that will be generated for expression in eukaryotic hosts:

For Prion protein expression in eukaryotic expression systems, cDNAs will be cloned into vector pPIC 3.5 K or pPIC 9 (which are pBR322 derived and therefore mobilisation defective vectors) for expression in Pichia pastoris GS115 and KM 71 or an equivalent Pichia pastoris strain.

Origin & function

From fish species in which the PrP gene sequences are still not identified, the sequence will be identified by use of degenerate primers followed by RACE PCR. The PCR-products will be transferred into a suitable vector for sequencing purposes (see under 7 and 8)

Partial or full length PrP cDNA from fish species from which the sequences have already been identified (eg rainbow trout and Atlantic Salmon), or may be identified in the future, will be cloned into an expression vector in order to obtain full or partial length Prion Protein. The obtained protein(s) will be used for the following purposes:

Firstly, in order to have an antigen available, which can be used for the generation of polyclonal antisera or monoclonal antibodies. Those polyclonal antisera or monoclonal antibodies can then be used for several purposes: a) detection of expression of the normal isoform of fish prion protein in various fish tissues; b) detection of potential formation of misfolded Prion Protein after in vitro conversion experiments; c) detection of potential formation of misfolded Prion Protein in fish infected with PrP (Sc) originating from a mammalian source.

Secondly, in order to generate correctly folded fish Prion Protein, which can be analysed for its 3D structure.

Thirdly, in order to perform in vitro conversion experiments.

Evaluation of foreseeable effects

Hazard to human health

For sequencing purposes, the complete or partial DNA/cDNA of PrP genes from various fish species will be inserted into a non-mobilisable vector. These constructs will be used in conjunction with a disabled E. coli strain.

Disabled E. coli strains are non-pathogenic to humans and animals and are unable to survive in the environment. The fish prion protein DNA. cDNA sequences that will be amplified, are coding for the normal prion protein gene of fish and not for a form which is thought to be associated with human disease or disease in mammals.

The fish prion proteins will be expressed using a vector described above (pET series or pGEX series or an equivalent to those) and used in conjunction with Escherichia coli BL21 or BL21 derived strains or with E. coli K12 or K12 derived strains. E. coli BL21 is considered unlikely to colonise and establish a persistent infection in the gut of a healthy individual. A study (Chart et al. 2000. An investigation into the pathogenic properties of Escherichia coli strains BLR, BL21, DH5a and EQ1. Journal of Applied Microbiology, 89, p1048-1058) has shown that BL21 is unlikely to be pathogenic, lacking any of the pathogenic mechanisms associated with E. coli strains involved in enteric infections. Therefore BL21 strains are now considered broadly equivalent to E. coli K12 (“Guidance on BL21”; paper relating to Newsletter 30, HSE).

For expression in an eukaryotic system, Pichia pastoris will be used, which is disabled and therefore non-pathogenic to humans and animals and unable to survive in the
environment.

The fish Prion protein genes have no association with any known hereditary or acquired animal disease and have not been shown to convert human forms of PrP into pathogenic isoforms.

Hazards to the environment
The proposed work uses disabled hosts and mobilisation defective or non-mobilisable vectors, which will not survive in the environment. The fish prion protein genes have no association with animal disease.

All laboratory waste GMMs and proteins expressed by the GMMs will be autoclaved on site before disposal.

According to the Advisory Committee on Genetic Modification Compendium of Guidance, non-expression activities in disabled hosts as well as expression of normal human or animal PrP genes are both required to be performed at containment level 2. This work will be done in a containment level 2 laboratory using the safety procedures appropriate for that level.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Inactivation and Disposal:-
All material for disposal (pipette tips, microcentrifuge tubes, Petri dishes, pipettes etc) is placed in biohazard autoclave bags and transported to the autoclave by authorised personnel in robust metal bins; the latter is done on a daily basis. Inactivation of GMMs is performed by autoclaving at 126°C for 30 minutes using an LTE scientific series 400 autoclave. Autoclaved recyclable items are washed and returned to the clean store. Autoclaved disposable material is discarded with normal laboratory waste. The degree of kill by autoclaving is effectively 100%. Generated fish Prion Protein (full and partial length) will also be autoclaved before disposal as described above.

Validation and Monitoring of Control Methods:-
The autoclaves are serviced every 3 months, and at each service independent thermocouples are used to demonstrate that the correct temperature and pressure have been reached for the required time. On subsequent runs, a chart recorder is used to verify that the correct conditions were reached. Should those conditions not be reached, the load will be retained until the autoclave has been serviced/mended.

A maximum of 101 of culture medium may occasionally be disposed of at one time. Contaminated material is placed in biohazard bags or dedicated steel bins prior to autoclaving. The autoclave is situated within the containment suite. Culture media and contaminated equipment is sterilised by autoclaving (121 degrees C, 15 psi, for 20-30 minutes depending on the load size and characteristics) prior to disposal. After autoclaving liquid waste is poured down the drains with copious amounts of water and solid waste is disposed of with the University's general rubbish. Records are kept of all autoclave runs, including the name of the operator, the type of material and the cycle characteristics. The chamber temperature for each run is recorded on a chart recorder and the effectiveness of the cycle checked using a sterilization indicator (Propper Manufacture Inc.). Each month the effectiveness of the autoclave is checked using spore strips (Propper Manufacture Inc.). Equipment which cannot be autoclaved, bench services etc. are disinfected using an amphoteric detergent Tego (ASAB). Swabs are taken around the containment laboratories on a monthly basis to confirm the effectiveness of the disinfection procedures.

Maximum culture volume 100 ml.
All waste is autoclaved at 121 degrees C for 15 minutes.
This method of deactivation was validated by plating out for growth on autoclaved culture - there was no growth. The autoclave is calibrated to NAMAS/UHAS/ISO9001 specifications and the temperature and time for each run is recorded.

For activities involving GMMs, describe the waste management measures which will apply to the activity

For activities involving GMMs, describe the waste management measures which will apply to the activity

Maximum culture volumes are 250 ml. Typically culture is on a small scale in broths (10 ml) or agar plates. Waste is transported in sealed autoclave bags within autoclavable containers to the

Autoclaving uses 121 °C for 30 min.

Performance is monitored by the use of Browns tubes, chart recording, visual monitoring of temperature and pressure dials. Additionally the autoclaves are service on at least an annual basis.

Historical Significant Changes

Historical Date of Additional Info
**Project Additional Information**

**Purposes of the contained use**

The purpose of the contained use is to minimise the risk to personnel of infection from the organisms used and genetically modified during the proposed programme. The proposed work will involve ADCP group 2 organisms, particularly Salmonella sp. Salmonella infection can result in a self-limiting gastrointestinal illness in healthy individuals. There is therefore a risk of infectious disease from this work and the purpose of the containment is primarily to minimise this risk. Additionally we consider that there is a low risk of transfer of uncharacterised genetic material within Salmonella sp. during experimentation.

It is possible that this work will be extended in the future to include other ADCP 2 organisms eg Campylobacter sp. and Listeria sp. requiring similar contained use.

**Recipient or parental organism**

Recipient strains of Salmonella may include S. Typhimurium and S. Enteritidis as well as other Salmonella species, and may include those previously isolated from foods. The resulting Salmonellae may be modified to contain reporter genes (eg genes for bioluminescence) and antibiotic resistance markers typically used in cloning vectors (eg ampicillin, kanamycin). This work will not include recognised more pathogenic species such as Salmonella typhi or S. paratyphi categorised as ADPC 3 pathogens.

It is possible in the future that this programme of work will be extended to include similar studies with other ADCP 2 organisms eg Campylobacter sp. and Listeria sp. (It is likely that related class 1 containment level 1 experiments to support this work will also be required eg the growth and isolation of plasmids from disabled E. coli host strains or and transfer of plasmids from disabled hosts to ADPC 2 pathogens).

**Host/vector system**

Vectors will be pUC derivatives in the first instance. pUC derivatives are of limited host range and considered as non-mobilisable. Genetic experiments may be required to transfer reporter genes within Salmonella either through the use of broad host range vectors or the transduction of reporter genes using phage such as P22 or wild type phages isolated from Salmonella sp.

The host systems will be derived from strains of obtained from recognised culture collections, academic institutions or those isolated in this laboratory from food samples but specifically not Salmonella typhor S. paratyphi.

**Origin & function**

Genetic constructs will be obtained from academic establishments or may be constructed within this laboratory. The intended function of the genetic constructs is to act as reporter systems. The reporter genes may be used as a measure of gene expression in an infected cell eg as part of a detection mechanism or for the detection of cell signalling responses during enrichment culture. An example of this is the plasmid pSB367 * This is a pUC18 construct and confers resistance to ampicillin. It contains a fusion of the Salmonella dublin spvRA promoter with the luxCDABE from Photorhabdus luminescens. The expression of the spv operon requires functional RpoS and results in bioluminescence when the spvRA promoter is induced.

**Evaluation of foreseeable effects**

It is possible that co-transfer of pathogenic determinants between the pathogens used may occur during genetic experiments eg transformation and transduction.
experiments. In this instance we are primarily concerned with the transfer of plasmid sequences containing reporter genes or construction of transducing phage carrying fragments of cloned reporter gene/vector sequences. However generalised transduction could potentially transfer large fragments of DNA and pathogenicity islands within strains. Any expression of co-transferred DNA in the absence of selective pressure is dependent on overcoming restriction and recombination barriers in the recipient cell.

The primary aim of transduction experiments will be to establish a lytic cycle in the recipient cell resulting in expression of the reporter gene and subsequent death of the recipient cell. It is unlikely that the proposed programme will result in the construction of more virulent Salmonella strains. The use of reporter genes is well established and not associated with any other activities.

A worst case scenario could envisage the co-transfer of a pathogenicity island during transduction experiments with a vector associated antibiotic resistance, followed by infection of laboratory personnel. Transfer of pathogenicity traits within Salmonella already could conceivably occur as a rare event during generalised transduction, however the resulting strain is not anticipated to be more pathogenic than existing Salmonellae. Antibiotic treatment is not used clinically for the treatment of Salmonellosis however in rare cases of septicaemia treatment with guinolone antibiotics can be used. Antibiotics associated with resistant markers commonly used in vectors eg for ampicillin and kanamycin are not routinely used to treat Salmonella infection. There are increasing concerns regarding the emergence of multiple antibiotic resistant Salmonella eg Salmonella enteritidis DT104.

Avoidance of infection of laboratory personnel can be achieved by Good Microbiological Practice, compliance with COSHH, adequate training of staff in the handling and safe disposal of microorganisms and making staff aware of hazards that may arise due to particular circumstances, eg increased risks for immuno-compromised or pregnant staff.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All waste materials will be autoclaved. These will include solid agar plates. 100ml liquid cultures, and plastic tips. Waste treatment will be carried out using LFI's waste autoclave operating at 121 C for 30 minutes. No viable cells of the GMM will survive the process. Waste treatment is monitored by a trained technician with records kept for every autoclave run, indicating temperature and time operated.

**Is an emergency plan required according to regulation 20?** N

**If yes, tick to confirm that it is attached to this form** N

**Tick to confirm that you have attached a risk assessment to this form** Y

**Tick if you are claiming exemption from disclosure for section of the risk assessment** N
The genetic modification safety committee reviewed example risk assessments associated with this work. The committee recommended that the proposed studies should use recognised disabled host strains and characterised strains as detailed in the risk assessment. It was recognised that the intended approaches used in the programme could eventually be applied to wild type strains of Salmonella eg the use of phage for detection of Salmonella sp. in enrichment culture.

It was noted that transfer between genera can be permitted from recognised disabled donor strains and would be carried out in the programme. It was agreed that such experiments would not include transfer between wild type strains of ACDP 2 pathogens eg between Salmonella and Campylobacter). Work with Salmonella typhi or S. paratyphi is not permitted since these are ACDP 3 pathogens. The proposed work on Salmonella sp was classified as class 2 containment level 2.

It was noted that experiments would be performed to examine the influence of signalling molecules from ACDP 2 organisms. It was noted that the proposed host strain Vibrio harveyi was a relatively safe Vibrio sp. However Vibrio sp are ACDP 2 pathogens and since this work involves other ACDP 2 organisms then the work should be considered class 1 containment level 2.

Any future studies other than those directly proposed within the risk assessments cannot be carried out without risk assessment and the approval of the GMSC.

A. Tissue culture.

All work involving genetically modified mammalian cells utilises established well-characterised cell lines of rat or human origin or primary cultures of animal cells as the host ie. they are especially disabled. The cells are unable to survive outside of the controlled tissue culture environment. Nevertheless, tissue culture fluids from these cultures are routinely aspirated off with disposable Pasteur pipettes and collected in a flask containing hypochlorous acid (4 'Presept' tablets per litre of medium). After a minimum of 4 hours, the inactivated waste is poured down a sink. Pasteur pipettes are immersed in a similar solution for at least 24 hours before being consigned to a glass-disposal bucket.

The maximum volume of culture fluid that may be released at any one time is 800 ml.

Any culture plates bearing viable cells that need to be disposed of are inactivated with 70% ethanol or bleach before being consigned to a waste bag for incineration.

B. Bacterial culture.

The following procedures conform to the manufacturers recommendations which guarantee inactivation of all mammalian cells and bacteria and validation is not required.

Bacteria used are commercially available disabled strains of E. coli with non mobilisable or poorly mobilisable vectors. Culture dishes containing agar and bacteria for disposal are placed in an autoclave bag and autoclaved prior to bagging for incineration.

Flasks containing media broth and bacteria are submerged in a bucket of sodium hypochlorite (5% commercial bleach) for 24 hours prior to washing and autoclaving.

Tubes containing bacterial residue are soaked for 24 hours in 1% "Virkon" disinfectant before washing and autoclaving.

That all users of transfected cells comply with the above procedure is regularly confirmed by the designated laboratory supervisors.

Our maximum bacterial volume at any time is 1.5 litres.

Cell Culture: we estimate approximately 2 litres of cell culture media used for GM cells.

Waste Deactivation:
- All liquid bacterial waste is collected in the flasks used to grow the E.coli. This is then autoclaved at 132 degrees C, 1.9 psi for 30 minutes. The liquid waste is then considered safe to dispose of to the drains with excess water.
- All liquid cell culture waste is added to Hycolin reagent for decontamination, (obtained from William Pearson Chemicals). Hycolin reagent conforms to BS6905:1987. One litre waste bottles have 20 ml of Hycolin reagent added to them prior to any routine culture work. All waste media is then added to this such that the final concentration of Hycolin, after the bottle is full, is 2%. Therefore, GM cell culture waste is never treated with less than the recommended 2%. This is then disposed of to the drains with excess water.
- All contaminated plasticware is autoclaved.
- All contaminated glassware is autoclaved.

Validation of the Deactivation Method
The Hycolin reagent is bought from a reputable source and is routinely used at the recommended concentration.
Our autoclave is serviced and performance tested by engineers from the manufacturers (Astell Scientific) every six months.

Monitoring of the Deactivation Method.
Hycolin disinfectant is a broad-spectrum disinfectant used at the recommended dilution for full effectiveness. Indeed, since we routinely add the waste to the disinfectant, there is no chance of inefficient deactivation due to poor mixing of waste and disinfectant. Given the severity of the treatment, and the fragility of mammalian cells, monitoring of the deactivation was felt to be unnecessary.

The efficiency of autoclaving is routinely monitored using sterilisation indicator tape. Bio-Hazard bags are not completely sealed in order to allow efficient steam sterilisation of the contents. Only if the indicator tape shows that sterilisation has taken place is the waste discarded.

Purposes of the contained use

The purpose of contained use is to reduce risk of contamination of the environment and infection. E. coli strains (commercially available) and their derivatives are unlikely to pose any health risk, don't have ability to survive in the environment due to the presence of various mutations. Campylobacter and Yersinia pseudotuberculosis strains are classified as Class 2 microorganisms. The GM strains of these bacteria (mutants) are likely to have decreased survival/virulence. Therefore, CL2 will provide adequate measure for containment of all strains and derivatives to be used in this study.

Recipient or parental organism

- E. coli - Class 1
- C. jejuni - Class 2
- Y. Pseudotuberculosis - Class 2

Host/vector system

Delivery vector for making C. jejuni mutants is plasmid pUC18, which cannot be maintained or replicate in this host unless it contains a fragment complementary to a gene target, in which case recombination will result in allelic replacement of the target gene with its modified copy.

In case of Y. pstb, a PCR product is used for gene delivery/recombination, which is assisted by the presence of lambda-red recombination system present in vector pAJD434. This helper plasmid carries trimethoprim antibiotic resistance marker used for selection. The vector is temperature sensitive and is lost at 42°C.

The mutants and complemented strains will carry a kanamycin or chloramphenical antibiotic resistance marker, or both.

E. coli host used for cloning will contain vectors, or plasmids carrying individual genes (or their fragments) from C. jejuni and Y. pstb, and will carry an ampicilling resistance marker.

Origin & function

The genes to be mutated in both C. jejuni and Y. pstb are potentially (by similarity to other bacteria) involved in stress response, virulence or survival in the environment. One set of genes encodes putative proteases playing a variety of functions in bacteria. Some of these enzymes are required for processing of other proteins, others - for digestion of bacteria survival in stress conditions, and in reduced virulence. Another set of genes to be targeted are those potentially involved in interaction with host cell receptors. Elimination of these gene products by mutagenesis is expected to reduced virulence properties of the recipient strains.

The insertion of antibiotic resistance markers does not increase bacterial virulence or ability to survive in the environment and is a standard genetic manipulation procedure.

Evaluation of foreseeable effects

Class 1 microorganisms (CL1 required)

- E. coli K12 strains to be used are designed for cloning experiments. They are non-pathogenic and unable to survive in the environment and are therefore classified as Class 1 organisms. Attenuated E. coli strains carrying fragments or full copies of genes (e.g. those encoding proteases or adhesins) originated from C. jejuni and Y. pstb.

Class 2 microorganisms (CL2 required)

- Wild types, mutants and complemented derivatives of C. jejuni and Y. pstb. Although mutations are most likely to result in reduction of virulence, a possibility of at least partial retention of virulence properties will remain, so that CL2 will be required. Confirmation of phenotypic changes will also require complementation studies, in which an exogenous copy of the inactivated gene will be introduced into the mutant. Since this gene will 1) only mimic the wild type copy 2) be expressed at suboptimal level from an artificial promoter 3) integrated as a single copy into bacterial chromosome, it will most likely not restore the full phenotype of the wild type strain and will not result in any increase in pathogenicity. Therefore, these construction and investigation of partially complemented strains not require containment level higher than CL2.
Recombinant E. coli strains

It is highly unlikely that cloning of individual genes and their fragments into attenuated E. coli will make the latter virulent. None of the genes cloned into these strains encode putative toxins and are highly unlikely to be able to convert a non-pathogenic recipient E. coli strain into a pathogenic organism. This is because (with some exception, e.g. as with cloning toxins or invasions) virulence normally requires expression of more than one virulence-related genes. We therefore consider that cloning/expression of genes in this host can be conducted under CL2.

The likelihood that the GMM will be released into the environment under the requirements of the containment level to protect human health is low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No experiments with plants or animals will be conducted

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The project will generate the following waste: liquid (up to 100ml) and agar plate cultures, contaminated pipettes, pipette tips and glassware. All contaminated waste, will be autoclaved on a “kill cycle” ensuring that the waste is held at a holding temperature of 121°C (15psi) for 15 minutes. This will kill all GMM's. Autoclaving efficiency will be monitored using thermocouple recorder, and Browne's indicator tubes (Type 1, Black spot) according to manufacturers protocol.

VIRKON (Antec International) will be used for all disinfection work involving wild type C. jejuni and Y. ptsb strains, their mutants and derivatives. 1% (v/v) use-dilution will be prepared fresh for us each day by adding the appropriate volume of concentrate to cold tap water, following the manufacturers instructions. The use-dilution may be stored for 24 hours only.

1% VIRKON is shown to be an effective disinfectant killing many bacteria including C. jejuni and Y.ptsb (see reference below). Any spillage will first be wiped out with dry tissue paper, then treated with tissue paper soaked with 1% VIRKON. The used contaminated tissue paper will be collected in bags/containers and autoclaved. Where appropriate (e.g. small bench areas) will be treated with 70% ethanol.

New staff will undergo appropriate training in order to minimise risk when working with these bacteria.

The work will be conducted in CL2 environment in a lab suite designed to the current safety standards and having all required equipment, including a Class 1 safety cabinet, which can be used if required. However, according to the current risk assessment the use of Class 1 safety cabinet is not required for this project because no experiments producing substantial aerosols (homogenisation and sonication) will be conducted, and due to low risk of infection associated with work involving these enteric pathogens, which can only cause infection when transmitted via oral route (usually with contaminated food/drinks). Therefore, the risk of infection with aerosol is low.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Project Additional Information

Purposes of the contained use

The purpose of the contained use is to prevent laboratory required infections and any contamination to the environment. Regarding all 3 activities, the commercially available laboratory cloning strains of E. coli that will be used are highly attenuated due to their multiple mutations and cannot survive in the environment. They are Class 1 microorganisms which are unlikely to pose any health risk. The expression of a single gene from the above organisms in E. coli will not render these organisms virulent. Nevertheless all work with recombinant E. coli will be conducted under CL2 conditions (in a class 1 safety cabinet in a category 2 laboratory).

For activities 1-3 the mutant strains of the above listed organisms are likely to have a marginal decrease in both virulence and survival and the complemented versions of these strains will express the relevant intact gene at suboptimal levels and will thus not be more virulent than the parent strain. All work will be conducted under CL2 conditions which will provide an adequate measure for containment for all strains and their derivatives.
For activities 1-3, Class 1 recipient strains will be attenuated, laboratory cloning strains of E. coli such as JM109 and DH5 alpha and class 2 recipient strains will include Neisseria spp., Helicobacter spp., Staphylococcus spp., and P. aeruginosa

Host/vector system

For activities 1-3, PCR cloning vectors such as pCR2.1, pJET and pCR-II-TOPO will be used to clone genomic DNA from the above listed organisms in a laboratory cloning strain of E. coli. Appropriate DNA fragments will be excised and cloned into the following vectors:

- Activity 1 For generating targeted mutant strains in Neisseria spp., Helicobacter spp., and Staphylococcus spp. plasmid pUC18/19 carrying the relevant gene disrupted by an antibiotic resistance gene such as the kanamycin resistance gene will be used for delivery of the disrupted gene to the microorganism for homologous recombination in the chromosome to take place. The pUC18/19 plasmid vectors will also be used for generating constructs for complementing the mutant strains and will carry the wild type gene and a different antibiotic resistance gene such as the chloramphenicol resistance gene.
- Activity 2 For generating un-marked, deletion mutant strains of P. aeruginosa, plasmid vector pMQ30 (Robert et al., 2006) carrying DNA upstream and downstream of the gene of interest will be used to permit homologous recombination in the recipient organism. The pBroadgate plasmid vector (Kovach et al., 1995) carrying the relevant wild-type gene will be used to complement mutant strains.
- Activity 3 For constructing the transposon library of mutants in N. meningitidis and N. gonorrhoeae the EZ:: TN<KAN-2> transposome kit (Epicentre will be used that permits the random integraton of the Tn903 kanamycin resistance gene into the chromosome. Plasmid vector pMR33 (Ramsey et al., 2012) will be used to complement selected mutant strains and will carry the appropriate intact gene from the wild type strain and the ermC gene which confers resistance to erythromycin. The pMR33 construct designed specifically for complementation in N. meningitidis and N. gonorrhoeae contains regions of homology with iga and neighbouring trpB and directs the insertion of the gene of interest and ermC into the intergenic region between these two genes by homologous recombination leaving iga and Neisseria and permits controlled expression of the relevant gene.

In activities 1-3, the antibiotic resistance markers that will be used are not the antibiotics that would be used to treat infection caused by any of these organisms.

References

Origin & function

For activities 1-3, the function of the PCR cloning vectors is to allow cloning of PCR products of the genes of interest form bacterial genomic DNA as well as antibiotic resistance genes for the purpose of creating plasmid constructs in E. coli. These constructs will then be used for generating targeted knock outs in Neisseria spp., Helicobacter spp., Staphylococcus spp and P. aeruginosa and for complementing the mutant strains of these organisms.

Specifically the function of the antibiotic resistance gene in the constructs designed to generate targeted gene knock outs or the Tn903-kanamycin resistance gene in the transposon for generating random mutants is 2 fold. Firstly the insertion of the antibiotic resistance gene disrupts the target gene or random gene respectively in the recipient strain and secondly it enables the selection of successful mutated cells following growth of the cells on the appropriate antibiotic. Like wise the second antibiotic resistance gene in complementation constructs enables the selection of successfully complemented strains by growth on the relevant antibiotic. Improtantly, the insertion of antibiotic resistance genes will not increase the virulence of the bacterium or its ability to survive in the environment and is a standard genetic manipulation used in microbiology.

Evaluation of foreseeable effects

For activities 1-3;
Recombinant attenuated E. coli cloning strains.
The attenuated laboratory strains of E. coli harbouring PCR cloning vectors or plasmid constructs for generating targeted knock out mutant strains or plasmid constructs for complementary mutant strains will merely carry an antibiotic resistance gene and a single gene or equivalent sized fragment of genomic DNA from Neiseria spp., Helicobacter spp., Staphylococcus spp. or P. aeruginosa. Since virulence requires the expression of multiple virulence-associated genes, the expression of one gene and at a low level in E. coli will not render this organism more pathogenic. The antibiotic resistance genes expressed by the GM strains are not the antibiotics that would be used to clinically treat infection caused by that organism. The likelihood that the GMM will be released into the environment under the requirements of the CL2 is extremely low. All construction and analysis of recombinant E. coli will be conducted under CL2 conditions.

The mutant strains are likely to be marginally less virulent than the parent strains.

The complemented strains carrying an intact copy of the inactivated gene will not be more virulent than the parent strain due to the inserted gene being integrated as a single copy into the chromosome and expressed at suboptimal levels. Thus the complemented strains are expected to show only partial restoration of the relevant wild type phenotype. Thus these strains will not require containment label higher than CL2.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No experiments with plants or animals will be conducted

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The project will generate the following waste: liquid (up to 100 ml) and agar plate cultures, contaminated pipettes, pipette tips and glassware. All contaminated waste, will be autoclaved on a "kill cycle" ensuring that the waste is held at a holding temperature of 134° (15 psi) for 45 minutes. This will kill all GMMs. Autoclaving efficiency will be monitored using thermocouple recorder, and Browne's indicator tubes (Type 1, Black spot) according to manufacturer's protocol.

VIRKON (Antec International) will be used for all disinfection work involving wild type E. coli and N. meningitidis strains and all recombinant strains of these organisms 1% (v/v) use-dilution will be prepared fresh for use each day by adding the appropriate volume of concentrate to cold tap water, following the manufacturer's instructions. The use-dilution may be store for 24 hours only.

1% VIRKON is shown to be an effective disinfectant killing many bacteria including N. meningitidis. Any spillage will first be wiped out with dry tissue paper, then treated with tissue paper soaked with 1% VIRKON. The used contaminated tissue paper will be collected in bags/containers and autoclaved. Where appropriate (e.g. small bench areas) will be treated with 70% ethanol.

New staff will undergo appropriate training. New staff working with N. meningitidis will be vaccinated in order to minimise risk when working with this organism.

The work will be conducted in CL2 environment in a lab suite designed to the current safety standards and having all required equipment, including a Class 1 safety cabinet, which will be used for all work.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

**Project Ref** 589/17.1

- **Date Ackn'd** 17/02/2017
- **CU2 Project Title** Regulation of protein phosphorylation in cardiomyocyte studies in vitro, pertaining to the development of heart failure
- **Class** Class 2
- **Culture Volume Class** < 1 Litre
- **Consent** Consent Granted

**Project Additional Information**

**Purposes of the contained use**

The level of protein phosphorylation in the individual cardiomyocyte of the heart has been identified to have a causative role in the development of heart failure. The level of phosphorylation is controlled by the balance in activity.
of a superfamilies of protein kinases and protein phosphatases. Therefore it is important to better understand how these proteins are regulated in heart failure and which of these protein may play a causative role in developing heart failure. The work outlined in this notification will use adenoviral (serotype 5) vectors to genetically modify cardiomyocytes in culture. The vectors to be constructed during these studies will allow us to express or silence the expression of wild type or mutated type 2A protein phosphatase catalytic subunits (PP2AC, PP4C and PP6C) and their associated regulatory subunits to delineate their role in the pathogenesis of heart failure.

Recipient or parental organism

Recipient will be primary (adult rat ventricular myocytes) or cell line (H9c2) cardiomyocytes both of which will be maintained/grown in cell culture

Host/vector system

The vectors to be used are attenuated adenoviral vectors. These will be designed to express wild type proteins, constitutively active or inactive mutants, or to produce siRNA to knock-down native protein levels. We wish to characterise the effects of these alterations on protein phosphorylation in cardiomyocytes in in vitro experiments. The adenoviral vector to be used is serotype 5 with deletions of the E1 and E3 regions. The probability of reversion to wild type is very low, as the deletions are non-contiguous, making rescue by homologous recombination with wild type adenovirus very unlikely.

Origin & function

| PP2A catalytic subunit and associated regulatory proteins of the scaffold "A" and regulatory "B" classes. Elevated activity and expression of these proteins are thought to contribute to the development of heart failure. | Adenovirus. |
| PP6 catalytic subunit and associated regulatory proteins from the sit4 associated proteins (SAPI -3) and ankyrin repeat domain (ANKRD) proteins ANKRD28/44/52. Unknown function in cardiomyocytes. | Adenovirus. |
| Type 2A protein phosphatase regulatory protein immunoglobulin binding protein 1 (IGBP1) also known as alpha4 is known to be antiapoptotic in mu-iple cell types. Unknown function in cardiomyocytes. | Adenovirus. |
| Type 2A protein phosphatase regulatory protein TIPRL(Tip41) thought to inhibit activity of type 2A protein phosphatases and promotes cell death in response to genotoxic stress. Unknown function in cardiomyocytes. | Adenovirus. |
| PKB rNT, constitutively active, kinase-dead and inhibitor-resistant forms) Kinase, implicated in diverse signalling events. Our recent evidence suggests that activation of PKB has an inhibitory effect on NHE activity. Intend to create inhibitor-resistant form to determine role in NHE regulation. Constitutively active form is oncogenic (ie. v-Akt: inhibits apoptosis, promotes constitutive activity of ERK pathway). | Adenovirus. |
| PKCalpha, PKCdelta, PKCepsilon kinases (GFP fusion or kinase-dead forms): Implicated in diverse signalling events in the cytoplasm and nucleus. Suggested to phosphorylate many ion channels, cytoskeletal proteins, receptors and transcription factors. Some isotypes, ie. PKCalpha are highly active in transformed cells and are growth promoters. | Adenovirus. |
| ERK1 , ERK2 rNT only) Extracellular-signal regulated kinases downstream of MEK and upstream of RSK. Protooncogene, but overexpression of wild type forms may promote mrosis . | Adenovirus. |
| MEK rytT, constitutively active or kinase-dead forms) Kinase, implicated in diverse signalling events in the cytoplasm and nucleus. Various isoforms to be used as upstream activators of MAPKs. Phosphorylates downstream MAPKs. MEKs exhibit high activity in transformed cells and are growth promoters. | Adenovirus. |
| Ras (NI? inactive and V12 constitutively active forms) Ras regulates downstream Signalling such as MAPK activation. | Adenovirus. |
WT and active mutants of Ras are growth promoters/oncogenes. Active Ras will not be used in primary human cells or in vivo. Adenovirus.

Gbetagamma: G-protein beta and gamma subunits. Regulates phospholipase Cgamma activation and downstream signalling. Adenovirus (bicistronic expression of both proteins from one mRNA)

Rac (N? inactive and V12 constitutively active forms) : Rac is a small GTP-binding protein that regulates downstream signalling such as MAPKisAPK activation. WT and active mutants of Rac are growth promoters/oncogenes. Adenovirus.

PKA-Rl ryvT and cysteine mutants) Regulatory domain of protein kinase A; binds cAMP and the catalytic domain; no known hazards. Adenovirus

PKD rNT, kinase-dead, Silencing) Protein kinase D; activated by PKC; phosphorylates several substrates such as cMyoBPC, troponin I, histone deacetylases; promotes increased MEF2 activity and hypertrophy in cardiac myocytes; no known hazards. Adenovirus.

MKK3 rNT, Dominant- negative, Constitutively active and truncated MKK3[3] form) : MKK3 dual-specificity protein kinase that activates p38-MAPK. Activated by different forms of cellular stress and inflammatory cytokines; no known hazards. Adenovirus.

Health and Safety Executive

MKK6 (WT and Dominant- negative form): MKK6 dual-specificity protein kinase that activates p38-MAPK. Activated by different forms of cellular stress and inflammatory cytokines; no known hazards. Adenovirus

G5K3-a and 13 (Wt)Glycogen synthase kinase, regulator of numerous proteins. Involved in a variety of different pathways and implicated in a number of diseases, including Type II diabetes, Alzheimer's disease, inflammation and cancer. Adenovirus

Calcineurin A (constitutively active): Calcium-dependent protein phosphatase; activates NFAT-dependent transcription; expression of constitutively active calcineurin A in mice resulted in diabetes. Adenovirus

CAIN: Calcineurin inhibitor protein; no known hazards. Adenovirus.

856alpha (full length and N-terminal domain): Targeting subunit of protein phosphatase 2a; determines localisation of phosphatase activity in cardiac myocytes; no known hazards. Adenovirus.

HDAC4, 5 & 7 Class 2a histone deacetylase isoforms; sequester pro-hypertrophic transcription factors in cardiac myocyte nucleus, which are released when HDAC is phosphorylated by PKD or CaMK; no known hazards. Adenovirus.

NHE1 (WT & drug-resistant or C-terminal domain fragments) Na+IH+ exchanger regulatory domain; wild type and various 5er:Ala mutants; target for several kinases; no known enzyme activity; unlikely to be hazardous. Adenovirus.

14-3-3 proteins binds to phosphorylated proteins, including NHE1 ; also mutant variant which cannot bind; no enzyme activity; not known to be hazardous. Adenovirus.

p90 ribosomal S6 kinase (isoform 1-4): Downstream target of ERK pathway, regulates a subset of growth factor-induced transcription factors and other cellular targets such as NHE1 . Intend to create silencing construct to decrease R5K expression. No known hazards. Adenovirus.

phospholemman: Regulator of NaK-ATPase activity in cardiac myocytes. Alters NaK-ATPase activity in response to
intracellular signalling via PKA, PKC; no known hazards. WT and 5er-Ala mutants. Adenovirus.
p38 MAPKL: p38 MAPK, all 4 isoforms (α, θ, V, ~); stress/cytokine-activated kinase, phosphorylates MAPKAPK2, ATF2, MEF2, heat shock proteins; no known hazards. Adenovirus.
Glutathione-S-transferase (GST): full length GST; involved in glutathiolation of proteins and lipids; active enzyme; not known to be hazardous. Adenovirus.
Luciferase: Firefly protein used as a reporter of eg MEF2 promoter activity; no known hazards. Adenovirus.
EGFP & ECFP Green fluorescent protein from jellyfish Aequorea victoria (and cyan fluorescent protein [CFP]); used as a reporter; no known hazards. Adenovirus.
beta-galactosidase full length beta-galactosidase; involved in metabolism of galactose; active enzyme; not known to be hazardous. Adenovirus.

Evaluation of foreseeable effects

All of the viral vectors to be used are attenuated and unable to reproduce without laboratory-specific helper cells to provide essential deleted genes in trans. In the intended recipient cells, the vectors are expected to express the specific proteins cloned into the vector, sometimes together with marker proteins such as green fluorescent protein, or to suppress the expression of native proteins. The expression or loss of the various proteins is anticipated to modulate the response of cardiomyocytes to various added factors, which will be tested in in vitro experiments. The modification of human cardiomyocytes in a contained manner is not likely to present a hazard.
The accidental inoculation of personnel with modified cardiomyocytes should also not be a hazard, as the cells should be rapidly cleared by the immune system.
Exposure of workers to viral vectors should also result in rapid clearance by the immune system. Any vectors which manage to infect cells will be unable to reproduce, so any effect of transgene expression should be minimal.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

None under the current project

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste (tips, serological pipettes, tissue culture plastic, vials and other containers) disinfected by immersion in 10% Microsol3+ overnight. After rinsing with water, plastic waste is disposed of via clinical waste stream (orange bags).
For liquid waste, Microsol3+ is added to 10 % and left overnight. Waste is then flushed down drain with lots of water.
Surfaces are wiped down with 10 % Microsol3+.
Microsol3+ is effective against bacteria, fungi and viruses, and overnight incubation at the stated dilution should result in 100 % kill.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y
The Kingston University Viral Genetic Modification Advisory Group (vGMAG) reviewed the assessment on 16th August 2016 and approved it at GM Class 2 with no amendments required.

### Project Additional Information

GM594/01.1 TRANSFERRED TO GM470 ON 18/02/2005
Purposes of the contained use

We are interested in studying the role of individual bacterial genes in (a) the pathogenesis of bacterial infection (b) the host immune response to products of these genes, and (c) killing by colicins. The studies are designed to increase our understanding of host-pathogen interaction and develop new preventative and therapeutic methods against invasive bacterial disease. We attempt to detect proteins of interest (usually vaccine candidates or antimicrobials) from sequence data or genomic expression libraries (eg in the phage based x-ZapII) and identify their encoding genes. We then amplify the genes by PCR, clone them in plasmid vectors and express them under the influence of IPTG. These will be used to carry out studies on the characterisation of the molecular, immunochemical and functional properties of the antigens of interest.

Recipient or parental organism

Neisseria: including Neisseria meningitidis, N. gonorrhoea and commensal Neisseria (eg N. lactamica)
Campylobacter: Campylobacter jejuni and C. coli.
Klebsiella: K. pneumoniae ssp and K. oxytoca.

Host/vector system

Hosts:
All are E. coli, derivatives of strain K12: Examples:

JM109 (recA1, endA1, gyrA96, thi, hsdR17 (rK-,mK+), relA1, supE44, (lac-proAB), [F’, traD36, proAB, lacIqZM15].
XL10-Gold (Tetr, (mcrA) 183, (mcrCB-hsdSMR-mrr) 173, endA1, SupE44, thi-1, recA1, gyrA96, relA1, lac hte, [F’proAB lacIqZ M15 Tn10 (Tet) Amy Camr].
XL-1 Blue (endA1, hsdR17 (rK-, mK+) relA1, supE44, thi-1, gyrA96, (lac-) [F’ proAB lacIqZ M15 Tn1].

Vectors (examples)
1. Plasmid vectors that will be used for studies of protein over-expression from native and inducible promoters (native constructs - pGEM-T, pBr4, pBR322, pUC18/19; inducible vectors - pBAD, pET etc) are considered non-Mobil sable or mobilisation defective. These plasmids will remain in the transformed host and will confer antibiotic resistance genes to the host. Examples of antibiotics to be used are tetracycline, kanamycin, chloramphenicol or ampicillin.

pBluescript: pUC19 derivative, which is non-mobilisable. It contains a colE1 origin of replication, T3 and T7 promoters, and an ampicillin resistance gene. It has an F1 origin that contains an initiator and terminator for M13 DNA replication and the lacZx peptide for blue/white selection.

pGEM: pUC19 derivative, which is non-mobilisable. It contains the colE1 origin of replication, SP6 and T7 promoters, ampicillin resistance marker and the lacZx peptide for blue/white selection.

pREP4: pACYC-184 derivative, which is non-mobilisable. It contains a kanamycin resistance gene and lacIq for constitutive expression of the lac repressor.

pQE30: pDS-56 derivative, which is non-mobilisable. It contains an ampicillin resistance gene and a 6x Histidine tag for Ni/NTA purification of expressed proteins.

PET and pBAD: non-mobilisable expression vectors that contain; ampicillin or kanamycin resistance genes and a 6x Histidine tag for Ni/NTA purification of expressed proteins (pET); or an arabinose inducible promoter for regulated, inducible expression (pBAD).

PCRT7/NT-TOPO and its related plasmids: pUC derivative, which is non-mobilisable. It contains an ampicillin resistance gene and a 6x Histidine tag for Ni/NTA purification of expressed proteins.
2. Phages:

zapII: a based expressed phagemid useful for cloning genomic DNA in the range of 2-10 kb. zapII contains the pBluescript replicon. At the junction between n and the pBluescript DNA sequences there is an initiator and terminator for M13 replication.

Transposons: Tn5 derivatives (eg EZ::TN transposomes from Cambio) which have been constructed to transpose once. Plasmid vectors that will be used for studies of protein over-expression from native and inducible promoters (native constructs - pGEM-T, pBR322, pUC18/19; inducible vectors- pBAD, pET etc) are considered non-Mobil sable or mobilisation defective. These plasmids will remain in the transformed host and will confer antibiotic resistance genes to the host. Examples of antibiotics to be used are tetracycline, kanamycin, chloramphenicol or ampicillin.

Origin & function

Origins of the geneic material are the above mentioned bacterial pathogens. They include:
Neisseria: including Neisseria meningitdis, N. gonorrhoea and commensal Neisseria (eg N. lactamica)
Campylobacter: Campylobacter jejuni and C. coli. Helicobacter pylori
Klebsiella: K. oxytoca and K. pneumoniae ssp.

Evaluation of foreseeable effects

All of the E.coli host strains that we propose to use are K12 derivatives, which are recognised to be non-colonising and are considered to be non-pathogenic to humans or animals. In addition, they have multiple auxotrophic requirements which are unlikely to be met in the environment and so they are assumed to have very limited survivability in the environment.

The pathogens are mostly human commensal and/or opportunistic bacteria. They are common colonisers of skin and mucosal surfaces. Normal healthy individuals, when exposed, usually become transiently colonised with no consequences. However, in susceptible individuals, the pathogenic bacteria can cause invasive disease and in some cases (particularly N. meningitidis) they are capable of causing life threatening diseases.

The plasmid vectors used are all non-mobilisable and are, therefore, unlikely to be transferred to other environmental bacteria. The genes cloned from these bacteria will initially be of unknown function. It is unlikely, however, that any DNA sequence will confer on the host a significant increase in fitness or pathogenicity to the host due to the multiple disablements present in the host and the multifactorial nature of pathogenicity.

The antibiotic cassettes that we propose to use as selectable markers to facilitate inactivation of genes in the bacteria will confer resistance to antibiotics that are not in use in either the treatment or prophylaxis of disease. Furthermore, the mutants can be constructed in such a way that the selectable marker can be subsequently removed where appropriate.

The proposed E. coli host strains are all disabled E. coli K12 derivatives are are in the biological agents hazard group 1. Although the introduction of cloned genes might conceivably increase the fitness or survivability of these organisms it is assumed to be very unlikely. However, because of the small potential increase in perceived hazard the recombinant organisms will be treated as biological agents hazard group 2 and, therefore, containment level 2 precautions will be applied. The organisms will, therefore, be provisionally classified as hazard group 2.

All the bacteria included in the study are in the biological agents hazard group 2. After inactivation of the genes of interest, it is highly unlikely (although theoretically possible) that there will be an increase in the virulence or fitness of the organism.

All manipulations of live bacteria (including host E. coli in which genes of interest are overexpressed) will be contained using containment level 2. Genetically modified bacteria and, where appropriate, host E coli in which genes of interest are overexpressed will be handled in a class 1 cabinet.
The containment precautions to be used are considered sufficient to reduce the risk of accidental infection, or release to the environment, to negligible or zero.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All bacteria will be handled and disposed of using rigorous procedures, including autoclave of all cultures and contaminated materials. All genetically modified E. coli will be cultured in volumes of less than 100 ml (except for large scale production in an E. coli expression host) in the Microbiology laboratory. Genetically modified bacteria will always be contained and handled in a class 1 microbiological safety cabinet within a category 2 laboratory. Genetically modified pathogenic bacteria will be cultured in volumes of less than 100 ml in sealed containers that can be autoclaved. All liquid cultures will be transferred in sealed containers to be autoclaved before disposal via the sink. Solid media on which modified bacteria have been cultured will also be transferred in sealed containers to be autoclaved before disposal. All liquid non-recombinant E. coli cultures will be sterilised in a 2% (v/v) phenolic disinfectant (Hycolin) for 24 hours before disposal down the sink waste. Solid media on which genetically modified E. coli have been grown will be autoclaved before disposal. If, in the unlikely event the genetically modified E. coli should escape the risk will still be negligible, as the host E. coli are disabled and unable to colonise a human host or persist in the environment. The risk of escape of genetically modified test pathogens will be negligible because of the level of containment that we propose to use. In the unlikely event of an escape of these bacteria the genetically modified organism is unlikely to survive for more than a very short time in the environment. The risk of transfer of vectors from genetically modified E. coli to environmental organisms is also low due to the non-mobilisable nature of the vectors to be used.

To reduce the likelihood of transmission of GMMs to people in the laboratory, in addition to the precautions detailed above (recombinant test bacteria and, where appropriate, recombinant E. coli to be contained and handled in class 1 cabinet) laboratory personnel will wear gloves to reduce the likelihood of contamination of hands. All waste produced while handling genetically modified test bacteria will be transferred immediately by the person handling the organism to be autoclaved. Contaminated laboratory coats will also be autoclaved.

These measures are considered to reduce the likelihood of any potential hazard effectively to zero.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The risk assessment were discussed thoroughly, and passed, at the appropriate committee.

Project Containment

<table>

02/03/2022
CD95 is a cell surface protein that transduces apoptotic signals critical to B cell development. Loss of CD95 function may also be important in the genesis of B cell lymphoma. We have made the novel observation that expression of CD95 in certain B cell lymphomas appears to be regulated by membrane trafficking (1). This project will investigate the mechanisms controlling trafficking of the CD95 molecule. The project is based on the creation of cell lines expressing tagged recombinant wild type or mutated CD95. Retroviral vectors are the most efficient tools for creating such cell lines.

The commercially available retroviral packaging cell line PT67 (expressing viral proteins gag, pol and env in trans) will initially be used to facilitate the production of replication incompetent retrovirus that can be used to introduce CD95 into other mammalian cells lines which will be used for trafficking studies.

Recombinant virus will be used to transduce the Burkitt's lymphoma - like cell lines Mutu I and Mutu III will also be transferred into immortalised (virus-negative) human breast cancer cell lines MCF-7.

Future studies may require introduction of constructs into additional, known virus-negative human cell lines.
All cell lines to be used are considered to be equivalent to ACDP hazard Group I and are routinely handled using Class I containment precautions.

Host/vector system

pRevTet off and pRevTre are commercially available retroviral vectors derived from moloney murine leukaemia virus and moloney murine sarcoma viruses respectively. The expression of cloned inserts within pRevTet off is tightly controlled using tetracycline. Both retroviruses are defective, that is they lack the genes necessary (gag, pol and env) to undergo a full found of replication outside their packaging cell line PT67N.

The cell line PT67N provides the genes in trans that are missing in the retroviral vector. This is a commercially available standard packaging cell line.

Virus containing the cloned insert is produced transiently in the packaging cell line and used to transduce the target cell lines Mutu I, Mutu III or MCF-7.

Origin & function

Human CD95 is readily available as a cloned reagent from investigators. A CD95/CFP (cyan fluorescent protein) fusion protein will be generated as well as fusion proteins containing mutations within CD95 itself. These constructs will be cloned into the pRevTet off vector under the tight control of the tetracycline operator and used to transduce the target cell lines. Trafficking of the wild type fusion protein and the effect of mutations on trafficking will then be observed.

Evaluation of foreseeable effects

Modification of the retroviral packaging cell line PT67 or the Burkitt's lymphoma - like cell lines Mutu I and Mutu III by introduction of recombinant CD95 is considered highly unlikely to affect the ability of these cell lines to establish themselves in a mammalian host. These GMOs are therefore considered to pose no significant risk to human or animal health or the environment.

The effects of expressing mutant forms of CD95 in cells already expressing wild type protein are unknown, however, the possibility of generating a trans-dominant mutant within an amphotropic retrovirus must not be discounted. CD95 is not an oncogene but deletion of CD95 has been linked to development of lymphoma. This situation could potentially arise if workers were accidentally exposed to packaged recombinant retrovirus and the virus became integrated into mammalian cells. This likelihood will be minimised by use of a Class 1 Microbiological safety cabinet for all manipulations involving packaged recombinant retrovirus and derivation of stable cell lines. The risk from accidental exposure of workers to recombinant retrovirus is also likely to be further reduced by the nature of the defective retrovirus which dictates that replication is only possible within the packaging cell. Once integrated into mammalian cells the retrovirus is unable to replicate and produce further virus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Once the cell lines have been established they are considered to pose no threat to human or animal health or the environment as the defective retrovirus can not undergo replication and viral particles are not produced. It is therefore requested that to make effective use of these reagents, once the cell lines have been established they are classified as equivalent to ACDP hazard Group 1 organisms allowing their use under containment procedures, appropriate for Class 1 activities.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid and liquid waste will be autoclaved to achieve a 100% kill. Autoclave waste will then be removed from the site by licensed disposal contractors prior to disposal to landfill.

Is an emergency plan required according to regulation 20?  

N

If yes, tick to confirm that it is attached to this form  

N
The initial assessment was modified to recognise the potential risk to human health of packaged retrovirus to be used for transfection into cell lines for trafficking studies and this part of the work was considered to require the additional containment precautions of a Class 2 activity plus the use of a Class 1 microbiological safety cabinet.

Project Ref 594/03.1

Date Ackn'd: 13/08/2003

CU2 Project Title: GENERATION OF PSEUDOTYPE VIRUSES CARRYING HEPATITIS C VIRUS OR HUMAN IMMUNODEFICIENCY VIRUS GLYCOPEPTIDES ON THEIR SURFACE

Class: Class 3
Culture Vol: Class 2 Culture 1-50 litres
Culture Volume: Class 3-4 Culture 500 ml

Non-GMM Consent Granted: yes

Project notified under transitional arrangements: N

Historical Significant Changes: GM594/03.1 TRANSFERRED TO GM470 ON 18/02/2005

Project Additional Information
Purposes of the contained use

The aim of this project is to develop a single cycle infection system to study the role of hepatitis C virus (HCV) and human immunodeficiency virus (HIV) glycoproteins in cell attachment and entry. The unavailability of an efficient culture system for HCV has restricted the study of the mechanisms of HCV infection and development of effective antiviral agents. Several research groups have developed systems to generate infectious pseudoparticles displaying heterologous viral glycoproteins in their functional form onto retroviral core particles. Recently, Bartosch et al. (2003) described such a system for producing pseudotype particles carrying functional HCV glycoproteins on their surface.

The pseudotype retrovirus systems utilise replication-defective packaging and transfer vectors. The transfer vectors containing the transgene are rendered replication-defective by inactivating critical genes involved in viral replication (eg the env, nef and vpr genes), which still retain the viral cis-acting sequences such as LTRs, packaging sequences and regions involved in reverse transcription. The transfer vectors are propagated by trans-complementing constructs (packaging vectors) which supply in trans the packaging proteins whose genes have been deleted in the transfer vector. The packaging vectors are also replication defective as they lack cis-acting sequences such as LTRs, packaging sequences, some structural genes (eg gag and pol) and regions involved in reverse transcription. The trans-complementing factors on the packaging vectors can be segregated and supplied as two separate complementing genomes, the first one for the Gag-pol proteins and the second one for the viral glycoproteins. For the generation of pseudotype particles, the glycoproteins derived from the virus of interest are used.

The project will utilise existing retroviral transfer/packaging vectors and vectors encoding HCV or HIV glycoproteins supplied in trans to produce infectious replication-incompetent pseudotype viruses. Three packaging/backbone vectors will be used: two derived from HIV and the other from murine leukaemia virus (MLV). Three systems will be used because they have been shown to have different efficiencies in different cell types.

HCV pseudotype particles generated in mammalian cells will carry recombinant RNA genome and are capable of infecting human (and possible animal) cells. The particles are likely to be hepatotropic due to the presence of HCV glycoproteins on their surface and could infect the target cells if accidentally injected into humans. Alternative routes of transmission are unlikely to be successful since the HCV envelope proteins will determine the tropism, and route of entry. Upon cell entry and uncoating the genome will be transcribed and proteins synthesized. However, the packaged RNA genome is incapable of replication and therefore no virus progeny will be produced.

HIV pseudotype particles generated in mammalian cells will carry recombinant RNA genome and are capable of infecting human (and possible animal) cells. The HIV envelope proteins will therefore confer the ability to infect cells expressing CD4 plus one of the known co-receptor molecules (eg CCR5 and CXCR4), which are predominantly, but not exclusively, expressed on cells of the immune system. The particles could therefore infect the target cells if accidentally injected into humans. Upon cell entry and uncoating the genome will be transcribed and proteins synthesized. However, the packaged RNA genome is incapable of replication and therefore no virus progeny will be produced.

Recipient or parental organism

HCV pseudotype particles generated in mammalian cells will carry recombinant RNA genome and are capable of infecting human (and possible animal) cells. The particles are likely to be hepatotropic due to the presence of HCV glycoproteins on their surface and could infect the target cells if accidentally injected into humans. Alternative routes of transmission are unlikely to be successful since the HCV envelope proteins will determine the tropism, and route of entry. The particles could therefore infect the target cells if accidentally injected into humans. Upon cell entry and uncoating the genome will be transcribed and proteins synthesized. However, the packaged RNA genome is incapable of replication and therefore no virus progeny will be produced.

Host/vector system

1st generation HIV vector (pNL4-3.Luc.R.E-): HIV is a category 3 human pathogen that is predominantly transmitted via sexual contact, vertical transmission (from infected mother to infant) and also via contaminated blood and blood products (eg needlestick injury). The transfer vector, pNL4-3.Luc.R.E-, is a disabled (ie replication-incompetent) retroviral vector carrying the provirus sequences derived from HIV isolate NL4-3. The construct has been rendered replication defective by introducing two frameshift mutations into the vpr and env genes. In addition, a reporter gene has been introduced into the nef gene, rendering the vector nef-. Two versions of the vector will be used. One has the reporter gene firefly luciferase (lux), whilst the other contains green fluorescent protein (GFP). This vector retains all the cis-acting elements (such as LTRs, packaging sequences and regions involved in reverse transcription) and encodes functional Gag-pol proteins necessary for particle assembly and secretion. In addition, it also encodes all the remaining viral proteins.

The pseudotype virus particles will be re covered from the vector backbone by co-transfecting mammalian cell lines with vector expressing CMV promoter-driven HCV envelope proteins E1 and E2 or HIV gp120/41 (see below). These pseudotype particles will package the original defective backbone pNL4-3-derived RNA.
2nd Generation HIV packaging/reporter vectors (Packaging vector pCMV D R8.91, lentiviral reporter vector pWPT-GFP; pCMV D R8.91 is a disabled (ie replication-incompetent) HIV-1 retroviral vector that has been rendered replication defective by removing the accessory genes vpr, vif, vpu and nef as well as the env gene. This acts as a source of reverse transcriptase and gag proteins, which assemble and package transcripts produced from the pWPT-GFP vector. This vector is the only genetic material transferred to the target cells. It comprises the transgene cassette (GFP) flanked by cis-acting elements necessary for its encapsidation, reverse transcription and integration. The vector is a self-inactivating (SIN) HIV-1-derived vector, which lose the transcriptional capacity of the viral long terminal repeat (LTR) once transferred to target cells. This minimises the risk of emergence of replication competent recombinants (RCR) and avoids problems linked to promoter interference. The post-transcriptional regulatory element of woodchuck hepatitis virus has been inserted to enhance transgene expression.

MLV (MLV-CMC pr-gag-pol and MLV- CMVpr-GFP): MLV is an amphotropic virus but is non-pathogenic to humans. Vectors derived from MLV are frequently used in gene transfer/therapy experiments. Here we propose to use a three systems for generating HCV pseudotype particles. The three vectors are: the MLV-CMVpr-gag-pol packaging vector (which serves as a source of retroviral packaging proteins and is transcribed via a CMV promoter), a transfer vector, pMLV-CMVpr-GFP (carrying CMV promoter-driven GFP transcriptional unit flanked by MLV LTRs and a packaging signal), and a plasmid expressing HCV glycoproteins (see below). Complete pseudotype particles will be produced from mammalian cells co-transfected with the three plasmids.

Vectors containing the HCV glycoprotein (envelope) genes: The HCV envelope genes E1 and E2 derived from various genotypes have been amplified via PCR and directly cloned into pcDNA3 based vectors that contain the CMV early promoter to facilitate mammalian protein expression.

E.coli host. The vectors will be maintain in the TOP10F strain of E. coli (F mcrA [mrr-hsdRMS-mcrBC], 80lacZ M15, lacX74, deoR, recA1, araD139 [ara-leu]7697, galU, galK, rpsL, endA1, nupG) or other K-12 derived laboratory strains that are non-colonising and disabled. The survival of these bacteria in the environment is expected to be low as they have multiple auxotrophic requirements that are unlikely to be met outside of laboratory culture: the recA1 disablement of TOP10F means that it is unable to repair DNA by homologous recombination and is UV sensitive, and the [ara-leu] 7697 mutation shows that it is auxotrophic for leucine, and unable to grow in the presence of arabinose.

pNL4-3.Luc.R.-E: The transfer vector, pNL4-3.Luc.R.-E, is a disabled (ie replication-incompetent) retroviral vector carrying the provirus sequences derived from HIV isolate NL4-3. The construct has been rendered replication defective by introducing two frameshift mutations into the vpr and env genes. In addition, a reporter gene has been introduced into the nef gene, rendering the vector nef. The original pNL4-3 clone was derived from NYS (5') and LAV (3') cloned directly from genomic DNA into pUC18.

This vector retains all the cis-acting elements (such as LTRs, packaging sequences and regions involved in reverse transcription) and encodes functional Gag-pol proteins necessary for particle assembly and secretion. In addition, it also encodes all the remaining viral proteins, apart from vpr, as well as a reporter gene. Production of pseudotype viruses occurs when this plasmid is co-transfected with the viral glycoprotein-carrying pcDNA3 vectors.

MLV-CMVP-pr-gag-pol: the MLV-CMVP-pr-gag-pol packaging vector serves as a source of retroviral packaging proteins and is transcribed via a CMV promoter. Production of pseudotype viruses occurs when this plasmid is co-transfected with the viral glycoprotein-carrying pcDNA3 and the MLV-CMVP-pr-gag-pol vectors.

MLV-CMVP-pr-GFP: pMLV-CMVP-pr-GFP ( carrying CMV promoter-driven GFP transcriptional unit flanked by MLV LTRs and a packaging signal), acts as a transfer vector. Production of pseudotype viruses occurs when this plasmid is co-transfected with the viral glycoprotein-carrying pcDNA3 and the MLV-CMVP pr-gag-pol packaging vector.

Vectors containing the HCV glycoprotein (envelope) genes: The HCV envelope genes E1 and E2 derived from various genotypes have been amplified via PCR and directly cloned into pcDNA3 based vectors that contain the CMV early promoter to facilitate mammalian protein expression. This vector acts as a source of viral glycoproteins for pseudotype formation.

Evaluation of foreseeable effects

The vectors may be able to undergo recombination with endogenous retroviruses present in the culture cells (or accidentally infected host), or package transcripts from
endogenous retroviral sequences. Also, the vectors could undergo recombination with wild-type virus. However the resulting recombinant would not be more pathogenic than the wild-type virus.

Pseudotype viruses could in principle cause infection, but would not replicate. The potential target cell would be dictated by the envelope proteins incorporated into the pseudotype virus (ie HCV envelope proteins). Infection by pseudotype virus would result in reverse transcription then possible integration of the packaged genome. This in turn might lead to the production of viral/reporter proteins, but as the genome is defective, new infectious virus would not be produced. The effect of GFP or luciferase expression on the host cell is unknown, whilst some of the HIV gene products have been shown to have some detrimental effects (eg apoptosis, toxicity etc), at least in vitro. Whilst, cells producing viral proteins would be targeted by the host immune response (eg cytotoxic T-cells), it can not be assumed that exposure to the GMM will not cause harm.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

HCV E1E2 pseudotypes produced using the pNL4-3 system: The parental virus for the pNL4-3 vector is a category III organism. Infection by the pseudotype virus would lead to the production of viral proteins and reporter proteins. The pathogenic potential of these proteins is largely unknown, although some effects have been reported in in vitro studies. Whilst the resulting pseudotype virus produced is infectious, it is not able to replicate. Infection could lead to insertion of the packaged genome into the host chromosome. However, it lacks known transforming sequences. The risk of recombination between the HCV E1E2 containing vector and the pNL4-3 is low. As the inactivating mutations within the pNL4 backbone are small deletions there is a small risk of reversion and subsequent production of wild type virus. However, the cell lines used to produce the pseudoviruses are incapable of supporting HIV replication. Even so, the viruses are infectious and are capable of integration and subsequent protein production. There is a small but real risk of the mobilisation of endogenous retroviral sequences and the formation of replicative competent retroviruses. Therefore we propose that the containment level for this aspect of work is Level 2, with the following additional precautions.

All work involving the pseudotype viruses to be carried out within a Class 1 or Class II safety cabinet located in a room where access is restricted at times when manipulations involving these viruses are taking place. The work will involve standard laboratory procedures, however, considering the routes of infection of the viruses (parenteral), no sharps or glassware will be used when handling the pseudotype viruses. All solid waste materials will be autoclaved and liquid waste disinfected with gluteraldehyde. Training records for all new staff using these methods will be kept.

HCV and HIV pseudotypes produced using the 2nd Generation HIV packaging/reporter vectors (Packaging vector pCMV DR8.91, lentiviral reporter vector pWPT-GFP): pCMV D R8.91 is a disabled (ie replication-incompetent) HIV-1 retroviral vector that has been rendered replication defective by removing the accessory genes vpr, vif, vpu and nef as well as the env gene. This acts as a source of reverse transcriptase and gag proteins, which assemble and package transcripts produced from the pWPT-GFP vector. This vector is the only genetic material transferred to the target cells. It comprises the transgene cassette (GFP) flanked by cis-acting elements necessary for its encapsidation, reverse transcription and integration. The vector is a self inactivating (SIN) HIV-1 derived vector, which lose the transcriptional capacity of the viral long terminal repeat (LTR) once transferred to target cells. This minimises the risk of emergence of replication competent recombinants (RCR) and avoids problems linked to promoter interference. The post-transcriptional regulatory element of woodchuck hepatitis virus has been inserted to enhance transgene expression. Complete retroviral particles are produced in the presence of a third vector containing the viral glycoproteins under study. Infection of actively replicating cells allows reverse transcription of the RNA genome and subsequent integration of the GFP marker protein. Upon accidental transmission, the transcribed GFP cDNA may become integrated into recipient cells. The transduced cells will contain viral genes on split plasmids. Details of the constructs and the demonstration that they do not give rise to replication competent viruses are available in Zufferey et al Nat Biotechnol. 15: 871-875. There is evidence that such replication defective retroviruses are not pathogenic when tested in mice. Therefore we propose that the containment level for this aspect of work is Level 2, with the following additional precautions:

All work involving the pseudotype viruses to be carried out within a Class 1 or Class II safety cabinet located in a room where access is restricted at times when manipulations involving these viruses are taking place. The work will involve standard laboratory procedures, however, considering the routes of infection of the viruses (parenteral), no sharps or glassware will be used when handling the pseudotype viruses. All solid waste materials will be autoclaved and liquid waste disinfected with gluteraldehyde. Training records for all new staff using these methods will be kept.
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 2: All work involving the pseudotype viruses to be carried out within a Class 1 or safety cabinet located in a room where access is restricted at times when manipulations involving these viruses are taking place. All solid waste materials will be autoclaved at 134-137 degrees C, 21.2-2.2 bar pressure with a holding time of 5 minutes. A chart record is maintained for each run. Autoclaves are also subject to quarterly thermocouple testing. All liquid waste known to be, or potentially infected with category 2 viruses will be discarded into a 500 ml polyethylene discard pot containing 50 ml of 100% Gagasept, so that when full with liquid waste the final concentration of Gagasept will be 10%. An enquiry date for the gagasept, which should be two weeks from the date of first use, will be written on the surface of the discard pot. If the discard pot is not full before this expiry date then the discard pot will be filled to 500 ml with water and left for 24 hours to inactivate virus. Preparation of working dilutions of Gagasept will be carried out within the class 1 cabinet.

Containment level 3: All liquid waste known to be, or potentially infected with category 3 viruses will be discarded into a 500 ml polyethylene discard pot containing 50 ml of Gagasept, so that when full with liquid waste the final concentration of Gagasept will be 10%. An enquiry date for the gagasept, which should be two weeks from the date of first use, will be written on the surface of the discard pot. If the discard pot is not full before this expiry date then the discard pot will be filled to 500 ml with water and left for 24 hours to inactivate virus. Preparation of working dilutions of Gagasept will be carried out within the class 1 cabinet. All solid waste will be autoclaved prior to disposal. Autoclaving of waste will take place using a destructive cycle of 126 degrees C for 45 minutes. The maximum load will be one autoclave bag (containing a maximum of 2 laboratory gowns) together with 4 discard pots. The autoclave is checked on a monthly basis by independent thermocouple testing using typical loads. Cabinet generated solid waste will be accumulated in paper bags placed within the cabinet. At the end of each working period the waste will be placed into an autoclave bag and transferred to the autoclave. Solid waste bags will be left open and screw-capped lids loosen prior to autoclaving to allow steam penetration. Discard of all Gigasept solutions will take place using the designated sink within the main virology laboratory.

No genetic manipulation work is carried out; operations confined to shake flask cultures (vol 50 to 800 mls). Solid waste (plate cultures) is autoclaved (15 psi/15 mins) then sent for incineration. Liquid waste is either autoclaved (15 psi/15 mins) or deactivated with Virkon (1% solution, min contact time 10 mins, following manufacturers instructions).

The maximum culture volume that could be released at any one time would be about 800 mls (contents of one shake flask).

AN INVESTIGATION OF THE ROLE PLAYED BY INTEGRINS AND CELL SURFACE RECEPTORS IN TISSUE REPAIR AND PATHOLOGY.

Purposes of the contained use

The purpose of this programme of work is to examine the role of integrins and cell surface receptors in tissue repair and pathology. The genes for integrins/cell receptors will be cloned and expressed or knocked out in human cell lines and primary cultures of human cells.

Recipient or parental organism

The recipient cells will either be human cell lines of mesenchymal origin (eg epithelial/keratinocyte cell lines) or primary cultures of human mesenchymal cells (eg muscle myoblasts).

The human cell lines that will be used in this programme of work are cells which have been in safe use for over ten years in a number of laboratories. The primary human cells on the other hand represent a greater inherent risk as they may contain adventitious agents.

Host/vector system

The hosts will be either human primary mesenchymal cells or human cell lines with a safe record of use such as H357. A number of viral vector systems will be used which lack the structural genes for particle formation and replication. In particular PRcCMV, PBaPuro, pLXIN and pLXS will be used in conjunction with the packaging cell lines AM12, E86 and PT67.

Origin & function
The genetic material will be obtained from human cells and will code for integrins/cell surface receptors. These genes will be inserted into host cells which lack the proteins they encode so as to determine the role played by these molecules in cell-cell and cell-extracellular matrix interaction.

**Evaluation of foreseeable effects**

Parental and recipient cells: The cell lines to be used in this programme of work have been in safe use for over ten years and are unlikely to cause harm to humans or the environment. The human primary cell could contain adventitious agents which may cause harm to humans.

Viral vector systems: The viral vector systems to be used are disabled and as such to not represent a risk to humans or the environment.

GMMs: The GMMs constructed in this programme of work will express integrin/cell surface receptors that may alter their tissue tropism. Thus while these GMMs represent no risk to the environment it is possible that they may cause harm to humans.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Conditioned media from GMMs and contaminated cell culture plasticware will be treated with a 1% solution of Virkon (final concentration) prior to disposal as clinical waste for incineration. Virkon treatment has been shown to rapidly produce 99.9999% virucidal, bactericidal and fungicidal activity. Contaminated serological pipettes and pipette tips will be autoclaved at 121 degrees C for 20 minutes prior to disposal as clinical waste for incineration. The autoclave to be used is regularly validated and services.

**Is an emergency plan required according to regulation 20?**

**Project Ref 596/06.1**

**Date Ackn'd**: 06/02/2006  
**Date Project Ceased**: 24/04/2012

**CU2 Project Title**: The molecular basis of resuscitation of Campylobacter jejuni from a viable but not-culturable (VBNC) state.

**Class Culture Vol Class**:  
**Class 2**:  
**< 1 Litre**:  

**Non-GMM**: Not Applicable  
**Consent Granted**: Not Applicable

**Project notified under transitional arrangements**: N

**Historical Significant Changes**: PROJECT TRANSFERRED TO GM 14 AND GM CENTRE CLOSED

**Recipient or parental organism**
- Campylobacter jejuni NCTC 11168
- Campylobacter jejuni 81-176

**Host/vector system**
- Genes encoding putative resuscitation factors will be cloned in E. coli using the plasmid pGEM-T-Easy (Promega UK Ltd., classified as non-mobiliseable (Bom-, Mob- and Tra-minus) by the ACGM). These genes will be inactivated by insertion of a gene encoding kanamycin resistance (aphA3) and re-introduced into C. jejuni NCTC 11168 and 81-176. As pGEM-T-Easy is not able to replicate in C. jejuni, double cross-over homologous recombination events will direct allelic replacement of the chromosomal wild-type copy of the gene with the mutated allele present in the vector. pGEM-T-Easy carries an ampicillin resistance gene.

- Genetic complementation will be done using an E. coli vector (pRRC) that delivers, by homologous recombination, cloned genes (under the control of a Campylobacter-derived promoter) into the 16S-28S rRNA spacer regions on the C. jejuni chromosome (Karlyshev and Wren 2005. Appl. Environ. Microbiol. 71:4004).

**Project Additional Information**

**Purposes of the contained use**
- Construction and complementation of defined Campylobacter jejuni mutants to investigate the function of genes potentially involved in resuscitation from the viable but non-culturable state.
This vector is not able to replicate in C. jejuni, is classified as non-mobiliseable (Bom-, Mob- and Tra-minus) by the ACGM and carries a chloramphenicol resistance gene.

Origin & function

C. jejuni genes encoding potential resuscitation factors (Genome sequence Genbank NC_002163; gene ID 904972, possible secreted transglycosylase; gene ID 904469, unknown function; gene ID 905140, possible secreted transglycosylase) will be amplified by PCR from genomic DNA of strain 11168.

PGEM-T-Easy is supplied by Promega UK Ltd.; pRRC will be obtained from London School of Hygiene and Tropical Medicine.

The gene encoding kanamycin resistance, aphA3, will be obtained from plasmid pLP1433 of Campylobacter Coli (Genbank M26832)

Evaluation of foreseeable effects

Trains will be disposed of by autoclaving on a kill cycle.

Although the genetically modified organisms produced in this project will be resistant to kanamycin or to both kanamycin and chloramphenicol, neither are antibiotics of choice for treatment of Campylobacter infections. Therefore the potential risks associated with the genetically modified organisms are the same as those of the parental strains and the likelihood of these risks being realised is low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The project will generate the following waste: broth- (of 100 ml maximum volume) and agar plate cultures of the GMOs, contaminated pipettes, pipette tips and glassware. All contaminated waste, will be autoclaved on a "kill cycle" ensuring that the waste is held at a holding temperature of 121 degrees C for at least 15 minutes. This will kill all GMOs. Autoclaves contain temperature probes to check the heat penetration and sterilisation indicator strips are also included in each run. Autoclaved liquid waste will be disposed down sinks. Autoclaved solid waste will be sent for incineration.

Please enter comments on the GM safety committee on the risk assessment

Part 1

The committee noted that this project was similar in nature to a programme of work previously approved by the HSE (GM596/99.1) but had the safety advantage over that programme of work in that the vector systems to be used could not replicate in the host organisms under any conditions. The committee also recommended that the inexperienced research on the grant be sent on a training course in good microbiological practice which has now been done.

TRANSFERRED TO GM554 ON CLOSURE OF GM601

Project Additional Information

02/03/2022
Purposes of the contained use

This research is to be notified as a connected programme of work utilising transfection of cDNAs into human cell-lines in order to induce expression of said gene products under the control of known promoters provided by plasmid vectors. It contributes to the research goal of understanding the contribution of genes to hormone signalling pathways, especially in relation to breast cancer.

Recipient or parental organism

Recipients are established human cell lines (eg breast cancer cell lines) and an immortalised normal breast epithelial cell line hTERT-HME1. Epithelial tumour cells can cause tumours when injected subcutaneously in immuno-compromised mice. However, the potential for harm is much less in immuno-competent humans, where the primary potential for harm comes from possible adventitious pathogens (viruses). Cell lines are expected to have limited survivability in the environment and modifications are not expected to increase their pathogenicity.

Host/vector system

The plasmid vectors are mobilisation deficient, devoid of significant known toxic or pathogenic potential and would be classified as class 1 were it not for their use in mammalian cell-lines. The design of the RheoSwitch Mammalian Inducible Expression System is such that the insert DNA is only expressed in the presence of RSL1 ligand, which is a synthetic non-steroidal compound and therefore extremely unlikely to be found in the environment. Any other vectors will be limited to similarly well characterised plasmids.

Origin & function

The primary inserts will be full length cDNAs encoding estrogen receptors Eralpha and Erbeta, derived from human normal or tumour tissues or cell line material. In addition cDNAs resulting from alternative splicing of the ER mRNA (for both Eralpha and Erbeta) will also be used. The cDNAs resulting from alternative splicing of the ER mRNA (for both Eralpha and Erbeta) will also be used. The cDNAs to be used are unlikely to include a toxic or pathogenic determinant although due to the unknown nature of the estrogen receptor variants, the deletion variants may have a deleterious effects on the recipient cell line.

Alternative gene products (eg X-box binding protein 1) will be limited to those unlikely to increase the toxic or pathogenic potential for harm, even when constitutively expressed or modified by addition of reporter proteins. Most inserts will be transcription factors, or genes known to modulate transcription (eg co-activators of co-repressors).

Some inserts may have been previously mutated by site-directed mutagenesis to pinpoint specific residues/amino acids involved in protein function. It is envisaged that insert modification (eg fluorescent labelling or tagging) is more likely be detrimental to gene function than enhance any latent pathogenicity or toxicity. Initial expression of the insert DNA will be induced only by addition of RSL1 synthetic ligand (requiring additional transfection with plasmid pNEBR-R1), subsequently a strong constitutive promotor may be used (eg CMV). Plasmid vectors additionally contain selective markers (eg G418 resistance).

Evaluation of foreseeable effects

Recipients are established human cell lines eg breast cancer cell lines: KPL-1, MCF7, ZR75, MDA-MB-231 and an immortalised normal breast epithelial cell line hTERT-HME1. These cell lines are biological agents for which containment level 2 is appropriate, owing largely to the fact that they are long-term cultures of human origin and are not fully characterised. The primary potential for harm comes from possible adventitious pathogens (viruses). Cell lines are expected to have limited survivability in the environment.

The primary inserts will be full length cDNAs encoding estrogen receptors (ER), cDNAs resulting from alternative splicing of the ER mRNA or alternative gene products, largely constituting related transcription factors. The cDNAs to be used are unlikely to include a toxic or pathogenic determinant although due to the unknown nature of the estrogen receptor variants, the deletion variants may have a deleterious effects on the growth properties of the recipient cell lines. Most insert DNA is naturally occurring in these cell lines, the experiments will merely control the level of expression of individual variants.

The plasmid vectors when used are mobilisation deficient, devoid of significant known toxic or pathogenic potential and would be classified as class 1 were it not for their
use in mammalian cell-lines. All sequences cloned will be of mammalian origin and unlikely to contain promoters active in non-mammalian organisms. Expression in mammalian cells is controlled by previously validated promoter elements (very strictly inducible in the case of the Rheoswitch system) and is unlikely to be observed outside of a controlled laboratory environment. Potential for transfer to and gene expression in other organisms is negligible and therefore negligible hazard to human health. Vectors are unlikely to alter pathogenic traits of the host.

There is little potential for alteration of pathogenic traits and no obvious significant increase on the hazards of the non-transfected cell lines.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

This work involves standard laboratory protocols, and there are no unusual procedures that require additional containment measures. Standards of work and containment are specified in the CCRT Code of Practice, with reference to the governing regulations and guidelines. All personnel should be familiar with the relevant safety documentation and have received training specifically for the use of GMM. Both unmodified and GM modified cells will be grown in small scale closed containers in a category 2 containment area. A class II safety cabinet will be used for all manipulations and both sharps glass containers will be avoided. As specified in the governing code of practice for biological agents.

Solid waste will be bagged, sterilised by autoclaving and later incinerated as clinical waste. Liquid waste in disposable culture flasks will be sterilised by autoclaving and incinerated as clinical waste. Other liquid waste will be sterilised by autoclaving and disposed of via the drains. The autoclave is situated within the laboratory suite and is managed by Wirral NHS Trust engineers. A programme of testing and quality assurance is carried out on a quarterly and annual basis and records kept.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Please enter comments on the GM safety committee on the risk assessment

The CCRT GM safety committee is satisfied that the risk assessment is suitable for the purpose stated, providing suitable records are kept and any significant variation notified. The assessment has been reviewed by the University Biological Safety Adviser who made a number of suggestions regarding the scope of the work, in particular that the work should be notified as connected programme, given the number of different phases that are proposed. These suggestions were incorporated in the final assessment.

Historical Significant Changes

Historical Date of Additional Info

02/03/2022
**Project Additional Information**

**Purposes of the contained use**
- To generate sufficient hepatitis B core antigen constructs with the potential to block the allergic response.

**Recipient or parental organism**
- The E.coli bacterial hosts are engineered to express recombinant hepatitis B core antigens (HBcAgs) that display short peptide sequences derived from human IgE or peptide mimics of these sequences. Recombinant HBcAg is a non-infectious capsid particle - (it forms the inner capsid in wild type virus) - composed of a single protein species that does not contain any hepatitis B virus genomic material.

**Host/vector system**
- **Hosts:** Escherichia coli K12 strains.
- **Vector to be used:** pPN1 (Brown, A. L. et al, Vaccine, 1991, 9, 595-601) - pAT153 based (Bom-/Nic-, Mob-, Tra-) that encodes the HBcAg.

**Origin & function**
- The HBcAg itself is expressed from a cloned copy of the HBcAg gene that has been engineered to allow the insertion of the peptide encoding sequence of choice (Brown et al, 1991, as above). Only low levels of expression are expected prior to the appropriate conditions such as the addition of an inducing agent to stimulate expression. The intended use of these constructs is to evaluate their potential as vaccine candidates against IgE mediated allergic disease. However, the effect of such a vaccine in vivo is not known.

**Evaluation of foreseeable effects**
- **Likelihood of hazard:** All procedures will be carried out according to good microbiological practice in a separate, controlled access laboratory. All residues and waste will be sterilised before leaving the laboratory. The chance of release to the environment is negligible.
- **Consequence of hazard:** Plasmid DNA is non-mobilisable and E.coli K12 hosts are used. K12 host cells are crippled for survival outside of a laboratory environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
- **For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
  - N/A.
  - **Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
  - All waste plasticware autoclaved at 130°C for 40 minutes and liquid culture and glassware treated with 30g/l Virkon for at least 30 minutes. Spillage of E.coli cells treated with Virkon powder to soak up liquid and powder removed with tissue wipes, 30 g/l Virkon solution used to clean area than 70% ethanol wipes. Tissue wipes autoclaved.
The GM Safety Committee had requested that an earlier draft risk assessment be split up. From the meeting minutes:

'Section A of the assessment covered expression of proteins resulting in both Cat 1 and 2 GMOs, whereas the Project Description stated that:

‘In circumstances where such a project will involve expression of a heterologous antigen which cannot be considered "highly unlikely to cause any harmful biological effect because the function of the protein is well understood or because it is encountered in high concentrations in nature" a separate and specific risk assessment will be carried out.

It was felt that these should be separated out so that there was a clear delineation between those projects which, as Cat 2, should be carried out in the side labs’.

**Project Additional Information**

**Purposes of the contained use**

To generate small quantities of N. meningitidis proteins, to develop an assay system for the proteins raised in more useful carriers.

**Recipient or parental organism**

The E. coli bacterial hosts are engineered to express recombinant N. meningitidis proteins. The BL21 (DE3) hosts have not been crippled to prevent survival in the harsh conditions of the external environment (unlike K12 host cells). However, the antigens derived from N. meningitidis have no known toxicity. GNA1220 shows some homology to the human SLP2 integral membrane protein but a cross-reactive response in humans to SLP2 is unlikely since it is localised on the cytoplasmic surface and membrane. The BL21 (DE3), BLR (DE3) and HMS174 (DE3) strains and derivatives thereof, are F and so are incapable of conjugation.

**Host/vector system**

Hosts: E. coli K12 or BL21 (DE3) and derivative strains. BL21 (DE3) derivative strains express proteins to repress basal levels of expression from the T7 promoter via degradation of T7 polymerase.

Vector to be used: pET17b or similar. Expression is driven by the T7 promoter.

**Origin & function**

The DNA sequences encoding the N. meningitidis antigens are derived by amplification reactions using genomic DNA as template. Genomic DNA purified from heat killed bacteria supplied by Dr Ray Borrows at the PHLS, Manchester.

**Evaluation of foreseeable effects**

i. Likelihood of hazard: All procedures will be carried out according to good microbiological practice in a separate, controlled access laboratory. All residues and waste will be sterilised before leaving the laboratory. The chance of release to the environment is negligible.

ii. Consequence of hazard: Plasmid DNA is mobilisation defective. The K12 host cells are crippled for survival outside of a laboratory environment. The BL21 (DE3) and K12 hosts to be used are both F and so are non-conjugative, further reducing the risk of transfer of genetic material. Antigens to be expressed are not known to be toxic.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
All waste plasticware autoclaved at 130°C for 40 minutes and liquid culture and glassware treated with 30g/l Virkon for at least 30 minutes. Spillage of E. coli cells treated with Virkon powder to soak up liquid and powder removed with tissue wipes, 30 g/l Virkon solution used to clean area then 70% ethanol wipes. Tissue wipes autoclaved.

The GM Safety Committee had requested that an earlier draft risk assessment be split up as it consisted of two different cell lines (HMS 174 and BL21) which resulted in different Containment Levels. We felt it was important to make it clear which was the Containment Level 2.

From the meeting minutes:

"It was decided to split ACGM076 into two separate risk assessments as BL21's result in a GMO Cat 2 and HMS174, a GMO Cat 1."

Non-GMM

Consent Granted: not applicable

Project notified under transitional arrangements: N
### Project Additional Information

#### Purposes of the contained use

To safely generate small amounts of haemoglobinases for our drug discovery programme.

#### Recipient or parental organism

Haemoglobinases are biologically inactive in E. coli due to expression as insoluble protein within inclusion bodies.

#### Host/vector system

- **Hosts:** Escherichia coli BL21.
- **Vectors to be used:** pUC-based.

#### Origin & function

Haemoglobinases are present in the digestive vacuole of the human malarial parasite Plasmodium falciparum and involved in the degradation of erythrocyte’s haemoglobin.

#### Evaluation of foreseeable effects

- **Likelihood of hazard:** All glass cultureware soaked in Virkon (30 g/l) then autoclaved, all waste and plastic will be autoclaved at 126°C for 15 minutes. All E. coli will be performed in negative pressure genetics rooms and large cultures placed in Class II hood when opened.
- **Consequence of hazard:** Plasmid DNA is non-mobilisable and transformed E. coli are a B strain.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A.

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A.

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid clinical waste must be autoclaved at 130°C for 40 minutes prior to being placed in the large yellow clinical waste safe in the external compound. The Clinical waste safe is collected regularly and the waste disposed of by incineration.

Liquid clinical waste and glassware must be treated with 30 g/l Virkon for at least 30 minutes. Gloves must always be worn when dealing with spills and breakages.
Minor spills:
Either cover the spill with Virkon disinfectant granules, leave for not less than 10 minutes and scoop up into a dustpan,
or, using double gloves, mop up the spill with a pad soaked in a 30 g/l Virkon solution.

Larger spills:
Either cover the spill with Virkon disinfectant granules as above,
or cover the spill with paper towels, moisten with 30 g/l Virkon solution and leave for at least 10 minutes before scooping up into a dustpan. Do NOT use a brush.

The scientists are referred to has017, the Code of Practice for Biological Hazards for more details.

The original risk assessment had given an Access figure (under the Brenner Scheme) of 10-3/1. On further investigation, we found that the ACGM guidance notes (Part 2A, Annex II, Part iii) say that BL21 cells may be given a value of 10-3. The risk assessment was altered and a Containment Level of 2 was given to the project. It was agreed that all work would be carried out in the Genetics Lab and the project was signed off.

Project Ref 603/02.1

Date Ackn'd CU2 Project Title
Project Additional Information

Purposes of the contained use

Libraries of Chlamydia trachomatis DNA will be created by cloning fragments of genomic DNA into expression vectors. The libraries will be used to transform attenuated strains of Salmonella typhi and the expressed peptides will be screened in a variety of assays.

Recipient or parental organism

Salmonella typhi CVD908 (aroC, aroD) and ACAM948 (aroC, aroD, htrA).

In a letter dated 25 November 1993 from Dr Stuart Smith, then ACGM secretary at the HSE, to Dr Stephen Chatfield, the developer of CVD908 and CVD908HtrA (same genotype as ACAM948) at Medeva, both strains fulfil the criteria of schedule 2 and qualify as Group 1 organisms.

Host/vector system

The vectors used will be non-mobilisable (eg pTrcHis, Invitrogen) which, when combined with the S. typhi strains described above, have been assigned an 'Access factor' (Brenner Scheme) of 10 (-6) (See Dr Smith's letter, above). The promoters used will be trc (high expression in the presence of IPTG) or htrA or nirB (induced in vivo by low oxygen tension or entry into macrophages).

Origin & function

The genetic material will be derived from Chlamydia trachomatis genomic DNA that is partially digested with restriction endonucleases. Fragments of approximately 1 kb will be cloned into the vectors. The vectors will provide an ATG start codon adjacent to the promoter and 5' of the cloning site, and stop codons downstream of the cloning site, such that in frame fusions can be created. In this system some inserts will be out of frame and no protein will be expressed whereas in other constructs fragments of C. trachomatis proteins will be produced and occasionally full-length proteins may be expressed.

The immunological characteristics of these expressed proteins and the resultant recombinant Salmonella strains will be assessed using a range of assays.

Evaluation of foreseeable effects

The majority of the polypeptides expressed will be fragments of C. trachomatis proteins and are unlikely to be biologically active since the library is designed for cloning of...
partial gene sequences. However, it is possible that a few of the expressed polypeptides may be biologically active or full-length proteins. If this were the case, only strains harboring plasmids where the promoter is htrA or nirB would be expected to synthesize the protein under natural conditions. This promoter has only limited activity outside animal tissue. The host range of S. typhi strains is limited to human and certain primates. In the event of colonization (which, given the phenotype of the strains, would be self limiting), the levels of protein expression will be highly regulated by the host strain and confined to certain tissues (e.g. the gut and reticuloendothelial system), therefore the likelihood of harmful effects is extremely low.

These strains cannot survive in the environment due to the presence of aro mutations. The possibility of complementation by the C. trachomatis aro or htrA genes exists. However this is highly unlikely given that full-length gene sequences of at least two separate genes would need to be expressed in the same bacterial host cell for this to occur. The aroA, aroC and htrA genes are located far apart in the bacterial chromosome.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid clinical waste must be autoclaved at 130 degrees C for 40 minutes prior to being placed in the large yellow clinical waste safe in the external compound. Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Excerpt from meeting minutes:

"This project is similar to the previous except the work is carried out in S. typhi rather than xxx. As a consequence, the Access figure is higher at 10 (-3), which takes the work into a Category 2. Work cannot start until the ACGM has reviewed the project".
Project Additional Information

**Purposes of the contained use**

Libraries of Chlamydia trachomatis DNA will be created by cloning fragments of genomic DNA into retroviral vectors. Replication-incompetent virus will then be generated using packaging cell lines, and used to infect antigen-presenting cells with subsequent expression of proteins. These APCs will be screened in a variety of immunological assays. Known epitopes will be expressed in order to validate the system.

**Recipient or parental organism**

Containment categorisation for production of the Chlamydia trachomatis expression library using retroviral vectors was assigned using the HSC's ACGM Compendium of Guidance (Part 2B Annex III) "Guidance for commonly used viral vectors - March 2000".
Disabled retrovirus vectors
Section 18, 19, 20, 23, 28 and 30.

The retroviruses generated cannot replicate in the environment because they lack functional gag, pol and env genes. They could, theoretically, infect a single cell but could not then produce more virus. The viruses themselves are not robust in the environment. Protein products are very unlikely to be produced at levels that would have a deleterious effect on other organisms.

The work was considered to be Cat. 2.

Host/vector system

The retroviral vectors initially used to generate the Chlamydia trachomatis expression library are mobilisation defective in lab strains of disabled E. coli (pFB, pCFB series from Stratagene, pL, pQ vector series from BD Biosciences). The packaging cell line (Amphopack 293 - BD Biosciences) has been tested to ensure that replication-competent viruses are not present in the culture medium. The indicator cells (HT-1080, ATCC CCL-121), used to demonstrate that the packaged library does not contain replication competent virus, are Biosafety level 1. When the library is transformed into the packaging cell line, replication-incompetent infectious virus (RIV) is produced and the categorisation changes from cat 1 to cat 2.

Origin & function

The genetic material will be derived from Chlamydia trachomatis genomic DNA that is partially digested with restriction endonucleases. Fragments of approximately 2kb will be cloned into retroviral vectors. The vectors provide a packaging signal for virus assembly, long terminal repeats (LTRs) to allow for integration into the target cell DNA, a promoter sequence, an ATG start codon, a multiple cloning site 3' of the ATG and stop codons downstream of the cloning site. The vector is provided in three frames such that in-frame fusions can be created. The vector does not contain functional gag, pol or env genes that are essential for production of replication competent virus. In this system some inserts will be out of frame in the vector and no protein will be expressed when the virus infects a target cell, whereas in other constructs fragments of C. trachomatis proteins will be produced and occasionally full-length proteins may be expressed.

Production of replication-incompetent virus (RIV) will occur only when vectors are transfected into a packaging cell line, which stably expresses gag, pol and env genes from different loci on the chromosome. Packaged RIV will be used to infect target cells, the immunological characteristics of these expressed proteins will be assessed using a range of assays.

Evaluation of foreseeable effects

The retroviruses generated cannot replicate in the environment due to lack of functional gag, pol and env genes. They could theoretically infect a single cell but could not then produce more virus. The viruses themselves are not robust in the environment. Protein products are very unlikely to be produced at levels that would have a deleterious effect on other organisms.

To demonstrate the absence of replication-competent viruses in vector stocks, direct plating of vector supernatant onto mitotically active indicator cells will be carried out (HT 1080 cells).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

N/A
All solid clinical waste must be autoclaved at 130 degrees C for 40 minutes prior to being placed in the large yellow clinical waste safe in the external compound. The clinical waste safe is collected regularly and the waste disposed of by incineration.

Liquid clinical waste and glassware must be treated with freshly made Precept solution (10g/500ml) and left for at least 20 minutes. Gloves must always be worn when dealing with spills and breakages.

Spills:
* Cover the spill with paper towels, moisten the Precept solution, leave for not less than 20 minutes and then remove to double autoclave bags and autoclave.
* Do NOT use a brush, and avoid creating aerosols.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

AM felt that he was erring on the side of caution by categorising this as 2, but supported this decision by stating this was standard throughout the industry as there is the potential for localised infection of a worker’s cells, albeit a very low risk.

The Gm work produces a maximum of 10 litres of liquid waste in a day, but the average is usually much less. All liquid waste is autoclaved as it is produced and is not stored. Solid waste is autoclaved. Each load is checked with indicators included in the material being autoclaved. The autoclave is on an annual maintenance contract with an external company and their work is checked form our insurance company.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Please enter comments of the GM safety committee on the risk assessment

Other(s)

The maximum volume of waste that could be released at any one time is 3 litres.
* All waste is treated by sterilisation in an autoclave prior to disposal via the sewer or as normal solid waste.
* The autoclave is regularly serviced and validated and used according to the manufacturer's instructions.
* The waste is monitored regularly - growth on agar during a 24 hour incubation period.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Waste Management

The maximum culture volume that could be released at any one time is 10 litres. All solid (e.g., bacterial cell pellets) and liquid (e.g., cell-conditioned culture medium) waste is treated with Virkon before disposal. When used according to the manufacturer's instructions, Virkon achieves 100% disinfection. Equipment (e.g., shaker flasks) used for culturing GMOs is disinfected with Virkon and then sterilised by autoclaving. Disposable cell cultureware is autoclaved and then incinerated.

Cultures of bacterial clones will be inactivated by autoclaving. Maximum volume of cultures will be 100 ml. The autoclaving process is monitored by temperature and pressure gauges and indicator tape is used to verify successful autoclaving (121 degrees C for 15-30 mins as appropriate).

Project Additional Information

Purposes of the contained use

The aim of this programme of study is to investigate the role of specific genes in the virulence of pathogens of the genus Streptococcus. It is anticipated that the identification of genes involved in streptococcal virulence will reveal proteins that may be suitable as targets for antimicrobial therapies or as vaccine candidates. Genes encoding various streptococcal proteins post-translationally modified with lipids (lipoproteins) and the genes involved in lipoprotein biosynthesis will be permanently inactivated in the host streptococci by means of either insertional inactivation or allelic replacement.

Recipient or parental organism

Various strains of Streptococcus agalactiae (Group B streptococcus), Streptococcus equi (subspecies equi and subspecies zooepidemicus) and Streptococcus suis will be modified by insertional inactivation or allelic replacement to inactivate specific genes. These streptococcal host strains are either human or animal pathogens and are within ACDP hazard group 2. It is anticipated that the inactivation of streptococcal genes encoding putative virulence factors will generate mutant strains that are less virulent than the parent strains from which they are derived. Indeed the demonstration of a role in virulence for any individual protein usually requires experimental evidence of attenuated virulence in mutant strains lacking the protein of interest.

Host/vector system

For insertional inactivation an internal fragment of the gene of interest will be cloned into an appropriate vector to generate a recombinant plasmid. In this work plasmids that cannot replicate in streptococci, such as the plasmid pVA891 (Macrina et al., 1983), will be used as vectors. When the recombinant plasmid is introduced into a suitable streptococcal host strain specific, homologous recombination between the cloned gene fragment and the endogenous gene in the host results in insertion of the entire recombinant plasmid into the gene of interest. Insertion of vector sequences into an open reading frame results in inactivation of the gene. The recombination event that leads to insertional inactivation can result in the expression of truncated forms of the proteins of interest but these truncated forms are likely to be non-functional.

In allelic replacement an in-frame deletion is made in a copy of the gene of interest. The gene harbouring the deletion is introduced into an integration vector to generate a recombinant plasmid. Vectors of the pG+host range (Biswas et al., 1993) will be used in these studies. These vectors have temperature sensitive origins of replication allowing replication at 28 degrees C but not 37 degrees C. Once the recombinant plasmid is introduced into a suitable streptococcal strain at 27 degrees C, increasing the temperature to 37 degrees C results in recombination between the cloned, deletion derivative of the gene and the endogenous gene in the host strain. This results in replacement of the endogenous gene with the deletion derivative. The deletion is targeted to regions of the gene that encode functional regions of the protein, in order to generate a mutant strain that lacks the activity of the protein of interest.

Origin & function

All target genetic material will originate from a parental streptococcal strain (see list of species above).

Evaluation of foreseeable effects

Any protein products arising from these manipulations are likely to be non-functional (and thus less hazardous than the corresponding product of the wild type).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not requested.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Contaminated liquid waste will be disinfected by autoclaving or treatment with Virkon, which have 100% kill rates. The disinfectant activity of Virkon has been validated for the streptococcal species being studied. Likewise all solid waste contaminated with GMMs will be autoclaved prior to final disposal. All autoclaving of GMM waste will be carried out in a validated autoclave. Autoclaved waste will then be disposed of as clinical waste.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

This application has been approved by the local genetic modification safety committee.

Project Ref 614/15.1

Date Ackn'd 22/07/2015

CU2 Project Title Knockout mutation and plasmid-based complementation of genes encoding AmpC beta-lactamases from clinical isolates of Enterobacteriaceae

Class 2 CultureVolClass2 < 1 Litre

Non-GMM Consent Granted

Date Project Ceased 10/09/2020

Project notified under transitional arrangements N
We will be analysing the parental, knockout and complemented strains using MALDI-TOF mass-spectrometry in order to develop a clinically-useful rapid diagnostic method testing method for AmpC bacteria.

Clinical isolates of Enterobacteriaceae: E.coli or Enterobacter cloacae. These are all designated as ACDP2

Host/vector system

The knockout mutagenesis will be carried out using the lambda Red based GeneDoctoring method (Lee et al. 2009 BMC Microbiol. 9: 252) followed by excision of the kanamycin cassette using the FLP recombinase expressed from pCP20 (Cherepanov & Wackernagel 1995 Gene 158: 9). The cloned beta-lactamase (blaAmpC) gene (with cognate promoter) for complementation of the knockout will be carried on a low-copy-number non-mobilisable plasmid (pACYC184). Plasmid construction will be carried out in standard K-12 lab strains of E.coli i.e. ACDP1 disabled or non-colonising hosts.

Origin & function

The proposed modification does not involve permanent introduction of foreign genetic material except for plasmid vectors. The blaAmpC knockout mutation will remove an antibiotic resistance from the modified strain but is not predicted to affect pathogenicity in any way. The complementation will replace this same antibiotic resistance gene (probably at a somewhat higher copy number). The major concern here would seem to centre on any potential for mobilisation of these antibiotic resistance genes, which are already naturally plasmid-borne in many clinical isolates (Phillipon et al. 2002 Antimicrob. Agents Chemother. 46: 1). We are not using any conjugative vectors and to the best of our knowledge the plasmids involved are all non-mobilisable, so we feel that the risks of significant spread of blaAmpC genes in the community, if any strains escape containment, are low and certainly insignificant compared to the existing natural background of blaAmpC horizontal genetic exchange. The selective markers carried on the plasmid vectors to be used here are either not clinically relevant for treatment of potential UTI or bacteraemias (e.g. those conferring resistance to kanamycin or chloramphenicol) or confer resistance to antibiotics which these AmpC bacteria are already resistant to (ampicillin).
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| Standard disposal route for contaminated plastic items (spreaders, loops) or small volumes of liquid is to disinfectant (1% Trigene / Distel) pots; larger volumes of liquid or larger plasticware / tubes are disposed of via autoclaving. Distel / Trigene is known to be effective against most non-sporulating bacteria and our decontamination protocol has been tested in use-dilution tests and shown to be 100% effective against various strains of E. coli, but will be re-validated against cultures of any host bacteria (Enterobacter cloacae) to be used during this project. Autoclaving at 121 °C for 15 minutes is well-established as an effective sterilisation method and can be assumed to result in 100% kill. Our autoclaves are serviced annually and physical parameters for each cycle are logged and checked. |

Is an emergency plan required according to regulation 20? Y

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Comments on a draft version of the RA were received from three members of the panel. No significant objections were raised, but several suggestions, for example about appropriate PPE, were incorporated in the final version of the RA as attached here. All comments can be supplied on request.

Bacteriology  Parasitology  Transgenic Birds  Microbiology Research
Virology  Transgenic Animals  Transgenic Fish  Gene Therapy
All material will be sterilised by autoclaving at 121 degrees C for 15 mins before disposal. Maximum volume will not exceed 5 L. Autoclave performance is monitored by the inclusion of indicator discs with every cycle. These discs change colour after the autoclave has reached 121 degrees C for 15 mins.

The maximum culture volume does not exceed one litre and this is then inactivated by treatment with presept tablets. These are used at one 5 g tablet per litre and the resulting solution left to stand for at least one hour before disposal down the sink. Solid waste material is disposed of by autoclaving prior to incineration.

### Project Additional Information

#### Purposes of the contained use

To investigate the effect of kinases and proteases in APP processing and Amyloid beta production

#### Recipient or parental organism

The HEK 293 cell line is a permanent line of primary human embryonic kidney transformed by sheared adenovirus type 5 (Ad5) DNA. The HEK 293FT cell line in addition to being transformed by Ad5 DNA dos stably and constitutively express the SV40 large T-Antigen to facilitate optimal lentivirus production (Naldini et al. 1996). HEK 293 and HEK293FT cell lines have been established in cell culture for many years and are well characterised. Being of human origin they may harbour adventitious agents that could harm humans, however, there are no reports of such occurrences. Primary rat cortical neurons are non-dividing cells which require special medium to grow. Both HEK293 cells and cortical neurons will be unable to survive outside the lab.

#### Host/vector system

The lentiviral system that we will be using is produced by Invitrogen and it has been widely tested in a variety of cell types. The system is derived from the Human Immunodeficiency Virus type 1 (HIV-1). Its genome has been divided into four distinct plasmids; a pLenti6 expression vector into which the gene of interest is cloned and three packaging plasmids which supply the helper functions and the structural and replication proteins in trans required to produce the Lentivirus.

To generate the lentiviral vector of interest, the pLenti6-expression construct containing the gene of interest is transfected into the 293FT producer cell line together with a mix of the three packaging plasmids. The 293FT producer cell line stably and constitutively expresses the SV40 large T antigen under the control of a CMV promoter. Studies have demonstrated maximal virus production in human 293 cells expressing large SV40 large T antigen (Naldini et al. 1996) making the 293FT cell line a particularly suitable host for generating lentiviral constructs. 48 to 72 hours after transfection, the viral supernatant is harvested and its titre determined. The viral supernatant can then be added to our mammalian cells of interest (HEK293 cells and rat cortical neurons).

The expression vector (pLenti6) contains a deletion in the 3' LTR (U3) that does not affect generation of the viral genome in the producer cell line, but results in self-inactivation of the lentivirus after transduction of the target cell through the inactivation of the viral genome promoter (Yee et al. 1987; Yu et al. 1986; Zufferey et al 1998). No recombinant viral particles containing our genes of interest can be produced even in the occurrence of co-infection with WT HIV-1(Zufferey et al. 1998).

Additional safety features are: the number of genes from HIV-1 that are used in the system has been reduced to three (i.e. gag, pol and rev) out of the nine genes present in the genome of the parental virus. Furthermore, the VSV-G gene from Vesicular Stomatitis Virus is used in place of of the HIV-1 envelope (Burns et al. 1993; Emi et al 1991; Yee et al 1994).

Genes encoding the structural and other components required for packaging the pLenti vector RNA are on three separate plasmids. All four plasmids have been engineered not to contain any regions of homology with each other to prevent recombination events that could lead to the generation of a replication-competent virus (Dull et al 1998).

Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, VSV-G_ in the 293FT producer cell line, none of them contain LTRs or the 0 packaging sequence. This means that none of the these HIV-1 structural genes are ever present in any infectious viruses. Expression of the gag and pol genes from one of the helper plasmids has been rendered Rev-dependent by virute of the HIV-1 RRE in the gag/pol mRNA transcript. Addition of the RRE prevents gag and pol expression in the absence of Rev (Dull et al. 1998).

#### Origin & function

APP(WT and APP processing mutants) as well as all other constructs were made in house.

Our aim is to make lentiviruses that express WT or APP processing mutants to produce a measurable amount of Amyloid-beta. We will then look at the effects of co-expressing various kinases or proteases on Amyloid-beta production. The expression of all genes will be under the control of the CMV promoter.

We would also like to establish the expression of RNAi using Lentivirus here in the lab. To do that we will transduce HEK293 cells and rat cortical neurons with a GFP or lacZ lentiviral vector and later transduce the same cells with a RNAi GFP or lacZ lentiviral vector and see whether we can block GFP or lacZ expression from those cells. The RNAi expression will be under the control of the U6 promoter. Similar experiments have been previously carried out in other labs (Haibin Xia et al 2002, Nature Biotech, 20, 1006-1010).
The mammalian cells are unlikely to survive outside the laboratory as they require special medium to grow. Therefore, it is unlikely that any harm would occur to the environment if any were released. As the GMMs are unlikely to survive outside laboratory, the consequences of release are negligible. Gene transfer from transfected mammalian cells is very unlikely. The inserted genes of interest are unlikely to provide a selective advantage to the host. The lentiviral-based vectors used are replication incompetent and have the additional safety features described above. The major risks of working with lentiviral vectors are associated with needle stick injury (however no needles will be used at any stage during the handling of the viruses), exposure to open wounds (gloves and disposable lab coat will be worn at all times and any open wounds will be covered), and inhalation (aerosolisation of viral stocks will be minimised; screw cap tubes will be used to centrifuge and to store the virus and sonication will not be used). Because the vector uses a VSV-Glycoprotein it is able to infect a wide range of mammalian cells including human cells. However, for the reasons given above the risk from infection of the user by the viruses is very low. No new replication-competent virus can be produced and therefore the viruses will not be able to propagate after infection. Although escaped virus might infect other mammals, the same considerations apply to human exposure and so are minimal. If humans or environment were to receive the virus the effects will be mainly dependent on the type of proteins that the infected cells would express. Below is a summary of the effect of overexpression of those proteins in mammalian cells:

- LacZ and GFP are considered non-pathogenic in the host cell lines.
- The recombinant APP proteins are considered non-pathogenic in HEK293 cells, however, overexpression in rat cortical neurons was shown to induce apoptosis (Lienlen-Campard et al 2002 JBC, 277, 15666-70) and mice overexpressing SW APP show degeneration of choline acetyl transferase-immunoreactive fibres in the environment of beta-amyloid plaques and activated glial cells suggesting a role of beta-amyloid and/or inflammation in specific degeneration of cholinergic synaptic structures (Luth HJ. et al, 2003 Brain Res, 977, 16-22). However the cells most at risk from infection are the lung and gut epithelium for which APP is non-pathogenic. Infection of neuronal cells is a highly unlikely event, and it is not clear that infection of a few neurones would be pathogenic to any other cells. The kinases and proteases to be studied are likewise not considered a hazard upon expression in mammalian cells.

To summarise expression of these recombinant proteins will not alter the pathogenicity and or oncogenicity of mammalian cells nor will they alter the viral characteristics.

Infection of neuronal cells is a highly unlikely event, and it is not clear that infection of a few neurones would be pathogenic to any other cells. The kinases and proteases to be studied are likewise not considered a hazard upon expression in mammalian cells.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All paper and plastic waste (tubes, tissue culture flasks, dishes, pipettes and tips) as well as small volumes of liquid waste, which will be collected in plates or flasks, will be collected in autoclavable bags. These will be sealed and autoclaved at 134 degrees celsius prior to disposal by inactivation.

Is an emergency plan required according to regulation 20? Y

If yes, tick to confirm that it is attached to this form Y

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment
Sharps are to be banned from the virus room, any procedures that involve sharps will have to be put before the Committee for specific approval. No such procedure is necessary for the present project. Security on the room was questioned and it was confirmed that the room is only accessible by those with specific card keys and these will only be sanctioned upon approval of a specific application to the Committee. Communication with others outside the room in the event of a spill was also considered. In the event of an accident the experimenter may not be able to easily leave the room to seek help. A telephone will now be installed in the room at all times during use. Waste handling and disposal was discussed and approved. The possibility of an escape of in the event of an accident was considered and it was felt that given the standard of the equipment and room, the small scale of virus production that will occur, an escape would not occur.

Purposes of the contained use

To investigate the effect of kinases and proteases in APP processing and Amyloid beta (AB) production.

Recipient or parental organism

The HEK 293 cell line is a permanent line of primary human embryonic kidney transformed by sheared adenovirus type 5 (Ad 5) DNA. HEK293T cell line stably and constitutively express the SV40 large T-antigen to facilitate optimal lentivirus production (Naidini et al., 1996). HEK 293 and HEK293T cell lines have been established in cell culture for many years and are well characterised. Being of human origin they may harbour adventitious agents that could harm humans, however, there are no reports of such occurrences. Primary rat cells require special medium to grow. HEK 293 cells and rat primary cells will be unable to survive outside the lab.

Host/vector system

We will be using a second generation lentiviral system (Zuffery et al., 1996). This system has been widely tested in a variety of cell types. It is derived from the Human immunodeficiency Virus type 1 (HIV-1).

For the second generation virus, the HIV-1 genome has been divided into three distinct plasmids: an expression vector into which the gene of interest is cloned (pHR-SIN-CSGW) and two packaging plasmids (pCMVR8.91 and pMO-G) which supply the helper functions and the structural and replication proteins in trans required to produce the Lentivirus.

To generate the Lentiviral vector of interest, the expression construct containing the gene of interest is transfected into the 293T producer cell line together with a mix of the two packaging plasmids. The 293T producer cell line stably and constitutively expresses the SV40 large T antigen under the control of a CMV promoter. Studies have demonstrated maximal virus production in human 293 cells expressing SV40 large T antigen (Naidini et al., 1996) making the 293T cell line a particular suitable host for generating lentiviral constructs. Forty-eight to 72 hours after transfection, the viral supernatant is harvested and its titre determined. The viral supernatant can then be added to our mammalian cells of interest (HEK 293 cells and rat primary cells). Both expression vectors contain a deletion in the 3’ LTR (U3) that does not affect generation of the viral genome in the producer cell line, but results in self-inactivation of the lentivirus after transduction of the target cell through the inactivation of the viral genome promoter (Yee et al., 1987; Yu et al., 1986; Zufferey et al., 1998). No recombinant viral particles containing our genes of interest can be produced even in the occurrence of co-infection with WT HIV-1 (Zufferey et al., 1998).

Additional safety features are: the number of genes from HIV-1 that are used in the system has been reduced to three (ie gag, pol, and rev) out of the nine genes present in the genome of the parental virus. Furthermore, the VSV-Gene from Vesicular Stomatitis Virus is used in place of the HIV-1 envelope (Burns et al., 1993 Emi et al., 1991; Yee et al., 1994)

Genes encoding the structural and other components required for packaging the lentivirus vector RNA are on two separate plasmids. All plasmids have been engineered not to contain any regions of homology with each other to prevent recombination events that could lead to the generation of a replication-competent virus (Dull et al., 1998). Although the packaging plasmids allow expression in trans of proteins required to produce viral progeny (eg gal, pol, rev, VSV-G) in the 293T producer cell line, none of them contain LTRs or the O packaging sequence. This means that none of these HIV-1 structural genes are ever present in any infectious viruses.

Expression of the gag and pol genes from one of the helper plasmids has been rendered Rev-dependent by virtue of the HIV-1 RRE in the gag/pol mRNA transcript. Addition of the RRE prevents gag and pol expression in the absence of Rev (Dull et al., 1998)

Origin & function

APP (WT and APP processing mutants) as well as all other constructs were made in house.

Our aim is to make lentiviruses that express WT or APP processing mutants to produce a measurable amount of AB. We will then look at the effects of co-expressing various kinases or proteases on AB production. The expression of all genes will be under the control of the SFFV promoter (Spleen Focus Forming Virus). We will also make lentiviruses expressing LacZ, nisLacZ GFP to use as sonctols of infection and markers for infected cells.

We would also like to establish the expression of RNAi using Lentivirus here in the lab. To do that we will transduce HEK293 cells and rat primary cells with a GFP or LacZ lentiviral vector and later transduce the same cells with a RNAi GFP or LacZ lentiviral vector and see whether we can block GFP or LacZ expression from those cells. The RNAi expression will be under the control of the U6 promoter. Similar experiments have been previously carried out in other labs (Haibin Xia et al., 2002 Nature Biotech, 20, 1006-1010).
The mammalian cells are unlikely to survive outside the laboratory as they require special medium to grow. Therefore, it is unlikely that any harm would occur to the environment if any were released. As the GMMs are unlikely to survive outside laboratory, the consequences of release are negligible.

Gene transfer from transfected mammalian cells is very unlikely. The inserted genes of interest are unlikely to provide a selective advantage to the host. The lentiviral-based vectors used are replication incompetent and have the additional safety features described above. The major risks of working with lentiviral vectors are associated with needle stick injury (however no needles will be used at any stage during the handling of the viruses), exposure to open wounds (gloves and disposable lab coat will be worn at all times and any open wounds will be covered) and inhalation (aerosolisation of viral stocks will be minimised: screw cap tubes will be used to centrifuge and to store the virus and sonication will not be used).

Because the vector uses a VSV-Glycoprotein it is able to infect a wide range of mammalian cells including human cells. However for the reasons given above the risk from infection of the user by the viruses is very low.

No replication-competent virus can be produced and therefore the viruses will not be able to propagate after infection. Although escaped virus might infect other mammals, the same considerations apply to human exposure and so are minimal.

If humans or environment were to receive the virus the effects will be mainly dependent on the type of proteins that the infected cells would express. Below is a summary of the effect of overexpression of those proteins in mammalian cells:

- **BACE, LacZ and GFP** are considered non-pathogenic in the host cell lines.
- The recombinant APP proteins are considered non-pathogenic in the HEK 293 cells, however overexpression in rat cortical neurons was shown to induce apoptosis (Kienlen-Campart et al., 2002 JBC, 277, 15666-70) and miceoverexpressing SW App show degeneration of choline acetyl transferase-immunoreactive fibres in the environment of beta-amyloid plaques and activated gial cells suggesting a role of beta-amyloid and/or inflammation in specific degeneration of cholinergic synaptic structures (Luch HJ et al., 2003 Brain Res, 977, 16-22). However, the cells most at risk of infection are the lung and gut epithelium for which APP is non-pathogenic.
- Infection of neuronal cells is a highly unlikely event, and it is not clear that infection of a few neurones would be pathogenic to any other cells. The kinases and proteases to be studied are likewise not considered a hazard upon expression in mammalian cells.

To summarise expression of these recombinant proteins will not alter the pathogenicity and/or oncogenicity of mammalian cells nor will they alter the viral characterists. Furthermore, the lentiviral particles used in this system are replication-incompetent and only carry the gene of interest. No other viral species are produced even in the occurrence of co-infection with WT HIV-1. There is therefore negligible risk to humans in the event of exposure.

**Project Ref** 622/05.1

- **CU2 Project Title**: Investigation of oligodendrocyte differentiation
- **Class CultureVolClass2 CultureVolumeClass3-4**: Class 2 1-50 Litres
- **Non-GMM Consent Granted**: Consent Granted
- **Project notified under transitional arrangements**: N

**Project Additional Information**
**Purposes of the contained use**

To investigate the effect of various transcription factors on oligodendrocyte differentiation.

**Recipient or parental organism**

The HEK 293 cell line is a permanent line of primary human embryonic kidney transformed by sheared adenovirus type 5 (Ad5) DNA. The HEK 293FT cell line in addition to being transformed by Ad5 DNA does stably and constitutively express the SV40 large T-Antigen to facilitate optimal lentivirus production (Naldini et al., 1996). HEK 293 and HEK 293FT cell lines have been established in cell culture for many years and are well characterised. Being of human origin they may harbour adventitious agents that could harm humans, however, there are no reports of such occurrences. Neural precursor cells (NPC's) are derived from embryonic, postnatal and adult murine tissue and required special medium to grow. Both HEK 293 cells and NPC's will be unable to survive outside the lab.

**Host/vector system**

The Retroviral system that we will be using is produced by Imgenex and it has been widely tested in a variety of cell types. RetroMaxTM retrovirus vector system is based on the pCL vector system developed by Naviaux et al. (1996). The system is derived from the moloney murine leukaemia virus (MMLV). Its genome has been divided into two distinct plasmids: a retroviral expression vector (pMX vector) in which the gene of interest is cloned and a packaging plasmid (pCL-Eco vector) which supplies the helper functions and the structural and replication proteins in trans required to produce the Retrovirus.

To generate the Retroviral vector of interest, the pMX-construct containing the gene of interest is transfected into the HEK293FT producer cell line together with the packaging vector. 24 hours after transfection the medium is changed to media suitable for growth of neutral precursor cells. Forty-eight to 96 hours after transfection, the viral supernatant is harvested and its titre determined. The viral supernatant can then be added to our mammalian cells of interest (HEK 293 cells and NPC's).

The expression vector (pMX) contains the 5' and 3' LTR derived from the MMLV. Although the vector contains the 5 prime half of the gag coding sequence, the initiation codon of this gag gene is deleted in the pMX vector. So, even in the event of recombination, the risk that replication competent virus will be produced is very low.

The pCL-ECO packaging vector has also been safety modified by deleting the packaging signal and the 3'LTR enhancer. This makes the RNAs of the helper genome un-packageable. The advantage of these pCL packaging plasmids is a high level expression of gag, pol, and env proteins with a balanced stoichiometry that is not achieved with either transiently or stably expressed split-genome packaging constructs. Furthermore, the packaging system pCL-Eco generates viral particles that will infect mouse and rat cells, but not human cells. This is due to a lack of tropism for human cells with the retroviral vectors. The viral envelope protein, gp70, determines which cells the virus will enter. The vectors expressing the mouse ecotropic envelope infect mouse and rat cells only.

Although the packaging plasmid allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, env) in the 293 producer cell lines, it does not contain the Ø packaging sequence. This means that none of these retroviral structural genes are ever present in any infectious viruses.

The expression of all inserted genes will be under the control of the PGK promoter.

**Origin & function**

All constructs will be made in house. Our aim is to make retroviruses that express Olig1, Olig2, the bHLH domain of Olig1, ID4, E47 and combinations of such. The constructs will be used to study Oligodendrocyte differentiation in neural progenitor cells.

**Evaluation of foreseeable effects**

The mammalian cells are unlikely to survive outside the laboratory as they require special medium to grow. Therefore, it is unlikely that any harm would occur to the environment if any were released. The release of GMM's or viral particles into the environment is very unlikely since all waste as well as any instruments that were in contact with viruses will be autoclaved prior to disposal by incineration. In addition all experiments will be in a small scale and even in the event of an accident there will be unlikely a release.

Gene transfer from transfected mammalian cells is very unlikely. The inserted genes of interest are unlikely to provide a selective advantage to the host.

The retroviral-based vectors used are replication incompetent and have the additional safety features described above. The major risks of working with retroviral vectors are replication incompetent and have additional safety features described above. The major risks of working with retroviral vectors are associated with needle stick injury.
(however no needles will be used at any stage during the handling of the viruses), exposure to open wounds (gloves and disposable lab coat will be worn at all times and any open wounds will be covered) and inhalation (aerosolisation of viral stocks will be minimised: screw cap tubes will be used to centrifuge and to store the virus and sonication will not be used). Otherwise, the cells most at risk are epithelial cells which are rapidly replaced and therefore unlikely to pose a hazard even upon receiving these constructs. Since viral work will carried out according to guidelines in a Biosafety Level 2 facility, it is very unlikely that any virus can infect mammals outside the laboratory. In addition, it is unlikely that the replication-deficient virus will be able to propagate after such an infection. Although escaped virus might infect other mammals, these viruses cannot infect human described above. The vectors can only become potentially infectious for human cells by recombination with mouse endogenous retrovirus genes encoding amphotrophic or polytropic envelopes.

If the environment (e.g. endogenous populations) were to receive the virus the effects will be mainly dependent on the type of proteins that the infected cells would express. Below is a summary of the effect of overexpression of those proteins in mammalian cells:

- **EGFP, bHLH domain of Olig1, hygromycin B phosphotransferase gene (hydro) and puromycin (puro) resistance gene (puro)** are considered non-pathogenic. Olig1 and Olig2 are basic helix-loop transcription factors and are expressed specifically in cells of the oligodendrocyte lineage (Zhou et al., 2000). Olig1 genes are strongly expressed in oligodendroglioma (Lu QR, 2001) and astrocytoma (Bouvier C, 2003). Immunoreactivity for Olig1 was also found in dysembryoplastic neuroepithelial tumors (Azzarelli B, 2004). Olig2 is also universally expressed in glioma (Ligon KL, 2004) and brain tumors (Lu QR 2001). However, no direct evidence exists that overexpression of Olig1 causes such glioma. Nevertheless, there is a slim possibility that overexpression of Olig1 and forms of Olig1 carrying the nuclear localisation signal could be oncogenic.

- **ID4** is a member of the helix-loop transcription factors and plays important roles throughout gastrulation, neurogenesis, cellular differentiation, proliferation and apoptosis. Due to its pivotal role in cell cycle control, Dysregulation might lead to cancer, e.g. bladder cancer, breast cancer and leukemia (de Candia, 2004, Wu Q, 2005). E47 is a member of the class 1 helix-loop-helix transcription factors that are expressed ubiquitously and are able to dimerise with tissue-specific class B bHLH factors to activate gene expression (Massari and Murre, 200). E47 plays a role in B-cell development and ectopic expression of E47 or E12 promotes the death of E2A-deficient lymphomas (Engel 1999).

Although mammals might be infected by escaped virus, the virus cannot propagate in infected animals. Therefore, spreading of virus to other animals cannot occur and the anticipated effects on endogenous populations are insignificant.

For the reasons given above (negligible risk of release of GMM, safety features of the vector system, limited tropism of the vector for mouse and rat cells), the potential risk arising from release of GMM for users and environment is very low.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

**Project Ref** 622/06.1

Investigation of oligodendrocyte differentiation.

**Project Additional Information**

To investigate the effect of various transcription factors on oligodendrocyte differentiation.
The HEK 293 cell line is a permanent line of primary human embryonic kidney transformed by sheared adenovirus type 5 (Ad5) DNA. The HEK 294 FT cell line in addition to being transformed by Ad5 DNA does stably and constitutively express the SV40 large T-antigen to facilitate optimal lentivirus production (Naldini et al., 1996). HEK 293 and HEK293FT cell lines have been established in cell culture for many years and are well characterised. Being of human origin they may harbour adventitious agents that could harm humans, however, there are no reports of such occurrences. The P19 cell line was isolated by implanting a 7 day old mouse embryo under the testis capsule of an adult which resulted in formation of a tumor (McBurney and Rogers, 1982). Tumor cells were grown in culture and one clone, P19, established as a line. P19 cells have a normal karyotype and reproduce rapidly and without apparent limit in culture; they express several early embryonic markers. P19 cells have been established in cell culture for many years and are well characterised. There are no reports that P19 cells may harbour adventitious agents that could harm humans. Neural precursor cells (NPC's) are derived from embryonic, postnatal and adult rodent tissue and require special medium to grow. HEK 293 cells, P19 cells and NPC's will be unable to survive outside the lab.

Recipient or parental organism

The HEK 293 cell line is a permanent line of primary human embryonic kidney transformed by sheared adenovirus type 5 (Ad5) DNA. The HEK 294 FT cell line in addition to being transformed by Ad5 DNA does stably and constitutively express the SV40 large T-antigen to facilitate optimal lentivirus production (Naldini et al., 1996). HEK 293 and HEK293FT cell lines have been established in cell culture for many years and are well characterised. Neural precursor cells (NPC's) are derived from embryonic, postnatal and adult rodent tissue and require special medium to grow. HEK 293 cells, P19 cells and NPC's will be unable to survive outside the lab.

Host/vector system

The lentiviral system that we will be using is produced by Invitrogen and it has been widely tested in a variety of cell types. The system is derived from the Human Immunodeficiency Virus type 1 (HIV-1). Its genome has been divided into four distinct plasmids: pLenti6 expression vector into which the gene of interest is cloned and three packaging plasmids which supply the helper functions and the structural and replication proteins in transrequired to produce the Lentivirus.

To generate the Lentiviral vector of interest, the pLenti6-expression construct containing the gene of interest is transfected into the 193FT producer cell line together with a mix of the three packaging plasmids. The 293FT producer cell line stably and constitutively expresses the SV40 large T antigen under the control of a CMV promoter. Studies have demonstrated maximal viral production in human 293 cells expressing SV40 large T antigen (Naldini et al., 1996), making the 293FT cell line a particularly suitable host for generating lentiviral constructs. Forty-eight to 72 hours after transfection, the viral supernatant is harvested and its titre determined. The viral supernatant can then be added to our mammalian cells of interest (HEK 293 cells and rodent neural precursor cells).

The expression vector (pLenti6) contains a deletion in the 3' LTR (U3) that does not affect generation of the viral genome in the producer cell line, but results in self-inactivation of the lentivirus after transduction of the target cell through the inactivation of the viral genome promoter (Yee et al., 1987; Ue et al., 1986; Sufferey et al., 1998). No recombinant viral particles containing our genes of interest can be produced even in the occurrence of co-infection with WT HIV-1 (Zufferey et al., 1998).

Additional safety features are: the number of genes from HIV-1 that are used in the system has been reduced to three (ie gag, pol, and rev) out of the nine genes present in the genome of the parental virus. Furthermore, the VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 envelope (Burns et al., 1993; Emi et al., 1991; Yee et al., 1994).

Genes encoding the structural and other components required for packaging the pLenti6 vector RNA are on three separate plasmids. All four plasmids have been engineered not to contain any regions of homology with each other to prevent recombination events that could lead to the generation of a replication-competent virus (Dull et al., 1998).

Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (eg gal, pol, rev, VSV-G) in the 293FT producer cell line, none of them contain LTRs or the 0 packaging sequence. This means that none of these HIV-1 structural genes are event present in any infectious viruses.

Expression of the gag and pol genes from one of the helper plasmids has been rendered Rev-dependent by virtue of the HIV-1 RRE in the gag/pol mRNA transcript. Addition of the RRE prevents gag and pol expression in the absence of Rev (Dull et al., 1998).

Origin & function

All constructs will be made in house.

Our aim is to make lentiviruses that express Olig1, Olig2, the basic helix-loop-helix domain of Olig1, ID4, E47 and combinations of such. The constructs will be used to study Oligodendrocyte differentiation in neural progenitor cells.
Evaluation of foreseeable effects

The mammalian cells are unlikely to survive outside the laboratory as they require special medium to grow. Therefore, it is unlikely that any harm would occur to the environment if any were released. As the GMMs are unlikely to survive outside laboratory, the consequences of release are negligible.

Gene transfer from transfected mammalian cells is very unlikely. The inserted genes of interest are unlikely to provide a selective advantage to the host.

The lentiviral-based vectors used are replication incompetent and have the additional safety features described above. The major risks of working with lentiviral vectors are associated with needle stick injury (however no needles will be used at any stage during the handling of the viruses), exposure to open wounds (gloves and disposable lab coat will be worn at all times and any open wounds will be covered) and inhalation (aerosolisation of viral stocks will be minimised; screw cap tubes will be used to centrifuge and to store the virus and sonication will not be used).

Because the vector uses a VSV-Glycoprotein it is able to infect a wide range of mammalian cells including human cells. However for the reasons given above the risk from infection of the user by the viruses is very low.

No new replication-competent virus can be produced and therefore the viruses will not be able to propagate after infection. Although escaped virus might infect other mammals, the same considerations apply to human exposure and so are minimal.

If the environment (eg endogenous populations) were to receive the virus the effects will be mainly dependent on the type of proteins that the infected cells would express. Below is a summary of the effect of overexpression of those proteins in mammalian cells:

- EGFP, bHLH domain of Olig1, hygromycin B phosphotransferase gene (hygro) and puromycin (puro) resistance gene (puro) are considered non-pathogenic. Olig 1 and Olig2 are basic helix-loop-helix transcription factors and are expressed specifically in cells of the ologodendrocyte lineage (Zhou et al., 2000). Olig1 genes are strongly expressed in oligodendroglioma (Lu QR, 2001) and astrocytoma (Bouvier C, 2003). Immunoactivity for Olig 1 was also found in dysembryioplastic neuroepethelial tumors (Azzarelli B, 2004). Olig2 is also universally expressed in glioma (Ligon KL, 2004) and brain tumors (Lu QR 2001). However, no direct evidence exists that overexpression of Olig 1 causes such glioma. Nevertheless, there is a slim possibility that overexpression of Olig1 and forms of Olig1 carrying the nuclear localisation signal could be oncogenic.

- ID4 is a member of the helix-loop-helix transcription factors and plays important roles throughout gastrulation, neurogenesis, cellular differentiation, proliferation and apoptosis. Due to its pivotal role in cell cycle control, dysregulation might lead to cancer, eg bladder cancer, breast cancer, and leukemia (de Candia, 2004, Wu Q, 2005).

- E47 is a member of the class 1 helix-loop-helix transcription factors that are expressed ubiquitously and are able to dimerize with tissue-specific class B bHLH factors to activate gene expression (Massari and Murre, 2000). E47 plays a role in B-cell development and ectopic expression of E47 and E12 promotes the death of E2A-deficient lymphomas (Engel 1999).

Although mammals might be infected by escaped virus, the virus cannot propagate in infected animals. Therefore, spreading of virus to other animals cannot occur and the anticipated effects on endogenous populations are insignificant.

For the reasons given above (negligible risk of release of GMM, safety features of the vector system), the potential risk arising from release of GMM for users and environment is very low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All paper and plastic waste (tubes, tissue culture flasks, dishes, pipettes and tips) as well as small volumes of liquid waste, which will be collected in plates or flasks, will be collected in autoclavable bags. These will be sealed and autoclaved at 134 degrees C prior to disposal by incineration.

Is an emergency plan required according to regulation 20? Y

If yes, tick to confirm that it is attached to this form Y

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

This application was discussed at the GMSC on 21st November 2005.

Historical Significant Changes
Project Additional Information

**Purposes of the contained use**

To develop analysis tools for investigating oligodendrocyte differentiation.

**Recipient or parental organism**

The Oli-neu cell line (Jung et. Al, (1995) Eur. J. Neurosci. 7:1245-1265) was established by immortalising enriched primary shake-off cultures of oligodendrocyte precursors from E15-mouse brains by expression of the oncogene t-neu. This oncogene has constitutively active tyrosine kinase activity, which induces unlimited expansion of these cells. Oli-neu cells have a normal karyotype and replicate rapidly and without apparent limit in culture; they express several early oligodendrocyte markers. Oli-neu cells have been established in cell culture for many years and are well characterised. There are no reports that Oli-neu cells may harbour adventitious agents that could harm humans.

**Host/vector system**

Introduction of the additional DNA constructs is not foreseen to constitute any additional hazard from the vector view point.

**Origin & function**

Oligodendrocyte specific promoter sequences upstream of lacZ and PLAP reporter constructs in pCDNA3.1 derived or pSEAP1-basic (Clontech) vectors. pTK-Hygromycin was purchased from Takara Europe/Clontech (Cat number 631750).

**Evaluation of foreseeable effects**

Oli-neu cell line was established by immortalising enriched primary shake-off cultures of oligodendrocyte precursors from E15-mouse brains by expression of the oncogene t-neu. This oncogene has constitutively active tyrosine kinase activity, which induces unlimited expansion of these cells. The disabled retroviral based vector used to introduce the oncogene is not able to repackage due to the lack of any encoded retroviral proteins. However it is possible (due to the presence of LTR sequences) that the retroviral/oncogene RNA could be package in the event of a co-infection with a WT retrovirus of a type that was able to interact with the Moloney Murine Leukemia Virus (MoMLV) packaging sequence. If this virus were able to infect a human cell this could result in the oncogene being introduced into human cells. Consultation with the ELL named vet and the vet at our animal supplier indicated that they thought this extremely unlikely since the neu cell line was established by immortalising enriched primary shake off cultures of oligodendrocyte precursors from E15 conceive a means for virus to be passed from an animal to the cells. In addition the ELL vet was of the opinion that retrovirus able to infect both mouse and human cells were very rare. This leaves the possibility that the cells were already infected when
we obtained them, however the supplier of these cells stated that they did not treat them as a risk and that there were no known risks associated with these cells. Arguing for a more rigorous containment is the fact that viruses do exist that can infect both murine and human cells and so could precipitate this hazard. In addition we have been informed that on rare occasions animal cell lines and primary cultures spontaneously produce infectious gammararetroviruses. Gammararetroviruses are able to package the MoMLV type packaging sequences.

The introduction of a t-neu expression construct into human cells could result in tumour induction, so is extremely undesirable. Release of the virus packaged t-neu expression construct into the environment is less of a hazard as these viruses are extremely labile and unless directly introduced into an animal that the virus can infect the hazard is low.

Gene transfer from transfected mammalian cells other than by the reconstituted virus detailed above is very unlikely. The mammalian cells are unlikely to survive outside the laboratory as they require special medium to grow. Therefore, it is unlikely that any harm would occur to the environment if any were released.

# Project Title

**Transduction of ReNcells with GFP or LRRK2 containing constructs using BacMam system**

## Purposes of the contained use

Investigate the effect of over-expression of mutant vs WT LRRK2 constructs on ReNcells viability/functions.

## Recipient or parental organism

ReNcell VM is an immortalized human neural stem cell line (ReNeuron Ltd., Guildford, Surrey, UK) derived from the ventral mesencephalon from 10-week fetal neural tissue. ReNcell VM cells were infected with high titer amphotropic retrovirus (TEFLY-A) carrying the immortalizing transgene v-myc plus a selection marker (Hoffrogge et al., 2006). This recently derived human cell line requires containment at level 2.

## Host/vector system

The BacMam 2.0 system uses a modified insect cell virus (baculovirus) as a vehicle to efficiently deliver and express genes in mammalian cells. The transgene encodes WT or mutant LRRK2 (Leucine-rich repeat kinase 2 (LRRK2), an enzyme with a kinase and GTPase domains).

## Origin & function

BacMam 2.0 Reagents, Life Technologies: Research purpose only.

## Evaluation of foreseeable effects

ReNcell VM cell line was derived from the ventral mesencephalon of 10-week fetal tissue. Maternal blood was negative for HIV, HTLV, HepB&C. ReNcells were transformed using the oncogene v-myc (Donato et al. 2007). In the event of gene transfer of this to human or other animal cells there is a serious risk of oncogenesis.
however this is extremely unlikely to happen since the gene is integrated into the ReNcell genome and the RNA encoding the v-Myc is unlikely to be packaged into an infections viral particle. To minimise the risk of transfer no sharps will be used in any procedure and the cells will be cultured under containment level 2 to avoid exposure to WT retrovirus.

BacMam 2.0 vectors can transduce human cells but in the absence of sharps and the use of limited volumes of virus preparation this is unlikely to occur to a human.

Gene transfer of the baculovirus based constructs from transfected mammalian cells is unlikely. In the event of a transfer of these constructs into a human it is not likely that they will be maintained as they will not integrate into the mammalian genome. The transient expression of LRRK2, mutants of LRRK2 or GFP is not thought to pose a risk to human helath.

BacMam vectors contain a post transcriptional response lement derived from the Woodchuck Hepatitus virus genome (WPRE) that has been shown to increase transgene expression by many folds. There is tenuous evidence linking WPRE to cancer induction. Since the baculovirus based vector DMA, even if delivered into a cell, is extremely unlikely to integrate into the genome its transient nature ensures the WPRE poses minimal risk (see HSE Compendium of guidance paragrap 13, page 120, section 2).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All paper and plastic waste (tubes, tissue culture flasks, dishes, pipettes and tips) as well as small volumes of liquid waste, which will be sealed in tubes or flasks, will be collected in autoclavable bags. These will be sealed, double bagged and autoclaved at 134°C prior to disposal by incineration. If imaging of live cells is required, plates will be securely sealed with adhesive membranes that allow only gaseous exchange before transfer of the plates from the containment level 2 suite to imaging facilities. Once imaging is completed, plates will be returned to the containment level 2 suite and disposed off as described above.

Is an emergency plan required according to regulation 20? N

### Investigating the function of genes implicated in Parkinson's Disease in cultured cells and primary neurons using HSV viruses to express full length wild type and mutant protein

#### Purposes of the contained use

To investigate the biological effects of expressing wild type (WT) and mutant proteins of interest in neuronal systems. Biological endpoints will include measurement of neurotoxicity, neurite shortening, mitochondrial homeostasis, and protein clearance.

**Experimental outline:**

1. Express target protein in primary neurons or cell lines using HSV viruses containing full length wild type and mutant protein or Azami Green separated by a 2A peptide sequence. Determine expression by western blotting and cell staining.
2. Determine the effects of expressing the different viruses mentioned above on cells using a number of fixed cell and live cell imaging assays. Assays will include mitochondrial integrity, neurite shortening, autophagy assays, and cell toxicity using the relevant cell dyes, imaging markers, and western blotting reagents.

#### Recipient or parental organism

**BE(2)-C** cells are derived from a human neuroblastoma. HEK293, SH-SY5Y, and NT2 are also human derived cell lines. All have been established in cell culture for many years and are well characterised. Being of human origin they may harbour adventitious agents that could harm humans, however, there are no reports of such occurrences. These cells will not be able to survive outside the laboratory.

The rat PC12 cell line is a permanent line derived from a transplantable rat adrenal phaeochromocytoma.
The mouse Neuro2A cell line is a permanent line derived from a spontaneous tumour in an albino strain A mouse. PC12 and Neuro2A cells have been established in cell culture for many years and are well characterised. These cells will not be able to survive outside the laboratory.

Rat primary neurons are cultured in Neurobasal media with B27 supplement. This media does not support dividing cells and the useful lifespan of cultures is approximately 30 days. These cells will not be able to survive outside the laboratory.

**Host/vector system**

The work will use HSV-1 strain 1764. All viruses will be disabled by deletion of ICP4 and Vmw65/VP16. As these genes are essential for virus replication and cytotoxicity, the resulting vectors will be replication incompetent and will only be able to replicate in complementing cells that provide these genes in trans (Fields Virology 4th edition (2001), ed Knipe DM et al., pub Lippincott, Williams and Wilkins). These vectors will therefore be non pathogenic and unable to productively infect any cell type other than the complementing cell line. The vectors will also have deletions in the latency associated (LAT) region. Insertion of gene expression cassettes will be into the LAT region.

**Origin & function**

Live disabled viruses produced by Biovex, Oxford (Amgen, UK; reference Anesti. A.M., P. J. Peeters, I. Royaux, and R.S Coffin. 2008. Efficient delivery of RNA interference to peripheral neurons in vivo using herpes simplex virus. Nucleic Acids Res. Vol 36:e86.) HSV viruses will be deficient in ICP4 and VP16 genes which are required for wild type HSV-1 replication and cytotoxicity respectively. The genes implicated in Parkinson's Disease will be inserted into the LAT region of the virus backbone.

**Evaluation of foreseeable effects**

The HSV viruses that will be used are disabled by deletion of ICP4 and VP16 genes. Although wild type HSV-1 is considered pathogenic the disabled vector backbone however will not cause harm to humans in the event of gene transfer.

The foreseeable effects of gene transfer from the genes implicated in Parkinson's Disease cannot be disclosed for business reasons.

It is not considered that expression of the Azami Green or 2A polypeptides would be in any way hazardous.

Whilst it is theoretically possible that the vector could recombine with a wild type HSV virus to generate a replication-competent wild type backbone virus that can express the transgenes, it is highly unlikely (given that the stock virus will only be used in a class II hood) as the two viruses would have to be replicating in the same cell(s) at the same time. However, as a precaution we will not allow any work with the modified viruses if the researcher has symptoms of an active HSV infection. It has also been shown experimentally that these vectors can not reactivate latent wild type virus to produce replication competent recombinant virus at detectable levels in either in vitro culture systems or in vivo in mice (Smith et al., 2003, Gene Therapy and Regulation, Vol 2 (1), p29-47). This suggests any person with a latent HSV infection is not at risk from any recombination events between vector and wild type viruses.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All manipulation of high titre virus will be in class II containment flow-hood. All paper and plastic waste (tubes, tissue culture flasks, dishes, pipettes and tips) as well as small volumes of liquid waste, which will be collected in plates or flasks, will be removed from the hood and placed in autoclavable bags. Any equipment for reuse will be bagged separately. These will be sealed and then double bagged prior to removal from the containment level 2 room. The bags will be directly placed in a leakproof crate which will be autoclaved at 134°C on site prior to the waste bags being taken off site for incineration.
The Safety Committee discussed this project and agreed that it required containment level 2. It was requested that the risk assessment form was modified to include explicit comments that the virus stocks would only be manipulated within the containment level 2 flow hood. Waste GMO inactivation and disposal were discussed and the Safety Committee agreed that the procedures described in the risk assessment form were appropriate. A question was raised as to the best course of action if a human were to become exposed to these virus constructs. It was thought that there was negligible risk unless the virus was inhaled, swallowed or applied to a wound (which will always be covered prior to commencement of any work). In these cases however little could be done except copious washing of the exposed tissues and long term medical follow up. It was emphasised however that it was not thought likely that the expression constructs would be a serious threat unless introduced into large numbers of neurons, which was thought extremely unlikely.

### Project Ref 622/18.1

- **Date Ackn'd**: 31/08/2018
- **CU2 Project Title**: Investigating abnormal protein spreading and aggregation using proteinopathy patient-derived brain samples in a mammalian expression system
- **Class**: Class 2
- **Culture Vol**: < 1 Litre
- **Culture Volume Class**: Consent Granted

- **Date Project Ceased**:  
- **Withdrawn**: N
- **Tick if notifying a connected programme of work**: N

- **Project notified under transitional arrangements**: N
### Project Additional Information

#### Purposes of the contained use

To measure abnormal protein spreading and aggregation using proteinopathy patient-derived brain samples in a cell system, which are transiently overexpressing genes implicated in dementia.

**Experimental outline:**
- Cells will be transfected with expression plasmids encoding disease related mutant genes of interest.
- Proteinopathy patient-derived brain samples will be added to the cell culture medium.
- Abnormal protein spreading and aggregation will be measured by fluorescent based imaging system. Agents that can potentially inhibit the spreading and aggregation of abnormal protein will be evaluated.

#### Recipient or parental organism

Lenti-X 293T cells are clonally selected from HEK293T cells, which are human derived cell lines and expressed SV40 large T antigen.

It has been established in cell culture for many years and is well characterised. Being of human origin it may harbour adventitious agents that could harm humans, however, there are no reports of such occurrences. This cell will not be able to survive outside the laboratory.

#### Host/vector system

The pcDNA3.1(+) vector is Bom/Nic negative, so is unable to undergo plasmid nicking and relaxing neccessary for conjugalional transfer, and is unlikely to be transferred to WT E.coli. In the event of a transfer to WT E.coli these constructs do not contain prokaryotic ribosome binding sites proximal to the inserted genes therefore expression of the encoded proteins will be minimal. Any protein expressed in E.coli would not constitute a threat to human health. The constructs are not thought to be able to alter the pathogenicity of E.coli.

It is considered that ingestion of bacterial culture or DNA could result in take up of small amounts of DNA into cells, which in the case of pcDNA3.1(+) vector would result in expression of the encoded proteins. However, cells at risk such as the gut epithelium are replaced on a regular basis and the vectors involved cannot replicate in mammalian cells in the absence of the SV40 large T antigen.

#### Origin & function

The gene implicated in demetia was inserted into pcDNA3.1(+) based expression vector. It was produced and provided by ThermoFischer scientific.
### Evaluation of foreseeable effects

It is considered that ingestion of a GMM culture or of DNA in sufficient quantity could result in take up of small amounts of DNA into eukaryotic cells however this is unlikely to occur due to laboratory practices and would only involve cells such as the gut epithelium that are replaced on a regular basis so would not result in harm to humans. Sharps will not be used so material is unlikely to be introduced into other tissues. It is not thought that any mutations would alter the risk of harm posed by these constructs. The foreseeable effects of gene transfer of the gene of interest cannot be made public for business reasons. Virus screening of the dementia patient-derived brain materials is not routinely performed. Therefore there is a small risk of these materials containing human virus. While it is highly likely that any virus will be inactivated during the extraction of the test samples, if virus were to survive they may propagate when incubated with the GMO. It is also unlikely but possible that rearrangement may occur to integrate the over expression construct into a human infective virus. Both of these scenarios pose a hazard to human health.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**Not applicable**

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All manipulations using patient brain materials with GMO cells will be in class II containment flow-hood. All paper and plastic waste (tubes, tissue culture flasks, dishes, pipettes and tips) as well as small volumes of liquid waste, which will be collected in plates or flasks, will be removed from the hood and placed in autoclavable bags. Any equipment for reuse will be bagged separately. These bags will be sealed and then double bagged and placed in a leak proof crate prior to removal from the containment level 2 room. The bags leakproof crate and contents will be autoclaved at 134°C on site prior to the waste bags being taken off site for incineration.

---

**Please enter comments on the GM safety committee on the risk assessment**

On 27th June 2018 the Genetic Modification Safety Committee discussed this project and agreed that it required containment at level 2 due to the treatment of a GMO with human brain samples that pose risk to humans and themselves require containment at level 2. In view of the length of time since Eisai last considered a containment level 2 project it was considered important that the procedures in place be checked. In particular the GMO Work Emergency Arrangements to ensure they are still applicable.

Project Additional Information
Purposes of the contained use

Recombinant vaccinia virus will be used to infect target cells in vitro, normally human B-lymphocytes derived from patients with cancer of the cervix. The recombinant (TA-HPV) is derived from the Wyeth strain of vaccinia and expresses human papilloma virus 16 and 18 fusion protein E6/E7. The virus is replication-competent and is not attenuated. Infected B cells will be used as in vitro targets to monitor the success of a vaccination schedule carried out using dendritic cells loaded with E6/E7 in vivo. The purpose of the vaccination is to induce an immune response to cancer cells expressing E6/E7 in vivo. The recombinant will be obtained from the University of Wales College of Medicine and no further genetic modification of the virus will be carried out at Velindre. Patients will not be exposed to vaccinia.

Recipient or parental organism

The recombinant (vaccinia TA-HPV) expresses an HPV16 and 18 E6/E7 fusion protein which is produced from the two separate sequences by a modification of the E6 termination codon. It is known that expression of E6 and E7 in mammalian cells is able to induce both immortalisation and a transformed phenotype so that infection of an individual with TA-HPV must be considered to increase the risk of carcinogenicity. However, vaccinia is a lytic virus, so that all infected cells die. In addition, the E7 sequence has been modified to abolish its ability to bind Rb and hence to cause immortalisation. Both these factors are considered to reduce the risk of carcinogenicity. Vaccinia itself is a pathogen and is in ACDP Hazard Group 2. The recombinant is considered to pose an elevated risk compared to wild-type Wyth strain vaccinia.

Host/vector system

Vector: Wyeth strain vaccinia virus (TA-HPV) expressing human papilloma virus fusion protein E6/E7. The sequence has been modified to reduce Rb binding and hence the risk of immortalisation of the host cell. The virus is replication competent, unattenuated and lytic.

Host: Mammalian cells in vitro. These will normally be human B-lymphocytes derived from patients with cancer of the uterine cervix.

Origin & function

The vaccinia recombinant TA-HPV has been constructed elsewhere and will be obtained from the University of Wales College of Medicine, Cardiff. Mammalian cells infected in vitro with TA-HPV will express the human papilloma virus 16 and 18 fusion protein E6/E7. These cells will then be used as targets for T-cells derived from vaccinated patients before vaccinia-induced lysis occurs.

Evaluation of foreseeable effects

Pathogenicity of vaccinia: Vaccinia is in ACDP Hazard Group 2. The Wyeth strain has been widely used in vaccination programmes and its effects are well characterised. Infection can lead to a vesicular lesion usually accompanied by a generalised infection. The lesion generally heals in about 10 days. In a recent case involving the accidental infection of a laboratory worker, lesions appeared on the finger and on a recently-pierced eyebrow. However, it is considered unlikely that infection will lead to a serious long-term sequelae. Skin penetration or mucosal contact is required for infection to occur.

Pathogenicity of TA-HPV recombinant: The recombinant expresses the human papilloma virus 16 and 18 fusion protein E6/E7. These proteins are known to have immortalisation and transforming potential; however the E7 sequence has been modified to reduce binding to Rb which will minimise the probability of immortalisation. Also, the fusion of E6 and E7 reduces the risk of transformation. Nevertheless the E6/E7 sequence must be considered to be potentially oncogenic so that pathogenicity of the recombinant is greater than that of the wild-type. However, the probability of carcinogenesis in vivo is reduced by cell lysis caused by vaccinia.

Hazard to the environment: Wyeth strain vaccinia has been widely used in wild animal vaccination programmes involving the release of genetically modified virus into the environment. This work has demonstrated that there is a low risk of environmental damage due to vaccinia. It is unlikely that this risk will be significantly greater in TA-HPV than in the wild type.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Small-scale solid and liquid waste will be generated (less than 100gm). All waste will be inactivated by autoclaving, and chemical disinfectants will not be permitted unless they are compatible with subsequent autoclaving.

Autoclaving will be carried out using a sterilizing criterion of 126°C held for 10 minutes. These conditions within the load are verified annually using positioned thermocouples. Autoclaved waste will be sealed in a yellow bag for incineration off-site as clinical waste.

**Project Ref** 624/02.1

**Date Ackn’ed** 18/06/2002

**CU2 Project Title**

CANCER GENE THERAPY USING THE CONVERSION OF ETHANOL TO ACETALDEHYDE MEDIATED BY ADENOVIRUS DELIVERED HUMAN ENZYME ALCOHOL DEHYDROGENASE (ADH).

**Class** Class 2

**CultureVolClass2** < 1 litre

**Consent Granted** not applicable
**Project Additional Information**

**Purposes of the contained use**
To examine the ability of cells over expressing the ADH gene to be damaged by excess acetaldehyde production following exposure to ethanol.

**Recipient or parental organism**
The adenovirus employed in these experiments is adenovirus serotype 5 (ad5). This virus is associated with childhood respiratory infections and most adults will have antibodies to the wild type virus. The virus has had the genes for the E1 gene (nucleotides 1-3533) completely removed. This gene is an absolute requirement for replication and so its removal makes it unable to replicate and so incapable of making infectious viral particles. The removal of the E1 gene has the effect of minimising the pathogenicity of the virus to human contacts. This removal places the virus in the ACGM Hazard group 1 'unlikely to cause human disease'.
The gene of interest is inserted into the site of the disabling mutation. This should minimise the theoretical possibility of recombination with wild type adenovirus.

**Host/vector system**
Cancer cell lines including:
- HBL 100
- Hela
- Jurkat
- Daudi

**Origin & function**
- *Adenovirus serotype 5*
The virus is made replication deficient due to deletion of E1 locus.
(ref He et al; PNAS 95; 2509-2514).

- *Human alcohol dehydrogenase beta 2 (ADH b2) enzyme cDNA.* Obtained from human liver cDNA (ref Ikuta et al PNAS 83; 634-638)

**Evaluation of foreseeable effects**
The risk to human health is low as; The virus has very low infectivity for human cells outside of the in vitro experimental setting. The virus is non-replicating. In infected cells the gene is expressed for 3-4 days only.
The gene encoded is a normal human gene expressed in many cells. The virus and the cDNA are non-oncogenic, non-toxic and harmless to human health. The modification to the virus will not expand the host range of the virus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All the cells, containers, pipettes etc used in the project using the adenovirus will be disposed of via the on site autoclave. This is validated annually and has an assumed 100% kill. Laboratory surfaces/hoods etc will be disinfected with sodium hypochlorite solution.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The committee are happy that this project poses a negligible risk to both human health and the environment. Purely for GM purposes it would be allocated to containment level 1, but as the work will involve primary human cells the project will need to be performed a category 2.

The maximum culture volume is 8 litres, which is later destroyed by autoclaving the isolated cells and equipment used in an industrial autoclave. Validation is carried out by post-autoclaving plate culture and cell counts made. It is monitored by sequential dilution of used bacterium and controlled culture in the same format. No survival has been detected to date. All surfaces are treated with Chloros.

### Project Additional Information

#### Purposes of the contained use

A murine chondrocyte cell line would provide a source of joint specific antigens including the model antigen Flu nucleoprotein (NP) that is expressed in the chondrocytes of CIINP14 mice. As reactive arthritis is likely to result from activation of MHC class 1 and class II-restricted T-cell responses (as well as possibly antibody responses), an immunogen that includes multiple relevant antigens may enhance the development of joint-specific disease. Immunisation with NP +ve chondrocytes would provide a known antigen, the response to which could be followed with tetramers etc., as well as uncharacterised antigens that may be more potent targets in the joint.

#### Recipient or parental organism

Murine chondrocytes expressing either wild-type or a temperature sensitive mutant of SV40 Large T-antigen. As chondrocytes will not produce recombinant virus or survive outside tissue culture the foreseeable effect on human health/safety or the environment is negligible.

2 cells containing pZipNeoSV(X)1 and producing helper-free recombinant retrovirus expressing either wild-type or a temperature sensitive mutant of the SV40 Large T-antigen. The effects described above apply here also with the exception that 2 cells will produce recombinant retrovirus. These viruses however, will only infect murine cells so it is still unlikely that Large T-antigen will gain access to human cells. However, in the unlikely event that SV40 Large T-antigen gains access to human cells it has the capacity to immortalise them.

#### Host/vector system

2 cells to be used in this study are transfected with pZipNeo SV(X) vectors. These contain the sequence required for viral packaging deleted from PMOV- but replace the viral gag, pol and env genes with an inserted transgene (see section C for description of cloning vector). These transfected cells are capable of producing helper-free, recombinant retrovirus (Cepko et al., 1984. Cell, 37:1053-1062). In this study, pZipNeo SV(X)1 vectors incorporate either Large T-antigen or a temperature-sensitive version of this gene which is derived from Simian Virus (SV)40.

#### Origin & function

SV40 Large T-antigen (from the DNA tumour virus simian virus 40), tsTAg (temperature sensitive mutant of the SV40 Large T-antigen gene).

The SV40 large T-antigen is found in early region of the virus together with the small T-antigen which together are sufficient for transformation of cell lines. Studies have shown that the large T-antigen alone is sufficient for establishment of primary cells but that these cells do not display a transformed phenotype hence the intention in this study to transform chondrocytes.

#### Evaluation of foreseeable effects

As mentioned immortalised chondrocytes and 2 producer cells will not survive outside tissue culture. They are unlikely to encounter murine hosts other than in experimental conditions in the case of chondrocytes.
Recombinant retrovirus will not infect human cells and is helper-free therefore can not replicate in murine hosts. However infection of mice could theoretically result in transformation of cells although this is unlikely as SV40 Large T-antigen transduced cells are non-tumourigenic in murine hosts. The cells will be handled as category 2 agents for all in vitro experiments, limiting the potential of exposure to the environment to a negligible level.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solutions that have been in contact with retrovirus, 2 cells or transformed chondrocytes will be treated with virkon disinfectant. All exposed materials will be autoclaved before disposal.

Is an emergency plan required according to regulation 20?

CU2 Project Title  
Class  
CultureVolClass2  
CultureVolumeClass3-4
In order to aid our studies of the human disease reactive arthritis which may be induced as a result of salmonella infection, we need to study the interaction of salmonella infected cells with antigen specific T cells. Model antigens, to which we have specific T cells for in the laboratory, will be expressed in salmonella. T cell responses to salmonella infected cells can then be assessed.

Recipient or parental organism

Strains of Salmonella typhimurium, some of which are attenuated.

Host/vector system

Non-mobilisable or mobilisation defective plasmid vector systems, using prokaryotic promoter system for expression of recombinant antigens.

Origin & function

In vitro and in vivo experimental use at containment level 2, for induction of immune responses and models of human disease.

Evaluation of foreseeable effects

Transformation of Salmonella with recombinant DNA plasmid vectors is not expected to increase virulence or infectivity of Salmonella. The organisms will be handled as category 2 organisms for all in vitro and in vivo experiments, limiting the potential of exposure to the environment to a negligible level.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

CU2 Project Title

USE OF RECOMBINANT ADENOVIRUSES TO STUDY THE EFFECT OF THE S AND N PROTEINS OF THE SARS VIRUS IN AN IN VIVO MOUSE MODEL.

Date Project Ceased

20/09/2006

Class

Class 2

Consent Granted

not applicable

Historical Significant Changes

TRANSFERRED TO GM 97 - 22/9/06
Project Additional Information

Purposes of the contained use

Recombinant adenovirus vectors encoding the S and N genes of the SARS virus under the control of the CMV promoter will be used to study the effect of these proteins in vivo. The recombinant adenovirus vectors will be administered to mice and tissues from treated mice will then be removed to examine the host immune response. In some experiments mice treated with one of these vectors will then be infected with virus or bacteria, for example influenza virus or salmonella. The aim is to be able to examine the effect of the S and N genes from SARS on the host immune response.

Recipient or parental organism

The recombinant adenoviruses will be obtained from another investigator Dr Tripp, in the Centres for Disease Control and Prevention in Atlanta, GA. The recombinants were made in his laboratory using the commercial AdEasy vector system from Invitrogen.

The SARS proteins S (spike) and N (nucleocapsid) are from the Urbani strain of SARS isolated by the CDC in Hong Kong. This strain was sequenced by the CDC and the S and N genes were then inserted into the adenovirus vectors in the CDC in Atlanta.

It is presently unknown whether the S or N proteins have any transforming potential or any harmful sequences. None have been reported.

Host/vector system

Adenovirus vector system

The recombinants are derived from the adenovirus serotype 5 genome and have deletions in the E1 and E3 regions of the virus genome. The E1 deletion prevents the recombinant virus from replicating and these viruses are therefore replication incompetent. Virus stocks can be prepared by growing in 293 cells where virus replication is made possible due to the expression in that cell line of an E1 helper function in trans. Viral stocks will be titred by plaque assay on 293 cells. The E3 region which is not essential for virus growth is also deleted.

Adenoviruses are associated with a number of mild disorders. The pathology results primarily from inflammation and loss of infected epithelial cells. Serotype 5 which will be used here commonly causes upper respiratory infections in the elderly and in young children. Adenoviruses are Biosafety Level II pathogens.

The adenovirus vectors do not express any harmful agents. The E3 region which encodes proteins involved in modulating the immune response of infected cells has been deleted. The recombinant adenoviruses are replication deficient due to a large deletion in the E1 gene.
Origin & function

The recombinant adenoviruses will be obtained from another investigator Dr Tripp, in the Centres for Disease Control and Prevention in Atlanta, GA. The recombinants were made in his laboratory using the commercial AdEasy vector system from Invitrogen.

The SARS proteins S and N are from the Urbani strain of SARS isolated by the CDC in Hong Kong. This strain was sequenced by the CDC and the S and N genes were then inserted into the adenovirus vectors in the CDC in Atlanta.

These constructs will be used to examine the effects of the S and N proteins of SARS on the host immune response. The vectors will be administered to mice and at certain time-points thereafter the mice will be sacrificed and tissues will be extracted.

Evaluation of foreseeable effects

The possibility that replication competence could be restored by rescue of the E1 deletion from the helper cell line or from wild-type adenovirus cannot be excluded. However even if this were the case, it is unlikely that the virus would be more pathogenic than the wild type adenovirus.

The inserted genes would not be expected to render the recombinant viruses able to replicate or to affect the tropism of the virus. Variations of S protein among strains of coronaviruses are responsible for host range and tissue tropism. However, as adenoviruses are not enveloped it is unlikely that the S protein of SARS will affect the tropism of the recombinant adenoviruses. It is unknown how the expression of the N and S genes of SARS will affect the host cells, as no work has been carried out examining this. So far there are no reports that either S or N protein is associated with toxicity or oncogenesis. Also neither is known to be closely homologous to human proteins against which autoimmune responses would be likely to be induced.

The possibility that the inserted sequences may be transferred to other related organisms is remote. The only potential risk may occur if the S or N genes of SARS were transferred to another corona virus. In that case potential problems may occur but the resulting virulence or pathogenicity if such an event occurs is not known.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No application for derogation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All the animal, culture and tissues culture waste will be disposed of by incineration according to the normal rules for Biosafety level II biological waste disposal. Liquid waste will be added to Virkon (final concentration 1%) and left for 24 hours. No microorganisms will be viable afterwards. Solid waste will be put in a metal box, sealed with autoclave tape, autoclaved at 134 degrees C for 30 minutes, before being sent to an on-site clinical waste incinerator. The degree of kill is 100%.

Is an emergency plan required according to regulation 20?

### Project Ref 628/03.2

**Date Ackn'd:** 07/11/2003  
**CU2 Project Title:** IN VITRO ANALYSIS OF THE INTERACTION OF HEPATITIS C VIRUS PSEUDOPARTICLES (HCV PP) WITH CELL LINES AND HUMAN PERIPHERAL BLOOD MONOCULEAR CELLS (PBMC) SUBSETS.  
**Class:** Class 2  
**Culture Volume:** ≤ 1 litre  
**Non-GMM Consent Granted:** not applicable  

**Project notified under transitional arrangements:** N  
**Withdrawn:** N  

**Historical Significant Changes:** TRANSFERRED TO GM 97 - 22/9/06  
**Historical Date of Additional Info:**  

**Significant Change ID:** 628/03.2a  
**Date of Significant Change:** 25/07/2007

### Project Additional Information

**Purposes of the contain use:**

In order to aid our previous studies of the interaction of the hepatitis C (HCV) E2 glycoprotein with different PBMC subsets and the possible immunomodulatory consequences of this interaction, we would like to carry out studies the HCV pp, which express heterodimers of E1 and E2 on their surface. The proposed work would include in vitro analysis of interaction of HCVpp with cell lines and PBMC subsets and investigation of whether HCVpp are able to modulate the activation/functions of different immune system cell types (derived from human peripheral blood), using a variety of in vitro immunological assays.

**Recipient or parental organism:**
Murine leukemia virus (MLV), which is a murine retrovirus classified as a category 1 pathogen.

**Host/vector system**

The vector packaged into the pseudotyped MLV particles encodes the marker protein green fluorescent protein (GFP). This is not thought to have any harmful properties. The particles will be pseudotyped with the HCV E1 and E2 proteins. These are not thought to be toxic or oncogenic, but there is some evidence to suggest that the E2 protein may be able to modulate the activation/functions of human lymphocyte subsets. However, it is very unlikely that accidental exposure to a small quantity of HCV pp (which are not able to replicate) would have any harmful immunomodulatory effects.

**Origin & function**

The HCVpp will be provided by our collaborators, the Institute Pasteur in Lille, France; they will not be produced here. The method by which the HCVpp are generated is described in Bartosch et al, *Journal of Experimental Medicine, 197:633-642 (2003)*.

In vitro experimental use at containment level 2.

**Evaluation of foreseeable effects**

Pseudotyping of the MLV-based particles with the HCV E1 and E2 proteins results in the particles having a tropism different to that of ecotropic MLV. HCVpp have been shown to bind to and enter human cells expressing what are thought to be HCV receptors (CD81 and other proteins) [Bartosch et al, *Journal of Experimental Medicine, 197:633-642, 2003*].

This alteration in tropism increases the potential for disease to be induced in humans, although the risk of this still remains very low. Although able to infect human cells, the pseudoparticles would not replicate therein, and expression of GFP within the transduced cells would be unlikely to have deleterious effects. However, it is possible that integration of the MLV vector could lead to modulation of host cell gene expression, and potentially to transformation of the cell.

It is very unlikely that sequences from the GFP-expressing MLV vector within the HCVpp would be transferred to another micro-organism during the course of the planned in vitro experimental work; and even should this occur, it is unlikely to be hazardous, as this vector only encodes GFP.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All equipment and waste that has been in contact with HCVpp will be disinfected using procedures approved for destroying the infectivity of lipid-enveloped viruses.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y
The committee recommended that each batch of HCVpp should be tested for infectivity on a murine cell line, and with this provisionally approved the work to be done at containment level 2.

### Project Additional Information

**Purposes of the contained use**

A recombinant influenza virus of subtype A/Victoria/3/75 (H3N2) has been generated by reverse genetics at the University of Reading. In addition, a series of derivative viruses based on A/Victoria/3/75 have been generated in which the open reading frame of the protein PB1-F2 has been deleted, truncated or extended. PB1-F2 is believed to induce apoptosis in immune cells (Chen et al., 2001). We aim to carry out apoptosis studies and mouse model studies to determine whether alterations in PB1-affect virus virulence.
A recombinant influenza virus of subtype B/Beijing/87 has also been generated at the University of Reading, as well as an isogenic virus in which the NB protein has been deleted. The NB protein is believed to function as an ion channel and, although dispensable in vitro, is believed to promote efficient viral growth in mice (Hatta and Kawaoka, 2003). We would like to confirm and extend these observations.

**Recipient or parental organism**

Influenza viruses infect humans and avians and cause a respiratory infection. Transmission is by respiratory infection via aerosols. The recombinant influenza viruses are unlikely to cause harm greater than their parental strains, which are themselves laboratory passaged and thus attenuated versions of naturally occurring influenza viruses, classified as class 2 pathogens. Both A/Victoria/3/75 and B/Beijing/87 have been used extensively in laboratories worldwide with no history of infection of workers or adverse effects as detailed in the following publications and citations therein:

In the event that the A/Victoria/3/75 virus does not produce obvious symptoms in mice, a virus with A/Panama/99 antigens and the same internal genetic backbone will be used. A/Panama/99 surface antigens were used to generate large quantities of vaccines throughout the world in recent years and no adverse affect are associated.

**Host/vector system**

Not applicable.

**Origin & function**

A recombinant influenza virus of subtype A/Victoria/3/75 (H3N2) has been generated by reverse genetics at the University of Reading. In addition, a series of derivative viruses based on A/Victoria/3/75 have been generated in which the open reading frame of the protein PB1-F2 has been deleted, truncated or extended. PB1-F2 is believed to induce apoptosis in immune cells (Chen et al., 2001). We aim to carry out apoptosis studies and mouse model studies to determine whether alterations in PB1-affect virus virulence.

A recombinant influenza virus of subtype B/Beijing/87 has also been generated at the University of Reading, as well as an isogenic virus in which the NB protein has been deleted. The NB protein is believed to function as an ion channel and, although dispensable in vitro, is believed to promote efficient viral growth in mice (Hatta and Kawaoka, 2003). We would like to confirm and extend these observations.

**Evaluation of foreseeable effects**

All mutations in influenza viruses to be used in this study will be attenuating for replication and therefore the hazards will be reduced. This includes the virus strain in which the PB1-F2 gene will be extended by 3 amino acids in order to retain the length of the wild-type gene. There is no expected alteration in host range since neither of these genes is associated with that trait. It is possible that the types of cells affected following infection with the PB1-F2 deletant will be reduced rather than extended.

Since influenza virus has a segmented genome, there is a possibility that reassortant viruses containing genes from the mutants might be generated within a laboratory worker who was coinfected with a wild type strain. We consider this unlikely, but advise all workers to refrain from experiments if influenza infection is suspected.

If reassortment did occur, the PB1-F2 deletion introduced into A/Victoria/75 is not associated with virulence and is likely to be an attenuating mutation. The virus harbouring deletion of NB from B/Beijing/87 is reported to be highly attenuated and cannot replicate efficiently in vivo (Hatta and Kawaoka). Therefore regardless of the genetic background of the virus harbouring these changes, we expect them to be attenuating.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
No application for derogation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All the animal, culture and tissues culture waste will be disposed of by incineration according to the normal rules for Biosafety Level II biological waste disposal. Liquid waste will be added to Virkon (final concentration 1%), and left for 24 hours. No microorganisms will be viable afterwards. Solid waste will be put in a metal box, sealed with autoclave tape, autoclaved at 134 degrees C for 30 minutes, before being sent to an on-site clinical waste incinerator. The degree of kill is 100%.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

The local GMSC are happy with this risk assessment (Ref 2003/018) provided the requirements in the associated risk assessment for influenza A and B viruses are adhered to.

Project notified under transitional arrangements  N
Purposes of the contained use

Influenza viruses induce apoptosis in cultured cells and in vivo. We have recently shown that influenza virus detrimentally affects early lymphoid progenitor cells by inducing apoptosis mediated by TNFalpha/LTalpha. An alternative reading frame of the PB1 gene called PB1-F2 of the influenza virus has been implicated in inducing apoptosis in vitro. We want to determine whether PB1-F2 is responsible for the apoptosis that occurs in the bone marrow (or other tissues) following infection of mice with influenza virus. We therefore wish to use a novel influenza virus (RG-X31-swine PB1) that has been generated by reverse genetics (RG) to examine these questions. The PB1-F2 open reading frame (ORF) is present in nearly all human influenza A strains but is absent from swine influenza isolates. Therefore by replacing the PB1 of the wild-type x 31 (A/H3N2) virus which contains the PB1-F2 ORF with the PB1 from a swine influenza virus (A/swine/NorthCarolina/44173/00) which does not, we will be able to address these questions. Mice will be infected with the wild type/recombinant virus and sacrificed at certain time-points to assess the degree of cell death in various organs and any other differences in pathogenicity caused by the recombinant virus.

The RG influenza virus RG-x31-swine PB1 will be obtained from St Jude Children's Research Hospital, Memphis TN, USA. The viruses are being made in the laboratory for our use.

Recipient or parental organism

Influenza viruses infect humans and avians and cause a respiratory infection. Transmission is by respiratory infection via aerosols. The strain of influenza virus is a reassortant which has the surface proteins of A/Aichi/68 and the internal genes of A/PR/8/34. It is a laboratory strain which is commonly used in immunological studies and is BioSafety Level 2 pathogen. The recombinant influenza virus is unlikely to cause harm greater than the parental strain, which is itself laboratory passaged and thus an attenuated version of a naturally occurring influenza virus.

Origin & function

We have recently shown that influenza virus detrimentally affects early lymphoid progenitor cells by inducing apoptosis mediated by TNFalpha/LTalpha. An alternative reading frame of the PB1 gene called PB1-F2 of the influenza virus has been implicated in inducing apoptosis in vitro. We want to determine whether PB1-F2 is responsible for the apoptosis that occurs in the bone marrow (or other tissues) following infection of mice with influenza virus. We therefore wish to use a novel influenza virus (RG-X31-swine PB1) that has been generated by reverse genetics (RG) to examine these questions. The PB1-F2 open reading frame (ORF) is present in nearly all human influenza A strains but is absent from swine influenza isolates. Therefore by replacing the PB1 of the wild-type x 31 (A/H3N2) virus which contains the PB1-F2 ORF with the PB1 from a swine influenza virus (A/swine/NorthCarolina/44173/00) which does not, we will be able to address the degree of cell death in various organs and any other differences in pathogenicity caused by the recombinant virus.

Evaluation of foreseeable effects

No hazards should arise from the alteration of wild-type x 31 to RG-x31-swine PB1. Neither virus growth nor tropism should be affected. The surface proteins HA and NA...
have not been altered. Reverse genetics enables a recombinant virus to be produced in a much safer way than previously because one has complete control of the genes being transfected to produce the recombinant virus. Therefore there is no possibility that other influenza virus genes can be introduced. It is expected that the inclusion of the swine PB1 gene would either not change the pathogenicity/virulence of x31 or make it less so.

Little is known about the new PB1-F2 protein as it has only recently been identified. It is not essential for viral replication in vitro. The evidence to date suggests its involved in modulating the host immune response to influenza A by caused death of immune cells. A synthetic version of PB1-F2 induces apoptosis in vitro and targeted mutations which interfere with expression of PB1-F2 induce less apoptosis than those that express PB1-F2.

There is no evidence that the PB1-F2 gene causes toxicity or has oncogenic properties.

02/03/2022
USE OF A NOVEL REVERSE GENETICS-GENERATED INFLUENZA VIRUS (RG-X31-156NS1) TO INVESTIGATE THE ROLE OF VIRUS-INDUCED APOPTOSIS

Influenza viruses induce apoptosis in cultured cells and in vivo. We have recently shown that influenza virus detrimentally affects early lymphoid progenitor cells by inducing apoptosis mediated by TNFalpha/LTalpha. The NS1 gene of influenza virus has been implicated in inducing apoptosis in vitro. We want to determine whether the NS1 gene is responsible for the apoptosis that occurs in the bone marrow (or other tissues) following infection of mice with influenza virus. We therefore wish to use a novel influenza virus that has been generated by reverse genetics (RG) to examine these questions. The NS1 gene in wild-type x31 will be replaced by the NS1 from the H5N1/97 virus, in order to assess whether a greater degree of cell death in bone marrow, thymus and other organs occurs as a result. Mice will be infected with the wild type/recombinant virus and sacrificed at certain time-points to assess the degree of cell death in various organs and any other differences in pathogenicity caused by the viruses.

The strain of influenza virus that will be the recipient of the foreign NS1 gene is x31 (H3N2). This strain of influenza virus is a reassortant which has the surface proteins of A/Aichi/68 and the internal genes of A/PR/8/34. It is a laboratory strain which is commonly used in immunological studies and is a BioSafety Level 2 pathogen. Research to date suggests NS1 is a virulence factor which plays a major role in inhibiting the IFN-mediated antiviral responses of the host. NS1 is a non-structural protein of influenza virus. It is an RNA binding protein which has been implicated in several regulatory functions during the influenza virus replication cycle:

1. It inhibits host mRNA polyadenylation.
2. It inhibits the nuclear export of mRNAs by binding to their poly (A) tail.
3. It inhibits pre-mRNA splicing.
4. It prevents IFN-mediated antiviral responses by binding to ds RNA.
5. It has been suggested to play a role in regulation of viral RNApolymerase activity.
6. It is able to stimulate the translation of specific viral mRNAs.

There is no evidence that the NS1 gene causes toxicity or has oncogenic properties.
Recombinant virus will be produced that replaces the NS gene or x31 with the NS gene of H5N1/97. Background: The H5N1/97 viruses transmitted to humans in 1997 and were highly virulent. Reactive hemophagocytic syndrome with elevated concentrations of proinflammatory cytokines were reported. Lethal H5N1 viruses (unlike other human, avian and swine viruses) are resistant to the antiviral effects of IFNs and TNFalpha. This resistance is associated with NS1 and is thought to be the mechanism of the high virulence of H5N1 viruses in humans. RE enables a recombinant influenza virus to be produced in a much safer way than previously (reassortment) because one has complete control of the genes being transfected to produce the recombinant virus. Therefore there is no possibility that the HA or other genes from the H5N1 can be included in the recombinant virus. The tropism or host range of RG-x31-156NS1 should not therefore be different from wild type x31. It would be expected that the inclusion of the H5N1, NS1 gene into x31 would make the resulting RG-x31-156NS1 virus more pathogenic (perhaps greater loss of body weight, more prolonged virus shedding) as a result of increased virus replication due to the resistance of the NS1 to aniviral cytokines.

Host/vector system

Not applicable.

Origin & function

The RG influenza virus will be obtained from Dr Richard Webby, St Jude Children’s Research Hospital, Memphis TN, USA. The viruses are being made in his laboratory for our use. Influenza viruses induce apoptosis in cultured cells and in vivo. We have recently shown that influenza virus detrimentally affects early lymphoid progenitor cells by inducing apoptosis mediated by TNFalpha/TLalpha. The NS1 gene of influenza virus has been implicated in inducing apoptosis in vitro. We want to determine whether the NS1 gene is responsible for the apoptosis that occurs in the bone marrow (or other tissues) following infection of mice with influenza virus. We therefore wish to use a novel influenza virus that has been generated by reverse genetics (RG) to examine these questions. The NS1 gene in wild-type x31 will be replaced by the NS1 from the H5N1/97 virus, in order to assess whether a greater degree of cell death in bone marrow, thymus and other organs occurs as a result. Mice will be infected with the wild type/recombinant virus, in order to assess whether a greater degree of cell death in bone marrow, thymus and other organs occurs as a result. Mice will be infected with the wild type/recombinant virus, in order to assess whether a greater degree of cell death in bone marrow, thymus and other organs occurs as a result. Mice will be infected with the wild type/recombinant virus, in order to assess whether a greater degree of cell death in bone marrow, thymus and other organs occurs as a result.

Evaluation of foreseeable effects

The possibility that the inserted sequences may be transferred to other influenza viruses is remote. The only potential risk may occur if the RG-x31-156NS1 virus was grown in eggs or tissue culture at the same time as other influenza viruses so that reassortment occurs. The possibility of this is remote. In the event of exposure the virus may cause infection in humans. One may expect the infection to be more virulent than wild type x31, due to the expected increase in resistance to anti viral cytokines. In te event that any person is exposed to the virus a prearranged protocol will be followed (see attached protocol called The Edward Jenner Institute for Vaccine Research: Protocol for staff working with influenza A viruses shown to have a higher risk of transmission to humans). All work with the recombinant influenza RG-x31-156S will be carried out in a Biosafety Level 3 facility. (An almost identical virus has recently been made in Dr Webby's department in St.Jude CRH but on the backbone of A/PR8/34 which is more virulent than x31. The work is carried out in Biosafety Level 3 facilities, Nat.Med. 8:950-954, Sept 2002). Immunosuppressed individuals or those with chronic respiratory problems will not work with these recombinants.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Culture volumes approximately 100ml

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No application for derogation

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid animal, culture and tissues culture waste will be disposed of by autoclaving followed by incineration according to the normal rules for Biosafety Level III biological waste disposal. Liquid waste will be added to Virkon Final concentration 1% for 24 hours) or chlorine compounds (0.2-3 for 10-30 minutes). No micro-organisms will be viable afterwards. Solid waste will be put in a metal box, sealed with autoclave tape, autoclaved at 134 degrees for 30 minutes, before being sent to an on-site clinical facility.

</tbody>
</table>
**Project Additional Information**

**Purposes of the contained use**

To construct recombinant paroviruses for cancer immunotherapy applications. Recombinant paroviruses expressing human and murine forms of oncofoetal antigen 5T4, single-chain antibody to 5T4, cytokines and immune co-factors such as B7-1.

**Recipient or parental organism**

Human cell lines such as 293T cells will be used to generate recombinant paroviral particles. 293T cells contain the SV40 large T antigen allowing expression of the capsid genes in the helper DNA plasmid. Paroviral particles (which are defective and cannot propagate themselves) are produced from separate DNA components; the recombinant paroviral molecular clone and a helper plasmid (which provides the capsid proteins in trans). Packaging cell lines stably expressing capsid proteins can also be used. (Mammalian cells eg. COS cells will also be used.)

**Host/vector system**

Disabled E. coli strains such as: JM109, XL1-blue SURE cells.

The rodent parovirus vectors based on MVM (minute virus of mice) and H-1 (Rat H-1) will be generated in 293T cells which being defective cannot propagate themselves in human cells.

**Origin & function**

Reporter genes such as β-galactosidase (lac-Z) or green fluorescent protein (GFP) will be used. Human and murine forms of the oncofoetal antigen 5T4 and its single-chain antibody will be expressed. Additional genes to express include immune co-stimulatory genes (B7-1) and cytokines.

Successful tumour suppression and tumour lysis in mouse models may lead to clinical trials.

**Evaluation of foreseeable effects**

Recombinant rodent parovirus particles will be generated using 293T cells. Viral titres ranging from 1-3 x 10^7 units/ml should be achieved. The recombinant paroviruses will be defective since they lack the functional capsid genes and cannot therefore undergo secondary infection.

Recombination events producing replication competent paroviruses (RCPs) are predicted to be low and can be further minimised by decreasing the homology between the two molecules. The use of packaging cell lines in which a number of copies of the helper construct are stably integrated into chromosomal DNA. RCPs will be tested for by plaque assay.
All of the recombinant parvoviruses generated lack the functional capsid genes and will only achieve a one hit transduction in target tumour cells. Only when such cells are in S phase will the NS gene product cause oncolysis. These defective parvoviral recombinants cannot undergo secondary infection and enter neighbouring cells.

Additionally, the recombinant viral stocks will be tested for the generation of contaminating replication competent viruses (RCVs) will be tested using established plaque-assay based standard operating procedures.

Contamination and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All cancer immunotherapy animal experimentation will be performed by animal license holders at the Institute of Virology, Mansfield Road, Oxford (GM No. 151).

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All work will be carried out at containment level 2. The ACGM Classifies Parvoviruses as containment level 1. However highly trained scientists will be carrying out all the laboratory activities in our containment level 2 facilities as recommended by ACGM for mammalian cell work.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All biological waste (liquid and solid) will be disposed of: liquid waste will be soaked in 1% Virkon for 2 hours: Solid waste will be autoclaved at 136°C for 15 minutes. Following autoclave treatment, this solid waste will be collected for incineration by a registered company.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment

The ACGM compendium of guidance classifies parovirus work as containment level 1. However, the research will be performed in our purpose built containment level 2 laboratories at the premises of Oxford BioMedica (also in accordance with ACGM guidelines).

All of the recombinant parvoviruses generated lack the functional capsid genes and will only achieve a one hit transduction in target tumour cells. Only when such cells are in S phase will the NS gene product cause oncolysis. These defective parvoviral recombinants cannot undergo secondary infection and enter neighbouring cells. Additionally, the recombinant viral stocks will be tested for the generation of contaminating replication competent viruses (RCVs) will be tested using established plaque-assay based standard operating procedures.

02/03/2022
The construction (cloning) and manufacture of recombinant AAV vectors with different serotypes (e.g. Serotypes 1-9) expressing various genes via different promoters.

Recipient or parental organism
Since AAV vectors are defective in nature (e.g. require co-infection with a helper virus in order to replicate) and are not associated with any human disease the hazards posed to human health associated with the recipient/parental virus are expected to be low. The main hazards are likely to arise from the properties of any inserted gene and will be risk assessed on an individual basis.

Host/vector system
Disabled E.coli strains such as: JM1 09, XL1 blue, SURE cells. The recombinant AAV vectors will be generated using helper+ virus — free system using human HEK293T cells. The AAV vectors are replication defective and cannot propagate themselves in human cells. Other cells lines may be used to evaluate the AAV vectors, refer to attached risk assessments. Any in vivo work will be carried out off-site.

Origin & function
The genetic inserts will include but are not limited to reporter genes (GFP, LacZ), cytokines, growth factors, angiogenic and angiostatic factors, enzymes, receptors, structural proteins, secreted factors each of which will be risk assessed on an individual basis. The promoters will include constitutive promoters such as CMV, tissue specific and regulated. The genetic material ( promoters and/or genes) may be of human or non-human origin. It is not expected that the genetic material will alter the phenotype or pathogenic traits of the AAV vector although each new recombinant AAV vector will be risk assessed on an individual basis.
Recombinant AAV vector particles will be generated in HEK293T cells. Viral particles up to $1 \times 10^{13}$ genome particles/ml could be achieved. The recombinant MV vectors (like the parental virus) are expected to be non-pathogenic to humans or other organisms, and will be replication defective since they lack the functional rep and cap genes, therefore there can be no secondary infection and transduction of neighbouring cells. Recombination events to produce a replication competent AAV (RCA) are predicted to be low, the only remaining MV sequence in the recombinant genome will be the inverted terminal repeats (ITR5). The possibility of the recombinant AAV recombining with a resident AAV-2 virus via the ITRs is theoretically possible (80% of human population have been exposed to MV-2), however the likelihood of generating a novel functional recombinant AAV capable of being packaged and able to replicate is low. The likely impact of the recombinant AAV on the environment is expected to be low, please refer to the individual risk assessments. Although non-targeted proviral insertions is seen with AAV vectors at low level it is expected to happen at passively low level (<10% genomes) and the likelihood of insertional mutagenesis is low, it has never been observed in numerous human clinical trials.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No plans for derogation from full containment for the determined class of activity.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Current version of Code of Practice 004: Disinfection and Decontamination will apply.
In brief the following procedures are routinely employed;
Liquids
All liquids are disinfected in 2% Virkon solution with the final concentration reaching no less than 1%. After a minimum of 60 minutes disinfected liquids are discarded to drains.
70% Ethanol/IMS are used for general cleaning of benches and minimisation of contamination.
Solid
All solid waste is autoclaved at 134°C for 10 minutes. The autoclaved waste is then collected for incineration by a licensed contractor.

Date of Significant Change

Project Additional Information

Purposes of the contained use

HIV-1 is a class 3, containment level 3 biological.

Envelope-replaced MLV-4070A will be contained at level 3 for precautionary reasons but has been risk assessed as a class 2 operation.

Recipient or parental organism

1) Lab strains of Human Immunodeficiency Virus-1 (HIV-1)

2) MLV-4070A (MoMLV-4070A Hybrid virus).

Host/vector system

Plasmid DNA encoding modified provirus will be propagated in K12 disabled nonpathogenic strains of E. coli such as TURBO (NEB), JM109 (Stratagene), DH5alpha (Invitrogen), Stbl2 (Invitrogen), ‘Clean genome’ (Scarab). Hazard group 1.
1) Mammalian cell lines permissive for HIV-1 infection such as C8166.

2) Mammalian cell lines permissive for MLV-4070A and Envelope-replaced MLV-4070A such as Hela and mammalian cell lines stably expressing the appropriate receptor to the respective heterologous envelope cloned into MLV.

Origin & function

1) Lab strains of HIV-1 such as NL4-3 will be modified. These strains will be attenuated in accessory genes vif, vpr, vpu and nef, and also optionally mad integration defective. These viruses will be evaluated for potential use as surrogate RCL positive control virus in RCL assay development.

2) MLV-4070A will be modified such that the amphotropic 4070A envelope has been replaced with a heterologous envelope with restricted tropism, such as those based on modified Sindbis virus envelope, and optionally made integration defective. These viruses will be evaluated for potential use as surrogate RCL positive control virus in RCL assay development. Modified MLV stably expressing the heterologous envelope will model a putative RCL derived from clinical retroviral/lentiviral vectors that utilise said heterologous envelope.

RCL assay development:
Both types of the above modified viruses will be evaluated for replication kinetics within tissue cultures of permissive cell types from low multiplicities of infection. Virus detection/quantification will be performed by quantitative RT-PCR of associated reverse transcriptase activity within virus-containing culture supernatants or qPCR of DNA from infected cells, wherein virus infectivity has been abolished by approved methods of inactivation stated within Oxford Biomedica Ltd’s Containment Level 3 codes of practice.

Evaluation of foreseeable effects

1) Lab strains of HIV-1 such as NL4-3 will be modified. These strains will be attenuated by mutation of accessory genes vif, vpr, vpu and nef such that no functional protein will be expressed, and optionally made integration defective by mutation of integrase and/or LTR sequences. These attenuated strains are expected to be less virulent than either parental or ‘field’ strains of HIV-1.

2) MLV-4070a will be modified such that the amphotropic 4070a envelope has been replaced with a heterologous envelope with restricted tropism, such as those based on modified Sindbis virus envelope. For example, derivatives have been engineered such that the broad tropism of wild type Sindbis virus envelope has been substantially reduced, and secondary mutations increase the efficiency of modified Sindbis entry into Dentric cells (dC). Whilst the modified Sindbis envelope may be more cytotoxic than the 4070a envelope, expression in DCs (Antigen presenting cells) would likely result in Sindbis modified envelope antigen presentation in vivo, resulting in immune repression and subsequent clearance. Overall, the proposed modified MLVs have been risk assessed and are not expected to pose greater risks to humans or the environment than MLV-4070A

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Envelope-replaced MLV-4070a-based viruses have been rated class 2 organisms but will be contained at level 3 fr precautionary measures. Oxford Biomendica Ltd would like to retain the option for derogation of a specific Envelope-replaced MLV-4070A-based viruses from containment level 3 to containment level 2 once a virus has been well characterised.

Overall, whilst the heterologous envelope replacing 4070A may be rated as potentially more cytotoxic than 4070A, the substantially reduced tropism compared to 4070A and the fact that no human infection of MLV has been reported to date, justifies the potential for derogation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
For containment level 2 activities, the current version of OXB's Codes of Practice 004: Disinfection and Decontamination will apply.

For containment level 3 activities, the current version of OXB's 'Containment Level 3 Codes of Practice' will apply

Project Ref 636/13.1

Date Ackn'd 01/07/2013

CU2 Project Title Manufacture of OXB's proprietary Lentiviral Vector platform for the delivery of therapeutic genes

Class 2

CultureVolClass2 51-500 Litres

Consent Granted

Project notified under transitional arrangements [N]

Withdrawn [N]

Tick if notifying a connected programme of work [N]
**Purposes of the contained use**

OXB has developed minimal lentiviral vector systems for the delivery of therapeutic genes based on either Equine Infectious Anaemia virus (EIAV) or Human Immunodeficiency Virus (HIV).

The therapeutic genes utilised include but are not restricted to dopamine biosynthetic enzymes, angiostatic proteins, growth factors or chimeric antigen receptor (CAR), OXB has previously notified the development of lentiviral vectors as a delivery system for laboratory scale activities. We are now in a position where we want to manufacture up to 100L of therapeutic vector.

**Recipient or parental organism**

Manual Equine Infectious Anaemia viral vectors (min.EIAV)

Minimal Human Immunodeficiency viral vectors (min.HIV).

The vectors are replication defective, self-inactivating and minimal to prevent replication competent lentivirus production. The vectors are replication defective, self-inactivating and minimal to prevent replication competent lentivirus production. The vectors are pseudotyped with Vesicular Stomatitis virus envelope proteins.

**Host/vector system**

The plasmids that will be used for the production of the minimal HIV and EIAV vectors will be manufactured to GMP standard by Contract Manufacturing Facility. The plasmids are propagated in K12 disabled non-pathogenic strains of E.coli.

Mammalian cell lines: the well characterised mammalian cell line 293T cells will be used. The cells require specialised growth media and as a result will not survive outside the laboratory environment.

**Origin & function**

The final product will be used in human clinical trials. The lentiviral vectors are all designed to be minimal and are replication defective. Their intended purpose is to deliver a functional version of the therapeutic gene to treat patients in human clinical trials; e.g. treatment of Parkinson's or B cell lymphoma. Please refer to the accompanying risk assessments for an example of OXB therapeutic products.

Each new GMO containing therapeutic genes will be risk assessed separately.

**Evaluation of foreseeable effects**

The vectors are pseudotyped with the Vesicular Stomatitis Virus envelope protein and are replication defective, self- inactivating and minimal to prevent replication competent lentivirus production. Therefore transduction with the lentiviral based GMO's will be limited to the intital target cell e.g. there is no intended cell-to-cell spread of the GMO.

Mammalian cell lines: the well characterised mammalian cell line 293T cells will be used. The cells require specialised growth media and as a result will not survive outside the laboratory environment.
Please refer to the accompanying risk assessments.

**Project Ref** 636/14.1
Equine Infectious Anaemia Virus (EIAV) or sequence-optimised EIAV that expresses heterologous viral envelopes

The aims of the research are 2-fold:

1. To identify EIAV variants with improved replication kinetics in human cell lines in order to test potentially beneficial mutations to Company's EIAV-based lentiviral vector system and
2. To develop an improved EIAV-based replication competent lentivirus (RCL) assay for testing clinical material

EIAV is a class 1 micro-organism but is contained at level 3 in order to protect naive equine populations in the UK

The envelope gene of EIAV will be replaced in this project. The modification of virus genomes will be based on EIAVΔ wherein one or more of the accessory genes have been functionally deleted. The accessory genes contribute to the pathogenic state in vivo but are not necessarily required for replication in vitro, so this attenuation is considered to be a significant safety feature.

Plasmid DNA encoding modified provirus will be propagated in K12 disabled nonpathogenic strains of E.coli such as TURBO (NEB), JM109 (Stratagene), DH5alpha (Invitrogen, Stbl2 (Invitrogen), 'Clean genome' (Scarab). Hazard group 1.

Immortalised human cell lines (e.g. HEK293, HeLa) stably expressing EIAC fusion protein

The envelope gene of EIAV will be replaced in this project. The modification of virus genomes will be based on replication competent EIAVΔ, wherein one or more accessory genes have been functionally deleted. The accessory genes contribute to the pathogenic state in vivo but is not required for replication in vitro, so this attenuation is considered to be a significant safety feature.
The basic viral genome will be modified such that heterologous viral envelopes will be inserted replacing the natural EIAV envelope.

The use of heterologous viral envelopes will be passaged through immortalised human cell lines expressing equine fusion proteins.

**Evaluation of foreseeable effects**

The envelope-modified EIAV variants will have altered tropism compared to wild type EIAV. It is likely that use of heterologous envelopes will greatly broaden the tropism of EIAV. However, it is expected that replication of these modified viruses will be restricted to cells wherein the EIAV U3 is active; this excludes human cells as huCT1 cannot participate with eTat and eTAR in activating the EIAV LTR. Moreover, the use of the background Δ accessory gene mutation in these viruses will make them highly attenuated in Equines. Therefore, it is expected that these modified viruses will only replicate in mammalian cells in vitro wherein the appropriate receptor is expressed and the EIAV U3 is active.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

No plans to derogate GMMs

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

For containment level 2 activities, the current version of OXB's 'Codes of Practice 004: Disinfection and Decontamination' will apply.

In brief all liquid waste is treated with 4% Virkon to give a final concentration of 1%, allowed to inactivate for minimum of 60 minutes before discarding to drains. All solid waste is autoclaved before collection by licensed contractor for incineration.

For containment level 3 activities, the current version of OXB's 'Containment Level 3 Codes of Practice' will apply.

In brief all liquid is treated with 4% Virkon to give a final concentration of 1% and allowed to inactivate for a minimum of 60 minutes before being autoclaved. The autoclaved liquid waste is removed from the CL3 and discarded to drains. All solid waste which has been in contact with biohazard is treated with Virkon allowed to decontaminate for 60 mins. The Virkon is removed and the solid waste autoclaved before collection by licensed contractor for incineration.

Please enter comments on the GM safety committee on the risk assessment
Comments from the GMSC: The risk assessment was approved on the proviso that all recommendations and amendments are completed. As per protocol the GMSC approved risk assessment is forwarded to the External Biological Safety Officer for final review and comment.

Comments from External BSO: Project 122 is the latest effort to make the OXB EIAV-based vectors acceptably efficient and to provide the basis for RCR detection. Working under CL3 is entirely appropriate. I am comfortable with the risk assessment and its conclusions, although I suggest the text "EIAV is the simplest retrovirus known" is replaced with "EIAV is the simplest lentivirus known".

**Project Additional Information**
Purposes of the contained use

The aim is to utilise lentiviral vectors that express genes which are useful in the treatment of human diseases. The vectors will be tested for their ability to transfer desirable characteristics to target cells in vitro and in vivo. It is anticipated we will be able to modify the properties of target cells such that they express the desired characteristics e.g. expression of innocuous reporter genes and therapeutic genes.

The initial study is to test the feasibility of the manufacture of the lentiviral vector encoding the therapeutic gene. If the initial study is successful than large-scale vector production will be undertaken to provide collaborators with sufficient material for clinical trials.

If large scale vector production is to be initiated, a manufacturing risk assessment will be drafted and submitted for approval by our GMSC.

As other projects arise i.e. the evaluation of different therapeutic genes; each body of work will be assessed by our GMSC separately.

Recipient or parental organism

The engineered lentiviral vector is a self-inactivating minimal lentiviral vector capable of delivering heterologous nucleic acid to dividing and non-dividing cells in vitro and in vivo. Tropism of the vector may vary depending on envelope pseudotype employed.

Host/vector system

Plasmids will be manufactured by a Contract Manufacturing Facility to a suitable grade necessary for vector production. The plasmids are propagated in K12 disabled non-pathogenic strains of E.coli.

Mammalian cell lines: the well characterised mammalian cell lines.

Vector System

The engineered vector is a self-inactivating minimal lentiviral vector capable of delivering heterologous nucleic acid to dividing and non-dividing cells in vitro and in vivo. Tropism of the vector may vary depending on envelope pseudotype employed.

Each new GMO containing novel therapeutic genes and/or envelope will be risk assessed separately.

Origin & function

The lentiviral vectors are all designed to be minimal and are replication defective. Their intended purpose is to deliver a functional version of the therapeutic gene to treat patients in human clinical trials. Please refer to the accompanying risk assessments for an example of therapeutic products.

Evaluation of foreseeable effects

The vectors are replication defective, self-inactivating and minimal to prevent replication competent lentivirus production. The vectors are pseudotyped with paramyxovirus envelope proteins. Therefore transduction with the lentiviral based GMOs will be limited to the initial target cell i.e. there is no intended cell-to-cell spread of the GMO.

Mammalian cell lines: the well characterised mammalian cell lines will be used. The cells require specialised growth media and conditions and as a result will not survive outside the laboratory environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation required.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For general laboratory activities the current version of Code of Practice 004: Disinfection and decontamination will apply. In brief the following procedures are routinely employed:

Liquids
All liquids are disinfected with 2% Virkon solution with the final concentration reaching no less than 1%. After a minimum of 60 minutes disinfected liquids are discarded to the drains.

Solid
All contaminated solid waste is autoclaved at 132°C for 10mins. The autoclaved waste is then collected for incineration by a licensed contractor.

Non infectious, non-GM, non-contacted biomaterial solid waste is segregated into yellow and black waste bags (provided by licensed waste contractor). This waste is collected by a licensed contractor for incineration.

For suspension vessels; Sodium hydroxide at the following concentrations 0.2M, 0.5M and 1M will be used to decontaminate tubing, cartridges etc. In addition all plastic ware that has been in contact with biological material will after sodium hydroxide treatment is placed in sealable containers in preparation for collection by a licensed contractor for incineration. The antiviral effects of different concentrations of Sodium hydroxide has been evaluated by OXB.

For suspension vessel related laboratory activities Standard Operating Procedures PR&DSOP 027 to 032 will apply.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment

The attached GM risk assessments (GMRA162 & 163) have been reviewed and approved by the GMSC. In addition OXB’s external Biological Safety Officer has reviewed and approved the assessments. The risk assessments are associated with laboratory scale activities for a feasibility study. If the feasibility study activities are successful additional work packages will be considered which includes scaling up to 200l scale. The increase in scale will be risk assessed as and when the work packages have been agreed.

### Historical Significant Changes

- **Historical Date of Additional Info**:  

- **Significant Change ID**:  

- **Date of Significant Change**:  

### Project Additional Information

**Purposes of the contained use**

Development (from wild type) and subsequent use of attenuated replication-competent lentiviral (RCL) in assays utilising replication proficient positive controls based on SIVagm (SIV strain found in African Green Monkeys).

**Recipient or parental organism**

Wild Type Simian Immunodeficiency Virus (SIV) - Classed as SCDP Hazard Group 3.

Creation of attenuated lab strains of this virus - Assessed as GM Class 3.

Both wild type and attenuated SIV viruses are anticipated to be replication competent within CD4+CCR5+ T-cells (primary or cell lines).

**Host/vector system**

1. Plasmid DNA encoding modified provirus will be propagated in K12 disabled strains of E. coli (e.g. TOP10, TURBO, JM109, DH5alpha and others) - ACDP Hazard Group 1*
2. Mammalian cell lines (e.g. lentiviral vector production cell lines such as HEK293/HEK293T, Tcell lines such as C8166-45 and Molt4-8) - ACDP Hazard Group 1)

Please note all our laboratories are designed to CL2 and we work to a minimum of CL2 even with HG1 organisms.
Origin & function

Origins of genetic material is wild type SIVagm virus. Attenuation will be achieved by removing pathogenic factors potentially without inhibiting replication competence.

RCL assay development:
Attenuated SIV virus will be evaluated for replication kinetics within tissue cultures of permissive cell types from low multiplicities of infection. Virus detection/quantification will be performed by quantitative RT-PCR of associated reverse transcriptase activity within virus-containing culture supernatants or qPCR of DNA from infected cells, wherein virus infectivity has been abolished by approved methods of inactivation stated within Oxford Biomedica UK Ltd's Containment Level 3 Codes of Practice.

Evaluation of foreseeable effects

Potential hazard to human health:
SIV is not a human pathogen, but is classed as ACDP Hazard Group 3 because of its ancestral link with HIV-1/-2, and therefore in theory may be able to cause pathogenic disease in humans should exposure be significant. SIV is capable of transferring its genome into dividing and non-dividing cells, though it is restricted to CD4+CCR5+ T cells.

Given the presence of human antiviral mechanisms, such as TRIM5α and APOBEC3G, accidental exposure to SIV is anticipated to be asymptomatic.

SIV is capable of infecting CD4+ T cells and integrates into the host cell DNA. There is a theoretical risk of insertional mutagenesis (and therefore potential oncogenesis) but since infection at high viral load is lytic in vivo there has been no report of this type of pathogenicity in T cells or from latent reservoir cells (e.g. macrophage).

Prokaryotes: Whilst the genes encoding SIV proteins will not be inserted immediately downstream of a bacterial promoter, it is expected that leaky expression of these genes may be disadvantageous for bacteria. It is not expected that any of these proteins will increase the tropism or pathogenicity of bacteria in humans.

Eukaryotes: All cell lines used in this project are classed as hazard group 1 but will be maintained at containment level 2 using microbiological safety cabinets at OXB. Pathogenicity of the mammalian cell lines for use in this study is not expected to be altered by SIV components. It is not expected that the SIV viruses will be capable of mobilising other sequences during production in HEK293(T) based cells or within T-cell lines.

Potential hazard to Environment:
WT SIV can be pathogenic to certain simian species, targeting CD4+CCR5+ T-cells. The properties of ‘wild type’ SIVagm are not expected to be altered; however, the GMM strain is essentially ‘lab adapted’ by passing in T-cell lines within a lab environment. For this reason, the strain is likely to be less ‘fit’ that field strains of SIVagm. The attenuated SIVagm strain is likely to be incapable of sustaining productive infection in monkeys.

The viruses do not harbour transgenic inserts. Plasmids will not encode known bacterial promoters directly upstream of Eukaryotic transgenes. However, viral promoters such as CMVp have been shown to have significant promoter activity in E.coli. High-copy number origin of replication plasmids will typically be utilised. Antibiotic-resistance gene markers: e.g. Ampicillin, Kanamycin, Blasticidin. The plasmid/E.coli host combinations will ensure that none of the plasmids will be mobilisable, hence maintenance in the human gut and transfer of antibiotic resistance to endogenous E.coli/gut bacteria is unlikely.

Most hazardous GMM (both to human health and environment): Attenuated SIV virus, although replication competent, will not harbour transgenic sequences but will be capable of infecting CD4+CCR5+ T cells. They are designed to be less hazardous than the wild type and to make the virus much less able to cause infections in both human and non-human primates. However, we intend to handle all such virus in the same way as wild type under CL3 conditions.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste procedures are all validated and described in the CL3 Codes of Practice 21:

COP021.4 Containment Level 3 (CL3) - Standard Operating Procedures for the Inactivation of Samples Generated in the CL3 Laboratory.
COP021.5 Containment Level 3 (CL3) Standard Operating Procedures for Decontamination and Disinfection of Waste Material.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  Y

The GMRA was introduced by the PI to the members of the GMSC and the committee had the chance to ask questions and make comments.

A recommendation was made to review the control measures required and to expand on in particular separation measures to ensure that during handling, equipment use and storage of the proviral WT SIV DNA the likelihood of inadvertent mixing and recombination with other pathogens used in the labs will be minimised.

This recommendation was addressed (see 'additional measures' in the GMRA) and the reviewed GMRA176 was approved by both the GMSC and our external consultant BSO.

All work involves ACGM class 1 organisms, so risk is minimal. Maximum individual culture volumes do not exceed 1 litre (routinely 500 ml). Liquid waste is deactivated overnight by addition of 10% Chloros (1 x 10,000 ppm available chlorine). It is then disposed of to drain with copious amounts of water. The decontamination is validated by the absence of viable cells in 3 x 100 ul samples of the decontaminated culture. This validation to be performed at approximately 6 monthly intervals and records retained by the GMSC secretary. Solid waste is disposed of by incineration at a validated facility.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The machine autoclaves at 136 degrees C for 30 minutes followed by 12 minutes free steam. The pressure is a maximum of 1.08 bar and a minimum of 1.06 bar.
In addition to the autoclave tape there is a temperature probe in the machine.

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

All waste generated will be autoclaved prior to off site incineration. The autoclave process will be undertaken on site and will be validated in accordance with the requirements of HTM 2010. Standard disinfection procedures will apply to all areas involved in gene therapy studies. The exact chemical disinfectant required will be specified in the risk assessment documentation and will be appropriately validated.

**Purposes of the contained use**

The purpose of the trial is to evaluate the safety and the risks of using OncoVEXGM-CSF to treat patients with melanoma and to see if OncoVEXGM-CSF can destroy these tumours as it destroyed tumours in animal test and human studies. This study may provide information on the usefulness of OncoVEXGM-CSF as a future treatment for melanoma and the safety and usefulness of OncoVEXGM-CSF as a treatment for melanoma.

Patients in this trial will be given either OncoVEXGM-CSF or GM-CSF (there is twice the likelihood of receiving OncoVEXGM-CSF) The Onco VEXGM-CSF will be directly injected into skin lesions and the dose will depend upon the number and size of lesions being injected, up to a total volume of 4.0mL in any one visit.

**Recipient or parental organism**
The target recipients are melanoma patients with unresectable stage IIIb, IIIc and IV melanoma that have volunteered for the clinical trial. These patients will be carefully selected based on the inclusion and exclusion criteria defined in the study protocol. The GMO will be administered by direct injection into the melanoma lesions.

Host/vector system

HSV-1 clinical isolate strain JS-1 (ECACC Accession Number 01010209) deleted for the genes encoding ICP34.5 and ICP47.

Origin & function

The WHO Vero cell line ATCC No X38 (Kidney, African green Monkey: cercopithecus aethiops) is used as the producer cell line for OncoVEXGM-CSF. The gene of interest is human GM-CSF. GM-CSF acts as a stimulator for dendritic cells. These cells are the most potent antigen presenting cells which can take up cell fragments and incoming pathogens, then present these antigens to the immune system inducing an immune response. Tumour cells typically fail to stimulate optimal antigen presentation and do not generate immune reactions that are sufficiently potent to prevent lethal tumour progression. The intended function of GM-CSF is to enhance functions of cells critical for immune activation against tumour cells.

Evaluation of foreseeable effects

It is unlikely that the modified viruses would pose a serious risk to humans, animals or plants. As the GMO is a virus, it requires host cells to replicate and does not form survival structures, such as seeds, spores and sclerotia. The GMO would not be expected to be able to survive in the environment if released. HSV is an enveloped virus that has been shown to be fragile and rapidly inactivated by dessiccation, lipid solvents and mild detergents. The fact that direct contact is required for transmission attests to the instability of the virus outside the host. The modifications made to the GMO would not be expected to have any effect on the ability of the virus to survive outside of its host since they do not affect or stabilise the lipid envelope of the virus.

The GMO contains deletions for the ICP34.5 and ICP47 genes. The deletion of ICP34.5 severely reduces the pathogenicity of the GMO whilst still allowing it to replicate in rapidly dividing cells, such as in tumours, and in culture. The GMO would be expected to be less pathogenic in humans compared to wild type virus. The therapeutic genes to be delivered are present in normal, healthy humans.

Infection is by contact and transmission by the aerosol route is not thought to occur. The GMO is being administered by direct injection into tumours and therefore most of the GMO will be in a localised area. The injection site will be covered by an occlusive dressing to prevent any potentially shed GMO from coming into contact with the environment. The most likely route of contamination of hospital staff handling the GMO is by needle stick, splashing of virus onto the skin or into the eye, or by contact with other contaminated material. The most likely route of contamination of others who come into contact with the patient is by contact with the injection site. In order to prevent transmission to third parties involved in the clinical trial, relevant precautions will be taken.

Low levels of virus shedding into urine have been detected in a very small number of samples tested in previous clinical trials of the GMO. Potential shedding of the GMO from urine is not thought to present a hazard as there is data to demonstrate that household disinfectants destroy the GMO. Experiments have shown that the risk of transmission of wild-type HSV from wastewater is minimal. The deletion of the ICP34.5 and ICP47 genes and the insertion of the hGM-CSF gene would not increase the ability of the GMO to survive in wastewater compared to wild type HSV.

It is not known wether the GMO can establish latency in man and if so, wether the virus would be able to reactivate. However, the human experience with the GMO to date has not shown this to be a risk as none of the dosed patients have developed lesions at the injection site or other symptoms suggestive of virus reactivation. Additionally, there are no reported incidences of establishment and/or reactivation from latency of other HSV-based oncolytic viruses.

Humans are the only natural host species for HSV and it is universally prevalent with approximately 80% of the human population being seropositive. Although other species can be infected experimentally, these appear to be "dead end" hosts. It is therefore unlikely that there would be gene transfer from the GMO to man or any other species.

Homologous recombination between different HSV strains can occur if the two viruses are undergoing replication in the same cell at the same time. However, it has been
shown that recombination between the GMO and a wild type virus cannot result in the generation of a wild type virus carrying the hGM-CSF gene.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

| N/A |

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

| N/A |

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All needles and syringes will be discarded into a designated sharps bin which will be sealed and then collected by the relevant contractor.

Used vials will be retained at the pharmacy until inventoried by the study monitor. They will then be removed and destroyed per hospital specific procedures. If the hospital does not allow the storage of used vials until they are inventoried by the study monitor, detailed records of the return or destruction of the vials will be maintained.

All other materials will be treated as clinical waste and disposed of in yellow clinical waste bags.

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

**Please enter comments on the GM safety committee on the risk assessment**

The GMSC questioned the safety aspects of intra tumoural injections and whether injections will be split between lesions. The research nurse confirmed these will be split by the investigator and that a maximum of 4 mls is given. Discrepancies on the needlestick and waste SOPs were noted, which required updating. There were queries on whether a negative pressure room was required, which is not needed for this trial, although it may be used for convenience purposes. It was confirmed that it was important for this to be included in the study paperwork. It was noted that contact is a main issue, and there was discussion on the protective clothing used and that it should all be disposable and single use only.

It was questioned if the disposal of PPE is treated as GM waste and it was confirmed by that this would go in yellow bags or in the red lidded bins.

It was confirmed that all patients connected with this study will be attending at the Chelsea site only but suggested that something should be put in place in case attendance in Sutton is required for any reason and that a contingency plan be added to the paperwork.

The chairman then confirmed that the Committee agreed that this study could go ahead, with relevant amendments being made as follows:

- Contingency plan to include Sutton if required.
- Clarify that the side room used does not need to be negative pressure.
- Reference to Virkon to be removed and replaced with Haz Tab solution or Milton.
- Waste disposal SOP to be updated.
- Needlestick SOP to be updated.
- Appendix C of the policy including staff list to be submitted to risk management prior to the trial commencing as per GM policy.

Project Additional Information

Purposes of the contained use

RP2 will be administered to subjects as an anti-tumour therapy, as part of a Phase I clinical trial to treat a wide range of solid tumour types. The initial clinical trial intends to test RP2 as a single agent and in combination with PD1 blockade in patients with solid tumours.

Recipient or parental organism

RP2 (rHSV-1 hGM-CSF/GALV-GP-R-/ahCTLA-4) is a selectively replication competent Herpes Simplex Virus-1 (HSV-1). The virus contains a codon-optimised sequence for GALV-GP-R-, a codon-optimised sequence for hGM-CSF, and the sequence for a single chain antibody-like molecule to human cytotoxic T-lymphocyte-associated protein 4 (CTLA-4). GALV-GP-R- expression leads to cell to cell fusion (syncytial) formation in infected tumour cells through binding to the constitutively expressed PIT-1 receptor for GAL V. This results in the death of the cells by membrane fusion. Since the RP2 selectively replicates in tumour cells, the expression of the GALV-GP-R- is minimised in normal tissues. The oncolytic destruction of tumour cells leads to the release of tumour associated antigens that are intended...
To engender an anti-tumour immune response, enhanced by the local expression of GM-CSF. This is intended to be further enhanced through GALV-GP-R- mediated fusion associated cell death, which is also expected to contribute to this immune effect. The immune response generated may then lead to immune destruction of distant, un.injected tumours, and/or delay the progression of distant disease, and/or vaccinate against relapse. The anti-human CTLA-4 antibody-like molecule which interferes with the interaction of CTLA-4 with B7 molecules on professional antigen presenting cells. This is intended to result in enhanced local T-cell activation due to blockade of the inhibition otherwise mediated by the CTLA-4/B7 interaction. The resulting enhanced anti-tumour T-cell activation, proliferation, and lymphocyte infiltration into tumours is intended to lead to improved local and systemic anti-tumour effect. RP2 is intended for direct injection into solid tumours.

**Host/vector system**

RP2 (HSV-1 hGM-CSF/GALV-GP-R-/ahCTLA-4) is derived from the RH018 strain of Herpes Simplex Virus-1. RP2 is produced in the Vero cell and released into the culture media during cell lysis, prior to purification.

**Origin & function**

RP2 was constructed using a new strain of HSV-1 (strain RH018). For the development of RP2, 29 new clinical strains of HSV-1 were obtained for comparison to identify more effective strains for development. Of the strains tested, strain RH018 was the most effective at killing a panel of human tumour cell lines, and selected for use in the construction of RP2.

RP2 expresses the immune stimulatory protein GM-CSF, which augments therapeutic activity. GALV-GP-R- binds to the Pit1 receptor, which is widely expressed on mammalian cells including human tumour cells. Pit1 is also critical for cell proliferation, and its expression is therefore unlikely to be lost or down-regulated in response to cancer treatment. The truncated R- version of the protein provides constitutive fusion activity without GALV (i.e. the virus) itself. Expressing GALV-GP-R- together with GM-CSF is expected to increase clinical activity as compared to only expressing GM-CSF. As well as causing direct tumour cell death by cell to cell fusion, cell to cell fusion followed by death is highly immunogenic and includes the release of immunogenic tumour antigen-containing exosomes. Expression of GALV-GP-R- from an oncolytic virus is therefore expected to improve systemic, immune mediated, effects, as well as effects in the directly treated tumour thereby increasing synergy with other immunemediated approaches to cancer therapy such as immune co-inhibitory pathway blockade.

The addition of the expression of an anti-humanCTLA-4 antibody-like molecule (ahCTLA-4) interferes with the interaction of CTLA-4 (expressed on a subset of activated T cells) with B7 (CD80/CD86) molecules on professional antigen presenting cells. This is intended to result in enhanced T-cell activation due to blockade of the inhibition otherwise mediated by the CTLA-4/B7 interaction. The resulting enhanced local anti-tumour T-cell activation, proliferation, and lymphocyte infiltration into tumours, is intended to lead to improved local and systemic anti-tumour effects, including in combination with PD-1 or PD-L1 blockade. Intratumoural expression of the anti-human CTLA-4 antibody-like molecule would also be expected to reduce toxicity as compared to systemic administration of an antihuman CTLA-4 antibody, including in combination with antibodies targeting PD-1 or PD-L1.

**Evaluation of foreseeable effects**

The oncolytic destruction of tumour cells leads to the release of tumour associated antigens that are intended to engender an anti-tumour immune response, enhanced by the local expression of GM-CSF.

This is intended to be further amplified through GALV-GP-R- mediated killing, fusion associated cell death which results in the production of the highly immunogenic exosomes and is expected to contribute to this immune effect.
immune response generated may then lead to immune destruction of distant, uninjected tumours, and/or delay the progression of distant disease, and/or vaccinate against relapse. The anti-human CTLA-4 antibody-like molecule which interferes with the interaction of CTLA-4 with B7 molecules on professional antigen presenting cells. This is intended to result in enhanced local T-cell activation due to blockade of the inhibition otherwise mediated by the CTLA-4/B7 interaction. The resulting enhanced anti-tumour T-cell activation, proliferation, and lymphocyte infiltration into tumours is intended to lead to improved local and systemic anti-tumour effects. RP2 is intended for direct injection into solid tumours.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

| N/A |

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

| No derogation is requested. |

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

| All used and unused RP2 and diluent vials used in preparation and syringes will be destroyed per institutional policy. As per the wild-type HSV-1 virus, the recombinant HSV-1 vector that represents RP2 are highly susceptible to dehydration, rapidly inactivated outside the host and easily inactivated (for example with 1 % sodium hypochlorite). As part of phase I of the clinical trial, biodistribution and shedding will be monitored. RP2 DNA levels in blood and urine will be determined at time-points outlined in the Schedule of Assessments of the clinical protocol (day 1, days 2 and 3, day 15, days 16 and 17, day 29, days 30 and 31, day 43, day 57 and as part of the follow up, 30 days and 60 days after the last dose of RP2). These samples will be collected prior to dosing on treatment visits. In addition, for the first three doses, samples will be collected after dosing at 6 (±2hr) hours. Swabs of saliva/oral mucosa, injection sites and exterior of occlusive dressings will also be obtained at these timepoints |

Shipment of RP2
1. RP2 and diluent will be shipped on dry ice, and should not be used if the dry ice is not present upon receipt at the clinical site. A temperature monitor will also be included with the shipment to assure shipment remained within temperature.
2. RP2 will be provided as a sterile frozen liquid in a single-use 3-cc glass vial with a gray Fluortec®-coated bromobutyl stopper, aluminum seal and a polypropylene cap. Each vial will contain a minimum of 1.0 mL RP2 in a buffer containing sodium phosphate, pH 7.4, sodium chloride, myo-inositol, sorbitol, human serum albumin (HSA) in water for injection (WFI). RP2 vials will be provided as concentrations of 10^6 PFU/mL, 10^7 PFU/mL or 10^8 PFU/mL.
3. Upon receipt of the study drug shipment, the pharmacist or study coordinator/research nurse will verify the condition of the study supplies, register the study drug via Interactive Response Technology (IRT), and document per instructions in the Pharmacy Manual and the IRT Manual.
4. The site must store the study drug in a limited access area at -70 DC or below. Only authorized site study personnel may access study drug.

All handling and management of IMP upon receipt in the pharmacy department to collection by research nurse will be as pharmacy SOP1.15, "Safe handling, spillage and destruction of GMO and trial specific dispensing procedures".

Administration of RP2 (NB First in Human)
1. This Phase 1 study is a multicentre, open-label, single agent dose escalation and combination treatment study of RP2. The study will be conducted in two parts.
   The first part of the study is an open-label, dose escalation first in human Phase 1 study to assess the safety and tolerability of RP2 and to determine the recommended Phase 2 dose (RP2D) to be used in the second part of the study.
2. The second part of the study is an open label design to further investigate safety of RP2 in combination with nivolumab. It will also assess the biological activity of multiple doses of RP2 in combination with nivolumab.
3. RP2 will be administered intra-tumourally in up to 36 participants in dosing cohorts. The appropriate amount of RP2 will be injected into the tumour and a record of the volume administered kept.
4. Please refer to section 6.2 of the protocol (v1.0 07Feb19) for further detail. Please refer to section 6.2.2 of the protocol (v1.0 07Feb19) for combination dosing with Nivolumab
5. The injection site should be swabbed with alcohol following injection, and then covered with a dry occlusive dressing for up to one week. If the dressing comes off before 1 week, it should be replaced if the injection site is oozing or weeping. Waste dressings should be disposed of according to institutional guidelines, e.g. by incineration.

Clean up and Disposal Following Treatment
1. All personnel should be advised that RP2 is classified as a level 2 biosafety hazard and therefore universal precautions must be observed by appropriately trained personnel when handling the IMP or contaminated equipment.
2. The sponsor recommends that during the study all staff involved in the administration of IMP and sample
3. Waste should be disposed of as per GM trust policy. All waste generated during this activity (including sharps, needle sets, vials and disposable safety clothing) that has been in contact with the IMP will be placed in a 5 litre yellow sharps bin, with a yellow lid. This will then be sealed at the patients' point of care with all standard information accurately completed on the side of the bin including study specific information and relevant contact details. A GM label must also be completed with the relevant department, date, and a signature and then fixed to the sharps bin.

4. The research personnel will then contact the waste department via extension 4591 (morning) or 4619 (afternoon) to dispose of the material.

5. Systematic decontamination of treatment area and surfaces must be undertaken with Antichlor following RP2 administration.

Patient Management Following Treatment and Discharge Advice

Patients are informed of common side effects. (PIS V1 25Feb19).

Treated patients may excrete the virus from the injected lesions. Close contacts are advised to wear protective gloves if they will be touching the lesions or dressing. Those who are immunosuppressed should avoid direct contact with the patient.

In the event of exposure to RP2, individuals are advised to clean the site with soap and water. RP2 is responsive to acyclovir or anti-viral drugs activated by the viral thymidine kinase gene.

Handling of Spills

All spillages must be dealt with immediately by the specialist nurse in charge.

Accidental exposures to Biohazard agents must be recorded on an Accident/Incident Form and reported to Occupational Health on the same working day as the incident.

A spillage kit should be available wherever RP2 is handled. If items are used from the spillage kit they must be replaced immediately after the spillage has been dealt with.

A spillage kit consists of the following items:

A laminated copy of this procedure
A 'Kimal' pre packaged spill kit containing:
- 2 pairs of sterile nitrile gloves (medium)
- 1 plastic apron
- 1 pair blue shoe covers
- 1 blue tray wrap
- 1 disposable gown (large)
- 1 fluid shield face mask
- 1 paper towel
1 yellow adhesive waste bag
1 x 5 litre sharps bin and lid
1 pack of lint free wipes
1 x 500ml bottle of Sterile Sodium Chloride 0.9% for Irrigation BP (for eye washing)
1 x tablet of Actichlor in 1 litre of water (Chlorine 100,000 ppm) or a virucidal agent such as 1% sodium hypochlorite or Virkon.

**Spillages**

1. Put on an apron, gown, fluid shield mask, shoe covers and 2 pairs of gloves.
2. Allow aerosols to settle; gently cover spill with paper towel and apply Actichlor or a virucidal agent such as 1% sodium hypochlorite or Virkon, starting at the perimeter and working towards the centre; allow sufficient contact time (30 min) before clean up. Put all used wipes into the 5 litre sharps bin.
3. When all the liquid has been mopped up, wash and dry the area twice using Actichlor solution and lint free wipes. Place used wipes into the 5 litre sharps bin.
4. Remove outer pair of gloves, overshoes and apron, dispose of in the 5 litre sharps bin.
5. Clean goggles and return them to the spillage kit.
6. Seal the 5 litre sharps bin and label with a Biohazard GM Medicines Waste sticker.
7. Ensure that the spillage kit is replaced.

**In the event of spillage onto clothing**

1. Staff involved in handling IMP should wear standard RM uniform. Patients should be supplied with hospital clothing during administration. In the event of any spillage onto protective clothing, the contaminated garment should be removed and placed into a yellow sharps bin. This should then be sealed with biohazard tape.

**In the event of spillage onto the skin**

1. Any spillage on to the skin should be washed off immediately with soap and water or the skin decontaminated using alcohol hand rub.

**Action in Case of Inoculation/Eye Splash Injury**

Where there is an additional risk of exposure to blood-borne viruses, this SOP should be used in conjunction with the Trust policy 181 Blood-Borne Virus Prevention of Infection (Needlestick Procedures).

In the case of needle stick injury, spillage on broken skin or splash onto mucous membranes (eyes or mouth), use the following procedure:

1. Discard the needle and/or syringe into a designated sharps bin.
2. In the event of exposure to broken skin or needle stick, clean the site thoroughly with soap and water or a skin disinfectant. See a physician for monitoring for signs of infection. Acyclovir or other anti-viral drugs may be administered prophylactically.
3. In the event of accidental exposure through a splash to the eyes or mucous membranes, flush with sterile sodium chloride 0.9% or clean running water for at least 15 minutes.
4. Contact the relevant personnel to inform them of the injury (the Principal Investigator who will inform the GM Safety Committee) and inform Occupational Health.
5. Complete an Accident/Incident Form.
6. Occupational Health will assess the exposed individual with regard to blood-borne virus (BBV) and determine whether any further medical surveillance and/or treatment are indicated.
7. In the event of inoculation/eye splash injury out of hours, if there is a risk of BBV in addition to risk of exposure to RP1, Trust policy 181 Blood-Borne Virus Prevention of Infection (Needlestick Procedures) should be followed. The physician responsible for the care of the patient receiving the drug, or whoever is on call for the unit, will assess the exposed individual. Occupational health should be informed as soon as they are open.
Gene therapy product RP3 (Common name rHSV-1/GALV-GP-R-/ahCTLA-4/hCD40L/h4-1BBL) is an oncolytic immunotherapy product that is developed for the treatment of solid tumours.

RP3 is a selectively replication competent herpes simplex type-1 virus which expresses a truncated version of the gibbon ape leukaemia virus fusogenic glycoprotein (GALV-GP-R-), an anti-human CTLA-4 antibody-like molecule (ahCTLA-4), human CD40 ligand (hCD40L), and a human 4-1BB ligand (h4-1BBL).

The genes coding for neurovirulence factor ICP34.5 and the HSV immunomodulatory protein ICP47 are deleted. The ICP34.5 deletion allows the virus to replicate as a single agent and in combination with anti-PD1 therapy in patients with solid tumours as part of a Phase I, multicentre, open label clinical trial to investigate the safety and tolerability.
Host/vector system

RP3 (rHSV-1/GALV-GP-R-/ahCTLA-4/hCD40L/h4-1BBL) is derived from the RH018 strain of Herpes Simplex Virus-1 (HSV-1). RP3 is produced in Vero cells and virus is released into the culture media by budding from the cells and during cell lysis, prior to purification.

Origin & function

RP3 was constructed to enhance anti-tumour activity by using a new isolate of HSV-1 (strain RH018). The RP3 virus is armed with coding sequences to express a truncated fusogenic protein from gibbon ape leukaemia virus, GALV-GP-R-, an anti-human CTLA-4 antibody-like molecule (ahCTLA-4), human cluster of differentiation 40 ligand (hCD40L), and human 4-1BB ligand (h4-1BBL).

The neurovirulence factor, ICP34.5-encoding genes, and the ICP47-encoding gene are deleted from the virus. The ICP34.5 deletion allowed the virus to replicate selectively in tumours. ICP47 is a protein that inhibits the major histocompatibility complex (MHC) class 1 antigen presentation pathway by binding to the transporter associated with antigen presentation (TAP). The ICP47 deletion also results in the increased and earlier expression of the HSV-1 US11 gene. ICP34.5 deletion reduces virus replication somewhat in tumours, as well as preventing efficient replication in normal tissue. The increased and earlier expression of US11 partially overcomes the reduced replication in tumours, but without decreasing tumour selectivity.

RP3 was engineered with the following exogeneous genes:

- Truncated fusogenic envelope glycoprotein from gibbon ape leukaemia virus (GALV-GP-R-) with the R-sequence deleted (R-). GALV-GP R- causes cell to cell fusion resulting in cell death. The truncated R- version provides constitutive fusion activity, which is intended to be beneficial for tumour treatment. GALV-GP-R- expression is under the control of the RSV LTR promoter.

- Human CTLA-4 antibody-like molecule, under the control of human cytomegalovirus (hCMV) promoter. This is intended to block the interaction of CTLA-4 with B7, a negative T cell immune checkpoint, which otherwise inhibits the potency of the immune responses that are induced.

- Human CD40 ligand (CD154 or hCD40L) under the control of Moloney murine leukaemia virus (MMLV) LTR promoter. CD40L binds to the CD40 receptor present on antigen presenting cells (APCs) such as dendritic cells and macrophages. CD40L-CD40 interaction results in the maturation of dendritic cells, intended to result in increased cross presentation of tumour antigens to CD8+ T cells. Mature dendritic cells further activate CD8+ T cells by increased expression of immune co-stimulatory molecules, intended to lead to enhanced antitumour immunity and immunological memory formation.

- Human 4-1 BBL, under the control of mouse cytomegalovirus promoter (mCMV). The 4-1 BBL binds to the 4-1BB (CD137) co-stimulatory signalling receptor present on CD8+ T cells. The 4 1 BBL binds to the 4-1BB (CD137) co-stimulatory signalling receptor present on CD8+ T cells. The 4-1BBL-4-1BB engagement results in activation NF KB, AKT, p38 MAPK, and ERK pathways. These signalling pathways induce the expression of survival genes and decrease the expression of pro-apoptotic genes thus resulting enhanced anti-tumour T-cell activation, proliferation, and lymphocyte infiltration into tumours, is intended to lead to improved local and systemic anti-tumour effects.

- CD40L is a protein that is primarily expressed on activated T cells and is a member of the TNF superfamily of molecules. It binds to cluster of differentiation 40 (CD40) on antigen-presenting cells. CD40L binds to the CD40 receptor present on antigen presenting cells (APCs) such as dendritic cells and macrophages. CD40L-CD40 interaction results in the maturation of dendritic cells, intended to result in increased cross presentation of tumour antigens to CD8+ T cells. Mature dendritic cells further activate CD8+ T cells by increased expression of immune co-stimulatory molecules, intended to lead to enhanced antitumour immunity and immunological memory formation.

- Human 4-1 BBL is also found on antigen presenting cells and binds to h4-1BB, a type 2 transmembrane glycoprotein receptor belonging to the TNF superfamily, expressed on activated T lymphocytes particularly CD8+ T cells, and induces secretion of high levels of IFN-γ by binding to 4-1BB protein. The 4-1BBL binds to the 4-1BB (CD137) co-stimulatory signalling receptor present on CD8+ T cells. The 4-1BBL-4-1BB engagement results in activation NF-KB, AKT, p38 MAPK, and ERK pathways. These signalling pathways induce the expression of survival genes and decrease the expression of pro-apoptotic genes thus intended to promote CD8+ T cell activation, survival, and increased cytokine production leading to augmented antitumour immunity.
intended to promote CD8+ T cell activation, survival, and increased cytokine production leading to augmented antitumour immunity. The initial clinical trial protocol intends to test RP3 in several tumour indications as a monotherapy and in combination with anti-PD-1 therapy.

**Evaluation of foreseeable effects**

No studies have yet been conducted with RP3 and therefore no data is available. HSV-1 is a proven virus for development into a safe and effective oncolytic therapy. Beneficial characteristics include:

- The large 152 Kb genome has non-essential genes that can be replaced with therapeutic genes or removed;
- Infection of many cell types, including tumour cells across species followed by the destruction of the cell by viral replication;
- The availability of effective anti-viral drugs to ameliorate any non-therapeutic viremia;
- The viral genome does not integrate into the host genome. From a safety perspective, wild type HSV-1 only rarely produces severe illness in immune competent adults.

The therapeutic strategy is to induce direct viral "oncolytic" destruction of tumours that is enhanced compared to previous oncolytic agents and combined with the enhanced induction of a systemic antitumour immune response mediated by the inclusion of anti-CTLA-4 antibody-like molecule and the immune co-stimulatory ligands hCD40L and h4-1BBL. This is intended to provide overall and long-term clinical benefit. The broad antitumour response that is anticipated, including to tumour neo-antigens, is expected to be synergistic with immune checkpoint blockade agents such as those targeting PD-1/programmed cell death ligand (PD-L1).

RP3 is intended for direct injection into non-neurological solid tumours.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

No derogation is requested.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All used and unused vials of RP3 will be disposed of per institutional policies and procedures and in line with the RP3 IB. Spills should be treated with virucidal agents, such as, e.g., 70% isopropanol, 1% sodium hypochlorite or Virkon solution. All materials contaminated with RP3 will be disposed of in compliance with local institutional polices and SOPs. Incineration is appropriate.

In the event of exposure to broken skin or needle stick, the site will be cleaned thoroughly with soap and water or a skin disinfectant. A physician for monitoring for signs of infection and occupational health will be contacted for support. Acyclovir or other anti-viral drugs may be administered prophylactically.

Patients will be provided full instructions and support from the Principal and co-investigators which will include care of the lesions and advice on shedding. Patients will be provided with spare dressings, instructions for use and safe disposal equipment which will be returned to the clinical site. In addition, the patients are given out of hours contact numbers and advice will be available from the clinical site team, if needed. All advice given will be in line with the sponsor instruction and the study protocol.

The Royal Marsden NHS Foundation Trust GMSC classified as Class 2.
A Phase 1/2a, Multicenter, Open-label Trial of TBio-6517, an Oncolytic Vaccinia Virus, Administered Alone and in Combination with Pembrolizumab, in Patients with Advanced Solid Tumors
The GMO (TBio-6517) is an oncolytic vaccine virus and is released in accordance with a clinical Trial Protocol Number TBio-6517-TUu001. The study is a Phase 1/2a, Multicenter, Open label Trial of TBio-6517, an Oncolytic Vaccinia Virus. Administered alone and in Combination with Pembrolizumab, in Patients with Advanced Solid Tumors.

It consists of a novel backbone named SKV built on clinical experience with first generation oncolybc vaccinia viruses. SKV was isolated from naturally-occurring variants of the parental Copenhagen stain of Vaccinia Virus. Compared to the parent vaccinia virus, TBio-6517 has several of the stamina genes removed, leading to tumor cell selectivity.

TBio-6517 expresses synthetically-driven transgenes encoding human anti-CTLA-4 antibody (ipilimumab), human FLT3L and human membrane bound IL-12p35. Details on the nature and Source of inserted genetic material are provided below.

**Upend**: FLT3L:
- Expends intratumoural CD141+ BatF3 DC, a potent cross presiding DC to facilitate epitope spreading
- Reduces T-cell attracting chemokines to 'inflame' turnout
- Associated with anti-PD1 responsiveness

**Antibody Anti-CTLA-4**
- Lowers threshold for T-cell activation
- May deplete Tregs

**• Targets subsets of exhausted CD8**

**Synergizes with anti-PD-1/PD-L1 immunotherapy**

**Cytokine: Membrane-bound IL-12p35:**
- Promotes Th1 and GD8+ cytotoxic T cell responses
- Activates innate immunity, including NK cells
- Reverses immune suppression of dysfunctional myeloid cells
- Abrogates suppressive activity of Treg cells
- Promotes priming via IFN-g mediated increase in MHC I processing and presentation

Encoding of these 3 transgenes in TBio-6517 restricts expression in tumor cells and thereby facilitates the creation of high local concentrations of these immune modulatory agents (IMAs) in the tumor microenvironment.

The modifications result in an attenuated, selective, replication competent organism which results in immunodulation of tumor cells.

The recipient of the GMO are adults over the age of 18 years who have existing advanced solid tumors. There are specific inclusion and exclusion criteria (identified in the protocol) which identifies a patient's suitability to fit in with the study population.

**DC** = Dendritic cell;  **NK** = Natural killer;  **Treg** = Regulatory T Cell

### Evaluation of foreseeable effects

There are no pathogenic properties in TBio-6517 that are not found in wild-type vaccinia virus. The genetic modifications in TBio-6517 does not replicate within the cell nucleus and as a result there is no integration into the host genome.

TBio-6517 selectively replicates within tumors.

Shedding and pustule formation will be monitored.

Horizontal transmission is not expected, but will also be monitored.

Replication and survival in the environment is not expected.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Because TBio-43517 is easily inactivated (as wild-type vaccinia is), testing/monitoring of the inactivation process has not been performed
Infectivity of the wild-type Vaccine virus, and thus TBio-6517, is reliant in part to its intact envelope. therefore, any chemical agents (liquid solvents and mild detergents) or physical inactivation (dehydration, heat, low pH) that disrupts the envelope reduces the infectivity.
All disposable materials which come into direct contact with TBio-6517 should be disposed of in standard biohazardous or sharps waste. This includes any syringes, needles, bandages etc. Non-disposable items such as medical equipment, linens etc. should be sterilized or laundered per hospital policy.
TBio-6517 can be inactivated through a variety of physical and chemical means. The US Centers for Disease Control (CDC) recommends that standard universal precautions and institutional policies be followed for cleaning and decontamination whilst handling Vaccinia virus based products.
Examples of chemical agents that have demonstrated inactivation properties include:
• At least 60% alcohol
• Bleach solution (with at least 0.6% of active chlorine) In the context of BSL-2 hood or demo hood use. it is recommended to follow with alcohol to prevent corrosion
• Other institutional recommended agents, hospital-grade disinfectants. or virocidals, such as but not limited to 1% cresylic acid, phenolics. chlonnated phenol. 2 5% phenol, 0.4% HCl, 7% sodium orthophenylphenate. and sodium hypochlorate
• The manufacturer's instructions should be followed to ensure adequate contact time and confirm the ability of the equipment to withstand the disinfectant used. All contaminated material should be disposed of in a clearly-marked biomedical waste container and discarded according to regular institution procedure for infectious waste.

Examples of physical inactivation methods include:
• Autoclave
• Hot soapy water (>71 degs C). Textiles and fabrics can be laundered in hot water (>71 degs C) with detergent and hot air drying. TBio-6517 should be transported in an appropriate sealed container. preferably shielded from light and labelled as a biohazardous material.

Recipient or parental organism:
Replication competent herpes simplex type-1 virus that is derived from HSV1 strain JS-1 (ECACC No. 01010209). The OncoVEX(GM-CSF) vector is deleted for the neurovirulence factor, ICP34.5. Deletion of this gene provides a virus that is non-pathogenic while providing the property of tumour selective replication. The vector is also deleted for ICP47, which blocks antigen presentation by blocking the transporter associated with antigen processing (TAP1 and TAP2). The vector also contains the...
coding sequence for human GM-CSF, a cytokine involved in the stimulation of T-cells. Human GM-CSF gene was cloned from an IMAGE clone 2340997/5808-K14 (UK HGMP Resource Centre). GM-CSF expression is under the control of the human cytomegalovirus immediate early promoter (HCMV IE). GM-CSF occurs normally in the human body. This cytokine is a licensed pharmaceutical product that is used to aid myeloid recovery following bone marrow transplant and chemotherapy, GM-CSF rarely causes anaphylaxis and cardiovascular disorders. Patients with congestive cardiac failure and renal insufficiency will be excluded from the clinical trial. However, only very low-level systemic levels of GM-CSF are expected following intra-tumoural inoculation of the virus where GM-CSF will be locally produced. Thus toxic effects associated with high levels of systemic GM-CSF are not anticipated.

The deletion of ICP47 and the expression of GM-CSF should enhance the immune response towards tumour cells. GM-CSF expression is under the control of the human cytomegalovirus immediate early promoter (HCMV IE). This is an infectious gene therapy product that replicates selectively in rapidly dividing eukaryotic cells. The parent vector is ACDP category 2 and ACGM level 2 containment is appropriate for OncoVEX(GM-CSF) vector due to the conditional replication competence of the vector, and the expression of a biologically active cytokine.

Host/vector system

Replication competent herpes simplex type-1 virus that is derived from HSV1 strain JS-1 (ECACC No. 01010209). The OncoVEX(GM-CSF) vector is deleted for the neurovirulence factor, ICP34.5. Deletion of this gene provides a virus that is non-pathogenic while providing the property of tumour selective replication. The vector is also deleted for ICP47, which blocks antigen presentation by blocking the transporter associated with antigen processing (TAP1 and TAP2). The vector also contains the coding sequence for human GM-CSF, a cytokine involved in the stimulation of T-cells. Human GM-CSF gene was cloned from an IMAGE clone 2340997/5808-K14 (UK HGMP Resource Centre). GM-CSF expression is under the control of the human cytomegalovirus immediate early promoter (HCMV IE). GM-CSF occurs normally in the human body. This cytokine is a licensed pharmaceutical product that is used to aid myeloid recovery following bone marrow transplant and chemotherapy, GM-CSF rarely causes anaphylaxis and cardiovascular disorders. Patients with congestive cardiac failure and renal insufficiency will be excluded from the clinical trial. However, only very low-level systemic levels of GM-CSF are expected following intra-tumoural inoculation of the virus where GM-CSF will be locally produced. Thus toxic effects associated with high levels of systemic GM-CSF are not anticipated.

The deletion of ICP47 and the expression of GM-CSF should enhance the immune response towards tumour cells. GM-CSF expression is under the control of the human cytomegalovirus immediate early promoter (HCMV IE). This is an infectious gene therapy product that replicates selectively in rapidly dividing eukaryotic cells. The parent vector is ACDP category 2 and ACGM level 2 containment is appropriate for OncoVEX(GM-CSF) vector due to the conditional replication competence of the vector, and the expression of a biologically active cytokine.

As regards the safety of this vector, there are a number of specific relevant points:
* The vector is deleted for ICP34.5 & ICP47, deletion of both of which renders the virus non-pathogenic.
* HSV and HSV vectors do not to integrate into the host DNA.
* The HSV thymidine kinase (TK) gene is intact in OncoVEX (GM-CSF) and expressed from the vector. This renders the viruses sensitive to anti-viral agents such as acyclovir, which can be used to block virus replication in the unlikely event that this is required.

There is no anticipated hazards should release of OncoVEX(GM-CSF) into the environment occur. However, procedures will be used to prevent contamination of the environment with OncoVEX(GM-CSF) even though (i)there is no anticipated hazard of OncoVEX(GM-CSF) to the environment and (ii) OncoVEX(GM-CSF) would not be expected to be able to survive in the environment if release occurred.

Origin & function

Replication competent herpes simplex type-1 virus that is derived from HSV1 strain JS-1 (ECACC No. 01010209). The OncoVEX(GM-CSF) vector is deleted for the neurovirulence factor, ICP34.5. Deletion of this gene provides a virus that is non-pathogenic while providing the property of tumour selective replication. The vector is also deleted for ICP47, which blocks antigen presentation by blocking the transporter associated with antigen processing (TAP1 and TAP2). The vector also contains the coding sequence for human GM-CSF, a cytokine involved in the stimulation of T-cells. Human GM-CSF gene was cloned from an IMAGE clone 2340997/5808-K14 (UK HGMP Resource Centre). GM-CSF expression is under the control of the human cytomegalovirus immediate early promoter (HCMV IE). GM-CSF occurs normally in the human body. This cytokine is a licensed pharmaceutical product that is used to aid myeloid recovery following bone marrow transplant and chemotherapy, GM-CSF rarely causes anaphylaxis and cardiovascular disorders. Patients with congestive cardiac failure and renal insufficiency will be excluded from the clinical trial. However, only very low-level systemic levels of GM-CSF are expected following intra-tumoural inoculation of the virus where GM-CSF will be locally produced. Thus toxic effects associated with high
levels of systemic GM-CSF are not anticipated. The deletion of ICP47 and the expression of GM-CSF should enhance the immune response towards tumour cells. GM-CSF expression is under the control of the human cytomegalovirus immediate early promoter (HCMV IE). This is an infectious gene therapy product that replicates selectively in rapidly dividing eukaryotic cells. The parent vector is ACDP category 2 and ACGM level 2 containment is appropriate for OncoVEX(GM-CSF) vector due to the conditional replication competence of the vector, and the expression of a biologically active cytokine.

The study will be a single arm open label upward titration of up to three dose levels of OncoVEX(GM-CSF) in combination with radiotherapy and concomitant cisplatin in the treatment of patients with locally advanced stage III and IV head and neck cancer with one or more nodal metastasis in the neck (N3-N3). Treatment with OncoVEX(GM-CSF) will be scheduled to commence on the day on which chemoradiotherapy begins. Patients will be admitted to the outpatients department or a day ward for all injections of virus. The injections will always be performed in a side room where the trial subjects can be segregated from other patients for safety reasons. Groups of four evaluable patients will be treated with dose levels of 10 (to the power of 6) pfu/mL on four occasions, 10 (to the power of 6) pfu/mL on one occasion followed by 10 (to the power of 7) pfu/mL on three occasions and 10 (to the power of 6) pfu/mL on one occasion followed by 10 (to the power of 8) pfu/mL on three occasions. The first dose of virus will be up to 2 mL per tumour (4 mL in total) of the dosage strength 10 (to the power of 6) pfu/mL given on the same day that treatment with cisplatin and radiation begins. Subsequent doses of virus (which will always be administered to the same nodes) will consist of a volume of up to 4 mL in weeks 3 (day 21), 6 (day 42) and 9 at a dosage strength of either 10 (to the power of 6), 10 (to the power of 7), or 10 (to the power of 8) pfu/mL depending on the dose level to which the patient is allocated. The timing of these doses is designed to avoid chemotheraphy-induced nadirs in the white cell count. The initial dose strength of 10 (to the power of 6) pfu/mL will be used in order to allow the patient to become tolerant to HSV1. Each injection will then be made, under local anaesthetic, along multiple tracks in order to disperse the vector throughout the tumour. Following injection, the injected tumour will be covered with a double occlusive dressing (Tegaderm) that must be kept in place for 24 hours. The injected tumour(s) will be swabbed 24 and 48 hours after injection in order to ensure that there is no shedding of virus from the injection site. If shedding or weeping is detected, the dressing must be replaced and changed every 24 hours, with the swabs repeated every 24 hours until shedding has ceased for at least 72 hours.

During the chemoradiotherapy the following clinical safety laboratory tests will be obtained at weekly intervals (including those tests taken prior to OncoVEX(GM-CSF) injection): Haematology (full blood count), clinical chemistry (including urea, creatinine and electrolytes, liver function tests). The following immunology laboratory tests will be obtained before the second, third and fourth injections of OncoVEX(GM-CSF): HSV-antibodies, antinuclear antibody (autoantibody). There will be a final follow-up visit one month after the week 10 investigations or one month after surgery. At this time, a physical examination will be conducted and blood samples will be obtained for haematology (full blood count), clinical chemistry (including urea, creatinine and electrolytes, liver function tests) and HSV-1 antibodies, antinuclear antibody (autoantibody). Adverse events and concomitant medications will be documented from the time of screening until the patient comes off study.

**Evaluation of foreseeable effects**

Treatment with OncoVEX(GM-CSF) will be scheduled to commence on the day on which chemoradiotherapy begins. Patients will be admitted to the outpatients department or a day ward for all injections of virus. The injections will always be performed in a side room where the trial subjects can be segregated from other patients for safety reasons. Before each injection, the ECOG score will be recorded. Vital signs (core temperature, heart rate, blood pressure) will be measured and recorded. The patients will be examined for the presence of active herpes labialis. If this is present, the injection must be delayed until healing occurs. Blood will be obtained for clinical chemistry and haematology. The patients will also be questioned about any symptoms that they are experiencing at the time and any medications they may be taking. Before the first injection, the node(s) that will be injected will be identified and allocated a tumour number. Where appropriate, the node(s) that will not be injected will also be identified and numbered. All nodes will be palpated and evaluated for injection site reaction prior to injection.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

| N/A |

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

| N/A |

For activities involving GMMs, describe the waste management measures which will apply to the activity

Maximum culture volume that could be released at one time is 100 ml. All waste (solid and liquid) is put through a standard steam pressure autoclave on site. The autoclave is maintained and monitored by Public Health Laboratory Services.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

The identification of proteins essential for cell cycle regulation.

**Recipient or parental organism**

- DH5x - Non-colonising disabled E. coli K12 derivative - Considered to be containment level 1.
- JM109 - Non-colonising disabled E. coli K12 derivative - Considered to be containment level 2.
- BLR (DE3)pLysS - Disabled BL21 derivative - Considered to be containment level 1.
- Rosetta - Disabled Turner derived strain - Considered to be containment level 1.

**Host/vector system**

Each of the DH5x, JM109, BLR (DE3)pLysS or Rosetta hosts will be transformed with a single vector contained within the lists below:

- Non-mobilisable vector series: pGEX, pGEM, pcDNA3.1, Bluescript, pACT, pBind, pGAD424, pGBT9, pFastBac, pYX or pRS.
- Mobilisation defective vector series: pET or pMAL.

**Origin & function**

DNA used in this project will be from human, mouse and yeast sources.

Products from such genes are expected to regulate the cell cycle.

**Evaluation of foreseeable effects**

The usage of non-pathogenic disabled and/or non-colonising bacteria in accordance with good microbiological practice, will limit human and environmental contamination, and as such pose a negligible risk to both. The provisional requirement for containment is therefore level 1.

The majority of genetic material used in this study has not been reported or believed to be oncogenic in nature, however, due to the cell cycle regulatory nature of such proteins, Prolifix wishes to assign containment levels relevant to oncogenes for all genes currently used within the company. Inclusion of such genes into the listed host/vector systems would not be expected to effect the host pathogenicity. However, classifying such genes as oncogenic, should raise the level of containment to level 2. All work will therefore be carried out in accordance with Schedule (8), table 1a, outlined in ‘A guide to the Genetically Modified Organisms (Contained Use) Regulations 2000’.

Worst case scenario - gut infestation of transformed bacteria.

The maximal viability of disabled bacteria in the gut is around seven days. During this period it is possible that the bacteria may express the cloned gene as a fusion protein. It is however unlikely that the proteins will be pharmacologically active, due to the inclusion of a fusion protein and/or the lack of post-translational modification in the chosen bacteria. It is also envisaged that the bulk of expressed protein will be present as insoluble inclusion bodies.
The choice of non-mobilisational and mobilisation defective vectors will make the risk of vector transfer to normal gut flora negligible. No genetic modifications undertaken will result in increased mobilisation status of the vector carrying the insert.

There is a theoretical risk of plasmid transfer to a contaminated human host, however the frequency of such an occurrence has been shown to be extremely low. Such a transfer would constitute a very low risk of human cell transformation, should the gene be expressed in the contaminated individual. However, since tumour formation arises as a result of a number of genetic modifications and gene deletions, the chance of tumour development in an infected host is negligible.

Fragments of genes will also be inserted into the same host/vector systems as detailed for whole genes. However, in these cases the risks involved would be expected to be that of the host (level 1), as the fragments will be less pharmacologically active and not capable of altering the pathogenicity of the host. However, such host/vector systems will be confined to containment level 2.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All bacterial pellets and bacterial contaminated material will initially be treated with Virkon at 1:200, which has been validated to give 100% kill against 22 E. coli strains when used in accordance with the manufacturers instructions. All waste will then be autoclaved in a routinely calibrated autoclave.

Bacterial supernatant resulting from bacterial culture centrifugation will be treated with Virkon at 1:200 in accordance with the manufacturers instructions, which will then be disposed of via the laboratory sink.

**Is an emergency plan required according to regulation 20?**

- [ ] Y

If yes, tick to confirm that it is attached to this form

- [ ] N

**Tick to confirm that you have attached a risk assessment to this form**

- [ ] Y

**Tick if you are claiming exemption from disclosure for section of the risk assessment**

- [ ] N

### Please enter comments on the GM safety committee on the risk assessment

The Safety Committee were satisfied that the proposed level 2 containment procedures are suitable for the notified GMM work to be safely conducted at Prolifix.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Maximum culture volume released at one time = 100 mls.
Waste deactivated in 10% hypochlorite for 24 hours, then autoclaved within Cytogenetics Centre.
Validation and monitoring of deactivation: For each autoclave run, the type of waste is recorded together with temperature and time of that particular run (by chart recorder).

### Project Additional Information

**Purposes of the contained use**

The purpose of this work is to study the biological function of genes expressed in the human malaria parasite *Plasmodium falciparum*. Work is primarily focused on genes involved in development of the sexual stage (transmitted by mosquito) of the parasite, but also aspects of the biology of the asexual forms are of interest. Our main approach is the use of gene deletion but also tagging of certain genes is used to study their localisation. The long term objectives of the study are to develop new effective anti-malarial drugs to prevent human disease. Work may also be carried out on a rodent malaria species (*Plasmodium berghei*) which does not infect humans.

**Recipient or parental organism**

Our aim is to produce mutant malaria parasites which are deficient in specific signal transduction molecules and are consequently unable to develop into specific life cycle stages. These organisms will therefore be attenuated to a degree and less viable.
Plasmodium falciparum is the most serious form of the malaria parasites to infect humans. In non-immune individuals, infection with the parasite can be fatal if not treated with drugs. The organism is therefore used under ACDP category 3 conditions at the LSHTM. There are several effective, safe drugs available which clear infection rapidly. Should an increase in resistance to a particular drug occur, alternative drugs with different mechanisms of action could be used. The chances of infection arising from the laboratory, however, are extremely low and would only result from injection to the organism directly into the blood stream.

Our experiments involve deletion or tagging of specified genes which usually results in decreased viability (or no change in viability) of the organism. It is therefore highly likely that infection with the unmodified organism would be the worst possible scenario. In other words, the modified organism is unlikely to be more hazardous than the wild type. Person to person infection does not occur. Transmission can only occur via an infected Anopheles mosquito which is maintained under strict laboratory conditions (controlled temperature, humidity and feeding) for 7-10 days. Infective malaria parasites can only survive in the blood stream or in sealed flasks containing human blood under strict conditions. It would therefore be impossible for the parasite cultures to come into contact with a mosquito.

**Host/vector system**

The plasmid vectors we use in these experiments which result in gene deletion or tagging are maintained by selective drug pressure, but are quickly lost on removal of the drug. Integration events maintain parts of the plasmid backbone which are responsible for propagating the plasmid in attenuated laboratory bacteria (under containment level one conditions).

**Origin & function**

Genes encoding green fluorescent protein used to study localisation of plasmodial proteins are obtained from commercial sources. Drug selectable marker genes are from heterologous sources for example the rodent malaria parasite species P. berghei.

The majority of the studies in our lab focus on enzymatic components of signal transduction pathways to gain an understanding of what controls progression of the parasite from one stage of its life cycle to another. Genes encoding these enzymes are amplified from P.falciparum itself by PCR.

**Evaluation of foreseeable effects**

The experiments that we will perform will attempt to produce forms which cannot develop into specific life cycle stages. In this way we hope to discover the genes which control the processes. Production of such forms would clearly reduce virulence.

It is highly likely that experiments will result in genetically modified organisms that are less virulent than the unmodified forms. In the extremely unlikely event that modified organisms had unexpected effects on drug sensitivity, several different types of malaria drugs are available which have different mechanisms of action (and targets in the cell). It is only in malarious areas of the world with high levels of malaria transmission, where a patient could be infected with multiple different clones (with resistance to more than 1 drug) of the organism, resistance to drugs is a problem. In the lab, infection with even 1 type of malaria parasite is an unlikely event.

When working with P. falciparum all necessary precautions are taken to avoid becoming infected with the organism. This is the case whether or not it has been genetically modified. It is extremely difficult to get infected in the lab because sharps objects are not used in a malaria culture lab. If suspected infection did occur then diagnosis could be quickly carried out and the necessary drug or drug combination prescribed. Infection would be quickly cleared and would not recur. The specified of human malaria parasite which recur cannot be cultured in the laboratory.

Since sharps are excluded from malaria culture labs, stab wounds should not occur. If they were to occur whilst using the organisms, diagnosis and appropriate drug treatment would be applied. The LSHTM is the home of the malaria reference centre where advice is given to people all over the world on which drugs to take and so local expertise is available.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste containing the organisms is decanted directly into a 10% solution of chloros and left there until the next morning before autoclaving even though contact with the solution will kill the organisms instantly. Malaria parasites are extremely sensitive to culture conditions. Even a slight rise in pH of the culture medium will kill them. Spillage is treated with a 70% ethanol spray which kills the organisms immediately. Solid waste is placed directly into autoclavable bins lined with bags. These are sealed and autoclaved following recommended procedures for ACDP category 3 containment. Autoclave tape indicates that the process has occurred. In all cases 100% killing is achieved.

Project Ref 654/01.3

Date Ackn'd 21/02/2001

Date Project Ceased

CU2 Project Title GENETIC TRANSFORMATION OF TRYPANOSOMA CRUZI AND LEISHMANIA

Class 3

Non-GMM Consent Granted yes

Culture Volume Class 3-4 upto 100 ml
The purpose of this programme of work is to study gene function in the related insect transmitted protozoan parasites Trypanosoma cruzi and Leishmania, particularly in relation to drug-resistance and infectivity. GM techniques are used to investigate genes encoding components of the oxidative defence system, the major surface glycoproteins, components of intracellular signalling pathways, and the major cysteine proteinase. Other experiments involve tagging parasites with marker genes to study subcellular localisation, immunological processes and mechanisms of sexual reproduction. The long term aim of this work is to develop better approaches to chemotherapy and vaccine design by gaining a greater understanding of parasite biology at the molecular level.

T. cruzi (the causative agent of Chagas' disease) is designated ACDP category 3 and Leishmania sp. (causative agents of visceral or cutaneous leishmaniasis) as category 2 or 3 depending on the sub-species. At LSHTM we use category 3 facilities for all Leishmania work. The experiments undertaken fall into 3 main types; those that could potentially result in gain of function (over-expression of endogenous genes or complementation) or a loss of function (gene knockout) or those that are likely to be neutral (expression of marker genes such as those encoding as firefly luciferase or green fluorescent protein). In gene knockout experiments the resulting recombinant organisms are likely to be deficient in some aspect of infectivity. Phenotypes associated with overexpression of components of the oxidative defence system (eg peroxidases) could include increased drug resistance, although this has not been observed. Complementation experiments are carried out on organisms that are attenuated or otherwise deficient in a defined function. In this case GM procedures are unlikely to produce an organism more hazardous than the wild-type.

The major risk associated with this programme, irrespective of the GM procedures, is infection of the worker. This risk is minimal if category 3 guidelines are followed. Infection with these parasites can only occur via broken skin or mucosal membranes. In addition parasites do not survive desiccation, are not free living and are not transmissible by any known insect vector in the UK. For these reasons the chances of environmental damage arising from this work can be regarded as remote or non-existent.

The overexpression experiments are performed with specific episomal vectors (pTEX, pcosTL) that are not maintained in T. cruzi or Leishmania in the prolonged absence of selective drug pressure. Gene deletion experiments are performed with linear DNA molecules that only function after integration into the parasite genome.

The genes used as drug-selectable markers are those that confer resistance to G418, hygromycin, phleomycin and puromycin. These bacterial genes were obtained from commercial sources.

Genes encoding red and green fluorescent proteins are used to investigate subcellular localisation in T. cruzi and Leishmania. Those encoding firefly luciferase and bacterial chloramphenicol acetyl transferase (CAT) are used for markers of gene expression in transfected parasites. Expression of mammalian ovalbumin in Leishmania
Donovani and T. cruzi is used as a marker for antigen processing.

Studies of oxidative defence in Trypanosoma cruzi involve modulating the expression of superoxide dismutase and thiol dependent peroxidases. The role of these enzymes in protecting the parasite from reactive oxygen species is being studied. Components of the adenylyl cyclase signal transduction pathways and members of the WD40 family are being investigated to determine their function in life-cycle regulation. Cruzipain, the major cysteine proteinase on the surface of T. cruzi has been postulated to have a role in host cell invasion and differentiation. This is being investigated by gene-knockout.

**Evaluation of foreseeable effects**

Most experiments (eg gene deletion) will result in genetically modified organisms that are less virulent or infectious than wild-type. Other procedures involving the expression of marker genes, as outlined above, are unlikely to affect the virulence phenotype. Some procedures, such as those involving expression of components of the T. cruzi oxidative defence system, may result in parasites with increased resistance to the drugs nifurtimox and benznidazole. However this outcome can also be achieved using more classical methods such as growing parasites in increasing concentrations of the corresponding drug.

Over-expression of proteins that have a role in regulatory events could enhance the ability of culture from T. cruzi epimastigotes (the non-infectious insect form of the parasite on which most GM experiments are performed) to develop an infectious metacyclic phenotype. In non-transfected cells of the X10/6 or CL Brener strains with which we work, typically 5-10% of the cells will develop into metacyclics after 12 days in culture. With other strains however, values of 70-80% are observed, a figure unlikely to be exceeded by recombinants of the X10/6 or CL Brener strains.

The control measures used when handling these organisms are in accordance with ACDP guidelines. All work is carried out in a category 3 containment laboratory with a class II microbiology safety cabinet. To prevent contamination stringent requirements including the wearing of goggles, gloves and face masks are implemented. As a matter of course, each worker is serologically tested every six months and advised that they should not act as a blood donor. These measures are designed to eliminate, as far as possible, the chance of accidental infection of laboratory workers. The chance of further spread can be regarded as extremely remote.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All cultures and waste materials are treated in situ by immersion in chloros (a powerful bleach), and then autoclaved. Culture flasks/vessels are treated with 70% ethanol, then chloros, then autoclaved. Each of these steps results in 100% killing. Autoclaves are monitored for temperature and pressure. Autoclave tape confirms treatment.

02/03/2022
Purposes of the contained use

The purpose of this is to generate or use available reporter gene mutants of Streptococcus pneumoniae, Pseudomonas aeruginosa and other respiratory pathogens to follow their uptake and handling by the innate immune system. In other experiments the genes that encode proteins on the bacterial surface which interact with innate immune proteins will be deleted. The long term aim is to understand of mechanisms of early resistance to infection.

Recipient or parental organism

S pneumoniae, Burkholderia cepacia, Pseudomonas aeruginosa, Klebsiella pneumoniae, Haemophilus influenzae are category 2 organisms. They will be derived from antibiotic susceptible isolates. For example the S pneumoniae strains 3 and 6B used in experiments will be penicillin susceptible. Experiments involving reporter genes
are extremely unlikely to alter virulence. In all cases so far reported this has provided to be the case. In gene knock-out experiments the resulting organisms are likely to be deficient in some aspect of infectivity. Complementation experiments in which the deleted gene is added back will be required if a "knock-out" phenotype is obtained. This is unlikely to generate an organism more hazardous than the wild-type.

Host/vector system

Deletion experiments will be accomplished with vectors incapable of autonomous replication in S pneumoniae or similar recipient organisms. Transformation results from integration by homologous recombination and selection is based on chloramphenicol resistance. Standard treatments of pneumonia have to assume that S pneumoniae is a potential cause and recommendations are a macrolide or doxycycline, or a newer fluoroquinolone for mild disease with little risk. A macrolide or extended spectrum cephalosporin or coamoxiclav is recommended for more severe disease or risk (Infectious Disease Society of America (2000) [ Bartlett et al (2000) Clin Inf Dis., 31, 347].

Origin & function

The aim of this project is to study the immune response to S pneumoniae, Ps aeruginosa, B cepacia, K. pneumoniae and H. influenzae which are respiratory pathogens. The reasons for examining this range of organisms is that they are bound by proteins of the innate immune proteins. It is the function of these proteins that we wish to test. This will be aided by the generation of a modified form of these bacteria expressing reporter genes green or red fluorescent protein or luciferase.

Deletions of genes that code for bacterial surface proteins or genes that code for enzymes that synthesise bacterial surface carbohydrate will generate bacteria which would typically have altered adherence properties or capacity to evade immune systems such as complement. In specific cases mutants would be generated that no longer interact with innate immune proteins such as C-reactive protein. There is no evidence that this or other such changes makes bacteria more virulent. Examples of this might be genes responsible for capsule formation in S pneumoniae. In the case of Ps aeruginosa an as yet unidentified gene that generates a protein of 35 kD would be deleted to generate a mutant that did not interact with innate immune proteins. These can be used to confirm the role of specific components of the innate immune response. Mutants will be used in vitro and in vivo experiments of resolving infection to examine immune response.

Evaluation of foreseeable effects

Reporter genes, GFP, RFP and luciferase have been used in many other systems. They have not been found to have toxic effects either on the modified organism or following introduction into a mammalian system. Examples include GFP in S pneumoniae [Kadioglu et al, (2001) FEMS Microbiol Lett 194, 105-10; ]; Luciferase in S pneumoniae [Francis et al., (2001) Infect and Immunity, 69, 3350] or GFP in Pseudomonas aeruginosa [Bloemberg et al., (1997) App and Env Microbiology, 63, 4543]. Gene deletion will be expected to have a neutral or negative impact on virulence. This should be reversed to wild type virulence on complementation (eg pneumolysis or autolysin in S pneumoniae; Berry et al., (1992) Microb Pathog 12:87-93). In another example of 126 deletion mutants of S pneumoniae, 36 were as virulent as the wild type and all others showed reduced virulence [Polissi et al., (1998) Infection and Immunity, 66, 5620]. Resistance is conferred by antibody to capsular types in normal individuals and absence of capsule renders the organism avirulent. K pneumoniae deletion mutants of surface structures [Regue et al (2001) J Bacteriol. 193, 3564-73] show reduced virulence. Examples of this are also available for H influenzae [Humphries and High, (2002) FEMS Immunol Med Microbiol 34;221-30]. Genes knocked out will be surface proteins and enzymes involved in synthesis of capsid structures.

Genetically modified organism will be grown at small scale always less than 1 litre. The organisms will be harvested by centrifugation in sealed buckets. All containers and other materials will be cleaned with ethanol and chloros and autoclaved. Both the laboratory for in vitro work and in vivo work are suitable for category 2 ACDP work as defined in that criteria. All waste is disinfected and autoclaved.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All cultures and waste are treated with chloros at the work bench and then autoclaved. Culture flasks will be treated with chloros and then autoclaved. All waste from mouse work will be autoclaved or incinerated. Autoclaved tape checks for the treatment and autoclaves are regularly monitored for efficiency.

Historical Significant Changes

Historical Date of Additional Info 08/05/2006 - centre also carrying
This proposal is an extension of a project for which we already have HSE permission to genetically modify the malaria parasite Plasmodium falciparum and the rodent malaria P. berghei (GM654/01.2). Here we propose to transmit genetically modified Plasmodium to Anopheles mosquitoes in the laboratory. Our main areas of interest are those genes involved in signal transduction and metabolism. To determine whether a specific Plasmodium gene of interest is essential for transmission to mosquitoes, it is necessary to delete this gene from the parasite genome and test for infectivity. Parasites are transfected with plasmid vectors containing a drug selectable marker by electroporation and genetically modified parasites are selected in the presence of the corresponding drug. Gametocytes (the transmissible sexual blood forms of the Plasmodium life cycle) are cultivated in vitro before feeding to female Anopheles mosquitoes to establish infection. The mosquitoes are then maintained at 24 degrees C and 75% relative humidity for ten 10 days and dissected to assess oocyst numbers in their midguts. Alternatively, after 14 days their salivary glands are examined for the presence of sporozoites. These experiments will allow us to determine which Plasmodium genes are essential for transmission to mosquitoes. This will define and validate new targets for transmission blocking drugs and vaccines.

P. falciparum causes the most serious form of malaria in humans that can lead to cerebral malaria or severe anaemia and can be fatal if left untreated. The organism is therefore maintained under ACDP category 3 containment at the LSHTM. The P. falciparum strain (3DT) that we routinely modify genetically is sensitive to all currently used anti-malarial drugs. If in the unlikely event that infection of laboratory personnel occurred or was suspected, drug treatment would be quick and effective. The 3D7 strain is currently being used worldwide to infect large numbers of volunteers in vaccine trials. Those not protected by experimental vaccines are readily treated and make a full recovery. P. berghei infects only certain rodents and cannot infect humans and is covered by local ACGM guidelines and does not require HSE notification. Therefore the majority of this document will deal with the human pathogen P. falciparum.

To our knowledge there is no instance of accidental P. falciparum infection in a UK laboratory. However, GM parasites causing an accidental infection in humans would be resistant only to the compound used for drug selection in vitro. This is usually pyrimethamine or an analogue (WR99210) but also neomycin and blasticidin can be used. Drug treatment of accidental infections would be quick and effective due to the availability of a range of antimalarial drugs (with distinct molecular targets) such as chloroquine, mefloquine, quinine, artesunate/artemether, and atovaquone/proguanil. Drug resistance in the modified parasites would not be a problem because of the drugs already available that could be used to treat accidental laboratory infections.

We propose to infect Anopheles mosquitoes with genetically modified P. falciparum parasites that have had a gene deleted. The genes of interest are thought to play an essential role in transmission to mosquitoes. If this is the case, then they would be expected to be less viable than unmodified parasites and attenuated to a degree. It is extremely unlikely that deletion of a gene would result in increased infectivity or virulence. It is more likely that infection with the unmodified organism would be a worst scenario.

Plasmid vectors are first constructed in various commercially available non-colonising E. coli strains (JM109, XL1Blue and XL10Gold, Stratagene) under ACGM containment level 1. These strains are considered as non-pathogenic for humans and other animals. The plasmids are based on the pUC series and are non-mobilisable. The plasmid vectors contain a drug selectable marker (usually a pyrimethamine-resistant human dihydrofolate reductase gene, but also neomycin phosphotransferase and blasticidin deacetylase genes can be utilised) whose expression is controlled by flanking P. falciparum sequences (usually calmodulin and heat shock protein 86). The plasmids are introduced into malaria parasites by electroporation and genetically modified parasites are selected under drug pressure. Integration by single crossover recombination results in incorporation of the plasmid backbone into the genome of the GM parasites. Integration by double crossover results in incorporation of only the drug selectable marker expression cassette. This part of the work has previously been given HSE permission (GM654/01.2). In experiments involving P. berghei,
Transfections can be carried out using linear DNA fragments comprising only the drug selection cassette flanked by around 0.5kb of the gene of interest.

### Origin & function

Genes encoding drug selectable markers are from heterologous sources such as human and the rodent malaria parasite P. berghei. Promoter and termination sequences are derived from P. falciparum and P. berghei. Reporter gene 'tags' such as Green Fluorescent Protein are obtained from commercial sources. The majority of work will be carried out on P. falciparum genes involved in signal transduction and metabolism, particularly in relation to development of the sexual (transmissible) stages of the parasite life cycle.

### Evaluation of foreseeable effects

These experiments are designed to produce GM P. falciparum that are unable to infect Anopheles mosquitoes. In this way we hope to identify genes that play an essential role in transmission of malaria parasites to mosquitoes. In the majority of cases, GM parasites will have no change or reduced capacity to infect mosquitoes. It is highly unlikely that the GM parasites will be more hazardous than the unmodified organism. Any accidental infection could be rapidly diagnosed and drug treated with one of several anti-malarial drugs available.

When working with P. falciparum in the laboratory, all necessary precautions are taken to avoid becoming infected with the organism. It is extremely difficult to get infected in the lab because sharp objects are not used in the culture lab. In this proposal we intend to infect mosquitoes with these GM organisms and so there is an additional risk of infection to laboratory workers. The safety precautions are dealt with below. It should be re-emphasised however that there is no reason to suspect that the GM parasites will be more hazardous than the unmodified organism. Neither modified nor unmodified P. berghei will have any affect on humans.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

A new Specific Code of Practice is in the process of being implemented relating to the handling of Anopheles mosquitoes infected with human malaria in the newly refurbished secure insectories and associated ACDP category 3 laboratory at the LSHTM. Relevant components are detailed below and will be rigorously applied to mosquitoes infected with genetically modified P. falciparum. Mosquito colonies of several genera, including Anopheles vectors of malaria, are held at LSHTM. Only guaranteed pathogen free stocks are routinely held. Any infected insects are always maintained under high security conditions in dedicated insectories. Facilities and working practices in the secure insectories are designed to meet containment level 3 equivalent guidelines to ensure safety of both workers and the public. The bite of a sporozoite positive infected mosquito could result in transmission of malaria. A female mosquito having taken an infective feed requires a minimum of 10-15 days at tropical temperatures before oocysts rupture and sporozoites migrate to the salivary gland. The relatively short longevity of female mosquitoes makes the percentage living long enough to become infective relatively low, and life expectancy post-infective short. Moreover, the developing malaria parasite within the mosquito is more sensitive to sub-optimal temperature and humidity than the mosquito itself. Unless multi-drug resistant strains are involved, rapid diagnosis, successful treatment and recovery are normally assured.

Risk of Infection

Risk to secure insectory users:

The bite of a sporozoite-positive infected mosquito could result in transmission of malaria. Prevention of mosquito release is a high priority and strictly regulated. Diagnosis and treatment is relatively straightforward. Use of multi-drug resistant strains of malaria is restricted. All users of the facility are suitably trained in entomological and parasitological techniques.

Risk to external individuals:

Whilst the tropical malaria vectors used are unable to establish populations under normal British environmental conditions, anyone bitten by an infective mosquito escaping from the secure insectory could develop malaria. To reduce this risk, the secure insectories have an interlocking double-door system. The doors to the insectory anti-room will only open singly, only one of the 3 at any one time. There is an "insect-o-cutor" flying insect killer installed within the anti-room. In reality, the risks are higher in individuals in close proximity to the secure insectory, in particular, the associated malaria culture laboratory which has restricted category 3 access. An infective mosquito escaping both the secure insectory and the associated culture lab would theoretically be able to bite any other member of school staff/student or visitor in the vicinity. The likelihood of an infected mosquito leaving the building and biting a member of the public is very low as environmental conditions in all but the hottest/most humid British summer are unfavourable to the Tropical mosquito species used. Risk of prolonged survival (more than a few days) is very low. Colonisation in the UK is not possible with
the species used. Malaria would be easy to treat but diagnosis may be less rapid in those not directly connected to the secure insectory and associated malaria culture laboratories.

Procedures for use of secure insectory

Access to the outer malaria culture laboratory is containment level 3 with restricted access. All procedures in the culture laboratory to be in accordance with the Specific Code of Practice for Plasmodium falciparum.

Access to the inner secure insectories is restricted. Only approved and suitably trained individuals have access through the interlocked double-entry doors which are controlled by key-code. The entry code will be changed regularly. The facility is fully sealed and insect-proof with double insect-proof mesh on all vents and sealed door.

Mosquitoes are only permitted entry into the secure insectory in either "infection pots" (cardboard pots and sealed netting covers) or netting cages within secondary sealed containers. The exact number of insects taken into the room will be recorded in the designated experimental log along with name of the Principal Investigator of the project and signature of the responsible person handling them. The log will hold details of the procedures taking place along with exact numbers of insects killed during, or on completion, of each experiment. The number of dead insects in the final log entry must correspond with the number originally taken into the facility as a further check to monitor accidental release. Any discrepancy between log total and actual number of insects in experimental pots must be immediately reported to the Departmental Safety Supervisor (or their deputy) and both doors to the insectory to remain sealed until a detailed check has been made. All inner surfaces of the secure insectory are white and unobstructed to facilitate easy detection of mosquitoes. Should a mosquito be released without verification of its subsequent capture/destruction, the Departmental Safety Supervisor will arrange for the facility to be sealed for a period of 30 days, or the use of a fast-acting non-residual pyrethrum insecticide to disinfect the facility.

No viable insects are permitted to be removed from the secure insectory. Before removal all mosquitoes will be disabled by either a) removal of both wings or b) total immersion in PBS or 70% alcohol. Chilling or anaesthetising are NOT suitable means of disabling insects as they may subsequently recover, although they may be used prior to other methods such as wing removal.

All dead insects, culture media and contaminated waste shall be treated as Cat 3 and disposed of as per code of practice for P. falciparum (10% Chloros overnight followed by autoclave). Items for re-use, such as glass feeding chambers, shall be left overnight in 10% Chloros followed by rinsing with 70% alcohol or autoclave to sterilise.

All users of the secure insectory in possible contact with insects must be under health surveillance with Occupational Health due to risk of sensitisation/allergy.

In conclusion, transmission of both GM and non-GM Plasmodium falciparum is routine in several laboratories worldwide and is already carried out in central London by our colleagues at Imperial College. We intend to follow the above stringent safety procedures to avoid release or infection with modified or unmodified P. falciparum.

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Protocol for working with Plasmodium falciparum.
Malaria parasites are extremely sensitive to changes in culture conditions; a slight rise in pH of the culture medium will kill them. All work with P. falciparum will be conducted in a designated containment level 3 laboratory. Actual manipulation of the organism within such labs is to full Cat 3 level although as there is no risk of airborne infection with this parasite. Consequently, there is a reduced necessity for airflow regulation in such areas. As the most significant risk of infection is via inoculation, the use of sharps and glassware is restricted wherever possible.

Waste disposal
Liquid waste containing P. falciparum is decanted directly into a 10% solution of chloros (10,000 ppm available chlorine) in autoclavable pots in class II cabinets. These are stored overnight before autoclaving even though contact with this solution would kill the organisms instantly. Solid waste is placed directly in autoclavable bins which are sealed and autoclaved in a newly built adjoining facility unit following recommended procedures for ACDP category 3 containment.
Decontamination and disinfection
The disinfectant of choice for P. falciparum is 10% chloros. Ethanol can also be used to decontaminate surfaces. All infective material, cultures and plasticware must be inactivated in 10% Chloros overnight before being transported in Cat 3 boxes to be autoclaved. Surfaces will be routinely cleaned with 70% ethanol after use. As there is no airborne risk from this parasite, laboratory fumigation is not considered necessary. Fumigation of safety cabinets would not inactivate parasites in culture spills so much be supplemented or replaced by surface decontamination with Chloros or ethanol.

Spillages and accidents
Spillages of infective material shall be contained to prevent their spread then treated with sufficient 10% Chloros to inactivate the material. Larger spills should be treated with undiluted Chloros and left overnight. All materials used to clean up a spillage will be autoclaved. All spillages and accidents must be reported to the Departmental Safety Supervisor as soon as possible. There must always be a fresh supply of 10% Chloros readily available in case of spillage or accidents.

Disposal of mosquitoes infected with P. falciparum
Mosquitoes that have been exposed to infectious blood containing P. falciparum mosquitoes are stunned immediately after feeding by chilling or ethyl acetate followed by physical immobilisation to render them non-viable (wings removed). After counts (of oocysts on day 10 or sporozoites on day 14) have been made, the mosquitoes are killed by prolonged freezing and placed in sealed containers within autoclavable bins. The remainder of the infectious blood is placed immediately into a pot 10% chloros overnight prior to autoclaving.

Health surveillance
All workers using P. falciparum must be registered with the Occupational Health Advisor. All individuals will be familiarised with the symptoms of malaria infection and a ready supply of suitable drugs for treatment will be available. Health records of personnel involved in this work will kept by the LSHTM for 40 years.

Please enter comments on the GM safety committee on the risk assessment

This submission has been prepared in consultation with LSHTM Biological Safety Officer for work involving genetic modification. He agrees that the GM parasite work should be category 3.

The submission has also been prepared in consultation with the Departmental Safety Supervisor for the Department of Infectious and Tropical Diseases. Information and advice on general safety procedures, but specifically relating to infected mosquitoes has been given.
The purpose of this work is to study the biological function of genes expressed in the human/simian malaria parasite Plasmodium knowlesi. We plan to transfet P. knowlesi parasites with plasmid DNA (vectors) containing all or part of selected P. knowlesi genes as well as plasmids to facilitate Cas9 nuclease mediated genome editing. The products of these genes are important in the maturation of the parasite, the invasion process and/or development within the invaded erythrocyte. Our main approach is the use of gene deletion or tagging of genes to determine protein localisation and function. The target genes will be those that encode proteins located on the surface of mature parasites or the infective stage of the parasite (the merozoite), proteases or signalling proteins important in parasite development and merozoite release, organelle specific proteins and factors involved in the parasite's metabolism. All of these are involved in maturation of the parasite, the invasion process or developmental events in the invaded erythrocyte. Understanding the role and function of these genes will contribute towards new intervention methods to treat or prevent human disease, including both vaccines and anti-malarial drugs.

P. knowlesi is a protozoan parasite of the phylum Apicomplexa, and is one of the agents responsible for causing human malaria. It is normally found south-east Asia where it is transmitted as a zoonosis from macaques via
mosquitoes of the Anopheles spp. It is possible to cultivate the asexual and sexual erythrocytic stages in tissue culture in vitro in donated human or macaque red blood cells. Whilst P. knowlesi can cause severe disease in humans (up to 7% of hospitalised cases develop severe disease) there is currently no evidence of drug resistance, in either field or laboratory strains, and there are several safe and effective drugs available which clear infection rapidly. Should an increase in resistance to a particular drug occur, alternative drugs with different mechanisms of action could be used. The chances of infection arising from the laboratory, however, are extremely low and would only result from the injection of the organism into the blood stream. The majority of our experiments involve deletion or tagging of specified genes which usually results in decreased viability (or no change in viability) of the organism. It is therefore highly likely that infection with the unmodified organism would be the worst possible scenario. In other words, the modified organism is unlikely to be more hazardous than the wild type.

Some experiments such as the introduction of nucleotide polymorphisms found in field isolates or replacement of endogenous genes with alleles from the closely related parasite P. vivax, may result in an increase in resistance to particular drugs or an increase in invasion efficiency in certain blood types. It is however important to note that malaria parasites maintained in vitro over extended time periods, such as those used in these studies, have a reduced virulence level when reintroduced to a host. Indeed, in recent work with collaborators we have demonstrated that these lines are initially avirulent when injected into rhesus macaques (a highly permissive host) and require multiple passages to regain wild type virulence levels. Thus, it is extremely unlikely that the parasites produced will be more hazardous than field isolates.

Person to person infection does not occur. Transmission can only occur via an infected Anopheles mosquito which is maintained under strict laboratory conditions (controlled temperature, humidity and feeding) for 7-10 days. Infective malaria parasites can only survive in the blood stream or in sealed flasks containing human/macaque blood under strict conditions. It would therefore be extremely unlikely for the parasite cultures to come into contact with a mosquito.

</tr>
</tbody>
</table>
b) To 'tag' the gene with a marker in order to detect and study the function and activity of the gene product.
   1) This can be done using sequences for GFP or related proteins cloned into a part of the target sequence in order to produce a fusion protein that can be detected by optical techniques such as fluorescence.
   2) Similarly this can be done using short peptide epitope tags (e.g. HA, cmyc, FLAG, Ty1 tags). Gene products modified with these tags can be readily detected using immunochemical techniques.

   c) Further functional studies on the protein by gene modification or truncation, or replacement with orthologous genes of other species of malaria parasites. This will help to determine the parts of the molecule that are required for its biological function. These truncated genes can also be tagged as in b).

   d) To overexpress genes of interest which are otherwise of low abundance (as episomes or integrated into a nonessential site of the parasite genome)

Origin of vector: pHH, pARL, pLN, pSSPF, pXL-BACII-hDHFR and pHTH plasmid series. These contain selectable markers (drug-resistance) and regulatory or mRNA stabilising elements (5' and 3' malaria UTRs).

Evaluation of foreseeable effects

The main concern when considering this project is that P. knowlesi is pathogenic to man. A code of practice (COP) is already in place (attached) to minimise accidental infection of laboratory workers. The parasite can only be transmitted through the mosquito secondary host or by direct contact with infected blood by injection or through cuts. No P. knowlesi work on these premises involves exposure to sharps such as needles or broken glass. The one exception to this rule is the use of glass slides for microscopic examination of parasite cultures, as no suitable alternative is currently available. All parent parasite lines have been screened for drug susceptibility and are known to be sensitive to chloroquine. Where this characteristic is likely to be altered by experiments, several other malaria drugs are available with different mechanism of action (and targets within the cell). In the unlikely event that a person is believed to have been accidentally infected, treatment with the appropriate anti-malarial drug will commence immediately. Infection would be quickly cleared and would not recur. P. knowlesi infections, unlike other species, cannot result in recurrent cases of malaria. The LSHTM is the home of the Malaria Reference Laboratory where advice is given to people all over the world on which drugs to take and so local expertise is available.

All used equipment and reagents are decontaminated before leaving the containment 2 tissue culture room (see COP) and thus no live modified parasite will be discarded and transported out of the room. If it is necessary to transport live parasites to another facility, e.g. for centrifugation or microscopy, the parasites are sealed (in a centrifuge bottle or sealed coverslip on a microscope slide) and transported in a sealed container. Work with P. knowlesi is undertaken under containment 2 guidelines and modification of the parasite does not pose greater risks of infection to humans. These modified paraSites will not be put through the mosquito cycle and thus there is no risk that they will enter the wild population. Most of the genes under study are unique to P. knowlesi and thus it would be difficult to transfer these genes to another organism.

The parasite will only be cultivated in vitro; no insect transmission will be undertaken. The work with live parasites is carried out in a sealed room so there will be no possibility of mosquitoes being infected and infecting the wider populace. The parasite is not viable ex vivo except in the special in vitro culture conditions used.

All parasite material is rendered non-infectious with reagents such as phenol or detergents before further analysis is carried out in non-category 2 containment facilities. Safety protocols for such reagents will be adhered to.

The vectors contain drug-resistance cassettes. The drugs most used in the parasite selection process (WR99210, neomycin, blasticidin and puromycin) are not in general use for the clinical treatment of humans or animals and thus the problem of drug resistance appearing in the human/animal population is not an issue. Less often, pyrimethamine is also used in selection of transgenics. Resistance to this drug in wild parasite populations is widespread, and it is not recommended for use alone for either prophylaxis or treatment of acute malaria. Ampicillin is used in the cloning of the vector in the bacterial host. This antibiotic has been in widespread use in standard laboratory molecular cloning protocols for a number of years and there have been no recorded cases of drug resistance linked to using these
vectors in bacteria.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The work with live parasites is required to be performed under Containment 2 facilities. However, once the parasite has been treated with denaturing reagents, such as phenol or detergents, the parasites are non-infectious and can be worked with under Containment 1 facilities.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Refer to Code of Practice, attached. All lab ware (pipettes, flasks, tips and tubes) and culture waste (spent growth medium) are treated by immersion in 10% chloros and left there until the next morning, even though contact with the solution will kill the organisms instantly. The medium is rendered colourless, or dark brown precipitates (parasitised erythrocytes) are observed as the killing process occurs. Solid waste is placed directly into autoclavable bins lined with bags. These are sealed and autoclaved at 121°C for 15 minutes before being discarded. Autoclave tape indicates that the process has occurred and there is 100% destruction of infectious material after these treatments. Spillages within the safety hood are treated with 70% Ethanol, which kills the organisms immediately. In the unlikely event of a large spillage outside of the safety hood, the spillage is contained with tissue paper and left overnight in 100% chloros. Small spillages are cleaned with 10% chloros and tissue paper which is disposed of in autoclave bins.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

This proposal and associated risk assessment and codes of practice were reviewed by the committee (by email circulation) and the committee is content with the submission.

Investigation into the effects of disruption/inhibition of energy metabolism on Mycobacteria tuberculosis and related organisms

Mycobacterium tuberculosis (Mtb) still claims more lives each year than any other bacterial infection and with the sharp increase in drug resistance in recent years, global tuberculosis (TB) control programs are under threat. The discovery of bedaquiline (BDQ) revolutionized the treatment paradigm for patients suffering from multi- and extremely drug resistant TB (MDR/XDR-TB). BDQ inhibits the ATP synthase of Mtb and has also brought mycobacterial bioenergetics and energy metabolism to the forefront of TB research, as well as new anti-TB drug discovery efforts.

Combination targeting of Mtb's energy metabolism is not completely understood. There is, however, a growing body of literature showing the significant rearrangement of Mtb's central carbon metabolism under BDQ treatment, to compensate for the rapid decrease in ATP levels. Less is known about the rearrangements induced by other energy metabolism targeting compounds, eg. Q203 and CFZ which especially target oxidative phosphorylation (OXPHOS). Better insight into these metabolic rearrangements driven by BDQ and other compounds would allow us to design drug regimens for rapid and synergistic killing of Mtb, via the complete shutdown of Mtb energy metabolism.

The aim of this project is to develop new research tools and methodologies to finely dissect Mtb energy metabolism, to identify metabolic vulnerabilities and aid in the development of new therapies for TB.

Our goal is to accelerate the development of novel anti-TB drug regimens via the establishment of in vitro/in vivo omic approaches to Mtb's energy metabolism pathways, and thereby determine the optimal targets which will help us in developing potential drug combinations for rapid and synergistic killing of Mtb. This will also help us to understand aspects of target-based drug antagonisms that might arise. It is also important to determine the effect of metabolic target inhibitors that have on the host metabolome to mitigate possible host side effects and to explain possible in vitro vs. in vivo regimen efficacy differences.
**Mycobacterium tuberculosis** (strains; H37Rv, H37Ra, Erdman) and Clinical Isolates (1st line drug susceptible only)
- Mycobacterium bovis BCG
- Mycobacterium kansaii
- Mycobacterium avium complex
- Mycobacterium marinum
- Mycobacterium smegmatis MC2-155
- E.coli lab adapted strains (for instance JM109, DH5α)

### Host/vector system

Vectors include:
1. pRH2502
2. pRH2521
3. pTIGC
4. pUC
5. pSMT3
6. pCRISpathbrick.
7. pTigC

**CRISPR-Cas and CRISPRi vectors** express an inducible Cas9/dCAS9 enzyme and a scaffold RNA sequence into which a small guide RNAs (sgRNA) can be inserted.

pTigC is a dual reporter fluorescent construct to enable GFP and TurboRed expression of viable and metabolically active bacteria.

Plasmids and similar constructs will contain origin of replication (COIEI, Ori E and pAL500), promoter for the gene of interest and an antibiotic resistance marker. No resistance marker will be used that could potentially alter the susceptibility of the GMM to 1st line antibiotics against infectious disease. These vectors will be non-mobilisable.

### Origin & function

The following list of genes is indicative of those to be investigated. Related genes may also be targeted.

#### Energy Metabolism pathways:
1. ctaE-qcrCAB – cytochrome bc1-aa3 (terminal oxidase)
2. cydABCD – cytochrome bd (terminal oxidase)
3. ndh-ndhA – NADH dehydrogenase (type II)
4. nuoA-J - NADH dehydrogenase (type I)
5. atpACDEFHG – ATP synthase
6. sdhABCD – succinate dehydrogenase
7. menABCDEGH – menaquinone biosynthesis
8. glcB - malate synthase
9. icl1/2 - isocitrate lyase (1 and 2)
10. pca - pyruvate carboxylase
11. pykA - pyruvate kinase
12. aceE - pyruvate dehydrogenase (E1 component)

#### Efflux pathways:
13. mmpL/S5 – efflux pump (multi-drug efflux, contributes to bacterial tolerance)
14. Rv0678 – mmpL/S5 regulator (efflux regulator)

**Luminescent reporter genes:** e.g. lux AB (from Firefly or Gaussia princeps), lux ABCDE (full operon) from Photobacterium luminescens or Vibrio harveyi

**Fluorescent reporter genes** - e.g. green fluorescent protein (GFP), red fluorescent protein (RFP), mCherry

**Selectable markers:** hygromycin (hyg) (not clinically used), kanamycin, spectinomycin, zeocin (not part of first line therapy), sometimes in combination with the sucrose and
the SacB enzyme as a counterselectable marker.

**Evaluation of foreseeable effects**

All strains with modified energy metabolism are expected to have moderate or severe growth defects. Gene inserts are restricted to reporter genes and are not expected to alter or contribute strain virulence or fitness. Efflux KO strains are expected to be more susceptible to anti-infective treatment. All selective antibiotic resistance markers will not contribute to front line antibiotic treatment resistance. There is no evidence that any of the GMM used in this project will be any more hazardous than parental strains.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Class 3 GMO:
All liquid waste infected with mycobacteria are discarded by adding surfanios disinfectant (minimum final concentration of 5%) and leaving overnight before placing in a clear autoclave bag and yellow rigid bins for autoclaving at a temperature of 134°C for 30 mins or 126°C for 20 mins depending on load. Autoclaved waste is then disposed of at a licensed facility.

All solid waste infected with mycobacteria will be placed in autoclave bags and rigid yellow bins, autoclaved and disposed of as above.

Class 2 GMO:
All waste is placed in clear autoclave bags and autoclaved, the waste is then placed in yelow/tiger striped bags and disposed of at a licenced facility.

Spillages are decontaminated with 70% ethanol.

Autoclaves are serviced bi-annually and validated and insurance inspected annually in accordance with LSHTM and manufacturers schedules.

Is an emergency plan required according to regulation 20? N

Please enter comments on the GM safety committee on the risk assessment
The GM Safety Committee discussed your new GM Class 3 Risk Assessment: LSHTM-0036.01: Investigation into the effects of disruption/inhibition of energy metabolism on Mycobacteria tuberculosis and related organisms.

The following discussion was recorded at the meeting:
* and * gave a brief description of the experiment.
* asked if they were planning to use MDR strains in the short term
* confirmed, not in the short term.
* requested this was removed from the GM sections of the Risk Assessment and can be added as a scientific change to the HSE if used in the future.
* questioned the Vacuuming filtration Technique in Section 1.2 and if this would release aerosols?
* explained this is being developed by *, it is in the very early stages and may not be used.
* queried with reference to comments submitted by * (section 1.3: rooms) if the Flow Cytometry is fixed in the Imaging/FACs room or in the CL3 for CAT3 use only.
* explained further discussions on how that is used in the CL3 are required and * is updating this information for lab users.
* pointed out that if the Flow Cytometry 1.2. is fixed in the CL3 Lab we need to consider if anything be moved between CL2 and CL3
* suggested the risk assessment needed to be clear what is done in CL2 and CL3 and aerosol risk in CL2
* added the COP and SOPs will help clarify this in more details.
* asked about if only lab strains mentioned in section 2.2.3 and is there would be a potential issue with complementation and over expression.
* explained that they would not be working with CRISPR-1 that affect complementation
* suggested they added this information in section 2.31 to make it clear.
* queried how will you contain work in CL2?
* answered there will be done in separate labs and work done separately
* asked about their use of sharps in section 2.3.8
* answered there were no plan to use them, but a handy resource.
* suggested to move to 5.8, and asked if sharps were used to dissect, in the BSF or main CL3 lab
* answered this is always done in the BSF
* added all infectious work is done in the MSC
* asked * how is the SOP managed
* answered they will be shared with GMSC. All pre-existing SOPs are being used and updated for this project.
* would like what disinfectants and deactivation, concentrations details to be included in the SOP also.
* queried if Class 1 is appropriate for this work (5.1)
* answered that although both give good operator protection, class 1 is less easily disturbed, the airflow is cleaner in a class 2 for sample protection.
* asked on behalf of * whether optimised fluorescent and bioluminescent reporter Mtb strains at LSHTM from the Gates imaging project will be used
* answered that they would use these as a handy resource and they fell within the remit of this GM project.

Please address the following amendments required:

After Section 1.3: The following declaration must be completed by the PI responsible for this project- ensure this section is completed.

Section 2: Ethics approval required
2.2:* needs spelling out in the first use
2.4.1: Remove the Downdraft tables technique from the risk assessment
4.11: most hazardous Procedure, performed in cat3 then on benches in CL2 (separate the work) also separate the Class 2 and 3 work throughout the form.
4.3: Units of the volumes should be added and checked throughout the form.
4.2-4.9: Routes of infection for all infectious agents should be included here.

Section 10: emergency procedures: Should be Bio Risk Manager, not BSO.
11.3: Electronic inventories samples needs to be mentioned here.

GM Classification: 3; Containment Level: 3
Consent: Approval from the HSE is required

For activities involving GMMs, describe the waste management measures which will apply to the activity

Waste which may contain GMOs is segregated from general laboratory waste and is transported to an autoclave within the same building in leakproof plastic containers. Solid waste is autoclaved for 30 minutes at 121 degrees C and then incinerated. Validation of autoclave function is provided by heat-sensitive detection strips, and by an internal pressure and temperature monitor.

Liquid waste (maximum 5L) is inactivated either by autoclaving for 30 minutes at 121 degrees C or using recommended disinfectants eg. Virkon (Antec International) at manufacturer's recommended dilution for a minimum of 24 hours, which has been validated by the manufacturer to achieve complete eradication of microorganisms. After sterilisation, liquid waste is released into public drainage system.

Maximum culture volume: 10 litres.

Waste deactivation
1. All culture media residues are autoclaved.
2. Surface decontamination and sterilisation of non autoclaved items with a 2% Virkon solution.
3. All dry wastes are disposed of as biological waste (in double yellow bags) and incinerated.

Validation of Method:
1. The autoclave is controlled via a load probe to run at 121 degrees C for 30 minutes (overkill cycle), the largest volume of waste ie. slowest to heat up, is probed, to ensure correct temperature for all vessels is achieved.
2. Contact culture tests have previously been performed (over 5 processes) on surfaces to confirm decontamination - no positive results.
3. Routine audits of the waste disposal route and contractor.

Monitoring of Method:
1. At the end of each autoclave cycle a chart is produced, which is checked and entered into a log book. The probe is calibrated in the autoclave every 6 months to ensure correct temperatures are being achieved.
2. Contact culture tests will be repeated every 3 months.

### Project Additional Information

#### Purposes of the contained use

HIV-1, HBV and HCV virus gene sequences will be cloned and manipulated (typically by site directed mutagenesis) in order to express wild-type and mutant recombinant proteins in E. coli and baculovirus. These proteins will be used to obtain crystal structure information and to develop biochemical assays. Non-infectious molecular clones of HCV will be manipulated in plasmid vectors for the development of new phenotypic drug resistance assays. In addition, full length HIV-1 and HBV clones will be manipulated to produce specific mutations that confer drug resistance (ref. Schinazi, RF, Larder, BA, Mellors, JW. Mutations in retroviral genes associated with drug resistance: 2000-2001 update. Int. Antiviral News (2000) 6, 65-91) and these will subsequently be either transfected into human cell lines to generate recombinant virus. For HBV specifically the state of the art is the use of recombinant baculovirus vector (rather than transfection) whereupon productive viral replication ensues. Full-length drug resistant or wild-type forms of HBV genome will therefore be inserted into baculovirus transfer vectors prior to the construction of recombinant baculovirus expressing infectious HBV genomes. ALL FULL LENGTH HIV/HBV TRANSFECTION/INFECTION EXPERIMENTS WILL BE CARRIED OUT IN A BIOSAFETY CATEGORY 3 FACILITY.

#### Recipient or parental organism

Disabled E. coli hosts (JM109, XL-1 Blue, DH5a, TOP10), spodoptera cells (Sf9, Sf21) and human hepatoma cells (HepG2, Huh7).

#### Host/vector system

Non-mobilisable plasmid vectors based around pUC, pGEM will be used for prokaryotic work. Standard baculovirus transfer vectors eg. pBacPAK8 and pBR322 based eukaryotic vectors eg. ptetHBV for insect and mammalian cell expression respectively.

#### Origin & function

Pre-existing full-length HIV-1 and HBV clones will be used for site-directed mutagenesis to enable replacement of specific viral sequences from drug and antibody-resistant clinical isolates. These will be used to express variant forms of specific viral enzymes and for generation of phenotypically resistant virus. All cell culture related virus work will be carried out in a biosafety category 3 facility.

Pre-existing HCV clones containing 90% of the genome (ie. non-infectious) will be used to isolate and express specific viral enzyme functions and to generate artificial chimeric replicons. The system used involves transcription of recombinant clones and direct transfection of RNA into recipient cells. Chimeric replicons will represent replicons in which the wild-type sequence is replaced by the homologous region from a drug-resistant isolate of the virus. At no stage will any clones be used which have potential for infectivity and there will be no possibility of recombination since multiple replicons will not, at any stage, be transfected into the same cell.

#### Evaluation of foreseeable effects

All experiments using HCV vectors will be undertaken with incomplete genomic clones which are incapable of generating infectious virus. Expression of HCV viral gene products in both prokaryotic and eukaryotic systems is well-documented and is not associated with hazardous consequences.

Full length HIV-1 and HBV clones used in these studies could be accidentally administered, although no evidence exists to suggest that this would cause infection. All staff handling these clones will be vaccinated against HBV and ensured to have protective levels of antibody prior to initiation of experiments. In addition, all handling of live HIV-1 and HBV infectious material will be carried out in a designated Category 3 laboratory under strict operating procedures.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be de-contaminated by treatment with 10,000 ppm chloros (100% kill) and all solid waste will be autoclaved (100% kill).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The risk assessment was reviewed by the genetic modifications safety committee and was accepted as appropriate.

All liquid waste including growth media that has come into contact with GMOs is decontaminated according to local rules, using either 1% Virkon (final concentration, according to manufacturers instructions) or a concentrated perchlorite solution, prior to disposal down the drain. All culture procedures are considered small scale in that less than 10 L volumes are disposed of at any one time. All solid waste is placed in yellow clinical waste bins, which are sealed and incinerated within 24 hours of collection by an external waste disposal company.

Date of Significant Change

Project Additional Information
Purposes of the contained use

To study the role of the p53 pathway in cancer. Genes such as MDM2 have been implicated as critical molecules in this pathway and to study this we need to be able to efficiently deliver these genes (also non-oncogenic genes such as p53, MTBP, E-MTBP and Lac-Z will be expressed from similar viruses) to a range of cell types - particularly had to transfect cells such as mouse embryo fibroblasts (MEFs) and a range of pancreatic cancer derived cell lines.

Recipient or parental organism

E. coli XL-Blue are a K12 derivative strain and are not expected to survive outside of the laboratory. There is no evidence that these bacteria are pathogenic.

MEFs and other cell lines would not be able to survive outside of the laboratory environment. Retroviral vectors have generally been designated as ACGM category 1 except where the gene to be inserted is pathogenic or where the envelope is human tropic. We propose to create replication defective retroviruses with either rodent or human tropic envelopes. Retroviral vectors with these modifications are ACGM2.

Host/vector system

The three-plasmid system would require at least 2 recombination events to produce a single fragment of DNA that could encode replication competent retrovirus (RCR). Since there is little or no homology between the three plasmids a single recombination event is unlikely.

Origin & function

MDM2 (for example) is known to be an oncogenic protein. Retroviruses are also inherently potentially oncogenic because they are obligate mutagens: when the provirus is integrated into the host genome, it may at random be integrated into a site that causes inactivation of a tumour suppression gene. MTBP, E-MTBP and p53 induce cell cycle arrest (Boyd et al, JBC 2000). We will be inserting wild-type p53. As yet the roles of MTBP and E-MTBP, a deletion mutant of MTBP, are not completely known, although it has been demonstrated that MTBP causes G1 arrest and E-MTBP inhibits tumour cell growth more effectively in the cell lines tested than either MTBP or p53.

Retroviruses are obligate mutagens: when the provirus is integrated into the host genome this might occur at random into, for example, a tumour suppression gene.

Evaluation of foreseeable effects

Bacterial transformation - the transformed strain will be no more virulent or pathogenic than the original.

The three plasmid system used should ensure that the virus is not mobilisable.

We expect moderately high levels of expression of the transduced genes driven by the MuMLV LTR.

These replication defective viruses could infect human cells.

Retroviral production - a VSV-G envelope will be used to improve infectivity of the virus but only to produce replication defective viruses containing a non-oncogenic insert. We will test supernatants for evidence of RCR by infecting permissive cells with viral supernatant and then passaging cells. Supernatant from these cells will be screened at weekly intervals by re-inoculating these at >/= 1/10 dilution onto permissive cells. MDM2 can readily be detected by western blot. By inoculating double null (MDM2/p53 null) MEFs we can readily detect even very low levels of MDM2.

MTBP and E-MTBP can readily be detected by western blot. By inoculating p53 null cells (H1299) p53 can also be detected by western blot. Lac-Z can be screened by in-situ Beta Gal assay.

Retroviral production - we will use either an ecotropic or a VSV-G envelope. These do not by themselves increase the pathogenic traits of the retrovirus although the VSV-G envelope which will be used to improve infectivity of the virus (it is monomeric and therefore higher tides of more stable virus can be produced c.f. eco/ampho-tropic retroviral envelopes) does alter the virus host range to include humans and other mammals.

The retroviral vector will also contain the neomycin gene, which will result in resistance to G418. This would not be used as a treatment for laboratory-acquired infection.

The major alteration affecting likely harm will be the inclusion of a known oncogene (eg MDM2) into the retrovirus. This will create the risk of transfer of an oncogene into mammalian in particular human cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
After bacterial transformation, flasks will be decontaminated by the addition of fresh 10% bleach.

During retroviral production, once the producer cells have been transfected with the 3 plasmid components they will be considered potentially infectious. BSL2 precautions will be required. Experiments will take place in a laminar flow hood with the operator wearing a disposable surgical gown (near opening) with snug fitting surgical latex gloves worn over the elasticated wrists of the gown. Care will be taken so as not to produce aerosolisation of viral containing supernatants. Items of equipment exposed to virus will be soaked in 1% Virkon or 1% sodium hypochlorite or 10% bleach for 15 mins before removal from the laminar flow hood and then disposed of in the usual manner: ie all solid waste will be incinerated and all inactivated liquid waste will be disposed of down the sink. Once cells are no longer required for producing virus, they will be destroyed by adding fresh 10% bleach and leaving for 24 hours before disposal as liquid or solid waste whichever is most appropriate. All solid waste will be transferred to yellow clinical waste bins and sent to the RLBUH for incineration.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMSC considered the risk assessment and decided that the use of potentially oncogenic inserts means that this project is Class 2. The GMSC were content that the workers involved were aware of the risks and were technically capable of working at Class 2 level. The laboratories to be used are adequate for this work. As an additional observation it was noted that Class 1 work would take place alongside this Class 2 project. The GMSC requested that all work to be carried out in the laboratories alongside this class 2 activity should be carried out to CL2 standards.

02/03/2022
All laboratory waste is disinfected or autoclaved prior to disposal from the Unit. General, non-hazardous waste, such as paper towels, are placed in normal waste bags for disposal.

**Solid Waste:**
All solid waste is autoclaved prior to disposal. Waste is placed in an autoclave bag, which is then transported in metal buckets to the autoclave. Following autoclaving at 121°C for 15 minutes, the waste is collected and removed from site by a specialist waste contractor.

**Agar Waste:**
All agar-containing waste e.g plates, are placed in a separate autoclave bag from other solid waste which is double-bagged prior to transporting in a metal bucket to the autoclave. Autoclaving is carried out as above.

**Liquid Waste:**
All liquid waste containing biological agents is disinfected overnight in a hypochlorite solution by the addition of Haz-Tabs to a chlorine concentration of >500ppm, prior to disposal down the drains, with copious water flow to allow adequate dilution.

**Sharps:**
The use of sharps e.g. hypodermic needles, scalpels, etc. is minimised. If they are used they are disposed of in rigid plastic ‘Sharpsafe’ containers. When full, these are collected and removed from site by a specialist waste contractor.

CU2 Project Title
Production of a knock-out model of PINK-1 in human cell lines.

Consent Granted
Not Applicable

Project notified under transitional arrangements N
### Project Additional Information

#### Purposes of the contained use

Generation of PINK-1 gene knockout human cell lines in order to create a model for the study of Parkinson's Disease.

#### Recipient or parental organism

Human cell lines.

#### Host/vector system

- Human cell lines such as HEK293, SOAS2, human neuroblastoma cell lines and 197VM human neural stem cells (ReNeuron).
- JS4, a recA-derivative of E. coli MC1061, a disabled K12 strain.
- Phoenix ampho cells, a non-mobilisable derivative of HEK293, free of adventitious agents.
- Vectors: PSUPERretro-puro, PWZLneo EcoR(non-mobilisable), PWZLBlastF(non-mobilisable) and PWZLBlastFEcoR

#### Origin & function

64i nucleotide RNAi constructs designed to knockout PINK-1 expression (Sigma Genesis Ltd). EcoRI fragment of the murine cationic transporter from Julian Downward as pWZLneoEcoR, originally made by D. Conklin.

#### Evaluation of foreseeable effects

Human cell lines will have ability to be infected by murine ecotropic viruses. The gene function of PINK-1 could be knocked out if the PINK-1 RNAi sequences were transferred to a human organism. The consequences of this are not clearly known, although loss of PINK-1 function is thought to be the underlying mechanism in autosomal recessive Parkinson's disease and is therefore associated with neurodegeneration in humans.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

- No GM animals or plants will be produced.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

- No derogation required.

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- Liquid waste and plastic disposable pipettes are chemically decontaminated with either 10,000ppm Chloros or 1% Virkon, followed by incineration (solid material).
- E. coli contaminated solid waste (agar plates, tips, pipettes is autoclaved at 121 C for 20 mins, followed by incineration. Solid waste from tissue culture such as dishes, tubes and flasks are also autoclaved before incineration.
The risk assessment has been approved by the local GM Safety Committee and accepted at Class 2.

Please enter comments on the GM safety committee on the risk assessment

The risk assessment has been approved by the local GM Safety Committee and accepted at Class 2.

Project Additional Information

Purposes of the contained use

To generate and use stable producer cell lines that produce high titre replication defective amphotropic retroviruses to be used for the immortilisation of freshly isolated primary human cells.

Recipient or parental organism

JS4, a recA-derivative of E.coli MC1061 (a disabled K12 strain). PA371, a non-mobilisable second generation mouse amphotropic producer cell line; TEFLYA and RD cells, both derivatived from TE671 cells, non-mobilisable. Phoenix ampho cells, non-mobilisable derivatives of HEK293, and primary human somatic cells.

Host/vector system

SV40 large T antigen and mutants.
Human catalytic subunit of telomerase and human papilloma virus 16/18.
E7 and E6 gene; Polyoma virus T antigens and mutants; Adenovirus E1A and mutants.
P53 GSE fragment and full length ORF for cellular genes.

Origin & function

SV40 T antigen, the catalytic of human telomerase, HPV E7 and E6 proteins, Polyoma virus T antigens, Adenovirus E1A and p53GSE are all immortalising genes that have the potential to extend the proliferative life span of normal somatic cells.

Evaluation of foreseeable effects

No GM animals or plants will be produced.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No derogation required.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation required.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste such as dishes and flasks will be imersed in 1% Virkon for >10 minutes, followed by autoclaving and then inceration.
E.coli liquid waste is inactivated by treatment with 1% Virkon for >10 minutes.
Liquid tissue culture medium is collected into containers containing sufficient Virkon for final concentration of not less than 1% and left for >10 minutes.
E.coli solid waste (agar plates, tips and pipettes) is autoclaved followed by incineration.
Solid waste from tissue culture (tubes, dishes, flasks and pipettes) is autoclaved followed by incineration.

After autoclaving or chemical disinfection, waste is put into yellow clinical waste bags or containers, collected centrally and transported by an approved waste route for incineration.

Established inactivation procedures in molecular biology laboratories, giving effectively 100% kill.
Records of each autoclave run are made and held by the Safety Officer.
The risk assessment has been approved by the local GM Safety Committee and accepted as Class 2.

*Page 10485 of 15326*
### Project Additional Information

#### Purposes of the contained use

Human neurons expressing either full-length normal or mutant Htt will be generated using STROC05 and 197VM neural stem cell lines transduced with pMSCV-based retroviral constructs. They will then be differentiated into neurons by the removal of key growth factors, which can then be used to set up co-cultures of primary human monocytes and macrophages isolated from Huntington's disease patients and control subjects to investigate neuronal-myeloid cell interactions.

The retroviral vectors to be used contain the full-length sequence of the HTT with either a normal (15Q) or mutant (138Q) CAG repeat length encoding the wild-type and mutant Htt proteins respectively. DNA prepared from E. coli bacterial cultures is packaged as a retrovirus by co-transfection into either HEK293 or BOSC23 cells with separate gag/pol and env packaging co-factor plasmids.

#### Recipient or parental organism

- E.coli K12 strains (eg DH5α, TOP10)
- HEK293T cells (human cell line for retroviral packaging)
- BOSC23 cells (human cell line for retroviral packaging)
- U937 cells (human lymphoma cell line)
- STROC05 cells (human striatal neural stem cell line)
- ReNcell 197VM cells (human neural stem cell line)

#### Host/vector system

- **pMSCVpuro-10366-Htt15Q**
- **pMSCVhyg-10366-Htt138Q**
- gag/pol+ & env plasmids

#### Origin & function

The inserted genetic material will encode the full-length human HTT (huntingtin) sequence (with either 15 or 138 glutamine repeats in exon 1 of the gene). Expression of Htt with an expansion in the number of glutamine residues in its exon 1 (>36Q; mHtt) is thought to be the key pathogenic determinant of Huntington's disease, an inherited neurodegenerative disorder in humans. Htt is widely expressed in human tissue, but its function is unclear. The protein has no sequence homology to other proteins, but it is known to regulate gene expression and may have a functional role in cytoskeletal anchoring or transport of mitochondria or vesicle trafficking. We intend to study the cellular effects of expression of htt in human neural stem cells.

#### Evaluation of foreseeable effects

mHtt expression in neurons is thought to be the underlying cause of Huntington’s disease in humans; the inserted gene product could be harmful to health in the event of its expression in the CNS. Viruses packaged from the pMSCV vector are capable of infecting human cells itself, but are unable to replicate because the viral structural genes are absent. Integrated proviruses are capable of being mobilized by superinfection with helper virus, but the likelihood is low because the cells to be used are not known to produce helper viruses and transduced cells will be cultured in isolation from other cell cultures.

The GMOs themselves are not able to establish infection and maintain propagation in humans or other species. Cultured mammalian cells, transduced or otherwise, are unable to survive outside of the laboratory environment and...
are not infectious. The E. coli bacterial strains are disabled, lack the necessary pathogenic mechanisms required to cause infection and will only have limited survival in the environment. Retroviral particles could conceivably infect cells of other species, resulting in the transfer of genetic material. Effects due to expression of target genes would be unlikely, but they could result in disruption of host genes depending on the site of insertion. Such effects would be limited by the inability of the virus to subsequently replicate. The absence of any potential of direct contact and the lack of survival of any of the proposed GMOs limits the potential effects on other species or the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be decontaminated with 1% Virkon for a minimum of two hours, prior to disposal with plenty of running water down a suitable designated sink. The degree of kill using 1% Virkon is 100%, as per supplier's information, and this procedure is well established in molecular/cell biology laboratories. Solid waste such as culture dishes and flasks will be decontaminated with 1% Virkon overnight. Solid waste from mammalian cell culture is autoclaved prior to incineration; this is a standard Departmental procedure for those areas in which Containment level 2 work is carried out. Following chemical disinfection (and autoclaving), all solid waste waste is put into yellow clinical waste bags or containers for collection in designated yellow bins and transport by an approved waste disposal route for incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The project was approved by the GM 669 committee. This work poses no risks to personnel or the environment when local rules and decontamination procedures are practised in conjunction with the engineering and administrative control measures for work at containment level 2.

02/03/2022
Expression of mouse prion protein in eukaryotic systems

To employ eukaryotic expression systems to produce the normal cellular form of the murine prion protein. The advantage of using such systems is they enable proper protein folding, disulphide bond formation, and posttranslational modifications such as signal cleavage, proteolytic cleavage, or/and glycosylation that we cannot obtain when using prokaryotic systems.

Recipient or parental organism

Insect cells: Spodoptera frugiperda 9 (Sf9)
Mammalian cells: Chinese hamster ovary (CHO), human embryonic kidney cells (HEK.293)

Host/vector system

pTriEx, pFastBac HT and other commercially available vectors to be used as necessary for baculovirus expression
PTriEx, pSV and pCMV series of vectors and other commercially available vectors to be used for expression in mammalian cells.
**Origin & function**

The vectors used are standard commercially available ones and are designed to allow the expression of the gene of interest. The mouse prion gene may be cloned from mouse cDNA or synthesised by commercial gene synthesis.

**Evaluation of foreseeable effects**

None of the strains of GMMs used are able to survive outside of a laboratory. The baculoviruses used are polyhedrin negative and have a much reduced survival time owing to increased susceptibility to dessication and ultraviolet light. The vectors used will confer antibiotic resistance to antibiotics commonly used in the laboratory, namely ampicillin, blasticidin, zeocin or hygromycin. Although it is theoretically possible that the prion protein could misfold from the cellular form to the disease associated form that could be harmful to health, even were this highly unlikely event to occur, the very low infectious titre of any material in combination with the transmission barrier for prions between mouse and human makes detrimental impact on human health extremely unlikely. The prion protein has been expressed by other laboratories with no reports of changes to the pathogenicity of the host.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

| Solid waste will be treated with 20,000 ppm sodium hypochlorite for one hour, or where this is not suitable then sodium hydroxide to a final concentration of 1 M will be used. GMM material will then by autoclaved prior to disposal by incineration. | Is an emergency plan required according to regulation 20? N |
| Liquid waste will be treated with 20,000 ppm sodium hypochlorite for one hour, or where this is not suitable then sodium hydroxide to a final concentration of 1 M will be used prior to disposal down the drain. | If yes, tick to confirm that it is attached to this form N |
| These represent established protocols for the inactivation of prions and should achieve a 100% "kill rate" | Tick to confirm that you have attached a risk assessment to this form Y |
| | Tick if you are claiming exemption from disclosure for section of the risk assessment N |

**Project Containment**

The project was approved by the GM committee. This work poses no risks to personnel or the environment when local rules and decontamination procedures are practiced in conjunction with the engineering and administrative control measures for work at containment level 2.
### Project Additional Information

**Purposes of the contained use**

**Recipient or parental organism**

**Host/vector system**

**Origin & function**
Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Is an emergency plan required according to regulation 20? [ ]

If yes, tick to confirm that it is attached to this form [ ]

Tick to confirm that you have attached a risk assessment to this form [ ]

Tick if you are claiming exemption from disclosure for section of the risk assessment [ ]

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

The maximum volume to be cultured will be 50 litres. Waste is deactivated by heating to 121 degrees C, either in an autoclave or in the germination vessel. Smaller quantities (including spills) are deactivated by addition of a suitable disinfectant and/or autoclaving. All methods have been validated. Methods are monitored by sampling post sterilisation.

Deactivation of waste is achieved through addition of a 1% solution of Virkon (Antec International, Sudbury). This solution is active against all bacterial, viral and fungal agents. Following addition of Virkon, liquid waste is flushed down the sink with copious amounts of water. The maximum culture volume to be disposed of at any one time would be 100 ml.

Validation of the deactivation method has been carried out by incubation of the cells with and without added Virkon followed by incubation at 37 degrees C. No cells were apparent upon microscopic examination when Virkon had been added.

Monitoring of the deactivation process is by microscopic examination following Virkon addition.

Likely maximum culture volume - 2 litres, in 4 x 500 ml batches.

Deactivation method -
1. Culture media collected into single flask.
2. Bleach (15% sodium hypochlorite, 5% anionic detergents) added to final concentration of 1% v/v
3. Culture media incubated at room temperature for 10 minutes to allow deactivation
4. Media disposed in normal waste water, with 10 volumes of water added.

Validation of deactivation method - before disposal of inactivated culture media, 100 ul sample taken and spread on LB Agar, and incubated overnight at 37 degrees C. No colonies should be present.

Monitoring of deactivation method - visual checks to be performed by workers, with double-checking performed by Biological Safety Officer. Disposal events to be recorded in Bacterial Culture log book, and countersigned by Biological Safety Officer.

---

**Project Additional Information**

**Purposes of the contained use**

To culture established containment level 2 cell lines (from the ATCC global bioresource centre). Insect and mammalian expression of exogenous non-hazardous genes for expression analysis and purification. Non-hazardous reporter genes will be used to test new transfection reagents. RNAi will be transfected into cell lines to downregulate target genes. Nucleic acid will be extracted from the cells. All contained experiments will involve research and development leading to the production of molecular biology research kits and reagents.

**Recipient or parental organism**

The following ATCC cell lines and Invitrogen cell lines will be used (ACTT number in brackets). Containment level 2 cells include 2983 (CRL-1573), COS-1 (CRL-1650), Hela (CCL-2). Containment level 1 cells include MCF7 (HTB-22), NIH/3T3 (CRL-1658), CHO-K1 (CCL-61), Jurkat (TIB-152), HepG2 (HB-8065), NIH/3T6 (CCL-96) and H15 (Invitrogen, UK) and SF9 (Invitrogen, UK).

**Host/vector system**

Not applicable, we will not be creating genetically modified whole organisms. Only using established cell lines grown in a monolayer and/or in suspension culture. We will transiently transfecting exogenous genetic material to these cell lines.

**Origin & function**

Green fluorescent protein, in the pACGFP1-N1 (BD Biosciences, UK) plasmid, Luciferase in the pGL4 vector (Promega, UK) and possibly other non-toxic reporter constructs will be transiently and stably transfected into cell lines including those mentioned in paragraph 1 of section 7. Expression levels will be manipulated using RNAi. Non-infectious chemical based transfection reagents will be analysed using these reagents. Green fluorescent protein, in the pACGFP1-N1 (BD Biosciences, UK) plasmid, Luciferase in the pGL4 vector (Promega, UK) and possibly other non-toxic reporter constructs will be transiently and stably transfected into cell lines including those mentioned in paragraph 1 of section 7. Expression levels will be manipulated using RNAi. Non-infectious chemical based transfection reagents will be analysed using these reagents.

The human gene Dicer (Accession NP 085124), the Celery gene Cell (Accession AF237958), the human gene DCP2 (Accession AY135173), RNAse inhibitor (human) will be expressed in bacterial and baculovirus expression systems. The recombinant proteins will be purified using FPLC.

Mouse hybridoma cell lines expressing non-hazardous immunoglobulin proteins will be grown and immunoglobulin purified by FPLC.

**Evaluation of foreseeable effects**

RNAi technology will be used to temporarily downregulate several non-essential cellular genes in the cell lines mentioned in section 7.

All of the work mentioned above will be carried out in a class 2 safety cabinet with appropriate waste disposal methods.
Potential hazards to human health are minimal. No hazards to human and/or environmental health have been published for the genes mentioned above.

RNAi transfection will be transient and specific to non essential genes, eliminating health risks for accidental human administration.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

During the maintenance and manipulation of cell lines waste will include live cells in culture media. The waste cells will be treated with Virkon (Anachem, UK) disinfectant following manufacturers protocols, autoclaved and then discarded into sewage system. This method of disposal has been validated to shown no viable organisms survive. The validation is on going to show no viable organisms survive the disinfection treatment.

Is an emergency plan required according to regulation 20?

Please enter comments on the GM safety committee on the risk assessment

Satisfied that the work proposed is of low risk to humans or the environment and that the containment and disposal procedures outlined are sufficient for the work described above.

The work is not involved in creating organisms which are viable outside the laboratory. No genes toxic to humans will be expressed. The majority of the work involved in this project is routine cell culture and does not involve genetic modification.

purposes of the contained use

The purpose of this work is in the in vitro and in vivo validation of potential antifungal targets through the production of either deletion mutants or conditional expression strains. Additionally, techniques for epitope tagging and the construction of promotor reporter constructs will be used, both for target validation purposes and in the evaluation of potential drug effects.

Recipient or parental organism

The ACDP class Candida albicans in hazard group 2. The organism may be considered a commensal of the normal flora of the digestive and genital tracts. Pathogenicity is essentially a result of changes in the hosts defence mechanisms; thus Candida can be termed an opportunistic pathogen. Candida infections (Candidiasis) range from superficial mucosal infections to serious life threatening systemic infections in the severely immunocompromised host.

Host/vector system

Vectors for transformation into C. albicans will have been constructed in E. coli. In all cases the vectors transformed into C. albicans will be integrated into the hosts genome via homologous recombination.

Origin & function

The majority of the work proposed involves the manipulation and alteration of existing C. albicans genes (for example gene deletions or promotor replacements). This will involve the targeted insertion of DNA into specific locations in the C. albicans genome. The inserted DNA will contain an auxotrophic marker for the selection of transformed cells (eg the C. albicans URA3, ARG4, HIS1 OR ADE2 genes). Foreign DNA present in the inserted DNA will include:

1. S. typhimurium hisG - present as a direct repeat around the C. albicans URA3 gene for gene deletions and subsequent recycling of the marker.
2. Tetracycline transactivator (itself a fusion between E. coli Tn10 tetR and viral VP16 activation domain) to regulate expression of C. albicans genes.
3. Reporter genes such as B-galactosidase, luciferase and yeGFP.
4. The E. coli plasmid backbones (pUC and pBR based) that the insert is contained on will in some cases become inserted into the genome.

Evaluation of foreseeable effects

The genetic modifications proposed would not be expected to increase the virulence of the GMO above that of the parental organism. Therefore the risk to human health can be considered equivalent to that of dealing with the parental organism. The only potential hazard, in healthy individuals, of handling Candida albicans would be from exposure resulting in a mucosal infection. However the risk of this hazard being realised, even if exposure occurred, would be low.

All the genetic modifications proposed would be non mobilisable therefore the risk of transfer of sequences to other micro-organisms is remote. The GMO’s produced would be potentially as fit as the parental organism and may therefore be able to persist in the environment if a breach in containment occurred. However, the GMOs would have no selective advantage. The risk to the environment is therefore very low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste is double bagged in autoclave bags and collected daily. These bags are stored in 60L plastic boxes for a maximum of 2 days before autoclaving. Waste is autoclaved for 15 minutes at 134 degrees C. The autoclave is serviced and calibrated every 3 months to ensure continued effectiveness.

Liquid waste is inactivated by chemical treatment. Culture vessels and supernatants are decontaminated with a 1:50 dilution of TRIGENE (Medichem International) and are...
left for 16 hours prior to disposal down laboratory sink. Glassware is then rinsed and washed by dishwasher, plastic ware is further autoclaved prior to disposal. This method has been validated to give 100% kill.

The major point to emphasize from the risk assessment is that none of the modifications proposed would be expected to increase the virulence of the GMO above that of wild type Candida albicans. Nor would the modifications impact on the sensitivity of the strain to currently used anti-fungal therapies. The assignment of the activities to class 2 is due to the risk posed by the recipient organism itself.

Please enter comments of the GM safety committee on the risk assessment
Protein misfolding in cells contributes to important diseases ranging from neurodegenerative disorders, such as Parkinson's Disease, to metabolic diseases such as type II diabetes mellitus. A common theme of these conditions is the accumulation, or the threat of accumulation, of misfolded and unfolded proteins that contribute to attrition of key cellular functions. Cells have an elaborate apparatus for recognizing and responding to the threat of protein misfolding, known as the Unfolded Protein Response (UPR). This apparatus has numerous components that promote fitness in the face of the aforementioned threat. Surprisingly, however, the machinery of the unfolded protein response also has components whose activity, in certain contexts appear to enhance the deleterious effects of misfolding [Ron, 2007 #3066].

Rational therapeutic interventions aimed at the pathophysiology of protein misfolding requires the establishment of experimental systems in which the threat of protein misfolding is imposed and the activity of various components of the response to misfolded proteins (the Unfolded Protein Response) are either inactivated or enhanced. Because the clinically-relevant burden of protein misfolding is experienced disproportionately by terminally-differentiated, non-dividing cells, the tools for constructing the aforementioned experimental system must be geared to manipulating gene expression in non-dividing cells.

HIV1-based lentiviruses, modified for safety and gene delivery have emerged as powerful tools for effecting changes in gene expression in terminally-differentiated cultured cells. Therefore, authorization is sought to use such vectors to enforce expression of genes encoding known misfolding-prone proteins in cultured mammalian cells and at the same time alter the cellular response to the misfolded proteins by introducing activated alleles, dominant loss-of-function alleles or shRNA inactivating alleles of genes encoding components of the unfolded protein response. By comparing the response of cells with diverse perturbations in the unfolded protein response to comparable burdens of protein misfolding we can begin to identify components of the unfolded protein response whose activation or inactivation (by pharmacological means) may be of therapeutic benefit in combating diseases of protein misfolding.

7.
Recipient or parental organism

The lentivirus is produced by co-transfecting the packaging plasmid mix and the transfer vector into human HEK293T cells.

The recipient cells will be various murine and human cells in culture.

Both the recipient cells and the producing cells are fastidious and non harmful. They cannot colonise the environment nor cause disease by colonizing human or animal hosts and thus are classified as Hazard Group 1.

Cells from human volunteers, which may be used in this project are uncharacterised and although themselves present no greater risk, may contain adventitious infectious agents and therefore will be handled at CL2 (risk assessment under COSHH regs).

Host/vector system

The pGIPZ and pTRIPZ lentiviral package systems and derivatives thereof like the pLenti6_V5 of invitrogen or the delivery vehicle for Sigman mission shRNA (pLKO.1–Puro) to be used were described by Kappes et al. 2001; Kappes et al. 2003; Wu et al. 2000; Wu et al. 2001 and developed by Open Biosystems. This new generation of lentiviral systems has been used extensively throughout the world and includes important features designed to enhance its biosafety:

The reverse transcriptase (RT) and integrase (IN) genes were split from the Gag-pol polyprotein-encoding gene and are provided in trans from two separate plasmid. The ENV function, provided by the VSV glycoprotein, is introduced in trans by a third plasmid and the only packaging signal is on the transfer plasmid that lacks important HIV genes. Thus, the probability of a series of recombination events that produce a replication-competent virus that can spread in and between hosts is vanishingly small. In the context of this project, the main risk is the consequence of primary infection of humans by high titre viral stocks (see below).

The lentivirus is produced by co-transfecting the packaging plasmid mix (four plasmids for gag, pro, RT, IN, VSV-G, rev and tat expression) and the transfer vector into the HEK293T cells. Particles are harvested over a period of 48 to 72 hours after transfection and are stored at -80C. If titres are low, the virus can be concentrated by ultracentrifugation. Transduction of recipient cells follows. These will be tissue cultures of primary human or other mammalian cell lines.

Origin & function

The shRNA sequences to inactivate genes in the host are derived from the host cell genome. They will be directed to genes that function in protein folding in the endoplasmic reticulum and the response to protein misfolding (examples include: chaperone-encoding genes like Erdj3, enzymes involved in oxidative protein folding like ErO11 and ErO11b, components of the unfolded protein response like Em1 or Eif2aK3). These genes are neither oncogenes nor tumor suppressor genes and thus accidental infection of a human host by these viruses is likely to have no greater consequence than infection by an "empty" virus.

To activate components of the unfolded protein response we will use cloned cDNA that will be over-expressed. As the genes in question are neither oncogenes nor tumour suppressor genes and thus accidental infection of a human host
by these viruses is likely to have no greater consequence than infection by an “empty” virus. To promote misfolded protein stress we will express known misfolding-prone mutants versions of secreted proteins, for example, Ins2 with a mutation that prevents proper disulfide bond formation. As the secreted proteins are not oncogenic and in fact harbour mutations that promote endoplasmic reticulum retention the are either inert or enfeeble the targeted cell, the risk of oncogenic transformation by a virus harbouring a misfolding prone protein are diminished compared to the empty virus. A theoretical exception to this principle is a retrovirus encoding a prion-forming protein, which could in an extremely fanciful scenario set up a prion infection in the host. Therefore, proteins with a potential to undergo prionization (e.g. mutant PrPsc) will not be used.

Following is a table of the specific genes:

- **List of mutant genes encoding proteins that misfold in the endoplasmic reticulum and that will be expressed from lentiviral vectors:**
  - Mouse Ins2C96Y: Encodes insulin, a hormone normally present in serum
  - Human PLAPC121S: Encodes placental alkaline phosphatase, an enzyme normally present in tissue
  - Human SERPINA1PiZ: Encodes a misfold serum protease inhibitor

- **List of genes encoding proteins that function in the processing of protein folding in endoplasmic reticulum or in the response to the stress of protein misfolding in the endoplasmic reticulum.** The expression of these genes will be inhibited by shRNA-containing lentiviral vectors or the genes will be over-expressed by lentiviral vectors:
  - Mouse or human Hspa5, Hsp90b1, ERDJ (1-6): Encode chaperones that folds proteins in the ER
  - Mouse or human PDI1, Erp44, Erp57, Erp72: Encode disulfide isomerases/transfereases than function in oxidative protein folding in the secretory pathway
  - Mouse or Human Ero1l, Ero1lb, Qsox1, Qsox2: Encode protein disulfide oxidases involved in protein folding
  - Mouse or human EIF2AK3, ERN1, ATF6: Encode detectors of unfolded protein stress in the endoplasmic reticulum

**Evaluation of foreseeable effects**

RNAi inactivation of most genes involved in protein handling in the endoplasmic reticulum or in the response to misfolded proteins, will enfeeble cells and render them more sensitive to misfolded protein load. Even those genes that encode proteins that are known to reduce the fitness of cells experiencing high levels of misfolded protein stress are not known oncogenes (example CHOP/Ddit3) Thus the risk associated with viruses encoding such genetic elements is predicted to be less than that or empty lentviruses. Gain-of-function of unfolded protein response components, which may have a benefit in the special circumstances of severe protein misfolding is unlikely to translate to a survival benefit for accidentally-transduced cells, let alone serve as an oncogenic event. Thus the risk posed by gain-of-function vectors is likewise less than that of empty viruses. Lastly, as noted above, the expression of a misfolding-prone protein is severely enfeebling to cells and part from the theoretical establishment of a new strain of prions the risk posed by such vectors is less than that of the empty ones.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none applied for
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All disposable culture/lab ware will be autoclaved and incinerated. Culture fluids will be treated with 1% Virkon for 0.5 hours, autoclaved and disposed to drains. Recyclable lab ware will be soaked in 1% Virkon for 16 hours. Bench/cabinet surfaces will be wiped down with 10% trigene and 70% ethanol. Spills will be sprinkled with Virkon powder/trigene and vernagel to solidify. Alternatively disinfected liquid waste will be gelled with vernagel in sealed containers labelled with autoclave tape and taken to the autoclave room for transfer to the incinerator. All solid waste will be collected in double autoclave bags, sealed with autoclave tape, labelled with the users name and the room number and will be autoclaved and incinerated.

Project Additional Information

Purposes of the contained use

Retroviral and lentiviral delivery of a selection of human genes to cytotoxic T lymphocytes (CTLs) to assess their role in regulating secretion of stored proteins required for the immune effector functions.

Recipient or parental organism

FOR CONSTRUCTION OF RETROVIRAL VECTORS
K12 or B derivatives of E. coli will be used as bacterial cloning hosts to generate plasmid expression clones in readiness for expression within specified packaging cell lines. These are disabled hosts that cannot colonise the human gut and have a history of safe use. These hosts may be considered equivalent to ADCP hazard group 1.

FOR PACKAGING RECOMBINANT RETROVIRAL PARTICLES
The packaging cell lines are of human or murine origin, which are well characterised and authenticated and are obtained from commercial sources. Examples of packaging cell lines likely to be used are HEK293T cells (amphotropic) to generate lentivirus or PT67 to produce retrovirus. They can be regarded as low hazard for GM activities and as hosts are suitable for containment level 1 precaution.

FOR RECOMBINANT RETROVIRAL INFECTION:
Human primary lymphoid cells (eg CD8+ blasts or CTL) can be considered as especially disabled hosts and as such may be considered to be equivalent to ADCP hazard group 1 however the cells have the potential to contain adventitious agents and as such must be handled at containment level 2 under COSHH.

Host/vector system

Lentiviral expression plasmid pHRSINcPPT-SGVC containing 5' and 3' LTRs, packaging signal and Rev response element from HIV-1
p8.91 packaging plasmid containing Gag, pol, rev, tat from HIV-1
pMD-G envelope plasmid containing VSV-G envelope protein.

These three vectors are co-transfected into a packaging cell line to generate replication defective lentivirus. This lentivirus expression vector is self-activating as it carries a deletion in the U3 region of the 3'-LTR. Upon integration into the host genome, the 3'-LTR is copied to the 5'LTR, rendering it transcriptionally inactive and therefore unable to generate a functional retrovirus. The HIV-1 Lentivirus based expression vector lacks any of the packaging genes (gag, pro, pol, vif, vpr, tat, rev, nef, eng), and requires the use of a packaging cell line based on HEK293 (ie HEK293T) and 2 other plasmids which provide gag, pol, rev, tat and VSVG. The HIV-1 elements in the lentivirus expression vectors (ie 5' and 3' LTRs and the psi packaging signal) allow packaging of the transgene itself. Therefore the number of genes from HIV-1 has been reduced to 4, ie gag, pol, rev and tat. Genes encoding the structural and other components required for packaging the viral genome are separated onto three plasmids. All three plasmids have been engineered not to contain any regions of homology and each other to prevent undesirable
recombination events that could lead to the generation of a replication-competent virus.

The packaging genes are provided by co-transfection of packaging vectors p8.91 (provides gag/pol, rev and tat) and pMD-G (provides VSV-G envelope) into the HEK293T cell line along with the expression vector. By using this enhanced 3-plasmid system, virus particles are produced that can infect human and mouse cells, but are replication deficient and therefore cannot be transmitted from one cell to another. Although the two packaging plasmids allow expression in trans of proteins required to produce viral progeny (eg gal, pol, rev, env) in the 293T producer cell line, none of them contain LTRs or the psi packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced. The rev response element allows for rev-dependant nuclear export of unspliced viral mRNA. The HIV-1 env gene is replaced with a Vesicular Stomatitis Virus envelope.

Overall then, only Lentiviral particles, which are unable to replicate, but which can deliver the gene of interest, are produced. Therefore the main risk is in their ability to deliver genetic material into a host genome and as described above, this is unlikely to pose any significant risk.

Retroviral expression plasmid pMSCV containing 5’ and 3’ LTR and packaging signals. The LTR is from murine stem cell viral and prevents transcriptional suppression in embryonic stem and embryonal carcinoma cells. Therefore driving high levels of constitutive expression. Retroviral expression plasmid pLEGFP-C1 containing 5’ and 3’ LTR and packaging signals from Moloney murine leukemia virus.

Either of the above 2 plasmids will be transfected into PT67 packaging cells to generate replication defective retrovirus. PT67 packaging cell line is derived from NIH3T3 cells, which have subsequently been stably transfected with 2 plasmids that contain the gag/pol and env gene. This cell line produces viruses, which are dualtropic and have a broad mammalian host range. Split genome design lowers the possibility of generating replication-competent virus. Only the expression plasmids contain the LTRs and the packaging signals and therefore the generated virus contains one of the structural genes rendering it replication defective.

As with the lentivirus the main risk with retroviruses is their ability to deliver genetic material into the host genome. This is unlikely to pose any significant risk.

Origin & function

Mammalian proteins implicated in a specialised lymphoid secretory pathway such as:
- Rab27a (studies have shown that transgenic mice expressing Rab27aGFP are healthy)
- Rab geranylgeranyltransferase: a rab modifying enzyme that adds a geranyl geranyl group to Rab27a and 4 other Rab proteins.
- Rab7 and RILP: Both involved in moving lysosomes along microtubules.
- Tubulin-GFP: forms microtubules along which lysosome move
- Actin-GFP: forms the sub-cortical cytoskeleton.
- LYST: a protein required for the final step of secretion of secretory lysosome.
- AP-3: a clathrin binding adaptor protein involved in sorting proteins to the lysosome.
- Perforin: a pore forming protein use by lymphocytes to form pores in target cells.

Other good candidate genes such as the microtubule motors kinesins or clip proteins that attach lysosomes to microtubules.

All of the above and other candidate proteins will be involved in the secretion of lysosomes in immune cells. None of the available literature indicates any oncogenic or harmful effect of these proteins.

Standard reporter genes such as GFP (Green fluorescent protein) from jelly fish, luciferase from firefly, and B-galactosidase from E. coli.

None of the above proteins are known to have harmful properties.

Standard antibiotic resistance genes such as Neomycin, hygromycin, puromycin and ampicillin.
Evaluation of foreseeable effects

No significant hazards have been identified from insertion of the foreign sequences into E. coli K12 or B derivatives. The vectors are based on the pUC backbone and are non-mobilisable. They are not expected to result in harmful physiological or pharmacological properties or to affect the pathogenicity of the cloning host or normal human defence mechanisms. Gene transfer is possible, but unlikely to be hazardous. The resulting GMOs are not expected to carry any additional risks compared to that of the un-modified recipients and as such can be handled at containment level 1.

Transfection of the HEK 293T cell line with the 3 plasmids is expected to result in the generation of a Lentivirus that is capable of infecting most mammalian cells and integrating into the host DNA but is incapable of replication. As stated above none of the inserted DNA is expected to have harmful physiological or pharmacological properties or to affect pathogenicity of cloning host or normal human defence mechanisms. Therefore all work, which involves the handling of the virus, or cell lines and tissues infected with the virus, will be done at containment level 2, with the use of a microbiological safety cabinet for procedures which generate aerosols.

Transfection of the pT67 cell line with the retroviral expression plasmids is expected to result in the generation of a retrovirus that is capable of infecting most mammalian cells and integrating into the host DNA but is incapable of replication. As stated above none of the inserted DNA is expected to have harmful physiological or pharmacological properties or to affect pathogenicity of cloning host or normal human defence mechanisms. Therefore all work, which involves the handling of the virus, or cell lines and tissues infected with the virus, will be done at containment level 2, with the use of a microbiological safety cabinet for procedures which generate aerosols.

**Project Additional Information**

**Purposes of the contained use**

To identify new candidate genes for development of drugs and vaccines against Leishmania. Specifically, Leishmania genes will be cloned into E. coli expression vectors to isolate protein, into eukaryotic expression vectors as DNA vaccines, and into Salmonella expression vectors to boost immune response following straight DNA vaccination. Gene function will be assessed by knock-out or over expression in vivo. Pathogens will be labelled using reporter genes to facilitate study of endosome/lysosome fusion events in infection studies.

**Recipient or parental organism**

Tagged GMOs will be readily visualised eg fluorescent E. coli transformed with Leishmania genes will be handled at containment level 1 except where the pBR322 based expression vectors are used which require containment level 2 conditions. Leishmania genes will be introduced into attenuated strains of Salmonella. The effect of this is unpredictable therefore resulting transfectants will be manipulated at containment level 2. The effect of knocking-out or over expression of Leishmania genes is unpredictable but will not increase containment level beyond 3, the level we use for all Leishmania work.

**Host/vector system**

The following host // vector systems will be used:

- E.coli-XL1-Blue DH5 alpha // pUC derivatives eg KSneopt'pALT-neo, pcDNA3;LaRP+cat; pBR322 derivatives eg pET, pKK233-2 pTECH; cLHYG cosmid containing Leishmania splice-acceptor site.
- Salmonella typhimurium wildtype, (triangle) aro A, (triangle) aro A/D // pBR322 derivatives eg pKK233-2 pTECH-2, pGRPnir B; pUC derivatives eg pcDNA3, pGFPmut3.1
- Leishmania major/mexicana/donovan/brazilienisis (lab strains) // pUC and pBR322 derivatives eg cLHYG, KSneopt', pALT-neo, LaRP + cat; pSP72-aNEOaGFP, pCRTM 2.1-aNEOaGFP
- Mycobacterium avium/ bovis (BCG) // p16R1; pKINTA

**Origin & function**

**Reporter genes**: to tag the pathogens for detection in in vitro infections studies.

Leishmania derived cDNAs (known + unknown): to express as proteins in E. coli; for mouse vaccination trials both a direct DNA vaccine and via transfected Salmonella.
To study gene function in Leishmania by knocking-out or over-expressing selected Leishmania genes.

**Evaluation of foreseeable effects**

The pathogenicity of Leishmania species and the hazard this imposes to experimental workers is already covered by Codes of Practice for cultivation in culture (June 1992) and in animals (January 1993). Genetically-modified Leishmania will be subject to the same safety protocols; the environmental risk is therefore no greater than with unmodified parasites.

The lifecycle of Leishmania involves transmission of extracellular parasite stages between hosts by a sandfly vector, followed by intracellular maintenance within macrophages in the mammalian host. No other organism is known to be at risk from infection. There is no sandfly colony in Cambridge, so transmission of the parasite, by inoculation of infective parasites into susceptible mammalian hosts, is impossible. The likelihood of hazard is therefore effectively zero.

The consequence of hazard would be the transmission of leishmaniasis to susceptible mammals, including man. Field studies in endemic areas show that <10% of people infected with the parasite get clinical disease. In susceptible individuals, the disease is treatable (as detailed in the Code of Practice, June 1992). Therefore, the consequence of hazard is low. Overall, the risk is estimated to be effectively zero.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

No derogation applied for.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All liquid waste is treated using 5% chloros for 24 hours prior to disposal. Animal waste is double-bagged within the containment facility and transported direct to the incinerator within the animal unit.

02/03/2022 Page 10536 of 15326
Project Ref 678/01.2

Purposes of the contained use

Dendritic cells are the professional antigen presenting cells of the immune system. We wish to examine the function of genes involved in antigen presentation, and genes that inhibit antigen presentation in dendritic cells. Primary human dendritic cells are non-dividing and therefore not readily transfectable using standard transfection technology. This necessitates the use of replication defective lentiviral vectors based on human immunodeficiency virus type 1 (HIV-1).

Recipient or parental organism

E. Coli transformed with pUC based vectors will be handled at containment level 1. We will use a three plasmid transient transfection system to generate recombinant, replication defective retroviruses. The lentiviral work will be performed at containment level 2. 293T cells will be transfected with: (i) pHRSin - an HIV-1 ‘self inactivating vector’ (SIN). cDNAs encoding the antigen presentation genes will be cloned into the HIV-1 derived SIN vector, which has a deletion in the U3 region of the 3’ long terminal repeat (LTR) of the DNA used to produce the vector RNA. during reverse transcription this deletion is transferred to the 5’ LTR and abolishes the transcriptional activity of the LTR, and as a result the production of full-length vector RNA is transduced cell is abolished. (ii) pCMVR8.0 - a vector containing the HIV-1 derived retroviral sequence encoding viral gag/pol tat and rev genes, from which the virulence genes vif, vpr, vpu and nef have been deleted. (iii) A plasmid encoding the envelope plasmid derived from vesicular stomatitis virus (VSV) G protein which is permissive for human cells.
Host/vector system

The following host // vector system will be used:
E. coli; K12//pUC derivatives carrying the ampicillin resistance genes driven by a bacterial promoter and containing (i) human immunodeficiency virus type 1 (HIV-1) -derived retroviral sequences encoding viral gag/pol and tat and rev sequences. (ii) Viral sequences encoding vesicular stomatitis virus (VSV) G protein. (iii) self-inacting retroviral vectors derived from HIV-1 with retroviral coding sequences eliminated, carrying eukaryotic promoters and marker genes (GFP) and antigen presentation genes. None of these plasmids contain bacterial promoters driving expression of the gene to be expressed.

Origin & function

To study the function of antigen presentation genes in dendritic cells. All genes are of known function and do not act as oncogenes. Human cDNAs encoding the transporter associated with antigen processing (TAP1 and TAP2, tapasin and class 1 genes. (ii) cDNAs encoding viral proteins from human cytomegalovirus US6, UL18 and the K3 gene from human herpes virus 8. (iii) Mutant forms of the above genes which will include point mutants and deletion mutants of putative functional domains. (iv) The reporter genes His, FLAS, GFP, and lacZ.

Evaluation of foreseeable effects

The risk of infection with retroviruses is through direct inoculation and this is unlikely to occur as there is no animal experimentation involved and needles are not being used. There is evidence that these replication defective retroviruses are not pathogenic when tested in mice. Further details of the constructs and the demonstration that they do not give rise to replication competent viruses are available in Zufferey et al Nature Biotechnology 15:871-5. Since the packaging unit of the lentivirus vector expresses only 4 HIV-1 genes (gag, pol, tat and rev) and the crucial virulence factors, Vpr, Vif, Vpu and Nef have all been deleted, this eliminates the possibility of a wild-type virus being reconstituted through recombination. In addition the use of a 'self-inactivation vector' further improves the safety as the transcriptional elements of HIV have been removed from the vector. Since the viral promoter has been abolished, synthesis of full-length vector RNA in target cells is prevented, minimizing the risk that a replication competent virus can occur, or that a cellular gene located downstream of the 3’ LTR will be aberrantly expressed. It would require two separate recombination events to generate replication competent virus - involving (i) recombination between the env gene and the packaging construct and (ii) a recombination event between the packaging construct (which lacks its own packaging signals) and the coding vector. The vector encoding the envelope gene has no homologous region with the packaging construct, thus the likelihood of such recombination occurring is extremely low and has never been recorded. Again, there is the theoretical risk of a recombination event with an endogenous human retrovirus, but no human endogenous lentivirus has been detected. However to ensure that no recombination event has occurred, supernatant from the transduced cell line will be checked rigorously for the absence of replication competent helper virus using assays for reverse transcriptase. In addition the retroviral expression vectors encode green fluorescent protein (GFP) in an IRES vector. Supernatant taken from the transduced cells will be incubated with NIH3T3 cells and these cells examined for expression of the GFP protein and tested by rtPCR for the presence of the inserted gene.

**Project Ref** 678/02.1

**CU2 Project Title**

TRANSGENE DELIVERY TO ES, YOLK SAC AND HAEMOPOIETIC CELLS AND MOUSE EMBRYOS USING RETROVIRAL VECTORS

**Date Ackn'd** 08/05/2002

**Date Project Ceased** 16/09/2019

**Class** Class 2

**Culture Volume** 1-50 litres

**Non-GMM**

**Consent Granted** not applicable

**Project notified under transitional arrangements**

**Historical Significant Changes**

Project transferred to GM3071

**Purposes of the contained use**

The purpose of this project is to study the biology of haematopoietic stem cells using the experimental approach of transgene delivery by means of retroviral vector.
systems. The biological questions we aim to address include the molecular controls regulating stem cell formation and stem cell plasticity as well as the molecular defects in stem cells that lead to leukaemia. The proposed work has therefore the potential to open up new areas for both fundamental and applied biomedical research with potential clinical relevance for the treatment of leukaemia.

Recipient or parental organism

E. coli transformed with pUCbased retroviral vectors will be handled at containment level 1. The retroviral work will be performed at containment level 2. The proposed retroviral systems incorporate the following safety modifications to prevent viral replication:
(1) The packaging genes are separated into two plasmids, which lack both LTRs and have no viral packaging signal.
(2) The following viral genes have been deleted from the packaging vector: env, vpr, vpu, vif and nef.
(3) The vectors expressing the packaged viral genome has a self-inactivating LTR (TATA box deletion) and expresses no viral gene products.
(4) Envelope is expressed on a separate vector.

Host/vector system

The following host/vector system will be used:
E. coli; K12/pUC derivatives carrying the ampicillin gene driven by a bacterial promoter together with viral genes and cDNAs driven by eukaryotic promoters that do not express in bacteria.

Origin & function

The purpose of the project is studying both normal and malignant haemopoietic stem cell biology. All the genes we want to deliver to cells are of known function. We will use disabled retro and lenti vectors and virus pseudotypes that only infect mouse cells whenever the inserts are potential oncogenes.

Insert DNA categories:
(1) Reporter genes (lacZ, GFP + variants, luciferase, PLAP) together with regulatory regions enhancers, promoters, silencers
(2) Cre recombinase gene, self-exising with regulatory regions
(3) SV40 large T antigen, HoxB4, Hox11, Notch1: potential oncogenic function (only to be used with ecotropic envelopes)
(4) SCL, Myod, myf5, pax3, pax7, pdx1, ngn3: transcription factors (only to be used with ecotropic envelopes)

Evaluation of foreseeable effects

We propose to generate transgenic mice using the lentiviruses. These mice will be housed in CBS (Addenbrooke's site Cambridge) together with all our other transgenic mice. Transgenic mice will only by produced for the inserts of category 1 (ie. inert reporter genes). Due to the design of the proposed experiments (see above) and the containment procedures of CBS, the environmental risk after introduction of the transgene is negligible.

The purpose of the project is to study the biology of the polycystin protein family in transfected cultured mammalian cells. One of the major blocks to the success of studies in cultured cells has been the difficulty in generating stable cell lines expressing the PKD1 gene product, polycystin-1. The PKD1 gene produces a ~14 kb mRNA with polycystin-1 having a predicted mass of >460 kDa. Standard cell transfection approaches have been unsuccessful in expressing such a large gene therefore the use of a lentiviral gene delivery system has the potential to allow new experimental approaches to study of polycystin to be developed.

Recipient or parental organism
E. coli transformed with the pUC based lentiviral vectors will be handled at containment level 1. The lentiviral work will be performed at containment level 2. The lentiviral system incorporates the following safety modifications to prevent viral replication:
1). PLENT16 contains a deletion of the 3’ LTR that does not affect generation of the viral genome in a producer cell line, but results in inactivation of the lentivirus after transduction into the target cell;
2). The number of genes from HIV-1 has been reduced to three (gag, pol and rev)
3). The VSV-G gene is used in place of HIV-1 envelop
4). Genes encoding the structural and other components required for packaging the viral genome are separated into four plasmids with no homologous regions to prevent undesirable recombination.
5). The lentiviral particles are replication incompetent and only carry the gene of interest.

Host/vector system
The following host/vector system will be used:
E. coli; pUC derivatives carrying the ampicillin gene driven by a bacterial promoter together with viral genes and cDNAs driven by eukaryotic promoters that do not express in bacteria.

Origin & function
The purpose of this project is to study the function of the polycystins in transfected mammalian cells in culture. The polycystins are involved in the regulation of normal kidney epithelial cell function that when disordered through gene mutation leads to an inherited disease in man called autosomal dominant polycystic kidney disease. This disease has no malignant potential. However the precise function of the genes encoding the polycystins, in particular, the PKD1 gene is not known. The disabled lentiviral gene expression system will be used to infect mammalian cells in culture with the PKD1 gene, functional mutants and reporter genes.

Insert DNA categories:
1) Reporter genes (GFP and variants; FLAG, His and V5)
2) PKD1 gene cDNAs and functional mutants.

**Evaluation of foreseeable effects**

The risk of infection with retroviruses is through direct inoculation, which is extremely unlikely as no needles are used in any of the experimental procedures involved in this project. In addition the lentiviruses used are replication defective as previously described and therefore not pathogenic.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None applied for.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid waste will be treated for 24 hrs with 2% Virkon or Presept tablets before disposal into the laboratory drainage system.
Alternatively disinfected waste will be gelled with Vernagel in sealed containers and removed for incineration.
Solid waste such as plastics will be double bagged before transfer to a waste autoclave within the building, and then disposed of by incineration on site.

Page 10543 of 15326
The nuclear hormone receptor PPARg (peroxisome proliferator-activated receptor gamma) is a ligand inducible transcription factor involved in a number of biological processes, including fat cell differentiation, glucose homeostasis and atherogenesis. A number of PPAR-specific agonists, including naturally occurring fatty acids and prostaglandin J2 and synthetic anti diabetic thiazolidinediones have been identified and shown to be useful tools for investigating the effects of PPARg stimulation in vivo. For example, thiazolidinediones accelerate differentiation of cultured preadipocytes into adipocytes, activate monocytes and increase leptin secretion from cultured trophoblasts. The effects of PPARg inactivation are poorly understood however. Animal studies using PPARg knockout mouse has been hindered by lethal phenotype and no antagonist ligand have been described. Patients harbouring loss-of-function PPARg mutations exhibit varying degrees of lipodystrophy and insulin resistance. In order to study the function of such mutant PPARg, they will be expressed in mammalian cells using a lentiviral expression system. A major advantage of the lentiviral system is the possibility to infect most cells from different species.

**Recipient or parental organism**

A 293 producer cell line will be used to generate the virus particles. Initially, we will analyse the effect of the mutants on the differentiation of murine 3T3-L1 preadipocytes in response to PPARg ligands. Subsequent experiments will address the effects on human preadipocyte and other relevant cells.

**Host/vector system**

A 293 producer cell line will be transfected with the gene of interest constructs and three plasmids each containing different and necessary proteins for virus formation will result in the generation of the viral particles. These three different plasmids used are CMV 8.9 (gag, pol and tat); pRSVrev (rev); pCMV-VSV-G (VSV-G). Only the pHR'CMV-GFP vector containing the gene of interest contains packaging signals and this will result in lentiviral particles which are replication incompetent and only carry the gene of interest. All cloning and lentiviral vectors lack sequences for prokaryotic expression.
Expression of PPARg and GFP are driven by the CMV promoter which is active in most mammalian cell types. The lentiviral particles are replication incompetent and only carry the gene of interest and GFP.

Origin & function

The human nuclear hormone receptor PPARg is a ligand inducible transcription factor involved in a number of biological processes, including fat cell differentiation, glucose homeostasis and atherogenesis which can be analysed in the appropriate cell lines.

Evaluation of foreseeable effects

Neither GFP nor wild type or mutant PPARg are recognised oncogenes, so work with these lentiviral constructs is not expected to pose a cancer risk.

Expression of PPARg and mutants will lead to differences in gene expression in mammalian cells. This will be evaluated by analysing differences in preadipocyte differentiation and gene expression patterns.

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use

Characterisation of novel Tissue inhibitor of metalloproteinase (TIMP) 1, 2, 3 and 4 mutants and chimeras and their comparison with wild-type TIMPs in a variety of mammalian cell models to assess their affects on cellular processes dependent on metalloproteinase activity.

Recipient or parental organism

The TIMP molecules are to be expressed from Ad5 adenovirally infected cells expressed from a CMV promotor. The expression of these proteins from Ad5 is not expected to change the properties of the Ad5 adenovirus in terms of increasing its pathogenicity. The recombinant TIMP-Ad5 are not expected to be more virulent in terms of infectivity or replication and host genome integration than wild type Ad5 adenovirus which is designated a Class ll pathogen by ACDP.

Host/vector system

Plasmid DNA will be produced in E. coli K12 strains which are class 1 pathogens and are assessed to be containment level ll microorganisms.

TIMP-Ad5 adenovirus are to be made by Flp dependent recombination by co-transfection of plasmid vectors pDC515 or pDC516 with pBHGFrt(triangle)E1E3, 3flp in HEK293T cells. Vectors pDC515/6 are non mobilisable and contain the TIMP gene and CMV promotor. pBHGFrt(triangle)E1E3,3flp encodes the Ad5 genome and can only produce adenovirus in mammalian cells which express adenoviral proteins E1 and E3, such as HEK293T after transfection. Further information can be obtained from www.Microbix.com who are the manufacturers of the vector system.

TIMP-Ad5 will be used to infect a variety of mammalian cell lines and primary cells. These are not expected to contain the adenoviral genes E1 and E3 and should not
produce viral particles after infection.

TIMPs 1, 2, 3 and 4 are from human cDNA and are inhibitors of metalloproteinases. Chimeras are made from the cDNAs encoding parts of human Furin, murine TACE and GFP, or the polypeptides KDEL, [Leu]17, V5 epitope and [His]6. These are to target TIMPs to particular cellular organelles (Fur, TACE, KDEL, [Leu]17, or to aid detection (GFP, V5, [His]6). Plasmid vectors pDC515/6 and pBHGfrt(triangle)E1E3,3flp are derived from vector pUC18 and recombinant adenovirus Ad5.

Evaluation of foreseeable effects

Replication deficient Ad5 are unlikely to cause disease for purpose of group II classification. However the nature of the inserted gene should be considered in the context of the recombinant virus. Work with adenovirus carries risk of allergy after repeated exposure. This effect is idiosyncratic and may manifest as conjunctivitis and rhino-tracheo-bronchitis. Ad5-CMV based virus are not known to cause these symptoms. However although the virions lack E3 protein and are compromised in their ability to establish and maintain an infection in human cells, should infection occur, the effect of elevated TIMP expression is difficult to predict due to the varied functions of these proteases they inhibit. However, decreases in ECM turnover through MMP inhibition, or inhibition of shedding of growth factors, receptors and cytokines, on balance, is likely to decrease cell survival. All TIMPs have been shown to decrease tumour survival in murine models when expressed by adenoviral infection (variety of transformed cells including epithelial derived cells). The Ad5 adenovirus is non-oncogenic and TIMPs, GFP, ADAM17 and Furin are not recognised as oncogenes. The oncogenic potential of short peptide sequences consisting of the V5 epitope, KDEL and the 17 amino acid Leucine rich peptide is not known.

Non-GMM Consent Granted: not applicable

Project notified under transitional arrangements: N

Historical Significant Changes: TRANSFERRED TO GM 973 - 23/5/07.

Project Additional Information

**Purposes of the contained use**

The use of co-culture of tumour epithelial cells with tumour stroma (fibroblasts and endothelial cells) to mimic aspects of tumour cell-cell interactions in vitro.

**Recipient or parental organism**

Human Mammary Fibroblasts (HMF clones A to D) and Human Mammary Microvascular Endothelial Cells (HMME clones 2 and 7) were obtained from Ludwig Institute for Cancer Research, London. The characteristics of the cells are described in the publication by O’Hare et al, PNAS, 2001, 98 p646-51. In brief, primary cells derived from breast tissue were immortalised by separate transduction with helper-free amphotropic murine-lukaemia-virus (MLV) encoding the catalytic subunit of human telomerase (hTERT) and a heat labile mutant of the simian virus 40 large tumour antigen (U19tsA58). The resulting cells are immortal, yet retain most genetic and phenotypic characteristics of the primary parental cells. The cells only retain immortality when cultured at the permissive temperature of 34 degrees C, and senesce after 15 passages at 37 degrees C. These cells have the hTERT and U19tsA58 genes stably integrated into the host cell genome by MLV retroviral transduction. They have been tested negative for the presence of LMV and are unlikely to produce LMV containing hTERT and U19tsA58 in the future. However as hTERT and U19tsA58 genes are potentially...
oncogenic, it is advised that the cells are cultured under containment level II conditions and the cell lines are classified as Class II organisms.

### Host/vector system

Cells are derived from primary fibroblasts and microvascular endothelial cells obtained from breast tissue explants.

The vector system used originally used to transform these cells is described in the publication by O'Hare et al, PNAS, 2001, 98p646-51. In brief the vectors used were helper-free amphotropic murine-lukaemia-retrovirus (MLV) containing resistance genes for antibiotics hygromycin and G418 to aid selection of clones which had integrated MLV stably into their genome.

NB. Only the cells derived from this vector system are to be used by the applicants. NOT the vector system itself.

### Origin & function

The human telomerase catalytic domain (hTERT) is derived by removal of the regulatory domains of human telomerase. Human telomerase maintains telomere length which is a means of regulating cell life-span. HTERT prevents telomere shortening and can lead to immortalisation of cells which express it.

The simian virus 40 large tumour antigen is a known oncogene and induces DNA synthesis by by-passing key cell cycle check points through interacting with regulatory proteins (c-myc, Ras). It also blocks p53 dependent apoptosis. U19tsA58 is a temperature sensitive mutant of SV40LTA which is inactive at 37 degrees C yet is active at the permissive temperature of 34 degrees C.

Expression of these constructs individually does not always lead to cell immortalisation, although expression of both will usually lead to complete transformation and immortalisation.

### Evaluation of foreseeable effects

Due to the nature of the hTERT and U19tsA58 genes stably inserted into the genome by MLV transduction there exists a very small but finite risk of a recombination event which could lead to production of amphotropic replication competent MLV containing either the hTERT or U19tsA58 genes should the cells come into contact with MLV or a derivative thereof. To further reduce the risk of recombination, the following will be adhered to.

1. Culture in Containment Category II facility following CIMR Containment II Code of Practice.
2. The cells are not to be cultured in the presence of murine cells.
3. All human cell lines which will be co-cultured with the immortalised fibroblasts or endothelial cells will be tested for the presence of MLV by PCR.
4. The fibroblast and endothelial cells will be tested monthly for the presence of MLV by PCR.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

CU2 Project Title: A study of inhibitory receptors and viral gene products using lentiviral expression vectors.

Class: Class 2
CultureVolClass2: 1-50 Litres
Non-GMM Consent Granted: Not Applicable

Project notified under transitional arrangements: N

Transfered to GM353 on 26/08/2016
# Project Additional Information

## Purposes of the contained use

1. Understanding the biochemical and molecular basis for the function of receptors for the constant (Fc) region of IgG, FcγRs and
2. Dissecting the role of viral gene products in lytic replication, the establishment of latency and immune evasion.

## Recipient or parental organism

The cell lines we wish to transfect are murine B-cells lines and primary human dendritic cells and macrophages. None of these cell types are readily transfectable using standard transfection technology, necessitating the use of lentiviral vectors based on human immunodeficiency virus type 1 (HIV-1).

## Host/vector system

A three plasmid transient transfection system will be used to generate recombinant, replication-defective retroviruses. 293T cells, a human cell line carrying SV40 T antigen will be transfected with:
- (a) An HIV-1 'self-inactivating vector' (SIN).
- (b) An HIV-1 derived retroviral sequence © a plasmid encoding the envelope plasmid derived from vesicular stomatitis virus (VSV) G protein.

## Origin & function

1. Human and mouse cDNAs encoding Fcγ receptors and their gamma chain subunits.
2. Human and mouse cDNAs encoding the soluble tyrosine kinase lyn.
3. MHV68 cDNA encoding M2 gene products.
4. Mutant forms of the above genes which will include point mutants and deletion mutants of putative functional domains.
5. The reporters His, FLAG, GFP, and lacZ.

Cells transduced with these genes will be used for the study of the effect of wild type and mutant Fcγ receptors on the response of cells to immune complexes and opsonised bacteria. We hope to examine their role on phagocytosis, endocytosis and intracellular trafficking of immune complexes, cytokine production and antigen presentation using techniques established within this laboratory.

## Evaluation of foreseeable effects

The genes to be expressed are not known to be harmful and so the classification of the work is determined largely by the nature of the host/vector systems. The lentiviral (HIV) vectors are disabled, self-inactivating (they are unable to propagate following transfection) and multi-component. Hence the risk of generating replication competent viruses (bearing the transgenes) is extremely low.

The lentiviral binding protein has been replaced by VSV G protein which confers potentially a much broader host range/tissue tropism. In response to this, these vectors will be at class 2. Furthermore, the VSV protein pseudotyping represents an aerosol/ingestion opportunity for infection in addition to the percutaneous risk associated with HIV. Therefore the risk assessment indicates the use of a microbiological safety cabinet for operator protection. Although complement sensitive, vectors bearing the VSV glycoprotein are reported to have increased environmental stability emphasizing the importance of paying due regard to principles of GMP/GOSH.

While there is a theoretical potential for animal infection with these virus vectors, all lentivirus work will be carried out in a building where no live animal work is undertaken thus minimizing the risk. Furthermore, as with inadvertent human contact, the viral vectors are self-inactivating and the expressed proteins are not known oncogenes. Thus the consequences of expression in a few cells would be minimal.

The worst case scenario therefore for an exposed individual would be infection of pre-cancerous cell by viral vector expressing immune evasion protein perhaps allowing tumour progression. The most accessible tissue is lungs, but likelihood is small (pre-cancerous tissue would be very much a minority tissue in healthy persons) and virus is
always handled in a safety cabinet. This scenario is considered highly unlikely to occur, as all evidence to date suggests that insertion of the M2 protein into other cells would not enhance proliferation or permit immune evasion. Moreover, there is no evidence that pre-malignant bronchial epithelium is surveyed by the immune system, and there is no data to suggest that a protein stimulating B cells could enhance immune evasion by epithelial cells.

Project Additional Information

Purposes of the contained use

We will produce viral particles using the FLP recombinase kit from Microbix. The gene of interest is cloned into pDC515 or pDC516, which contains a CMV promotor or pDC511 and 512 containing the SV40 promotor, allowing expression to be checked under Containment Level 1 conditions prior to generation of virus. Virus is made by co-transfection of the pDC vector with pBHgfrDE1E3, 3FLP in NautCell 293T cells, where FLP recombination occurs producing viral particles. This will be performed under Containment Level 2 conditions in compliance with the institute code of practice.

Recipient or parental organism

E. coli: All strains are K12 derived thus disabled and non-colonising. Vectors are mobilisation defective. Mammalian cells: pDC515/6. Vector is non-mobilisable.
Adenovirus: Microbix adenovirus and all commercially prepared adenoviral genomes are based on Ad5 which is replication deficient but can enter a variety of human cells.

Host/vector system

E. coli, K12 pBr322 based
Mammalian Cell pBR322 based
Mammalian cell Ad5 based virion post infection (E1 deficient).
NautCell293T Ad5 based virion.

Origin & function

Human origin
SiRNA is synthetically derived- used to inhibit expression
cDNAs - used for over expression
Evaluation of foreseeable effects

Replication deficient Ad5 are unlikely to cause disease for purpose of group II classification. However the nature of the inserted gene should be considered in the context of the recombinant virus. Work with adenovirus carries risk of allergy after repeated exposure. However although the virions lack E1/E3 proteins and are compromised in their ability to establish and maintain and infection inhuman cells.

Over expression of MMPs through inadvertent infection by RAd5 virus expressing the enzymes via a CMV or SV40 promotor may result in increases in ECM degradation and hence increases in cellular proliferation and migration. High levels of over expression of most MMPs in tumour cell lines in mouse models of subcutaneous xenotransplation results in increased tumour growth. It is possible therefore that increased rates of cell growth may occur on adenoviral expression. Although increased MMP expression is increased on neoplastic transformation in most tumour types, increased MMP expression itself is not thought to cause cellular transformation at the genetic level, hence MMPs are not considered oncogenes. Effects of ADAM knock down are even harder to predict in vivo through inadvertent infection of sirRNA expressing adenovirus. With the exception of ADAM10 (embryonic lethal due to lack of Notch/Delta processing) or TACE (EGF like knockout phenotype due to poor shedding of EGF ligands) all other mouse knockouts made so far as ADAMs are viable and have no severe phenotypic differences from their wild type litter mates which have been defined as yet.

The virus is physically relatively stable, so need good practice to ensure it isn't spilled and left to present a hazard at some future point; the host range of Ad5 is naturally limited to man and therefore the virus will not infect animals or plants nor, due to its disablement, spread to the wider human community. Bacteria and mammalian cells are unable to survive outside of laboratory culture conditions.

See attached protocol for further details.

In summary, there is little evidence that either knock down of MPs or their over expression would have long term effects, should any pathology result from inadvertent infection by adenovirus. Adherence to the code of practice for containment 2 facilities should be adequate for preventing inadvertent infection.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applied for.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste will be treated with either 2% virkon overnight in labelled containers. Liquid post disinfection will be gelled with Vernagel and placed in sealed containers and taken to room 1.23 for incineration. Solid waste will be placed in double autoclave bags, secured with autoclave tape labelled with room no and user name, followed by autoclaving and incineration. Liquid spills will be treated with 2% Virkon (non metallic surfaces) or 10% Trigene (metallic surfaces), absorbed with paper towels which will then be autoclaved. Surfaces will be routinely cleaned with 10% Trigene.

We will produce viral particles which have both ecotropic and amphotropic ranges of tropism, using replication defective MSCV v2.1 based retroviral vectors. The gene of interest is cloned into these vectors which concomitantly either express GFP or an antibiotic resistance marker. Viral particles are produced following transient co-transfection of 294T cells with the retro/lentiviral vector and one (ecotropic) or 2 (amphotropic) packaging constructs. This will be performed under containment level 2 conditions in compliance with institute practice.
Recipient or parental organism

E Coli - All strains are K12 derived thus disablinn and non-colonising. Vectors are non-mobilisable. Mammalian cells - MSCV vector is non-mobilisable. Retrovirus - MSCV vectors are based on replication defective retroviral genomes and FUGW vectors on replication defective lentiviral genomes.

Host/vector system

Host - 293T cells/vector - MSCV retrovirus or FUGW lentivirus
Host - Mammalian cell, post infection/vector - MSCV retrovirus or FUGW lentivirus (replication incompetent).

Origin & function

Human origin
cDNA - for overexpression.
siRNA - synthetically derived to be complimentary to human sequence, used to inhibit protein expression

See attached project application for details.

Evaluation of foreseeable effects

Risk Assessment for human health:
The most obvious potential risk to human health is the expression of oncogenes within accidentally infected human cells. This would be impossible for exotropically packaged retrovirus or lentivirus, but is theoretically possible for amphotropically packaged retrovirus or lentivirus. Theoretically these viruses can infect human cells and lead to integration and expression of the insert in dividing cells. In turn, expression of oncogenes or potential oncogenes or of endogenous genes through insertional mutagensis could potentially be harmful to human health. There is also the theoretical potential for propagation of the virus through recombination and the generation of replication competent retrovirus (RCR). The MSCV vector is replication defective and the production of RCR will be minimised by the use of a 3 plasmid transfection system to prevent recombination. However, testing for RCR will be performed for each batch of amphotropic virus using a marker recovery assay (each virus also expresses either a GFP marker or an antibiotic resistance marker) and only batches negative for RCR will be utilised further.

For lentiviruses, theoretically these viruses can also infect human cells and lead to integration and expression of the insert in dividing and non-dividing cells. In turn, expression of oncogenes or potential oncogenes or of endogenous genes through insertional mutagensis could potentially be harmful to human health. There is also the theoretical potential for propagation of the virus through recombination and the generation of replication competent retrovirus (RCR). The FUGW vector is replication defective and the production of RCR will be minimised by the use of a 3 plasmid transfection system to prevent recombination. However, testing for RCR will be performed for each batch of amphotropic virus using a marker recovery assay (each virus also expresses either a GFP marker or an antibiotic resistance marker), and only batches negative for RCR will be utilised further. In addition, although the lentivirus has modifications to increase transcription and nuclear import (the WRE and HIV-1 flap element respectively) which might theoretically increase the risk of expression in infected human cells, it is replication defective and the SIN modification of the 3'LTR is duplicated in the 5LTR upon reverse transcription. This results in the transcriptional inactivation of the provirus and decreases the likelihood of insertional mutagensis. These vectors also have a 5'LTR modification (U3 region replaced with CMV promoter) which along with the use of a 3 plasmid transfection system reduces the possibility of recombination and minimises the risk of production of RCR. Recently concern has been raised with regard to the WRE element, as mice transplanted with control vectors containing this element have developed tumors. Therefore, in keeping with GTAC and SACGM recommendations these vectors will be handled at containment level 2.

To decrease the likelihood of infection standard measures to decrease percutaneous as well as aerosolised transmission of the virus, such as no use of sharps ans work to be performed within a class II microbiological safety cabinet will be adopted. Aerosolised virus is theoretical risk to infect the respiratory epithelium, but its production would be minimised as above. In addition the respiratory epithelium is terminally differentiated, has a high turn-over and it is unlikely that the haematopoietic specific oncogenes involved in this proposal would have any effects on this tissue in the unlikely event of infection. Moreover, malignancy is a multistep process and it is unlikely that any single "hit" would initiate transformation and in occassional experiments where oncogenes were coexpressed this would be by cotransduction making dual infection of the same human cell highly unlikely. Also VSVg pseudotyping results in complement sensitivity increasing the likelihood of immunological neutralisation in human hosts. However, during the production and concentration of retrovirus, the transduction of cells and the subsequent analysis of these cells, CL2 conditions will be strictly adhered to.
Both viral particles are relatively unstable and standard practices will ensure adequate decontamination of facilities. Bacterial and mammalian cells are unable to survive outside of laboratory culture conditions.

See attached protocol for further details.

In summary, there is little evidence for the likelihood of hazardous long-term effects from accidental infection and overexpression of an oncogene. Adherence to the code of practice for containment 2 facilities should be adequate for prevention of inadvertent infection.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
None applied for.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Waste will be treated with 2% Virkon overnight in labelled containers. Liquid post disinfection will be gelled with vernagel, placed in sealed containers and taken to room 1.23 for incineration. Solid waste will be placed in double autoclave bags, secured with autoclave tape and labelled with the room number and user name, followed by autoclaving and incineration. Liquid spills will be treated with 2% Virkon (non-metallic surface) or 10% trigene (metallic surfaces) and absorbed with paper towels which will then be autoclaved. Surfaces will be routinely cleaned with 10% trigene.

**Project Additional Information**

**Purposes of the contained use**

To identify novel functional roles of MHC and leukocyte receptor complex encoded immunoreceptors through expression analysis and proteomics techniques. Primary human dendritic cells are non-dividing and are not readily transfecatable using standard techniques. This project will therefore require the use of replication defective lentiviral vectors based on human immunodeficiency virus type 1 (HIV-1).

**Recipient or parental organism**

1. E. coli K12 disabled/non-colonising.
2. 293T (human epithelial kidney) especially disabled cells.
3. An HIV-1 "self inactivating" vector (SIN) which has a deletion in the U3 region of the 3' longterminal repeat (LTR) of the DNA used to produce the vector RNA; has sequence encoding virulence genes vif,vpr and nef deleted; bears envelope protein VSVG (the vector thus has altered hostage/tropism) The vector is split over 3 plasmids and is therefore replication disabled.
4. Primary human dendritic and other cells.

**Host/vector system**

E.coli K12-pUC plasmid derivatives, which are non-mobilisable and bearampicillin resistance, bearing- a ) HIV-1 derived retroviral sequences encoding viral gag/pol and tat and rev sequences, b) viral sequences encoding VSVG protein, c) HIV-1 vector bearing eukaryotic promoters, markers and antigen presentation genes. None of these plasmids possess promoters capable of driving expression of the genes to be expressed in bacteria. Any background expression will not result in active proteins being produced. None of the proteins are intrinsically toxic.
293T cells - plasmids bearing the HIV vector components and the genes of interest will be transfected to produce infections vector particles which are harvested for expression work. Human cells of interest - HIV viral vector particles will be used to infect these for further analysis.

**Origin & function**

To study antigen presentation genes using retroviral expression vectors in mammalian cells. All of these genes have functions in the interaction between immune cells.

i) ULBP/RAET molecules; these proteins are structurally related to MHC class 1 molecules and bind to the activating immunoreceptor NKG2D.

ii) HLA-F and TAPBPR to examine trafficking tagged constructs

iii) B7 related BTN ann BTN2L to examine cellular localisation and interacting proteins

iv) mutant forms of the above genes which will include point mutants and deletion mutants of putative functional domains

v) reporter genes FLAG, myc, GFP and Protein A

**Evaluation of foreseeable effects**

None of the bacterial or cellular GMMs produced will have characteristics significantly different from the hosts; many of the genes (eukaryotic) will be in the wrong context to exert any effect on bacteria (prokaryotic) and the eukaryotic cells will be especially disabled. The products are not intrinsically toxic and cannot exert effects on other cells upon release from producer cells-most require membrane insertion for functionality.

The HIV vector is replication disabled and is unable to produce infections progeny from the initial round of infection. Potentially replication competent retrovirus (RCR) could be generated from the producer cells but as the vector is split over a number of plasmids and is self inactivating, the number of recombination events required to restore a functional genome make the probability extremely low. The vector has an altered host range/tropism: usually retroviruses are spread by percutaneous introduction. The VSVg protein potentially allows this as well as transmission via contact and aerosol. Although the virus is unable to infect beyond the initially infected cells, there is potential that the virus could insert into host DNA, thereby causing insertional mutagenesis and possibly adverse effects, but this is also of low probability.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be treated for 24 hrs with 2% Virkon (effectively 100% kill) before disposal into the laboratory drainage system. Alternatively disinfected waste will be gelled with Vernagel in sealed containers and removed for incineration, 100% kill. Solid waste such as plastics will be double bagged before transfer to a validated waste autoclave within the building. (100% kill) and then disposed of by incineration on site (Addenbrooke's Hospital is GM registered for this purpose)

**Project Additional Information**

**Purposes of the contained use**

To investigate the genetic causes of Type 1 Diabetes (T1D) using lentiviral transfection of RNA interference (RNAi) to knockdown KIAA0350, RBM17, and IL2RA in human cell lines.

**Recipient or parental organism**
### E. Coli K12
- Jurkat cell line
- Human CD4+ and CD8+ T cells
- These are all disabled, non-pathogenic to man and cannot survive in the environment.

### Host/vector system
- Lentiviral pLBm (HIV-1 based vector with vsvg envelop)
- Plasmid + gag/pol genes
- Plasmid + rev gene
- Plasmid + vsvg gene
- 239 cell line

### Origin & function
- RNAi corresponding to
  - KIAAO35O (uncharacterised, associated with TI D)
  - IL2RA, (IL2 receptor associated with TI D)
  - RBM17, (splicing regulatory gene expressed in T cells)
- Expression of RNAi in cells will result on knockdown of the corresponding gene in a sequence specific manner

### Evaluation of foreseeable effects
- If a human is infected by the RNAi, the genes will be knocked down in the infected cells only, as the virus is non replicating. Knock down of the genes in a limited set of cells may not be lethal and is not expected to result in any aberrant immune response. The effect of knocking down RBM17 and IL2RA would lead to less proliferation of the infected T cells.
- The genes are not oncogenes, nor known to be involved in tumour suppression.

**Project Additional Information**

**Purposes of the contained use**

The project aims are to understand how non-tuberculous mycobacteria (NTM), specific types of gram negative bacteria (E coli (non-verotoxigenic strains isolated from sputum), P. aeruginosa) and gram positive bacteria (S pneumoniae, S aureus) interact with macrophages to avoid intracellular killing and how pharmacological manipulation of cellular processes (such as the phagosomal ionic environment and macro-autophagy) might enhance intracellular bacterial killing and/or modulate release of
inflammatory mediators.

Recipient or parental organism

NTM (excepting M. bovis BCG) are ubiquitous organisms occurring naturally in the environment (in domestic water, soil and houses). While they can cause lung infections in people with pre-existing structural lung disease (such as Cystic Fibrosis and Chronic Obstructive Pulmonary Disease), they are not pathogenic in healthy people and are not transmissible from person to person. Untransfected, it is usually handled in CL2 areas. M. bovis BCG is still in current world-wide use as a live vaccine against M. tuberculosis and is not pathogenic in health.

Host/vector system

pSMT1 plasmid carrying the luxAB genes from Vibrio harveyi and green fluorescent protein (GFP), Cyan FP, Yellow FP or Red FP; under the control of the constitutively active mycobacterial GroEL (hsp60) promoter; mycobacterial and E. coli origins of replication and a hygromycin resistance cassette. The vectors will not be translated by eukaryotic cells.

Origin & function

pSMT1 plasmid carrying the luxAB genes from Vibrio harveyi and green fluorescent protein (GFP), Cyan FP, Yellow FP or Red FP; under the control of the constitutively active mycobacterial GroEL (hsp60) promoter; mycobacterial and E. coli origins of replication and a hygromycin resistance cassette.

luxAB genes from Vibrio harveyi and green fluorescent protein (GFP) purchased from Clontech

Episomal insertion of plasmid DNA will result in generation of cytoplasmic green fluorescent protein (GFP) and luciferase (lux) as previously utilised in M. bovis and M. tuberculosis (Kampmann et al 2000). No selection advantage is anticipated for LUX-tagged or GFP tagged mycobacteria or bacteria.

Evaluation of foreseeable effects

NTM (excepting M. bovis BCG) are ubiquitous organisms occurring naturally in the environment (in domestic water, soil and houses). While they can cause lung infections in people with pre-existing structural lung disease (such as Cystic Fibrosis and Chronic Obstructive Pulmonary Disease), they are not pathogenic in healthy people and are not transmissible from person to person. Untransfected, it is usually handled in CL2 areas. M. bovis BCG is still in current world-wide use as a live vaccine against M. tuberculosis and is not pathogenic in healthy people. Untransfected and luminescently tagged M. bovis BCG are currently handled in CL2 facilities.

Untransfected and luminescently tagged S. pneumoniae, S aureus, P aeruginosa and E. coli are currently handled in CL2 facilities. While all can cause infections in man, the risk to healthy laboratory staff of these bacteria is extremely low. They will be handled in the tissue culture hoods and no procedures have the potential to generate aerosolised bacteria. The risk of inhalation therefore is extremely low.

ii) the inserted genetic material

The inserted plasmid has no eukaryotic promoter, encodes a luciferase gene and green fluorescent protein, which, in all mycobacteria examined to date, is retained intracellularly. The encoded proteins, lux and fluorescent proteins, have benign metabolic type activities (light production, fluorescence) which would have no significant effect on bacterial or cellular gene expression, though products may be toxic to cells expressing high levels. Extracellularly they have no signalling effects and are of very low toxicity. There is no effective way to deliver genetic material to human cells in these conditions.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Bench tops and spills will be wiped with a disinfectant (1% sodium hypochlorite, or 70% alcohol). Spills will be covered with disinfectant soaked towels for at least 15 min and then wiped. GMM will be killed by addition to 1% sodium hypochlorite for at least 15 min. (as recommended in ‘Standard safety practices in the microbiology laboratory: www.cdc.gov’).

Liquid and solid waste will be double bagged, autoclaved and then incinerated.

Date Project Ceased |

02/03/2022
Purposes of the contained use

Lentiviral vectors based on replication disabled HIV. We will use the Lenti-X Expression system developed by Clontech. Our gene of interest will be cloned into one of the Lenti-X fluorescent expression vectors or the Lenti-X Tet-On and Tet-Off advanced inducible expression systems. The proteins required for replication and packaging of the recombinant viral genome are produced from four different, separate vectors for added safety. In this new quadruple, split-gene packaging: gag, pol, VSV-G (env), and rev are expressed from four separate vectors. This further reduces the incidence of replication-competent lentivirus (RCL) to even less than that of other commonly used third-generation systems. The lentiviral expression system will be used under Containment Level 2 conditions in compliance with the institute code of practice.

Recipient or parental organism

E. coli: Strains of bacteria used for initial construction and plasmid amplification are derived from E.coli K12 and are therefore disabled and non-colonising. Packaging vectors of Clontech’s Lenti-X Packaging Systems are the derivates of pUC, which are non-mobilisable and therefore the possibility of transfer of inserted genetic material enabling for example drug resistance to other organisms is negligible.

Mammalian cells: Mammalian primary cells or cell lines are especially disabled and unable to survive or propagate outside of laboratory culture.

Lentivirus: The vectors are part of the Lenti-X Lentiviral Expression system by Clontech. Although these vectors are based on the lentivirus human immunodeficiency virus (HIV) and this is a HG 3 pathogen, vectors are all third generation replication defective and considered class 1. In addition the Clontech’s Lenti-X Vectors contain less than one-third of the wild-type HIV-1 genome. These wild-type sequences mainly consist of the viral LTRs and packaging signal. All essential replication genes have been completely removed and are instead supplied as separate DNA entities in the Lenti-X HT Packaging Mix. Clontech’s Lenti-X HT Packaging System also uses a split-gene packaging strategy to provide the viral packaging elements on individual plasmids that physically separate the viral envelope, env (usually VSV-G), and sequence from the gag-pro-pol sequences.

Host/vector system

Host: Standard mammalian tissue culture cell lines including HeLa cells, fibroblasts, MDCK cells and prostate cancer cell lines such as LNCaP and PC3. In addition we will use primary fibroblasts isolated from the Snell’s waltzer (myosin VI KO) mouse.

Vector: Lentiviral vectors based on replication disabled HIV

Origin & function

The proteins we are working with are either known cytoskeletal, structural proteins ubiquitously expressed in mammalian cells or other known mammalian proteins with no identified toxicity. Therefore a low damage factor is to be expected from their aberrant expression. Recent publications, however, show that myosin VI is dramatically overexpressed in prostate cancer tissues. At present it is not known whether myosin VI is the causal factor for malignant transformation and therefore it will be treated as a
potential oncogene until more information becomes available.

**Evaluation of foreseeable effects**

The vectors are part of the Lenti-X Lentiviral Expression system by Clontech. Although these vectors are based on the lentivirus human immunodeficiency virus (HIV) and this is a HG 3 pathogen, vectors are all third generation replication defective and considered class 1. The vectors used will be self inactivating (SIN). A deletion inactivates transcription form the proviral LTR, so reducing the potential for transcriptional activation of cellular genes and also prevents mobilization of any RCR. However as the virus integrates into the host cell DNA there is still a potential for insertional mutagenesis to occur.

A plasmid encoding the envelope protein from vesicular stomatitis virus envelope protein G (VSV-G) increases the host cell range/tissue tropism and makes it permissive for human cells, including quiescent cells. This feature means that there is a risk of infection through contact/aerosol transmission in addition to the normal HIV percutaneous route. Such particles are also physically more stable.

All Clontech lenti-X expression vectors contain a woodchuck hepatitis virus posttranslational regulatory element (WPRE). Vectors carrying the WPRE element are possibly able to promote tumours in animals and therefore should be handled at CL2.

The proteins we are planning to overexpress or downregulate are either known cytoskeletal proteins ubiquitously expressed in mammalian cells or other known mammalian proteins with no identified toxicity. Therefore a low damage factor is to be expected. Recent publications show that myosin VI is dramatically overexpressed in prostate cancer tissues. At present it is not known whether myosin VI is the causal factor for malignant transformation and therefore it will be treated as a potential oncogene until more information becomes available.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

none applied for

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All disposable tissue culture plastics will be autoclaved and incinerated. Culture medium will be treated with 2 % Virkon for 16 h and disposed to drains. Liquid spills will be treated with 2% Virkon (non metallic surfaces) or 10 % Trigene (metallic surfaces), absorbed with paper towels, which will then be autoclaved. Benches are cleaned with 10 % Trigene.

Project transferred to GM170 on 28/07/2014

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

Hormones such as glucagon-like peptide 1 (GLP-1), and glucose-dependent insulinotropic polypeptide (GIP) play key roles in postprandial nutrient homeostasis, but little is known of the molecular mechanisms underlying and regulating their release from enteroendocrine cells. Enteroendocrine cells lie scattered throughout the gut epithelium and at least 16 different types, classified by the secreted hormones, have been defined, amounting together to about 1% of the gut epithelium. While they are not readily distinguishable from the surrounding enterocytes (nor from each other) by live cell microscopy, we have recently successfully labeled enteroendocrine cells by expressing fluorescent protein markers under the control of the relevant hormone promoter either delivered as a stable transgene in mice or after adenoviral transfection of mixed gut epithelial cells in primary culture.

We now wish to further investigate the stimulus secretion coupling in these cells using:
which has resulted in increased tumor frequencies in mice, these viruses should be considered class 2. The lenti viral particles in this project will be 'pseudotyped' with the  hepatitis B virus post-transcriptional regulatory element) to boost viral titres and gene expression, and as this element can express an oncogene (part of the X-protein), administered accidentally and the defective replication and self-inactivation of the virus. As some of the commercially available vectors contain the WPRE (woodchuck posttranscriptional regulatory element) to boost viral titres and gene expression, and as this element can express an oncogene (part of the X-protein), of nearby genes due to integration within these genes be excluded. However, as problems arising from the insertion site have only been reported in studies involving third generation (distinguished in the UK by deletion of the tat-gene and replacement of the tat-responsive promoter in the 5'LTR by heterologous alternatives). The theoretical potential for re-emergence of replication competent virus through recombination has been significantly reduced in these vectors, by splitting the replicative, (a) Replication disbaled adenovirus vector, based on Ad5. This virus is deleted for essential replication functions (E1A region) and can only replicate in cells complementing this function (HEK 293 cell lin). Naturally the virus is transmitted by aerosol to respiratory tissues from where it may infect adenoid tissue. There are no reports of other infections such as enteric/kidney. However as the vector is incapable of completing a single round of replication, no progeny virus can be produced and infection would be (self) limited to any initial cells exposed. The number if cells affected would be related to the amount of virus encountered but effects would not progress to any extent approaching natural disease. The vector is considered HG 1.

Recipient or parental organism

Recipients:

a) E.coli: Strains of bacteria used for initial construction and plasmid amplification are derived from E.coli K12 and are therefore disabled and non-colonising.
b) Mammalian cells: Recipients will be various mammalian cells in culture. Most are moderately well characterised (eg HEK293 cell, GLUTag cells) and considered fastidious and non harmful, cannot colonise/cause disease, (ACDP hazard group 1). Primary epithelial cultures established from unscreaned human intestinal tissue could harbour infectious agents and should therefore be handled at containment level 2.

Host/vector system

(1) Replication disbaled adenovirus vector, based on Ad5. This virus is deleted for essential replication functions (E1A region) and can only replicate in cells complementing this function (HEK 293 cell lin). Naturally the virus is transmitted by aerosol to respiratory tissues from where it may infect adenoid tissue. There are no reports of other infections such as enteric/kidney. However as the vector is incapable of completing a single round of replication, no progeny virus can be produced and infection would be (self) limited to any initial cells exposed. The number if cells affected would be related to the amount of virus encountered but effects would not progress to any extent approaching natural disease. The vector is considered HG 1.

(2) Replication disabled lentivirus. Although the starting viruses like HIV themselves are hazard group 3 pathogens, vectors considered for his proposal are all second or third generation (distinguished in the UK by deletion of the tat-gene and replacement of the tat-responsive promoter in the 5'LTR by heterologous alternatives). The theoretical potential for re-emergence of replication competent virus through recombination has been significantly reduced in these vectors, by splitting the replicative, packaging and envelope functions and the desried transgene over ≥ three independent plasmids, therefore requiring multiple recombination events to generate replication competent virus. The emergence of replication competent virus is therefore unlikely and such viruses would be expected to have lost the transgene. In addition, many accessory functions/pathogenicity determinants such as vif have been deleted and they are all self-inactivating, carrying the SIN-deletion in the 3'LTR, including re-activation after integration into the host genome and as the U3 promoter is thereby compromised reducing the risk of transactivation of genes near the integration site. But, as the constructs all carry other (usually constitutively active (eg CMV)) promoters to drive expression of the transgene this can not be excluded, nor can the inactivaton of nearby genes due to integration within these genes be excluded. However, as problems arising from the insertion site have only been reported in studies involving administration of very high viral titers, the likelihood of similar problems in this study is considered low, taking into account the comparitively low viral titers likely to be administered accidentally and the defective replication and self-inactivation of the virus. As some of the commercially available vectors contain the WPRE (woodchuck hepatitis B virus post-transcriptional regulatory element) to boost viral titres and gene expression, and as this element can express an oncogene (part of the X-protein), which has resulted in increased tumor frequencies in mice, these viruses should be considered class 2. The lenti viral particles in this project will be 'pseudotyped' with...
vesicular stomatitis virus envelope protein G (VSVG); this increases host cell range/tropism and such vectors may represent an aerosol means of transmission in addition to the expected percutaneous risk from lentiviruses. Such viruses are more stable and can be purified to high titre. However, they are rendered sensitive to complement.

Origin & function

The expressed proteins range from fluorescent markers, such as GFP, which are unlikely to be harmful, and fusion proteins of fluorescent proteins with activity retaining protein kinase A catalytic subunit (overexpression of which might alter cell physiology, although the probe has successfully been used to investigate cAMP responses in pancreatic beta-cells, without altering their normal Ca²⁺-homeostasis or stimulant-secretion coupling) to other proteins involved in enteroendocrine physiology. Similarly the knock down targets are genes involved in enteroendocrine physiology, including, but not restricted to, glucokinase, SGLT-1 and Kir6.2. As overexpression or knock-down of such genes is unlikely to transform infected cells and is not expected to be toxic, the risk to human health or the environment from accidental infection is considered low.

Evaluation of foreseeable effects

As constitutively active promotors are used, virtually every transfected cell will be expected to express the inserted cDNA or shRNA. The expressed proteins range from fluorescent proteins with activity retaining protein kinase A catalytic subunit (overexpression of which might alter cell physiology, although the probe has successfully been used to investigate cAMP responses in pancreatic beta-cells, without altering their normal Ca²⁺-homeostasis or stimulant-secretion coupling) to other proteins involved in enteroendocrine physiology. Similarly the knock down infected cells and is not expected to be toxic in context of the transfected cells nor after release of proteins from lysed cells the risk to the environment due to accidental infection is considered low. Cells will remain especially disabled and unable to survive outside of laboratory culture.

1) Adenovirus: Adenoviruses are generally species specific; Ad5 infects humans and does not naturally infect other animals (but can experimentally infect cotton tail rats, which are not endogenous in the UK). Therefore there is no risk to other organisms. The virus is replication incompetent therefore could not spread to the wider human population from any infected individual.

2) Lentivirus: VSVG enables these vectors to infect a wide variety of animal cell types including those of different mammalian species. There may be enhanced environmental stability. However the viruses are replication disabled; they cannot produce progeny virus and so cannot spread to the wider human population or other animals.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none applied for

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All disposable tissue culture plastics will be autoclaved and incinerated. Culture medium will be treated 2% Virkon for 16 h and solidified prior to incineration. Liquid spills will be treated with 2% Virkon (non metallic surfaces) or 10% Trigene (metallic surfaces). Absorbed with paper towels, which will then be autoclaved/incinerated. Benches are cleaned with 10% Trigene.

Is an emergency plan required according to regulation 20? Y

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form N

Tick if you are claiming exemption from disclosure for section of the risk assessment N
This project has been reviewed by the Institutes Biological Genetic Safety. The Committee is satisfied that the risks have been properly addressed and the work will be carried out under the appropriate controls and conditions.

### Project Additional Information

**Purposes of the contained use**

For a viral infection to be successful the virus must survive in the presence of the host immune response. Viral survival strategies have evolved to modify or evade these host immune responses including the modification of host immunoreceptors. This project addresses the modification of host immunoreceptors by the human herpesvirus and lentivirus families.
Human herpesviruses are a family of enveloped double-stranded DNA viruses. There are three subfamilies: alphaherpesvirinae [herpes simplex viruses 1 and 2 (HSV-1, 2); varicella zoster virus (VZV)], betaherpesvirinae [human cytomegalovirus (HCMV), human herpesvirus-6 (HHV-6) and human herpesvirus -7 (HHV-7)] and gammaherpesvirinae [Epstein-Barr virus (EBV) and Kaposi's sarcoma herpesvirus (KSHV)]. The herpesviruses are ubiquitous pathogens of all vertebrates, although infections are usually highly species specific. All herpesviruses apart from KSHV and HSV-2 infect the majority of the human population (seroprevalence of HSV-1, VZV, HCMV, HHV-6 and -7, EBV is 50-100% depending on the population studied, whereas HSV-2 approximately 20%, KSHV 1-50% depending on the population studied). One common feature of all herpesvirus infections is lifelong viral persistence after primary infection despite a strong cell-mediated immune response. Each virus can generate a latent infection in certain cell types. In immunocompromised individuals, such as recipients of organ transplants and patients with advanced HIV infection, reactivation of herpesviruses such as VZV, HCMV, EBV and KSHV, has the potential to cause severe disease.

Human immunodeficiency virus (HIV) is the lentivirus that causes AIDS. This condition is characterised by progressive failure of the immune system, which allows opportunistic infections and cancers to thrive. HIV-1 establishes chronic infections, affecting approximately 33 million people worldwide. Despite considerable advances in HIV science, the goal of eradicating HIV- remains elusive.

There is already considerable evidence of immunoreceptor modulation by herpesviruses and lentiviruses; for example, MHC class I is removed from the cell surface by HSV, HCMV, EBV and KSHV as well as HIV. This proposal aims to investigate novel mechanisms and consequences of viral manipulation of host immunoreceptors during infection. We aim to investigate both (a) the role of individual viral genes on host immunoreceptors (herpesviruses and lentiviruses), as well as (b) whole viral infection in both lytic and latent phases (herpesviruses only). (a) We will clone individual viral genes into delivery vectors, and deliver them to relevant cultured host cells. We will then characterise he effects of theses modifications on the host cell. (b) We will generate herpesviral and disabled HIV-1 stocks in established human cell lines from viral seed stocks in established human cell lines from viral seed stocks or bacterial artificial chromosomes encoding the viral genome. Clinical isolates and their genetically modified derivatives will be used as well as laboratory adapted strains. In vitro infection of human cell lines and primary cell lines will then be carried out to model both lytic and latent viral infections. We will then characterise the effects of these viral modifications on the host cell. Viruses with deletions of, or tags attached to individual genes will be utilised in order to further characterise cellular effects.

Recipient or parental organism

Recipients will be various mammalian cells in culture. Most are well characterised and considered ACDP hazard group 1. Cells from volunteers are uncharacterised and although themselves present no greater risk, may contain adventitious infectious agents and therefore will be handled at CL2 (risk assessment under COSHH regs). Mammalian primary cells or cell lines are especially disabled and unable to survive or propagate outside of laboratory culture. Culture cells expressing the viral genes may be altered in particular surface proteins they express but those changes will not over ride the especially disabled nature of the cells.

The herpesviruses to be studied as detailed above are all ACDP hazard group 2 and will therefore be handled at CL2 within a class II microbiological safety cabinet (MSC). Pregnant or known immunocompromised individuals will not perform any of this work. The modified herpesviruses should be no more pathogenic than wild type. Although there are virus deletion mutants with increased virulence over their parent (for example deletion of A41L in vaccinia virus), to our knowledge, herpesvirus deletion mutants that show increase in virulence have not been described.

Viral gene delivery vectors (retroviruses, lentiviruses) to be used are those typically considered class 1 GMMs, and will all be self-inactivating, and therefore once packaged, are unable to propagate. A three plasmid transient transfection system will be used to generate the recombinant retroviruses and lentiviruses, thereby decreasing the likelihood of recombination within the packaging cell lines to generate replication competent virus. The retroviral vectors are based on the Moloney murine leukaemia virus in which the gag, pol and env genes have been deleted. Gag and pol are supplied in trans on a packaging plasmid. We will generate VSV-G pseudotyped virus in order to deliver the virus particles to human cells. The lentiviral vectors are based on an HIV-1 self inactivating vector (SIN) containing a deletion in the U3 region of the 3’LTR of the virus. In addition, the gag, pol, env, nef, vpu and vpr genes have been deleted. Again, a second packaging plasmid encoding gag, pol, rev and tat will be used along with the plasmid encoding VSV-G to make pseudotyped viruses that will enter human cells. A packaging plasmid encoding nef, vif, vpu and vpr may also be used, in order to improve transduction efficiency of primary human cells. While VSV-G increases host range and their tropism and mode of transmission may also be altered from that exhibited by wild-type retroviruses, aerosol risk to the airway epithelium appears limited but the inability to infect the apical cell surface. The AdZ adeno viral vector system will be used to generate recombinant adenoviruses. These vectors carry a deletion of the E1 gene region rendering them replication incompetent in non-complementing cell lines. In addition, the E3 region (important for viral pathogenesis and immune evasion) has also been deleted making them less pathogenic in...
humans. They are those typically classed as class 2 GMMs and remain so as the inserts are placed within the deleted regions. All three types of viral vectors will be harvested and used in a CL2 laboratory.

The molecular clone that encodes the disabled HIV-1 to be used in this project is derived from the HIV-1 backbone and is currently approved for use when working under CL2 conditions in the Department of Medicine at Addenbrooke's Hospital, Cambridge. To increase the safety of the system, the vector components are segregated onto 2 plasmids: an HIV-1 molecular clone with a critical env deletion and a second plasmid expressing the VSV-G envelope protein. None of the individual plasmids is capable of generating infectious viral particles and, to avoid the generation of replication competent virus via homologous recombination, the constructs do not contain overlapping homologous sequences. Since none of the cell lines or vectors carry intact env-encoding sequences, infectious HIV particles cannot be produced.

The viruses and viral delivery vectors we will use are ACDP hazard group 2/class 1 GM. The viruses are deactivated by treatment with trigene, virkon or 70% EtOH and autoclaving. Therefore following the waste procedures outlined below should eliminate risk of spread to the environments. Many of the herpesviruses are also strictly human specific, therefore there is no risk of spread to other animals or plants. The viral vectors are all replication disabled so will be unable to disseminate in the wider animal or human populations. Modifications will be to add a tag such as a fluorescent protein to viral proteins, or to delete or disrupt viral genes and subsequently restore them. Expression of tags is not expected to be detrimental to human health or the environment. Deletions/disruptions to viral genes are not expected to increase infectivity/pathogenicity. Herpesvirus genes cloned into viral gene delivery vectors may confer an ability to alter immune responses to infected cells. However, the large number of viral immune evasion genes encoded by the human herpesviruses demonstrates the need for a virus to encode more than one immunoevasin in order to effectively evade human immune responses.

We will only express a single herpesviral gene in each gene delivery vector. As the vectors are disabled, any accidental infection of the epithelial cells of the researcher would be localised. Transduced cells would not be able to produce viral particles. Due to the high turnover rate of epithelial cells, any localised infection would not be expected to be long lasting.

Pseudotyped env-deleted HIV-1 viral particles are replication deficient, but theoretically able to transduce epithelial cells of the researcher. If this occurred, all HIV-1 proteins except env would be expressed, but no replication competent virus would be formed. This protein expression would not be expected to cause harm, and the Mammalian tissue culture cell lines (eg HFF2, THP-1, KG-1, HeLa, U373, U937, Huh7, HCT116, Jurkat, Daudi, NK-92, NK-L, HL60, 220, T1, 293, Ramos). Primary human cells (eg monocytes, dendritic cells, T cells, B cells, NK cells). Human herpesviruses including HSV-1 (eg strains: F, KOS, 17, SC16), HSV-2 (eg strains: 333, HVD), VZV, EBV, HCMV (eg strains: Toledo, Merlin, TB40/E, VR1814/FIX-BAC and laboratory adapted strains AD169 and Towne), HHV-6, HHV-7 and KSHV.

A disabled HIV-1 virus with a critical env deletion will also be used.

Bacteria: Top10, Sure 2, alpha-select, clean genome.

Viral gene delivery vectors including retroviruses, lentiviruses and adenoviruses.

Bacterial artificial chromosomes (BACs) that cover the genomes of the herpesviruses and adenovirus serotype 5 so that insertion/deletions in the viral genome can be generated in vitro prior to the generation of recombinant viruses.

Standard cloning vectors (such as TOPO and pcDNA3) and BAC shuttle vectors will be used to clone viral gene disruptions (such as truncations) and to add inserts-tags onto viral genes or to rescue deletion viruses. In addition, these cloning vectors will be used to express individual viral genes to allow their study in host cells.

The HIV-1 molecular clone with the env deletion will be used for targeted gene disruption in vitro prior to the generation of lentiviral particles.

Origin & function

Inserts:
Inserts will be used to label herpesviral and lentiviral genes to enable their visualisation during viral infection (such as the YFP, GFP or RFP fluorescent tags) or to simplify
biochemical analyses of viral genes (such as HA, Strep, Myc and Flag tags). To examine the biological role of individual herpesviral and lentiviral genes, gene deletions/disruptions and subsequent reconstitutions will also be used.

Expected biological action of inserted DNA/RNA or transcribed/translated gene product:
The inserts will be commonly used markers/tags as detailed above. Apart from fluorescence, these tags are biologically inert; their expression should not increase viral virulence or fitness.

Deletion or disruption of viral genes is not expected to increase virulence. For reconstitution of deletion viruses, only the original gene will be re-inserted and therefore no increase in virulence over the original strain is expected. No modifications will be made that are designed to introduce new biological activities into viral proteins. Over-expression of viral genes in viral gene delivery vectors should not pose any risk additional to use of the viruses themselves.

Evaluation of foreseeable effects

Pseudotyped particles have previously been classified as class 2.

Bacterial artificial chromosomes and plasmids will be used to generate recombinant virus. These contain antibiotic resistance markers which could in theory present a problem to the user if they become infected with the bacteria in which the plasmids/BACs were grown. However, in practice the bacterial strains we use are highly attenuated and unlikely to cause disease, while the antibiotic resistance markers encoded by these plasmids/ BACs (Ampicillin, kanamycin and chloramphenicol) are active against antibiotics which are no longer in general use in clinical practice. So whilst the plasmids/BACs pose no threat in a bacterial culture, once transfected into eukaryotic cells the recombinant DNA can be packaged into infectious virions and transfection will therefore be carried out in a CL2 laboratory and subsequent cultures treated as live virus.

The disabled nature of the bacterial hosts will not be altered by the plasmids or BACs in use - no expression is anticipated and would not in any case be compatible with bacterial systems. The bacterial strains we use are highly disabled and unable to replicate to any extent outside the lab. Never-the-less, appropriate control measures, including disinfection (with virkon) of liquid cultures and autoclaving of bacterial plates, will be taken.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Conventional molecular biology techniques will be used for cloning in a CL1 laboratory. Bacterial artificial chromosomes and viral gene delivery vectors will be transfected into mammalian cell lines in a CL1 laboratory then transferred to the CL2 laboratory within 24 hours of transfection (to allow us to evaluate transfection efficiency with a fluorescence microscope). All manipulation of liquid will be carried out in a class II Microbiological safety cabinet (MSC) to reduce the risk of aerosol dissemination. Tubes for ultracentrifugation of virus for the production of concentrated virus stocks will be loaded in MSC into buckets that will be sealed and transported to the ultracentrifuge in secondary containers. Similarly, once the ultracentrifugation is complete, the tubes will be transported back to the CL2 laboratory and the buckets opened in the MSC to allow the virus to be resuspended and aliquoted. Since there is no -80° storage facility in our CL2 laboratory, small aliquots of virus will be transported to 5.29 in secondary containment for storage. Fluorometric and microscopic analysis will be conducted on fixed samples, and protein and nucleic acid analysis will be conducted on material which has been lysed in the CL2 facility prior to transport to the laboratory.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The ultracentrifuges available for concentrating virus preparations are outside of CL2 labs. Virus preparations will be sealed within the centrifuge tubes and buckets within the MSC in CL2 and transported in a shatterproof container. The surfaces of centrifuge tubes and transport containers will be decontaminated with detergent prior to removal from CL2 and only be re-opened once returned to the MSC in CL2. The 'comments' section of the ultracentrifuge logbook will be used to warn other users that the centrifuge contains a CL2 organism. Following centrifugation, the buckets will be returned to the MSC in the CL2 for processing. The buckets will then be immersed in detergent in the MSC prior to removal back to 5.14 for cleaning, rinsing and drying.

The -80 degree freezer for storing virus preparations and supernatant is also outside of the CL2 labs. Vessels containing supernatant and concentrated virus preparations will be decontaminated with Trigene and put into a shatterproof container for transport to and storage at -80 in Lab 5.19.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All liquid waste will be disinfected with Virkon overnight, gelled using Vernagel, double bagged, sealed and labelled for autoclave then incineration according to the Department CL2 procedures. All solid waste will be double bagged and labelled for autoclave then incineration (pipettes will be disinfected in 1% trigene before removal from MSCs to prevent drips). Work surfaces will be wiped down with trigene and 70% ethanol. Small spillages will be mopped up immediately with tissue and disinfected with 1% trigene or 2% virkon. Large spills will be covered with absorbent paper and then sprayed with 10% trigene or 2% virkon, and then mopped up after 30 minutes. The absorbent material will then be disposed of in the solid autoclave waste.

This project has been reviewed by the Institutes Biological & Genetic Modification Safety Committee. The Committee is satisfied that the risks have been properly addressed and the work will be carried out under the appropriate controls and conditions.

**Project Additional Information**

**Purposes of the contained use**

The nature of T-cell surface receptors (TcR, costimulators CD28, CTLA-4, ICOS) signalling pathways responsible for regulation of T-cell activation and adhesion and mobility. Our objective is to study the role of costimulators CD28, CTLA-4, ICOS, PD-1 as well as adaptor proteins SLP-76, ADAP and SKAP-55 and the kinases including ZAP70, LCK FYN and GSK3. Over-expression or down regulation of the target genes in cell lines and primary cells using transfection. T-cell function in vitro including activation, proliferation, and adhesion will be examined.

**Recipient or parental organism**

Mammalian cells: Mammalian primary cells or cell lines are especially disabled and unable to survive or propagate outside of laboratory culture.

**Host/vector system**

- Host Human or murine cell lines, such as Jurkat DC27, T8.1, A20, 3A9 or primary cells and other cell lines such as 3T3, 293T, phoenix cells.
- Retroviral vectors (pinco, MigR1, pMX, pMDG, pMLV-GP, p8.91, pGIPZ)
- Lenti-viral vector (HIV-1 self-inactivating vector SIN, pFIP)
- pLKO.1 vector (lentiviral (HIV)-based plasmid)
- plasmid encoding the envelope plasmid derived from vesicular stomatitis virus (VSV) G protein

Cells will be transfected with retroviral or lentiviral plasmids and viral supernatant harvested (max vol 30ml/vector/transfection) and used to infect target T-cell lines or primary T-cells. After infection twice target cells are harvested and used for functional assessments. Max culture vol of target cells is 100ml/cell type, if viral supernatant is frozen for stock, viral supernatant is aliquot in small vial (~2ml/vials) and stored in allocated areas or boxes in -80 degree freezer. 200 µl will contain approximately 1 x 10^6 TU/ml

For example, shRNAs will be cloned into the pLKO, 1 transfer vector which is compatible with standard two plasmid (packaging vector with rev gene and envelope vector) or a three plasmid (packaging vector without rev gene, envelope vector, and rev expression vector) packaging systems. In the case of MISSION shRNA, the viral particles cannot be propagated and are replication incompetent.

A three plasmid transient transfection system will be used to generate recombinant replication-defective retroviruses 293T cells, a human cell line carrying SV40 T cell antigen will be transfected with (a) An HIV-1 self inactivating vector (SIN) cDNAs encoding the genes of interest will be cloned into the HIV-1 derived SIN vectors, which have a deletion in the U3 region of the 3' long terminal repeat (LTR) of the DNA used to produce the vector RNA. During reverse transcription this deletion is transferred to the 5' LTR and abolishes the transcriptional activity of the LTR and as a result the production of full-length vector RNA in transduced cells is abolished (b) An HIV-1 derived retroviral sequence encoding viral gag/pol tat and rev genes, from which the virulence genes vif, vpr, vpu and nef have been deleted and (c) a plasmid encoding the envelope plasmid derived from vesicular stomatitis virus (VSV) G protein. This is a well defined lentivirus system that is in use under our GM centre No 678.

**Origin & function**
The genes targeted are involved in aspects of cell signalling, activation and proliferation and are not expected to be toxic. None of the proteins are known oncogenes and are therefore highly unlikely to foster tumour progression.

**Evaluation of foreseeable effects**

Mammalian primary cells or cell lines are unable to survive or propagate outside of laboratory culture.

The genes targeted are involved in aspects of cell signalling, activation and proliferation and are not expected to be toxic. None of the proteins are known oncogenes and are therefore highly unlikely to foster tumour progression.

The vectors used will be self inactivating (SIN). A deletion inactivates transcription from the proviral LTR, so reducing the potential for transcriptional activation of cellular genes and also prevents mobilization of any RCL. However as the virus integrates into the host cell DNA there is still a potential for insertional mutagenesis to occur.

A plasmid encoding the envelope protein from vesicular stomatitis virus envelope protein G (VSV-G) increases the host cell range/tissue tropism and makes it permissive for human cells, including quiescent cells. This feature means that there is a risk of infection through contact/aerosol transmission in addition to the normal HIV percutaneous route. Such particles are also physically more stable.

The genes or other sequences of interest will be delivered by an integrative process leading to potential long-term expression for the life of the target cell. The results of such expression for most of the sequences will not be severe and will be limited to the cells targeted and no further.

VSV-G enables the vector virus to infect a wide variety of mammalian cells. There may also be enhanced environmental stability. However, the viruses are replication disabled, they cannot produce progeny virus and so cannot spread to the wider human population or other animals. The possibility of RCL being generated and released is negligible.

The MISSION TRC lentiviral particles are replication incompetent.

None of the modifications will alter the broad properties of the vectors. They will remain replication disabled and so are biologically contained.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

Project Additional Information

Purposes of the contained use

Intracellular protein misfolding/aggregation are features of many late-onset neurodegenerative diseases, called proteinopathies. These include Alzheimer's disease,
Parkinson's disease, tauopathies, and ten known neurodegenerative diseases caused by (CAG) in trinucleotide tract expansions that encode abnormally long polyglutamine (polyQ) tracts. These polyQ diseases include Huntington's disease (HD), Huntington's disease-like 2, spinocerebellar ataxias (SCA) types 1,2,3,6,7 and 17, spinobulbar muscular atrophy (SBMA) and dentatorubral-pallidoluysian atrophy (DRPLA). Currently, there are no effective strategies that slow/prevent the neurodegeneration resulting from these proteinopathies. Huntington's disease (HD) is a devastating autosomal dominant neurodegenerative condition that manifests with abnormal movements, psychiatric symptoms and dementia. The HD gene encodes a large protein called huntingtin that contains more than 3000 residues. Exon 1 of the wild-type gene contains the stretch of uninterrupted CAG trinucleotide repeat, which is translated into a polyglutamine (polyQ) tract. Asymptomatic individuals have 35 or fewer CAG repeats and HD is caused by 36 or more repeats. CAG repeat number inversely correlates with age-of-onset of symptoms; the greater the number of CAG repeats, the earlier the age-of-onset. Genetic and transgenic experiments argue that HD and related polyQ diseases are caused predominantly by toxic gain-of-function mechanisms. One of the pathological hallmarks shared by all the known polyQ diseases is the presence of aggregates (also known as inclusions) comprising the mutant protein in affected neurons. The toxicity of polyglutamine-expanded proteins may be attenuated if one can enhance their clearance. We have shown that one way of doing this, at least for mutant huntingtin and ataxin 3 is to enhance macroautophagy, which we will call autophagy. Autophagy is a bulk degradation process that mediates the clearance of long-lived cytoplasmic proteins and organelles. Autophagosomes are formed by double-membraned structures, which engulf portions of cytoplasm. Autophagosomes ultimately fuse with lysosomes, where their contents are degraded. If one blocks autophagy, then one slows the clearance of intracytoplasmic aggregate-prone proteins that cause many neurodegenerative diseases, including Huntington's disease, SCA3, point mutations in alpha-synuclein (causing forms of Parkinson's disease), and wild-type and mutant forms of tau (causing various dementias). This increases aggregation and toxicity. Conversely, our data suggest that autophagy upregulation may be a rational therapeutic strategy for such diseases, as drugs that upregulate this pathway via both mTOR-dependent and independent pathways enhance mutant huntingtin clearance in an autophagy-dependent fashion in cell-culture and in vivo, leading to attenuated disease phenotype in animal models of HD and SCA3.

Our laboratory aims to understand the biology of Huntington's disease and related conditions. To this end we need to be able to study potential modifier genes for this disease and related diseases by knockdown and overexpression. Ideally, we need to do some studies in primary neurons, where viral delivery is preferable to standard transfection. We also study the biology of autophagy both at basic level (where we are seeking to understand the machinery and signalling processes), as well as at the applied level where we study possible drug targets with therapeutic potential. Again, viral delivery of constructs or RNAi is a powerful to enable more effective transduction or efficient delivery into primary neurons.

Recipient or parental organism

Recipients will be various mammalian cells in culture and primary murine cells. Most are well characterised and considered ACDP HG1.

Host/vector system

We propose using a system with lentiviral vectors based on HIV-1. We will use a three plasmid transient transfection system to generate recombinant, replication defective retroviruses in 293T cells. In this system virus replicative, packaging and envelope vectors and the transgene vector are split over three plasmids, requiring multiple recombination events to generate replication competent retrovirus (RCR). Any RCR generated would lose the transgene during recombination events. Many accessory functions/pathogenicity determinants such as vif have been deleted. Vectors insert into the host cell DNA after infection leading to retention of the transgene for the life of the cell. These viruses may transduce non-dividing e.g. (neurons) as well as dividing cells. The transfected vectors are as follows: (i) An HIV-1 ‘self inactivating vector’ (SIN). CDNAs encoding the genes will be cloned into these vectors which have a deletion in the U3 region of the 3' long terminal repeat (LTR) of the DNA used to produce the vector RNA. During reverse transcription this deletion is transferred to the 5' LTR and abolishes the transcriptional activity of the LTR, and as a result the production of full-length vector RNA in transduced cells is abolished. (ii) An HIV-1 derived retroviral sequence encoding viral gag/pol tat and rev genes, from which virulence genes vif, vpr, vpu and nef have been deleted (iii) A plasmid encoding the envelope plasmid derived from vedoric stomatitis virus (VSV-G) protein which is permissive for human cells. This is a well defined lentivirus system that is in use under our GM centre No 678. In addition to this standard protocol replication deficient lentiviral particles may be obtained from commercial sources, such as Dharmacon SMART vector 2.0 Lentiviral shRNA particles or Sigma MISSION shRNA. Or commercially available lentiviral production systems such as Block-IT shRNA vector systems (Invitrogen) may be used . The latter is also based on a multi-plasmid strategy whereby a pLenti based expression vector containing the DNA sequence of interest is transfected along with 3 packaging plasmids. These plasmids supply the helper functions as well as structural and replication proteins in trans required to produce the lentivirus, also using a (VSV-G) as a pseudotyping envelope. As some commercially available vectors contain the WPRE (woodchuck hepatitis B virus post-transcriptional regulatory element) to boost viral titres and gene expression and as this element can express and oncogene, which has resulted in increased tumour frequencies in mice these viruses should be considered class 2. During production and concentration of retrovirus the transduction of cells and the subsequent analysis of these cells level 2 containment will be strictly adhered to. This will involve standard measures to decrease percutaneous as well as aerosolised transmission of the virus i.e. by avoiding sharps use and working in a class II MSC.
Origin & function

a) cDNA or shRNA for genes encoding potential modifiers of Huntington's disease and related conditions, including forms of Parkinson's disease and other dementias and mutant forms of these gene b) cDNA or shRNA for genes encoding modifiers of autophagy c) markers and reporters derived from fluorescent proteins.

For a) the wild-type function of genes involved in Huntington's disease and related conditions is not fully understood however it is thought that the disease-causing genes posses a toxic-gain of function. For b) either an increase or decrease in cellular autophagy would be expected. For c) the markers and reporters would not be expected to have any cellular effect.

Evaluation of foreseeable effects

The expression of genes involved in Huntington's disease and other related conditions may be cytotoxic in neuronal cells as these genes cause late onset neurodegenerative diseases, however the likelihood of exposure of this tissue type to the viral vectors is extremely low. The action of the expressed proteins or shRNAs which modulates autophagy is unlikely to be cytotoxic and the fluorescent reporter constructs which are expected to be biologically inert. None of the genes to be used are known oncogenes and are therefore unlikely to foster tumour progression. The expression of any of these genes, even in the long term, in a minor population of cells at the likely sites of exposure is unlikely to be harmful and expression will not spread beyond exposed tissues. Additional risk comes from insertional mutagenesis following exposure. In the main this risk comes from the possibility that the arising mutation would initiate oncogenesis. Whilst this cannot be ruled out it is unlikely and by handling these constructs at CL2 we aim to reduce this risk to acceptable levels.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Standard bacterial cloning (CL-1) Generation of high titre virus stocks with established cell lines: tissue culture with primary cells and immortalised cell lines, infection of these cells with lentiviral vectors (CL-2). Characterisation of autophagy or fluorescent properties of transfected cells: No work with active viral particles will be performed outside containment level 2. Cultures will be washed with viral free media and either used at least 48h after viral transfection or fixed before being transferred to designated microscopic setups, flow cytometry or bench areas at CL-1. Cells used at containment level 1 or 2 will be autoclaved/incinerated at the end of the procedure. All media exposed to the cells will be treated with Virkon and solidified prior to incineration. All spills will be treated with Virkon. All sharps will be avoided.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None applied for

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All disposable culture/lab ware will be autoclaved and incinerated. Culture fluids will be treated with 2% Virkon for 16 hours and disposed to drains. Recyclable lab ware will be soaked in 1% Virkon for 16 hours. Bench/cabinet surfaces will be wiped down with 70% ethanol. Spills will be sprinkled with Virkon powder.

Please enter comments on the GM safety committee on the risk assessment

This project has been reviewed by the institutes Biological Genetic Safety. The Committee is satisfied that the risks have been properly addressed and the work will be carried out under the appropriate controls and conditions.
The defining feature of eukaryotes like ourselves, compared with our prokaryotic ancestors, is the presence of membrane-bound subcellular compartments (the endomembrane system), each of which has a distinct protein composition. This means that our cells need to direct >500 different membrane proteins to the correct location, and then either to keep them there or ensure they move about in an orderly fashion via vesicle-mediated intracellular trafficking. There are many examples of genetic disorders that affect trafficking, either because of mutations in cargo proteins or because of mutations in the trafficking machinery itself. The current project is focused on identifying and characterising gene products underlying the formation, function and maintenance of the endomembrane system and understanding the pathophysiological consequences of defects in this system. In particular, we are planning to investigate adaptations of this system supporting tissue-specific functions including, but not limited to, neurotransmitter release, glycolipid metabolism and melanosome biogenesis. This requires efficient manipulation of...
Specifically we intend to alter the expression and/or function of candidate genes and gene products in various tissues and cell lines using Knock-down and/or overexpression of candidate genes, including modified versions, for example harbouring specific mutations and/or detectable epitopes/domains. The function of the endomembrane system will be monitored through expression of reporter constructs bearing detectable biologic tags. To introduce these synthetic constructs to many culture adapted cell lines lipofection based approaches will be sufficient, additionally all constructs will be tested in this manner prior to viral vector construction. Where it is necessary to introduce synthetic constructs into either hard to transfect cell lines or isolated primary cells/tissues in culture adenoviral and/or lentiviral approaches will be used as appropriate.

Recipient or parental organism

a) E. coli: Strains of bacteria used for initial construction and plasmid amplification are derived from E. coli K12 and are therefore disabled and non-colonising.
b) Mammalian cells: Recipients will be various mammalian cells in culture. Most are moderately well characterised (eg HEK293 cells, HeLa cells) and considered fastidious and non harmful, cannot colonise/cause disease (ACDP hazard group 1).
c) Primary cultures established from mouse tissue explants are fastidious and non-harmful (ACDP hazard group 1).
d) Primary tissues and cells isolated from humans are themselves no more hazardous but are unscreened and therefore may harbour infectious agents, therefore all work using human primary cells/tissues will be undertaken at containment level 2

Host/vector system

Replication disabled adenovirus vector, based on Ad5. This virus is deleted for essential replication functions (E1A region) and can only replicate in cells complementing this function (HEK293 cell line). Naturally the virus is transmitted by aerosol to respiratory tissues from where it may infect adenoid tissue. There are reports of other infections such as enteric/kidney. However as the vector is incapable of completing a single round of replication, no progeny virus can be produced and infection would be (self) limited to any initial cells exposed. The numbers of cells affected would be related to the amount of virus encountered but effects would not progress to any extent approaching natural disease. The vector is considered GM class 1.

Replication disabled lentivirus. Although the starting viruses like HIV themselves are hazard group 3 pathogens, vectors considered for this proposal are all second or third generation (distinguished in the UK by deletion of the tat gene and replacement of the tat-responsive promoter in the 5'LTR by heterologous alternatives). The theoretical potential for re-emergence of replication competent virus through recombination has been significantly reduced in these vectors, by splitting the replicative, packaging and envelope functions and the desired transgene over ≥ three independent plasmids, therefore requiring multiple recombination events to generate replication competent virus. The emergence of replication competent virus is therefore unlikely and such viruses would be expected to have lost the transgene. In addition, many accessory functions/pathogenicity determinants such as vif have been deleted and they are self-inactivating, carrying the SIN-deletion in the 3'LTR, inhibiting re-activation after integration into the host genome and, as the U3 promoter is thereby compromised reducing the risk of transactivation of genes near the integration site. But, as the constructs all carry other (usually constitutively active (eg CMV)) promoters to drive expression of the transgene this can not be excluded, nor can the inactivation nearby genes due to integration within these genes be excluded. However, as problems arising from the insertion site have only been reported in studies involving administration of very high viral titers, the likelihood of similar problems in this study is considered low, taking into account the comparitively low viral titers likely to be administered accidentally and the defective replication and self-inactivation of the virus. As some of the commercially available vectors contain the WPRE (woodchuck hepatitis B virus post-transcriptional regulatory element) to boost viral titres and gene expression, and as this element can express an oncogene (part of the X-protein), which has resulted in increased tumour frequencies in mice, these viruses should be considered class 2. The lentiviral particles in this project will be 'pseudotyped' with vesicular stomatitis virus envelope protein G(VSVG); this increases host cell range/tropism and such vectors may represent an aerosol means of transmission in addition to the expected percutaneous risk from lentiviruses. Such viruses are more stable and can be purified to high titre. However, they are rendered sensitive to complement.

Origin & function

The inserted genetic material will encode cDNA and/or ShRNA of/for genes involved in the formation, function and maintenance of the endomembrane system. Marker/Reporter constructs bearing detectable tags (including but not limited to fluorescent proteins such as GFP and short peptide tags such as C-myc). Specific gene families targeted include, but are not limited to, those responsible for forming vesicle coats, including adaptor proteins (i.e. AP complexes 1-5) and structural coat proteins.
such as clathrin as well as gene families underlying enzymatic activity with the lumen of the endomembrane system such as galactocerebrosidase (GALC). Additionally we will target newly identified gene products performing accessory functions to endomembrane system formation and specific vesicular protein cargoes. Inserted genetic material will specifically target the function of the endomembrane system. These manipulations are not expected to alter oncogene expression or transform the target cells. Additionally, inserted genetic material and products thereof will have restricted localisation to expressing cells. The risk to human health from accidental exposure is therefore low.

**Evaluation of foreseeable effects**

The majority of gene products will have actions within the cytoplasm of the cell and as such are unlikely to be secreted or have actions beyond the expression cell. Where secreted gene products are introduced to act as markers for secretory function they will carry biologically inert, but detectable, epitope tags and as such are again unlikely to have actions beyond the expressing cell. As overexpression or knock-down of such genes is unlikely to transform infected cells and is not expected to be toxic in context of the transfected cells nor after release of proteins from lysed cells the risk to the environment due to accidental infections is considered low. Cells will remain especially disabled and unable to survive outside of laboratory culture.

1) Adenovirus: Adenoviruses are generally species specific; Ad5 infects humans and does not naturally infect other animals (but can experimentally infect cotton tail rats, which are not endogenous in the UK). Therefore there is no risk to other organisms. The virus is replication incompetent therefore could not spread to the wider human population from any infected individual.

2) Lentivirus; VSVG enables these vectors to infect a wide variety of animal cell types including those of different mammalian species. There may be enhanced environmental stability. However the viruses are replication disabled; they cannot produce progeny virus and so cannot spread to the wider human population or other animals.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Mechanisms of protein degradation - using (i) overexpression or depletion of tagged or untagged genes involved in protein breakdown in lentiviral and retroviral systems

Purposes of the contained use

All mammalian cells have to control their protein content to remove damaged proteins and regulate cell growth. Any disruption in cellular protein levels can cause uncontrolled cell turnover or the accumulation of misfolded proteins that occur in neurodegenerative conditions. The major mechanisms for controlling intracellular protein levels are through ubiquitination, proteasomal degradation and autophagy. This project aims to address how ubiquitinated proteins are differentially selected and efficiently delivered to the proteasome for degradation. The research encompasses several main themes:
1) How different polyubiquitin chains are decoded.
Specificity in the ubiquitin system is generated by the ability of ubiquitin to form eight different polyubiquitin chain linkages. Each type of ubiquitin linkage must be correctly interpreted to facilitate the desired outcome, and ubiquitin binding proteins (UBPs) provide this critical link between chain recognition and cellular fate. For example, we showed chain-specific UBPs facilitate lysine-48 chains to bind the proteasome but block lysine 63-chains from binding this degradative complex. UBPs for other polyubiquitin chain types were unknown, but we have identified UBPs that selectively recognize lysine-11 polyubiquitin chains, an abundant linkage with a critical role in regulating mitosis. Using biochemical and cell biology approaches we aim to investigate the function and physiological importance of these lysine-11 specific UBPs.

2) How ubiquitin binding proteins regulate protein turnover.
We will use forward genetic screens in near-haploid human cells (KBM7) to identify genes required to regulate the degradation of proteins by the proteasome. By the insertion of random mutations into cells expressing fluorescent proteasome reporters, we can identify genes required for the efficient degradation of these ubiquitinated substrates. Retroviral gene traps and CRISPR (Clustered Regularly Interspaced Short Palindromic Repeats) technology will be used in the screens. As ubiquitination is also involved in non-proteasomal degradation, we will examine how ubiquitinated proteins are recruited to autophagy and lysosomal pathways.

3) Regulation of the hypoxia response pathway.
We will use forward genetic screens and proteomics to determine novel genes in the regulation of hypoxia inducible transcription factors (HIFs, a pathway critically regulated by ubiquitination). Genes identified as regulating HIFs will be characterized in cell line based assays and primary cells (macrophages and fibroblasts) for their importance in the hypoxia response. Other oxygen-dependent regulatory mechanisms, for example oxidative phosphorylation and protein hydroxylation, will also be studied.

To investigate these aims we will use lentiviruses and retroviruses to:

a) Generate stable mammalian cell lines encoding UBPs, ubiquitin enzymes, genes regulating protein breakdown or oxygen consumption of cells using pHRSIN vectors.

b) Use shRNA with pSIREN vectors to confirm the function of genes identified in the mutagenesis screens.

c) Generate stable knock-out or knock-in (tagged) cell lines of genes identified in the genetic screens using CRISPR technology in lentiviruses encoding the Cas9 nuclease and guide RNAs (sgRNA) (pLKO-TRC).

d) Use stable and tetracyclin-inducible shRNA and sgRNAs.

These stable cell lines will be utilised to further characterise the cellular effects of genes required in the regulation of the ubiquitin proteasome system.
Viral gene delivery vectors including retroviruses, lentiviruses, and adenoviruses.
The lentivirus and retrovirus plasmids contain the WPRE-X
2nd generation retrovirus and lentivirus packaging systems will be used.

All liquid waste will be disinfected with Virkon overnight, gelled using Vernagel, double bagged and sealed and labelled for autoclave then incineration according to the Department CL2 procedures. All solid waste will be double bagged and labelled for autoclave then incineration (pipettes will be disinfected in 1% Distel before removal from MSCs to prevent drips). Work surfaces will be wiped down with Distel and 70% ethanol. Small spillages will be mopped up immediately with tissue and disinfected with 1% Distel or 2% virkon. Large spills will be covered with absorbent paper and then sprayed with 10% Distel or 2% virkon, and then mopped up after 30 minutes. The absorbent material will then be disposed of in the autoclave waste.

Modulation of innate immunity by viral infections

Class 2

CultureVolClass2 1-50 Litres

Non-GMM

Consent Granted

Project notified under transitional arrangements N
Human herpesviruses are a family of enveloped double-stranded DNA viruses. There are three subfamilies: alphaherpesvirinae [herpes simplex viruses 1 and 2 (HSV-1, 2); varicella zoster virus (VZV)], betaherpesvirinae [human cytomegalovirus (HCMV), human herpesvirus-6 (HHV-6) and human herpesvirus-7 (HHV-7)] and gammaherpesvirinae [Epstein-Barr virus (EBV) and Kaposi's sarcoma herpesvirus (KSHV)]. The herpesviruses are ubiquitous pathogens of all vertebrates, although infections are usually highly species specific. All herpesviruses apart from KSHV and HSV-2 infect the majority of the human population (seroprevalence of HSV-1, VZV, HCMV, HHV-6 and -7, EBV is 50-100% depending on the population studied, whereas HSV-2 approximately 20%, KSHV 1-50% depending on the population studied). One common feature of all herpesvirus infections is lifelong viral persistence after primary infection despite a strong cell-mediated immune response. Each virus can generate a latent infection in certain cell types. In immunocompromised individuals, such as recipients of organ transplants and patients with advanced HIV infection, reactivation of herpesviruses such as VZV, HCMV, EBV and KSHV, has the potential to cause severe disease.

Human immunodeficiency virus (HIV) is the lentivirus that causes AIDS. This condition is characterised by progressive failure of the immune system, which allows opportunistic infections and cancers to thrive. HIV-1 establishes chronic infections, affecting approximately 33 million people worldwide. Despite considerable advances in HIV science, the goal of eradicating HIV-1 remains elusive.

Human herpes- and lenti-viruses encode multiple factors that modulate innate and adaptive immune defences, however viral subversion of interferon (IFN)-mediated innate immunity is at best partly understood. One survival strategy exemplified by HIV has included the destruction or modification of host antiviral restriction factors, for example Tetherin, APOBEC proteins and the SERINCs. Existing data suggests that there may nevertheless be a number of unidentified factors that act against HIV. The evasion of restriction factors by herpesviruses remains relatively poorly characterised, although PML nuclear body proteins including Sp100 and Daxx have activity against several viruses.

This project aims to characterise novel mechanisms of viral subversion of the IFN response, focusing on new restriction factors that act against herpesviruses and HIV. Therapeutic inhibition of the interaction between these antiviral factors and their viral antagonists could lead to novel antiviral strategies in infected individuals. We have recently conducted proteomic screens of herpesviral infections that have identified candidate novel antiviral restriction factors.

We aim to investigate both (a) the role of individual viral genes on host antiviral proteins (herpesviruses and lentiviruses), as well as (b) whole viral infection in both lytic and latent phases (herpesviruses only). (a) We will clone individual viral genes into delivery vectors, and deliver them to relevant cultured host cells. We will then characterise the effects of these modifications on the host cell. (b) We will generate herpes viral stocks in established human cell
lines from viral seed stocks or bacterial artificial chromosomes encoding the viral genome. Clinical isolates and their genetically modified derivatives will be used as well as laboratory adapted strains. In vitro infection of human cell lines and primary cell lines will then be carried out to model both lytic and latent viral infections. We will then characterise the effects of these viral modifications on the host cell. Viruses with deletions of, or tags attached to individual genes will be utilised in order to further characterise cellular effects.

Recipient or parental organism

Mammalian tissue culture cell lines (eg HFF2, HFF-TERT, THP-1, KG-1, HeLa, U373, U937, Huh?, HCT116, Jurkat, Daudi, NK-92, NK-L, HL60, 220, T1, 293, 293T, Ramos).
Primary human cells (eg monocytes, dendritic cells, red blood cells, skin fibroblasts, endothelial cells, T cells, B cells, NK cells).
Human herpesviruses including HSV-1 (eg strains: F, KOS, 17, SC16), HSV-2 (eg strains: 333, HVD), VZV, EBV, HCMV (eg strains: Toledo, Merlin, TB40/E, VR1814/FIX-BAC and laboratory adapted strains AD169 and Towne), HHV-6, HHV-7 and KSHV.
An HIV-1 viral vector with a critical env deletion will also be used.
Bacteria: Top10, Sure 2, alpha-select, clean genome, DH5a, ccdB SurvivalT1R Chemically Competent E. coli

Host/vector system

Viral /Cell Vectors
Viral gene delivery vectors including retroviruses, lentiviruses, and adenoviruses.
Plasmids and other nucleic acid vectors
Bacterial artificial chromosomes (BACs) that cover the genomes of the herpesviruses and adenovirus serotype 5 so that insertion/deletions in the viral genome can be generated in vitro prior to the generation of recombinant viruses.
Standard cloning vectors (such as TOPO, pcDNA3, Gateway pDONR221, pDONR223, and Gateway pDEST derivative destination vectors) and BAC shuttle vectors will be used to clone gene disruptions (such as truncations) and to add inserts/tags onto genes or to rescue deletions. In addition, these cloning vectors will be used to express individual genes to allow their study in host cells.
The HIV-1 viral vector will be used for targeted gene disruption in vitro prior to the generation of lentiviral particles.
Inserts
Inserts will be used to (i) label genes to enable their visualisation during physiological and biological studies of intracellular infection (such as the YFP, GFP or RFP fluorescent tags) and protein function, (ii) encode mammalian proteins that have already been characterised and are thought to be involved in restriction of viral infection with no known toxicity or oncogenicity (for example Sp100 and Daxx in addition to other characterised proteins that may function as restriction factors), or (iii) to simplify biochemical analyses of genes of interest (such as HA, Strep, Myc and Flag tags). To examine the biological role of individual genes, gene deletions/disruptions and subsequent reconstitutions will also be used.

Origin & function

Expected biological action of inserted DNNRNA or transcribed/translated gene product:
The inserts will be commonly used markers/tags as detailed above. Apart from fluorescence, these tags are biologically inert; their expression should not increase viral virulence or fitness, or activity of the target genes. Deletion or disruption of viral genes is not expected to increase virulence. For reconstitution of deletion viruses, only the original gene will be re-inserted and therefore no increase in virulence over the original strain is expected.
modifications will be made that are designed to introduce new biological activities into proteins. Over-expression of viral genes in viral gene delivery vectors should not pose any risk additional to use of the viruses themselves. Overexpression of already-characterised human genes such as Sp1 OO/Daxx should not pose any additional risks.

Technique used to introduce insert or vector into host:
Standard molecular biology cloning techniques will be used to delete/disrupt and add tags to viral genes within BACs or viral vectors (detailed above). Vectors will then be introduced into mammalian cell lines by transfection for generation of recombinant virus. The resultant recombinant virus will then be harvested and used directly for infection of cells, or will be concentrated and stored at -80°C for subsequent infection of host cells. The infection protocol varies depending on the virus. For example, VZV remains cell associated and therefore must be introduced by cocultivation of infected cells with the target cell. We will use a centrifugal enhancement of viral infectivity to introduce lentiviruses, while HCMV will be allowed to bind to cells on a rocking platform in concentrated form before being transferred to 37°C which will allow virus entry.

Evaluation of foreseeable effects

(i) the host! recipient micro-organism including viral/cell vectors
Health and Safety
Executive

Recipients will be various mammalian cells in culture. Most are well characterised and considered ACDP hazard group 1. Cells from volunteers are uncharacterised and although themselves present no greater risk, may contain adventitious infectious agents and therefore will be handled at CL2 (risk assessment under COSHH regs).

The herpesviruses to be studied as detailed above are all ACDP hazard group 2 and will therefore be handled at CL2 within a class II microbiological safety cabinet (MSC). Pregnant or known immunocompromised individuals will not perform any of this work.

Viral gene delivery vectors (retroviruses, lentiviruses) to be used are those typically considered class 1 GMMs, and will all be self-inactivating, and therefore once packaged, are unable to propagate. A three- or four-plasmid transient transfection system will be used to generate the recombinant retroviruses and lentiviruses, thereby decreasing the likelihood of recombination within the packaging cell lines to generate replication competent virus. The retroviral vectors are based on the Moloney murine leukaemia virus in which the gag, pol and env genes have been deleted. Gag and pol are supplied in trans on a packaging plasmid. We will generate VSV-G pseudotyped virus in order to deliver the virus particles to human cells. The lentiviral vectors are either based on an HIV-1 self-inactivating vector (SIN) containing a deletion in the U3 region of the 3` LTR of the virus, or based on a Gateway pDEST vector. In addition, the gag, pol, env, nef, vif, vpu and vpr genes have been deleted. Again, additional packaging plasmids encoding gag, pol, rev and tat will be used along with the plasmid encoding VSV-G to make pseudotyped viruses that will enter human cells. A packaging plasmid encoding nef, vif, vpu and vpr may also be used, in order to improve transduction efficiency of primary human cells. While VSV-G increases host range and their tropism and mode of transmission may also be altered from that exhibited by wild-type retroviruses, aerosol risk to the airway epithelium appears limited by the inability to infect the apical cell surface.

The AdZ adenoviral vector system will be used to generate recombinant adenoviruses. These vectors carry a deletion of the E1 gene region rendering them replication incompetent in non-complementing cell lines. In addition, the E3 region (important for viral pathogenesis and immune evasion) has also been deleted making them less pathogenic in humans. They are those typically classed as class 1 GMMs and remain so as the inserts are placed within the deleted regions. All three types of viral vectors will be harvested and used in a CL2 laboratory.

The HIV-1 viral vector to be used in this project is derived from the HIV-1 backbone. To increase the safety of the system, the vector components are segregated on to 2 plasmids: an HIV-1 molecular clone with a critical env deletion and a second plasmid expressing the VSV-G envelope protein. None of the individual plasmids is capable of generating infectious viral particles and, to avoid the generation of replication competent virus via homologous
recombination, the constructs do not contain overlapping homologous sequences. Like the retroviral and lentiviral vector systems described, the use of this system has previously been approved when working under CL2 conditions. Since none of the cell lines or vectors carry intact env-encoding sequences, infectious HIV particles cannot be produced.

(ii) the inserted genetic material
Modifications will be to add a tag such as a fluorescent protein to viral proteins, or to delete or disrupt human or viral genes and subsequently restore them. Expression of tags is not expected to be detrimental to human health. Deletions/disruptions to viral genes are not expected to increase infectivity/pathogenicity. Herpesvirus genes cloned into viral gene delivery vectors may confer an ability to alter immune responses to infected cells. However, the large number of viral immune evasion genes encoded by the human herpesviruses demonstrates the need for a virus to encode more than one immunoevasin in order to effectively evade human immune responses. We will only express a single herpesviral gene in each gene delivery vector.

(iii) nucleic acid vectors
Bacterial artificial chromosomes and plasmids will be used to generate recombinant virus. These contain antibiotic resistance markers which could in theory present a problem to the user if they became infected with the bacteria in which the plasmids/BACs were grown. However, in practice the bacterial strains we use are highly attenuated and unlikely to cause disease, while the antibiotic resistance markers encoded by these plasmids/BACs (Ampicillin, kanamycin, streptomycin and chloramphenicol) are active against antibiotics which are no longer in general use in clinical practice. So whilst the plasmids/BACs pose no threat in a bacterial culture, once transfected into eukaryotic cells the recombinant DNA can be packaged into infectious virions and transfection will therefore be carried out in a CL2 laboratory and subsequent cultures treated as live virus.

(iv) the resulting genetically modified micro-organism
The disabled nature of the bacterial hosts will not be altered by the plasmids or BACs in use - no expression is anticipated and would not in any case be compatible with bacterial systems. Cultured cells expressing the viral genes may be altered in particular surface or intracellular proteins they express but these changes will not over ride the especially disabled nature of the cells. Cultured cells expressing the genes functioning in viral restriction may additionally alter intracellular pathways (for example, Sp100 and Daxx have additional roles in regulation of immunity and apoptosis but these changes will not over ride the especially disabled nature of the cells. Viral vectors containing the viral genes may be able to alter the surface expression of cells they infect thereby altering the immune response. As the vectors are disabled, any accidental infection of the epithelial cells of the researcher would be localised. Transduced cells would not be able to produce viral particles. Due to the high turnover rate of epithelial cells, any localised infection would not be expected 10 be long lasting. Pseudotyped env-deleted HIV-1 viral particles are replication deficient, but theoretically able to transduce epithelial cells of the researcher. If this occurred, all HIV-1 proteins except env would be expressed, but no replication competent virus would be formed. This protein expression would not be expected to cause harm, and the pseudotyped particles have previously been classified as class 2. The modified herpesviruses should be no more pathogenic than wild type. Although there are virus deletion mutants with increased virulence over their parent (for example deletion of A41L in vaccinia virus), to our knowledge, herpesvirus deletion mutants that show an increase in virulence have not been described.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Brief description of types of laboratory procedures:

Conventional molecular biology techniques will be used for cloning in a CL 1 laboratory. Bacterial artificial chromosomes and viral gene delivery vectors will be transfected into mammalian cell lines in a CL 1 laboratory then transferred to the CL2 laboratory within 24 hours of transfection (to allow us to evaluate transfection efficiency with a fluorescence microscope). Generation of virus stocks from seed stocks and BACs involving standard tissue culture with established cell lines. Ultracentrifugation of virus. Tissue culture and subsequent infection of established cell lines and primary human cells with virus stocks by co-culture. All manipulation of liquid will be carried out in a class II Microbiological safety cabinet (MSC) to reduce the risk of aerosol dissemination. Tubes for ultracentrifugation of virus for the production of concentrated virus stocks will be loaded in MSC into buckets that will be sealed and transported to the ultracentrifuge in secondary containers. Similarly, once the ultracentrifugation is complete, the tubes will be transported back to the CL2 laboratory and the buckets opened in the MSC to allow the virus to be resuspended and aliquoted. Since there is no -80’ storage facility in our CL2 laboratory, small aliquots of virus will be transported to 6.2 in secondary containment for storage. Fluorometric and microscopic analysis will be either be conducted in the CL2, or on fixed samples, and protein and nucleic acid analysis will be conducted on material which has been lysed or fixed in the CL2 facility prior to transport to the laboratory.

For proteomics analysis, the cells will be lysed in relatively harsh conditions and subsequently centrifuged, as detailed and justified below.

All primary cell lines are screened (e.g. commercially available cell lines from Lonza screened for HIV, HBV, HCV and mycoplasma), and are immortalised and passaged (e.g. human skin fibroblasts). Regardless of the screening results, the blood-derived primary cell lines will permanently remain in the CL2 laboratory.

Health and Safety

Executive

Additional control measures (i.e. safety procedures and devices) required for specific activities: Standard CL2 procedures including wearing double gloves, lab coats and closed shoes will be adhered to. Waste liquid will be decontaminated within the MSC with virkon prior to solidification with Vernagel and autoclaving. All other non-liquid contaminated waste material will be autoclaved. Aerosol resistant pipets and pipet tips will be used to pipet virus. Any spillage can be adequately decontaminated with trigene detergent. These procedures are described in greater detail below.

If other facilities are to be used, what are the risks to others and how will they be conveyed?

The ultracentrifuges available for concentrating virus preparations are outside of CL2 labs. Virus preparations will be sealed within the centrifuge tubes and buckets within the MSC in CL2 and transported in a shatterproof container. The surfaces of centrifuge tubes and transport containers will be decontaminated with detergent prior to removal from CL2 and only be re-opened once returned to the MSC in CL2. The ‘comments’ section of the ultracentrifuge logbook will be used to warn other users that the centrifuge contains a CL2 organism. Following centrifugation, the buckets will be returned to the MSC in the CL2 for processing. The buckets will then be immersed in detergent in the MSC prior to removal back to 5.14 for cleaning, rinsing and drying.

The -80 degree freezer for storing virus preparations and supernatant is also outside of the CL2 labs. Vessels containing supernatant and concentrated virus preparations will be decontaminated with Trigene and put into a shatterproof container for transport to and storage at -80 in Lab 6.2.

Justification for this:

1. Following transduction of cell lines all material containing viral particles is removed and disposed of as described below. At this point it is no longer classified as containment 2 and is moved to containment level 1.

2. For proteomics analysis, cells will be lysed as described below. Post lysis, cells and any associated virus are no
longer biologically hazardous. The remaining downstream processing requires equipment and chemicals unsuitable for our CL2 facility, e.g. specialised centrifuge-ware, chemicals that must be weighed inside a fume hood, and other items that cannot be transferred to CL2.

3. For proteomics experiments involving biotinylation, cells will be briefly cultured in the cold room. The protocol requires incubation at 4 degrees with either gentle rocking or end-over-end rotation. This is currently not possible within CL II facilities. The cells will be transported in sealed contained and waste/surfaces will be cleaned as described below. There will be no manipulation of CL II material within the CL I labs.

Protocol for Lysis

Cells will be washed three times in PBS (by centrifugation and re-suspension in the case of suspension cells and by aspiration in the case of adherent cells). Adherent cells will be recovered by scraping and then pelleted after washing, or directly lysed on the plate after washing.

Cell lysis:

a. Cell pellets re-suspended in 8M Urea/TRIS 1.25units/uL Benzonase and vortexed until pellet is solubilized and incubated at room temperature for 15 minutes.

OR

b. Cell pellets re-suspended in 2% SDS/TRIS and vortexed until pellet is solubilized

OR

c. Cell pellets re-suspended in 6M Guanidine / HEPES and vortexed until pellet is solubilised.

OR

d. Cell pellets are re-suspended in 1% Triton X-100, TBS, 1.25units/uL Benzonase and protease inhibitors and incubated for 15 minutes at room temperature with occasional shaking. Lysed cells are centrifuged to removed debris and supernatants taken for further processing.

Protocol for Biotinylation

In the case of suspension cells, after pelleting in an Eppendorf tube by centrifugation the pellet is resuspended in biotinylation mixture and the entire Eppendorf sealed into a 50mL Falcon Tube. For adherent cells, the biotinylation mixture is added to the culture dish and the dish placed inside a sealed box.

The outer surface of the 50mL falcon tubes or sealed box will be disinfected with Trigene before removal of from CL II to end-over-end rotator or platform rocker in the cold room. The period of incubation is 30 minutes. The cold room doors will be clearly labelled that CL II material can be found within, likewise on the respective shakers. Aftenward the tubes/box wi ll be returned to CL II microbiological safety cabinet before proceeding with the protocol.

Hazards relating to biotinylation mix and other chemicals are covered in risk assessment MPW001 and require no especial modification for CL II.

Control measures to be used when removing CL2 samples from the Containment 2 suites.

Users should use common sense and take all reasonable precautions to avoid the risk of accidents including spills. Biological or GM material should be sufficiently contained in the event of a foreseeable incident.

All liquid material MUST be in a sealed liquid tight container which must be placed in a water-tight plastic or metal outer container, lined with absorbent material to soak up any leakage of liquids.

In the event of an EMERGENCY material MUST be returned to a Containment level 2 suite and left in the MSC Class 2 hood for at least 30 mins before the container is opened and dealt with appropriately.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

(i) the recipient micro-organism including viral/cell vectors (Give ACDP hazard group or appropriate containment level for handling)

The viruses and viral delivery vectors we will use are ACDP hazard group 2/class 1 GM. The viruses are deactivated by treatment with trigene, virkon or 70% EtOH and autoclaving. Therefore following the waste procedures outlined
below should eliminate risk of spread to the environment. Many of the herpesviruses are also strictly human specific, therefore there is no risk of spread to other animals or plants. The viral vectors are all replication disabled so will be unable to disseminate in the wider animal or human populations.
Mammalian primary cells or cell lines are especially disabled and unable to survive or propagate outside of laboratory culture.
Bacteria: the bacterial strains we use are highly disabled and unable to replicate to any extent outside the lab. Nevertheless, appropriate control measures, including disinfection (with virkon) of liquid cultures and autoclaving of bacterial plates, will be taken.
(iii) the inserted (donated) genetic material
Fluorescent proteins are not toxic, nor reported to have deleterious effects on exposure. Deletion/disruption and subsequent reconstitution of viral genes will not introduce any new translated genetic material into the parental viruses, and will therefore pose no extra risk.
(iv) nucleic acid vectors
BACs and cloning vectors and easily destroyed in the environment and therefore pose no risk on their own.
(iv) the resulting genetically modified micro-organism
None of the inserts or deletions in cells, vectors or viruses will be able to alter the non hazardous status of the recipients with respect to environmental risk.
Waste procedures and inactivation methods for the GMM:
All liquid waste will be disinfected with Virkon overnight, gelled using Vernagel, double bagged and sealed and labelled for autoclave then incineration according to the Department CL2 procedures. All solid waste will be double bagged and labelled for autoclave then incineration (pipettes will be disinfected in 1% trigen before removal from MSCs to prevent drips). Work surfaces will be wiped down with trigen and 70% ethanol. Small spillages will be mopped up immediately with tissue and disinfected with 1% trigen or 2% virkon. Large spills will be covered with absorbent paper and then sprayed with 10% trigen or 2% virkon, and then mopped up after 30 minutes. The absorbent material will then be disposed of in the autoclave waste.

02/03/2022
The reversible phosphorylation of tyrosine residues on proteins serves as a critical switch in the regulation of fundamental cellular processes including growth, adhesion and movement, and is control led by the antagonistic actions of protein tyrosine kinases and protein tyrosine phosphatases (PTPs). PTPs function as critical "off" switches, antagonising oncogenic kinase signaling, and can initiate signaling cascades in their own right. The molecular mechanism of tyrosine phosphatase catalysis has been well characterised, however, the extracellular regulation and relevant substrates of many receptor tyrosine phosphatases have yet to be discovered. Recent technical developments in areas such as gene editing, organoid culturing, proteomics, and next generation sequencing mean that now is the perfect time to reveal physiological roles and regulatory mechanisms of this important protein family. We aim to understand the functional role of PTPs (specifically PTPRL) in the modulation of signal transduction, protein function and cellular/tissue responses; and their impact on physiological or disease states.

In order to ascertain such information, we will need to alter the expression of candidate genes involved in such processes, using knock-down or overexpression approaches; in addition, to manipulating their function using knock-in constructs, which harbour specific mutations, deletions and/or fusions. Although such manipulation (at least transiently) of cellular proteins structure or function in culture-adapted cell lines can be achieved using standard transfection protocols (lipofection-based, PEI or electro po ration), lentiviral methods will allow long-term (stable)
expression in difficult to transfect cell lines, and isolated primary cells and/or tissues.

Recipient or parental organism
Various established mammalian and human cell lines.
Various primary mammalian and human cell lines.
Murine tissues/explants cultured ex vivo.

Host/vector system
Lentiviral vectors based on replication-disabled HIV.

Origin & function
cDNA and/or shRNA off for genes involved in regulating the phosphorylation state of various proteins involved in signal transduction and/or the modulation of cellular function (including but not limited to members of the PTP (protein tyrosine phosphatase) family of proteins, specifically PTPR). Marker and reporter constructs that bear detectable tags for our gene of interest, such tags include but are not limited to GFP, c-myc, BirA and FLAG. Plasmids involved in CRISPR-Cas9-mediated gene editing, which encode Cas9 variants, guide RNAs targeting our gene of interest and donor template DNA (containing a desired mutation, fusion or marker/reporter). Finally, we will target newly identified gene products that modulate or are a downstream target of protein tyrosine phosphatase activity.

Evaluation of foreseeable effects
We expect the majority of our constructs to increase decrease or otherwise alter protein phosphorylation, signal transduction and protein, cellular or tissue function; however, as the specific role of PTPs is ill-defined the exact outcome is uncertain. Despite this, PTPs are linked to regulating kinase signal transduction and therefore could possibly act as tumour suppressors. Conversely, we would not expect any cellular effects from the expression of markers or reporters.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Culture media will be disinfected with virkon or trigene
Leftover packaging cells and contaminated plasticware will be discarded in a double bagged clear biohazard bag, sealed with red and white tape and placed in a Cfl2 waste bins for autoclaving

Project Ref 678/17.1

Investigating the molecular cell pathology of axonopathies.

Class 2

< 1 Litre

Non-GMM

Consent Granted

Project notified under transitional arrangements

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use

Our work is focused on study of neurodegenerative genetic conditions, such as hereditary spastic paraplegias (HSPs) and hereditary motor and sensory neuropathies (HMSNs), in which long axons degenerate. Study of these conditions
provides an opportunity to understand molecular mechanisms that are crucial for axonal function. The aims of this project are to understand the normal and pathological functions of proteins encoded by genes mutated in these conditions. To do this we will generate cell models that have i) undergone genome editing by CRISPR-Cas9 methodologies to generate knock-outs, knock-ins, or endogenously tagged (e.g. GFP-tagged) forms of the protein or, ii) over-express wild-type or mutant forms of the protein, including epitope-tagged forms. As we have a special interest in developing neuronal cell models, we will use lentivirus to provide effective delivery in these non-dividing cells. In most cases we will produce the lentiviral particles ourselves, but we may opt to purchase commercially prepared lentiviral particles (e.g. selected from the Sanger Whole Genome CRISPR arrayed library, via Sigma Aldrich). The functions of the genes/protein that we will target tend to concentrate in certain pathways, namely, membrane traffic pathways, lipid metabolic pathways, mitochondrial function, nucleotide metabolism, axon guidance and myelination.

Recipient or parental organism

Mouse primary neurons/fibroblasts or human induced pluripotent stem cells and cell lines differentiated from them, including neurons.

Immortalised mouse or human cell lines, including fibroblasts, HeLa cells, MRC5 cells, PC12 cells, SHSY-5Y, HEK293T cells and other well characterised cell lines.

These are all regarded as especially disabled.

Host/vector system

2nd or 3rd generation lentiviral systems. These vectors may incorporate the WPRE.

Origin & function

Mutation of all of the genes/proteins that we will work on is associated with human neurogenetic disease in which long axons degenerate. The associated clinical picture is of progressive limb weakness and in some cases loss of sensation. A subset of the proteins are associated with additional neurological features, such as developmental learning problems or cognitive impairment. The encoding genes are not known oncogenes or tumour suppressors, nor are the proteins growth factors or growth factor receptors. Inserts may also contain CRISPR-Cas9 reagents, such as guides to target genes for knock-out/knock-in or sequences encoding the Cas9 protein. Cas9 has no known deleterious functions when expressed on its own. In addition, inserts may also encode commonly used tags, such as GFP. Apart from fluorescence, these tags are biologically inert.

Evaluation of foreseeable effects

Generation, purification and use of lentiviruses in cell culture: The systems used will be second or third generation lentiviral systems. These systems enhance biosafety by splitting the components necessary for virus production across multiple plasmids (3 for 2nd-generation systems, 4 for 3rd-generation systems). The components of both systems are i) a lentiviral transfer plasmid encoding the insert of interest. The transgene sequence is flanked by long terminal repeat (LTR) sequences, which facilitate integration of the transfer plasmid sequences into the host genome. Many lentiviral transfer plasmids are based on the HIV-1 virus. For safety reasons, transfer plasmids are all replication incompetent and may contain an additional deletion in the 3’LTR, rendering the virus “self-inactivating” (SIN) after integration, ii) packaging plasmid(s) and iii) envelope plasmid.

Safety Features of the Lentiviral Systems. The 2nd-generation lentiviral system contains a single packaging plasmid encoding the Gag, Pol, Rev, and Tat genes. The transfer plasmid contains the viral LTRs and psi packaging signal. The envelope protein Env (usually VSVG due to its wide infectivity) is encoded on a third, separate, envelope plasmid. The 3rd generation system further improves on the safety of the 2nd generation. First, the packaging system is split
into two plasmids: one encoding Rev and one encoding Gag and Pol. Although safer, this system can be more cumbersome to use and result in lower viral titers due to the addition of one additional plasmid. Second, Tat is eliminated from the 3rd generation system through the addition of a chimeric 5’ LTR fused to a heterologous promoter on the transfer plasmid. Expression of the transgene from this promoter is no longer dependent on Tat transactivation. Use of these systems means that the probability of a series of recombination events that produce a replication-competent virus that can spread within and between hosts is very small.

Risks associated with lentiviral systems. The viral vector would be able to transduce many tissues should it come in contact with them. Aside from any risks associated with the inserted DNA or CRISPR guide sequences (which are likely very small, see below), the main theoretical risk is through random insertional mutagenesis. The true risk of this is unclear. The major hazard is therefore represented by the packaged virus prior to infection of the target cells and residual virus in the medium of infected cells. The two potential transmission routes are by external exposure (either skin lesions or mucous membranes; only in the case of very high titres and aerosol production) and by accidental injection/inoculation using sharps. In the context of this project, the main risk is of primary infection of humans by high titre viral stocks that have been concentrated by ultracentrifugation.

Risks associated with the modified cells. Lack of the proteins (as associated with CRISPR-mediated knockout) is likely to reduce cellular health, perhaps even reducing the oncogenic risks posed by the lentiviral vector. Expression of altered versions of the proteins under investigation is also likely to reduce the biological fitness of the modified cells. The genetically altered cultured cells produced (especially neurons) will be unable to survive outside of laboratory culture.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All disposable culture/lab ware will be autoclaved and incinerated which eliminates 100% of the infectious material. Culture fluids will be treated with 2% Virkon for 16 hours (which eliminates 100% of infectious material) and absorbed with Vernagel. Recyclable lab ware will be soaked in 1% Virkon for 16 hours. Bench/cabinet surfaces will be wiped down with 70% ethanol. Spills will be sprinkled with Vernagel powder, then transferred to autoclave bags and the area wiped down with distal or similar detergent.

**Project Ref** 678/19.1

- *Date Ackn'd*: 18/04/2019
- *CU2 Project Title*: Investigating the molecular cell biology of human pathophysiology using viral vector systems
- *Class*: Class 2
- *CultureVol*: 1-50 Litres
- *Consent Granted*: Non-GMM

**Historical Significant Changes**

- *Date of Additional Info*: 02/03/2022

**Project Additional Information**

- *Purposes of the contained use*:

  Our work is focused on study of the molecular and cellular mechanisms of human pathophysiology. This includes study of membrane and lipid traffic pathways, immune function, host-pathogen interaction, protein folding, homeostasis and degradation, oxygen and metabolite sensing, neurodegeneration, cell signalling and ribosome assembly. Study of these cellular processes provides important insights into normal human physiology, as well as an understanding of the molecular mechanisms by which normal physiology can be disrupted to cause human disease. To achieve our aims we require to generate cell models using viral systems.

- *Recipient or parental organism*:

  02/03/2022
Rodent primary cells (e.g. immune cells, fibroblasts, neurons, glia), human primary cells (e.g. skin fibroblasts, muscle cells, immune cells or glia), or human induced pluripotent stem cells and cell lines differentiated from them, including neurons. Immortalised rodent, monkey, canine, porcine, bovine and human cell lines, including fibroblasts, HeLa cells, MRC5 cells, PC12 cells, SHSY-5Y, HEK293T, H35, AR42J, GH3, INS1, CHO, MBDK, MDCK, Vero, COS cells and any other well-establisehd and characterised especially disabled mammalian cell lines. These are all regarded as especially disabled.

### Host/vector system

**Retroviruses:** Retroviral transfer vectors, such as pLXIN or pQCXIP are based on the Murine Moloney Leukemia Virus backbone but without the structural genes needed for virus production and replication. These are provided by independent packaging vectors incorporated into packaging cells.

Lentiviruses: 2nd or 3rd generation lentiviral systems.

The above vector classes may incorporate the woodchuck hepatitis virus postranscriptional regulatory element (WPRE).

**Adenovirus:** The AdEasy adenoviral vector system is used to generate recombinant adenoviruses. These vectors carry a deletion of the E1 gene region rendering them replication incompetent in non-complementing cell lines. In addition, the E3 region (important for viral pathogenesis and immune evasion) has also been deleted making them less pathogenic in humans.

### Origin & function

**Origins:** Adenoviral, Retroviral and Lentiviral system vectors are obtained commercially, from bona fide academic laboratories or from vector repositories (e.g. Addgene).

Gene inserts will be cloned from standard cloning vectors (such as TOPO or pcDNA3). Guide RNAs and short hairpin RNAs will be generated commercially.

**Intended Functions:**

- We will use viral delivery to undertake:
  - i) genome editing by CRISPR-Cas9 methodologies to generate gene knock-outs, knock-ins, endogenous tagging (e.g. incorporating GFP-tag sequences), or inhibition/enhancement of expression. These studies may include genome-wide screens.
  - ii) over-expression of wild-type or mutant forms of proteins under study, including epitope-tagged forms.
  - iii) expression of guide RNAs for CRISPR-Cas9 targeting and short hairpin RNA (shRNA) for protein knock-down, including in genome-wide library screens.

### Evaluation of foreseeable effects

Generation, purification and use of lenti- and retro- viruses in cell culture.

The retroviral vector system used is a 3rd generation system based on the Murine Moloney Leukemia Virus. Replication defective retroviruses will be made by transient transfection of retroviral transfer plasmids (such as pBMN, pLXIN and pQXCI series) into packaging cells lines such as Phoenix (ampho or ecotropic). These packing cells line express gag, pol and env genes separately, thus it would require multiple recombination events to generate replication competent viruses (likelihood extremely low).

For lentiviral work, second or third generation systems will be used. These systems enhance biosafety by splitting the components necessary for virus production across multiple plasmids (3 for 2nd-generation systems, 4 for 3rd-generation systems). The components of both systems are i) a lentiviral transfer plasmid encoding the insert of interest. The transgene sequence is flanked by long terminal repeat (LTR) sequences, which facilitate integration of the transfer plasmid sequences into the host genome. Many lentiviral transfer plasmids are based on the HIV-1 virus. For safety reasons, transfer plasmids are all replication incompetent and may contain an additional deletion in the 3'LTR, rendering the virus "self-inactivating" (SIN) after integration, ii) packaging plasmid(s) and iii) envelope plasmid.

Safety features of specific lentiviral systems.

The 2nd-generation lentiviral system contains a single packaging plasmid encoding the Gag, Pol, Rev, and Tat genes. The transfer plasmid contains the viral LTRs and psi packaging signal. The envelope protein Env (usually VSVG due to its wide infectivity) is encoded on a third, separate, envelope plasmid. The 3rd generation system further improves on the safety of the 2nd generation. First, the packaging system is split into two plasmids: one encoding Rev and one encoding Gag and Pol. Although safer, this system can be more cumbersome to use and result in lower viral titers due to the addition of one additional plasmid. Second, Tat is eliminated from the 3rd generation system through the addition of a chimeric 5' LTR fused to a heterologous promoter on the transfer plasmid. Expression of the transgene from this promoter is no longer dependent on Tat transactivation. Use of these systems means that the probability of a series of recombination events that produce a replication-competent virus that can spread within and between hosts is very small.

**Risks of operator infection with retro- and lenti-viral systems.**

Retroviruses generated using the ecotropic packaging cells are capable of infecting and stably integrating DNA into murine cells, while viruses generated using the
amp phototropic packaging cells are capable of infecting and stably integrating DNA into a broad range of cells, including human cells. However, the risk of human or rodent infection using the above viral system is extremely low as the virus can only infect via direct inoculation. Thus, if no sharps are used in combination with good laboratory practice the risk of infection is extremely low.

VSVG pseudotyped lentivirus can transduce many tissues should it come in contact with them. Here, the two potential transmission routes are by external exposure (either skin lesions or mucous membranes; only in the case of very high titres and aerosol production) and by accidental injection/inoculation using sharps. The most significant hazard is therefore represented by the packaged virus prior to infection of the target cells and residual virus in the medium of infected cells. In the context of this project, the main risk for primary infection of humans is by high titre viral stocks that have been concentrated by ultracentrifugation.

Aside from any risks associated with the inserted DNA or CRISPR guide sequences (which are likely very small, see below), the main theoretical health risk of infection in most cases is the risk of random insertional mutagenesis. The true risk of this is unclear, although the risk of transduction leading to tumourigenesis or other untoward harm following exposure is related in part to the titre of the viral vector and exposure of the operator to quantities of virus high enough to cause such effects would be unlikely during standard laboratory-based manipulations of retro- or lenti- viral vectors.

Vectors bearing the WPRE insert have been reported to increase tumours in experimental animals and interim advice from SACGM is to handle any such vectors at CL2 minimum. The classification of insert-bearing vectors may remain at class 2 but is subject to additional risk mitigation (measures to guard against needle stick, careful handling of high titre stocks).

Adenoviral systems:

Although most adenoviral work is assessed at CL1, this system is included here to take into account the possibility of targeting for manipulation oncogenes, tumour suppressor genes or other genes that could theoretically pose a human health risk.

Generation, purification and use of adenoviruses in cell culture.

The adenoviral vector system used is the AdEasy vector system. Replication deficient adenoviruses are made by cloning genes of interest or versions of those genes (dominant negative constructs, or fusion proteins) into a transfer vector containing the cytomegalovirus promoter and an IRES-GFP (internal ribosome entry site with Green fluorescent protein) sequence. Transfer vectors are then cloned into the p-AdEasy-1 packaging plasmid that lacks E1 and E3 sequences, which is then transfected into the packaging cell line HEK293 (containing the E1 replication sequence) to generate recombinant replication-deficient adenovirus.

Safety features of adenoviral systems

The AdEasy vector system carries a deletion of the E1 gene region rendering them replication incompetent in non-complementing cell lines. In addition, the E3 region (important for viral pathogenesis and immune evasion) has also been deleted making them less pathogenic in humans. The chances of a recombination event within the packaging cells rendering replication competent adenovirus is very low and is further minimized by not serially propagating the adenovirus in the packaging cells. Additionally, adenoviral DNA integrate into the genome with very low efficiency and so is not usually transferred to daughter cells during cell division, significantly reducing the likelihood of any prolonged in vivo expression, for example of oncogenes.

Risks of operator infection with adenoviral systems

Adenovirus can transduce mammalian tissues by external exposure or by accidental inoculation using sharps. Adenoviral vectors carry the E1 gene deletion rendering them replication incompetent and the E3 gene deletion making them less pathogenic in humans. Since adenoviruses do not usually integrate their DNA into their host there is little chance of prolonged expression of transgenes within human cells.

Risks to the operator associated with biological activity of inserted DNA/RNA delivered by viral systems.

In some cases, particularly with retro- or lenti- viral systems, the inserted DNA may encode an oncogene that could become integrated into the genome of infected cells, and tumour suppressor genes may be targeted with CRISPR-Cas9 or shRNA. This could theoretically be harmful to human health - the true health risks of this are unclear, but are likely to be relatively small as malignancy is a multistep process and it unlikely that any single “hit” would initiate transformation. Inserts may also contain DNA encoding known Mendelian disease genes other than oncogenes/tumour suppressor genes, or reagents that would silence such genes. Again the true risks of this are unknown, but the risk to the operator is likely to be minimal, as in most cases it is unlikely that disease target tissues would be accessible to viral particles, and infection of a very small proportion of accessible bodily cells is very unlikely to be harmful in most cases. As above, the major hazard is presented by the packaged virus, particularly when concentrated.

Inserts may contain CRISPR-Cas9 reagents, such as guides to target genes for manipulation, sequences encoding the Cas9 protein, or Cre-recombinase or the tetracycline-controlled transactivator (TTA). Cas9, Cre-recombinase and TTA have no known deleterious functions when expressed on their own. In addition, inserts may also encode commonly used tags, such as GFP. Apart from fluorescence, these tags are biologically inert.
Risks associated with the modified cells. Lack of the proteins (as associated with CRISPR-mediated knockout) is likely to reduce cellular health, perhaps even reducing the oncogenic risks posed by the lentiviral vector. Expression of altered versions of the proteins under investigation is also likely in many cases to reduce the biological fitness of the modified cells. The genetically altered cultured cells produced will be unable to survive outside of laboratory culture. In the highly unlikely event that cells are inoculated into an operator, they would be expected to be recognised as non-self and destroyed by the immune system. The risk of such modified immortalised cells is unlikely to be greater than the equivalent risk posed by immortalised cell lines in common use. Primary cells may pose a risk of adventitious infection, which is minimised by the mitigation procedures in place.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All disposable culture/lab ware will be autoclaved and incinerated which eliminates 100% of the infectious material. Culture fluids will be treated with 2% Virkon for 16 hours (which eliminates 100% of infectious material) then disposed of down drains. Recyclable lab ware will be soaked in 1% Virkon for 16 hours. Bench/cabinet surfaces will be wiped down with 70% ethanol. Spills will be sprinkled with Vernagel powder, then transferred to autoclave bags and the area wiped down with distal or similar detergent.

Is an emergency plan required according to regulation 20? 

If yes, tick to confirm that it is attached to this form

Project Ref 678/19.2
Our goal is to develop and apply molecular and cellular methods approaches to understand host-parasite interactions during the erythrocyte stages of the malaria parasite life cycle, and use this data to identify and prioritise drug and vaccine targets. A key technique in this work is the experimental modification of the sequence or expression levels of specific Plasmodium genes. This enables us to generate and test hypotheses about the role of these genes in general parasite viability and fitness; as well as investigate specific phenotypes that are necessary for erythrocyte invasion, drug resistance, and development transitions. A better understanding of these critical interactions may lead directly to the development of new prevention and control measures such as drugs or vaccines.

**Recipient or parental organism**

*Plasmodium falciparum*

*Plasmodium knowlesi*

**Host/vector system**

**Hosts:**

*Plasmodium falciparum* wild type parasite strains. Standard lab-adapted strains will be used, primarily 307, as that is the strain from which the *P. falciparum* reference genome sequence was generated, or NF54, the parental strain of 307. In certain circumstances other lab-adapted strains will be used in place of 307, such as 7G8, HB3, Od2, or strains recently adapted from clinical isolates. In some cases these strains may be resistant to one of more currently used antimalarial drugs, but none are resistant to all frontline drugs so clinical treatment options are always available.

*Plasmodium knowlesi* parasite strains. Currently only two *P. knowlesi* lines are available for in vitro culture in human erythrocytes (PMIO: 23267069, 24506567); if others become available they will be tested and used if they have advantages, such as increased transfection efficiency. There is currently no known drug resistance in *P. knowlesi*
parasites, and the in vitro cultured line is susceptible to all current frontline antimalarials.

Vectors:
Plasmodium transfection vectors are not commercially available, although some previously produced vectors are available from ATCC through the Malaria Research and Reference Reagent Resource Center (www.mr4.org). Vectors to be used in this study will be obtained from this source, or from research colleagues, then adapted to contain the gene or gene fragments of interest. Essentially all vectors consist of three elements:
1. antibiotic resistance gene with associated expression elements to allow propagation in E. coli (usually encoding Ampicillin or Kanamycin resistance);
2. drug resistance cassette with associated Plasmodium expression elements to allow positive selection in P. falciparum and P. knowlesi (usually anti-folate drug resistance encoded by T. gondii or H. sapiens DHFR, or genes that enable resistance to Blasticidin or Gentamicin);
3. an expression or gene targeting cassette to either express the gene of interest in Plasmodium falciparum or Plasmodium knowlesi or direct insertion of the construct to a specific genomic location in order to ablate or modify the endogenous gene, for example by adding an epitope or fluorescent tag to the encoded protein.
The vectors may be based on a number of scaffolds, most commonly on a pUC type backbone, but also including the pJazz linear vector system (Lucigen) that can accommodate large genomic inserts (on average ~8 kb).
For CRISPR/Cas mediated genome editing, two additional components will be included - a cassette expressing Cas9 endonuclease and a cassette expressing target-specific gRNA. These may be either included on a single vector that will be co-transfected into parasites together with a "donor homology" region supplied on a second vector that facilitates homology repair and editing of the target gene, or as a PCR product, which will direct the desired genome modification. However, alternative designs incorporating the gRNA into the donor homology construct are also possible.

Constructs containing modified Plasmodium genes or fragments of such genes will be generated and propagated in E. coli. Constructs will then be introduced into Plasmodium strains by transfection and selected for using drugs. Constructs will either be maintained as episomes, or will integrate in a targeted manner into the Plasmodium genome.
For CRISPR/Cas genome editing, parasites will be co-transfected with a plasmid to express the Cas9 endonuclease and specific guide RNA (gRNA), as well as a homology repair vector to modify the targeted locus. Note that Plasmodium parasites lack the non-homologous end-joining (NHEJ) DNA repair pathway, meaning that all repair happens via homologous recombination, necessitating the presence of the homology repair vector.
Genetic modifications are aimed at dissecting the fundamental biology of human-infective malaria parasites. Gene inserts and transfection vectors are expected to affect parasite biological function through:
• The placement of epitope tags or fluorescent proteins (GFP or others) to investigate protein localisation
• Disruption of genes either alone or in combination, and assessment of the impact on parasite fitness/viability (e.g. how long genetically modified parasites take to go through their life cycle compared to wild type), or on specific developmental stages (e.g. the ability to invade human erythrocytes).
• Allelic replacement of individual genes with modified versions, either altering individual amino acids/regions in the encoded protein (e.g. to probe protein function), or replacing a gene from one species with that of another (a particularly useful approach in P. knowlesi, which can express genes from P. vivax, which is the major cause of malaria outside Africa, but cannot itself be cultured in vitro).
• Testing the impact of a mutation on resistance to one or more drugs, including those used for positive selection (typically the antifolate WR99210, Blasticidin, or G418), or experimental antimalarial compounds developed by colleagues and collaborators; or to antibodies to prove the vaccine potential of specific targets.
Evaluation of foreseeable effects

Plasmodium falciparum is classified by the ACDP as a Hazard Group 3 human pathogen. Plasmodium knowlesi is classified as Hazard Group 2. Both species are capable of causing human malaria and as such we culture both organisms within the same facility and under the same control measures. A range of symptoms can arise from malaria infection, including general symptoms such as fit-like illness and, in severe cases, coma and death. No vaccine is available.

Parasites are naturally transmitted via a mosquito vector. In the laboratory, we culture both the parasite stage that infects red blood cells as well as the stage that is able to infect mosquitoes, but do not carry out any mosquito infection experiments. Infection of humans in the lab would therefore require direct injection into human blood circulation. There is a LOW risk of blood stage infection of a worker where a penetrating wound occurs. This risk is mitigated by a strict "no-sharps" policy in the derogated CL3 suite. If such an injury were to occur, the injured worker would be referred to an infectious diseases specialist at the nearest hospital (Addenbrookes) and presumptive antimalarials prescribed if deemed necessary. Any onward human transmission is extremely unlikely as it would require a mosquito vector to be available in the local environment with appropriate temperature and humidity conditions (26°C and 80% respectively). These conditions are almost never seen in England. There is no evidence for aerosol-based transmission.

GM Plasmodium strains will have no increased ability to infect humans relative to non-GM strains. In some GM parasites a product will be expressed, for example fluorescent or luciferase-based reporters, either individually or fused to parasite proteins. These products are unlikely to be biologically active in humans. There is no evidence that P. falciparum or P. knowlesi proteins can act as toxins or allergens in humans or can act as oncogenes. Gene inserts could theoretically alter the pathogenicity of the modified line relative to the parental parasite line. However in the majority of cases these modifications will generate GM parasites that are essentially equivalent to non-GM lab or field strains or are less fit than their wild-type counterparts. Introduction of the transfection vectors will make the GM parasite resistant to one or more drugs used for positive selection (typically the antifolate WR99210, Blastiaidin, or G418). However, none of these drugs used for plasmid selection in Plasmodium parasites are in wide use as frontline anti-malarials.

P. falciparum and P. knowlesi are only able to infect humans and certain species of non-human primates. Given the inability of free-living parasites to survive in the environment, and the absence of non-human primates from the Institute or its surroundings, there is no risk of release of genetically modified parasites to the environment. GM parasite stocks held in liquid nitrogen are not infectious in that state.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We request derogation from the requirement to carry out this activity in a laboratory that:
- Is sealable for fumigation
- is maintained at negative air pressure relative to the pressure of the immediate surroundings
- has an autoclave inside the laboratory suite

This request is made in accordance with advise provided in "Biological agents: Managing the risks in laboratories and healthcare premises"; Appendix 3.2 Work with Hazard Group 3 parasites. Justification for these derogations is based on the route of infection for malaria parasites which is direct injection into the blood. There is no evidence of aerosol-related infection.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Any waste in contact with *P. falciparum* or *P. knowlesi* will be disinfected via approved methods and disposed of by incineration following autoclaving. Liquid waste disinfection is carried out with 1 % (w/v) Virkon (final concentration) for 20 minutes, or 5 minutes exposure to 5g/L Klorsept (final concentration) is used as an alternative. This is then disposed of via the drains after dilution with 5 times volume of water. Both treatments have been validated, and specifics are listed in the CL3 handbook; they give effectively 100% kill.

All biological waste that cannot be disinfected (e.g. blood bags) and all solid waste from the CL3* suite will be autoclaved prior to final disposal. Once a biohazard bag is full, the neck of the bag is folded over and the bag placed in an approved rigid sealable container to contain any leaks. All workers wear appropriate PPE when handling waste. Sealed waste containers should be kept inside the CL3* laboratory suite until ready to be collected in the designated waste area by the CIMR custodians.

On arrival of the custodians, the CL3 waste is passed to them, and is taken for immediate autoclaving in the main waste autoclaves. The trolley used in this operation will not contain any other forms of waste. Autoclaved waste is destroyed by incineration following examination of the autoclave run report.

All autoclaves are subjected to an annual inspection to written schemes, annual validation reports, and quarterly servicing. Waste runs are validated to achieve a minimum hold time of 3 minutes at 134°C, equivalent to a 30-log reduction in viability of indicator spores.

Project Ref 678/19.3
Our work is aimed at the generation of drug-like substances (mainly small molecules) for the treatment of neurodegenerative disorders such as Alzheimer's disease, Parkinson's disease, Huntington's disease and other neurodegenerative diseases. This is carried out over several stages all of which may involve use of virally mediated nucleic acid transfer. To achieve our aims we require to generate cell models using viral systems.

Recipient or parental organism

Mouse primary cells (e.g. neurons, glia), human primary cells or human induced pluripotent stem cells and cell lines differentiated from them, including neurons. Immortalised human, monkey, canine, porcine, bovine and rodent cell lines, including fibroblasts, HeLa, MRCS, PC12, NRK, SHSY-5Y, HEK293T, H35, AR42J, GH3, INS1, CHO, MBDK, MDCK, Vero, COS cells and other well characterised mammalian cell lines. These are all regarded as especially disabled.

Host/vector system

Lentiviruses: 2nd or 3rd generation lentiviral systems. Vectors may incorporate the WPRE. Adeno-associated virus (AAV): “gutless” pAAV ITR vector containing inserted gene of interest; AAV vector containing Rep and Cap coding sequences; Adenovirus helper vector required for replication.

Origin & function

Intended Functions:
Inserts may contain the following:
• siRNA to knock down expression of an endogenous gene of interest.
• Wild type human or rodent genes, of interest due to their involvement in a physiological or pathological pathway, but which do not cause disease on their own.
Evaluation of foreseeable effects

For transfer of viral plasmids into mammalian cultured cells (e.g. HEK293T cells) for viral production, standard chemical transfection reagents will be used (e.g. Lipofectamine).

Viral particles will transduce host cells through natural tropism.

Amplification of transfer plasmids and helper plasmids: Plasmids will be propagated and purified using standard E.coli strains (e.g. DH5alpha, STABLE2) and standard techniques of recombinant DNA technology (CL1).

Generation, purification and use of lentiviruses and AAV in cell culture.

Lentivirus:

For lentiviral work, second or third generation lentiviral systems will be used. These systems enhance biosafety by splitting the components necessary for virus production across multiple plasmids (3 for 2nd-generation systems, 4 for 3rd-generation systems). The components of both systems are i) a lentiviral transfer plasmid encoding the insert of interest. The transgene sequence is flanked by long terminal repeat (LTR) sequences, which facilitate integration of the transfer plasmid sequences into the host genome. Many lentiviral transfer plasmids are based on the HIV-1 virus. For safety reasons, transfer plasmids are all replication incompetent and may contain an additional deletion in the 3'LTR, rendering the virus “self-inactivating” (SIN) after integration, ii) packaging plasmid(s) and iii) envelope plasmid.

The 2nd-generation lentiviral system contains a single packaging plasmid encoding the Gag, Pol, Rev, and Tat genes. The transfer plasmid contains the viral LTRs and psi packaging signal. The envelope protein Env (usually VSVG due to its wide infectivity) is encoded on a third, separate, envelope plasmid. The 3rd generation system further improves on the safety of the 2nd generation. First, the packaging system is split into two plasmids: one encoding Rev and one encoding Gag and Pol. Although safer, this system can be more cumbersome to use and result in lower viral titres due to the addition of one additional plasmid. Second, Tat is eliminated from the 3rd generation system through the addition of a chimeric 5' LTR fused to a heterologous promoter on the transfer plasmid. Expression of the transgene from this promoter is no longer dependent on Tat transactivation. Use of these systems means that the probability of a series of recombination events that produce a replication-competent virus that can spread within and between hosts is very small.

Lentivirus can transduce many tissues should it come in contact with them. Here, the two potential transmission routes are by external exposure (either skin lesions or mucous membranes; only in the case of very high titres and aerosol production) and by accidental injection/inoculation using sharps. The most significant hazard is therefore represented by the packaged virus prior to infection of the target cells and residual virus in the medium of infected cells. In the context of this project, the main

Adeno-associated virus:

AAV is non-pathogenic in humans and is only able to replicate in the presence of adenovirus. AAV systems for production of viral particles for gene transfer employ replication defective “gutless” AAV vectors which have the Rep and Cap genes required for the viral life cycle replaced by the inserted gene of interest and expressed using a separate vector. An additional vector contains adenoaviral genes required for replication. Once in a host cell AAV will replicate if a helper virus is present, or otherwise be incorporated in the host genome at a specific location or in the absence of the Rep gene, form episomal concatamers.

AAV can transduce many tissues should it come in contact with them. Here, the two potential transmission routes are by external exposure (either skin lesions or mucous membranes; only in the case of very high titres and aerosol production) and by accidental injection/inoculation using sharps. The most significant hazard is therefore represented by the packaged virus prior to infection of the target cells or organism and residual virus in the medium of infected cells. In the context of this project, the main
risk for primary infection of humans is by high titre viral stocks that have been concentrated by ultracentrifugation. There is negligible risk of random insertional mutagenesis. The defective virus is not incorporated into the host chromosome, so in dividing cells the virus is diluted and degraded over time, but it does persist in non-dividing cells. The main risk is therefore from the inserted DNA sequence. Inserted DNA may contain mutant genes responsible for neurodegenerative diseases in humans. The potential for accidental inoculation of an operator to result in manifestation of disease is very low (lower than for example the risk from oncogenes) as widespread transduction in the CNS from peripheral exposure would be extremely unlikely. 

Inserts may contain CRISPR-Cas9 reagents, such as guides to target genes for manipulation or sequences encoding the Cas9 protein. Inserts may contain Cre-recombinase or the tetracycline-controlled transactivator (tTA). None of these inserts have known deleterious functions when expressed on their own. In addition, inserts may also encode commonly used tags, such as GFP. Apart from fluorescence, these tags are biologically inert. Lack of the proteins (as associated with CRISPR-mediated knockout) is likely to reduce cellular health, perhaps even reducing the oncogenic risks posed by the lentiviral vector. Expression of altered versions of the proteins under investigation is also likely in many cases to reduce the biological fitness of the modified cells. The genetically altered cultured cells produced (especially neurons) will be unable to survive outside of laboratory culture. In the highly unlikely event that cells are inoculated into an operator, they would be expected to be recognised as non-self and destroyed by the immune system. The risk of such modified immortalised cells is unlikely to be greater than the equivalent risk posed by immortalised cell lines in common use. Primary cells may pose a risk of adventitious infection, which is minimised by the mitigation procedures in place.

Lentivirus: 

Production of lentivirus: Whenever possible, we will use 3rd (or subsequent) generation lentiviral systems. The lentivirus is produced by co-transfecting the packaging plasmid mix and the transfer vector into HEK293T packaging cells. A typical scale of viral production might include 1-10 10 cm dishes producing a total of up to 300 mL of viral supernatant. Particles are harvested over a period of 48 to 72 hours after transfection and are stored at -80C. If titres are low, the virus can be concentrated by ultracentrifugation. During this process, the potential hazard from aerosolization of the virus will be mitigated by the requirement that buckets will be sealed and unsealed in a biosafety cabinet and that the outside of the buckets be decontaminated before they leave the biosafety cabinet (see below). Transduction of recipient cells: These will be tissue cultures of human or other mammalian cells (potentially including human and mouse primary cultured cells) and the scale of the transduced sample will be up to 40 single or multiwell plates or flasks, with volumes of 0.05-150 ml per well/flask, depending on plate format, with a total volume of up to 1200 ml (typical volumes will be around 250ml). The recipient cells will be incubated with the virus for 4-24hours after which the viral supernatant will be removed and inactivated. The cells will be washed 3 times in PBS and new virus free medium added. Following 48 hours of virus free culture, the cells can be removed to CL1 as any residual viral particles should no longer be active at that point, so the cells do not pose a biosafety risk. Analysis and selection of transduced (recipient cells): Western blot, plate reader assays, FACS or fluorescence microscopy to analyse protein expression can be used to estimate transduction and transfection efficiency of the viral constructs. If microscopic analysis is required before the 48 hr post viral clearing period, samples will be fixed in 4% formaldehyde for 10-20min prior to removal from CL2, which should inactivate any virus. FACS analysis samples may be fixed as above, or living cells may be transported to the CIMR FACS facility (which is approved for CL2 samples) in leak- and shatter-proof containers. Recipient cells may be treated with antibiotic selection (puromycin or blasticidin or other selective agent). Adeno-associated virus: 

Production of adenovirus: Genes of interest are cloned into AAV genome plasmid containing EGFP driven by the strong mammalian CMV promoter, between two ITRs. This is co-transfected into HEK293 cells along with a helper plasmid containing all the serotype functions required for AAV production in a transient system and an AAV packaging plasmid containing the Rep and Cap coding sequences. Transduction of recipient cells: As with lentivirus. Analysis and selection of transduced (recipient cells): As with lentivirus AAV virus particles may be used for CNS-targeted gene transfer in vivo in mice. This may be done either systemically through tail vein injection into young adult mice, or through intracranial injection carried out stereotactically under general anaesthesia. In both cases, the number of viral particles and the time required for expression of the virally transferred DNA will need to be determined empirically. Expression will be confirmed by immunofluorescence in brain sections and by direct detection of mRNA or protein products of the gene of interest. One aim of this work is to inject AAV into mice, either systemically or intra-cranially. This work will be carried out in CL2 facilities in either CBS or the Ann McLaren building.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All disposable culture/lab ware will be autoclaved and incinerated which eliminates 100% of the infectious material. Culture fluids will be treated with 2% Virkon for 16 hours (which eliminates 100% of infectious material) then disposed of down drains. Recyclable lab ware will be soaked in 1% Virkon for 16 hours. Bench/cabinet surfaces will be wiped down with 70% ethanol. Spills will be sprinkled with Vernagel powder, then transferred to autoclave bags and the area wiped down with distal or similar detergent.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The maximum culture volume that could be released by a single spill or breakage is 3L.

Deactivation Procedures
* Disinfectant (2% w/v Virkon) is used for spills and cleaning surfaces.
* In the event of spillage, the area can be effectively disinfected and the wider environment is unlikely to become contaminated.
* Liquid biohazard waste is inactivated with 2% w/v Virkon (1% final concentration) for at least 16 hours prior to disposal to the drainage system.
* Pipettes and Class II cabinets are decontaminated using Microsol3 (distributors: Anachem).
* Waste contaminated with biologicals is autoclaved at 131 degrees C for 30 minutes. It is then placed in yellow plastic clinical waste bins that are sealed before removal from the site for incineration.
* Waste contaminated with chemicals only (no biologicals) is placed in yellow plastic clinical waste bins that are sealed before removal from the site for incineration.
* Lab coats are autoclaved at 131 degrees C for 30 minutes before laundering.

Use of Virkon validated and monitored by viability testing.

Project Additional Information

Purposes of the contained use

Initially, for feasibility studies involving the infection of target cell lines with MLV (expressed in producer cell lines), leading eventually to screens for biologically active compounds.

Recipient or parental organism

MLV genome is stably incorporated into the genome of producer cell lines in such a way that the packaging signal required for viral genomic packaging into viral particles has been removed rendering the virus replication incompetent. In addition components of the viral genome (gag/pol, and env) have been separated. In some procedures, however, producer cell lines with the ability to produce viral particles containing packaged viral genomic env gene only (or chimeric forms thereof) will be constructed.

Amphotrophic (4070A) MLV is being used for the feasibility studies, it has a broader host range than ecotropic (Molony) MLV and is able to infect human cells in culture. There is some research that indicates that the replication competent form of this virus is able to survive in non-human primates (Characterization of replication-competent retroviruses from nonhuman primates with virus-induced T-cell lymphomas and observations regarding the mechanism of oncogenesis. Vanin EF, Kaloos M, Broschi C, Nienhuis AW.; J Virol 1994 Jul;68(7):4241-50). There are, however, no examples of this virus infecting humans.

In order for replication competent virus to arise with the fully replication incompetent system a double recombination event would have to arise. However, for the envelope packaging system only a single recombination event would be required to generate replication competent virus.

Host/vector system

Host System: Parental human cell lines able to produce part of all of the MLV proteins, which auto-assemble and bud from the cell surface to form either capsid particles (product of gag/pol) or full virus particles (product of gag/pol and env) containing no genome. In addition any DNA contained between a 5 and 3' LTR with a packaging signal will be processed into the viral particles.

Vector System: Amphotrophic MLV particles containing packaged DNA. This DNA is able to stably insert into the genome of actively dividing target cells.

Target Cell Lines: Normal tissue culture cell lines (including murine, canine, bovine and human types).
### Origin & function

**MLV origin:** Plasmid vectors containing elements of MLV genome transfected into producer cells.

The function of modified MLV is to deliver genetic material to target cell lines. Specific modifications to env (i.e. the display of toxin proteins, such that they are incorporated on the viral surface) effectively limit the ability of the virus to infect target cells by sequestering the viral particles away from the viral receptor proteins.

### Evaluation of foreseeable effects

**Foreseeable Effects**

The use of an envelope packaging system makes the likelihood of replication competent MLV arising as the result of recombination more of a possibility, when compared to systems where none of the retroviral genetic elements are packaged (i.e. fully disabled retroviral vectors). This factor and the display of proteins on env will be the major considerations when evaluating risk to human health and the environment.

**Effects on human health**

With regard to hazards arising from the inserted gene(s) and potential protein products, the following should be considered (it should be stated that these genes are linked to env to produce chimeric envelope):

- **Toxic** - e.g. toxin genes: the display of toxin proteins on env (at approximately 1010-12 molecules per ml) results in a potential dose (during virus production) of only a few picograms of toxin per ml which is several thousand times below the level required to produce any affects for protein toxins, it is therefore unlikely that any transfer of genetic material would result in production of toxic proteins, by the host cells, that would pose a risk.

- **Allergenic** - e.g. from viral proteins or other expressed proteins: there is no data that would indicate the potential allergenicity of MLV proteins or chimeric env proteins.

- **Oncogenic** - e.g. growth factors: the display of growth factor proteins on env (at approximately 1010-12 molecules per ml) results in a potential dose of only a few picograms of growth factor per ml which is below the level required to produce any physiological effect, it is therefore unlikely that any transfer of genetic material would result in production of growth factors, by the host cells, that would pose a risk.

An infection involving MLV is only likely to occur by direct fluid transfer i.e. needle-stick injury or transmission via a wound. However, the virus would have to be introduced in a fairly large quantity (several ml) it would have to survive in the blood until it was able to infect actively dividing cells and it would also have to survive the immune system. The probability of modified MLV causing harm to humans is negligible.

**Effects on the Environment**

MLV occurs naturally in the environment and is a well characterised mouse pathogen, any modifications should place the virus at a selective disadvantage when compared to wild type virus. The probability of release into the environment and harm arising from this release is very low.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**Not applicable**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

- **Waste generated as a result of tissue culture activities:**

  a) All contaminated solid waste, plastics etc., (not including liquid waste) is placed into double autoclave bags housed in a leak-proof stainless steel autoclave box (with lid). This autoclave using a standard cycle 121C, at 2 bar for 30 minutes, the autoclave generates a fully audited, printed record for each run, these are stored in a company.
archive. The autoclave is under a maintenance contract by the manufacturer and is regularly serviced. Waste Material from the autoclave is discarded into permanently sealable leak-proof plastic bins destined for incineration by an approved contractor. This can therefore be considered as 100% kill.

b) Liquid waste (i.e. generated by removal of media from cultures) is disinfected (Tegodyne, 50m/L) overnight before discarding. Tegodyne has been tested by the manufacture and is known to be 100% effective in the activation of retroviruses, when used at the correct concentration.

Spills will be mopped up with suitable qabsorbent material (for example Whatmans spill containment granules), this will then be treated as solid waste, surface will then be treated with a suitable disinfectant (Tegoydne or virokon). 

Monitoring: Viral stocks generated will be tested for the presence of replication competent MLV, please see attached SOP. If as a result of testing RCR's are detected then all experimental material relating to the tested viral stock will e destroyed by chemical inactivation (Tegodyne) and autoclaving.

</tbody>
</table>
### Purposes of the contained use

Use of adenovirally transfected mammalian cells for the purpose of drug discovery, including human ion channels, GPCR'S or kinases. Various experimental techniques may be used including automated electrophysiology, radiochemical and biochemical assays using live cells or cell lysates.

### Recipient or parental organism

Mammalian cell lines including but not limited to: HEK 293, CHO KI and human cystic fibrosis bronchial epithelial cells.

### Host/vector system

**Adenovirus 5 vector system:**

The gene of interest is incorporated into the attenuated adenoviral adaptor plasmid which does not contain the E1 region. This vector is co-transfected with a helper plasmid which contains the remaining coding sequence of the adenovirus, without the E2A region. When the adaptor and helper vectors are transfected into the host cell line, per C6-2A, a human retinal cell line engineered to produce the E1 & E2A gene products replication incompetent adenovirus is produced. The virus is purified and used to transfect host cells which then express the inserted gene. These cells are then used in experiments.

### Origin & function

This is a replication deficient E1 and E2 deleted, type 5 attenuated adenoviral vectors carrying RNAI or CDNA sequences that have been generated at BIOFOCUS (a Galapagos company) in Leiden. The virus is produced in per C6 cell line from Crucell, Leiden. The viruses are laboratory reagents for research, testing and evaluation purposes only, they are not for diagnostic or therapeutic use. The goods are classified as biological specimens category B (UN 3373) and are generated using cell culture techniques (they are not antiserum, blood fractions, nor a modified immunological product. They are not a vaccine for human nor veterinary use. They are not a ferment).

### Evaluation of foreseeable effects

The virus is non-replicative human virus that can only propagate within the packaging cell line.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

---

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1. Liquid waste collected from flasks & plastics is decontaminated overnight using Phoraid disinfectant. This is left in a sealed container overnight to ensure 100% kill.
2. Solid waste is placed in a yellow biohazard bin. The bin is lined with two biohazard autoclave bags which at the end of the working day are sealed and the lid locked in position so that the container cannot leak or the lid removed. The bins are labelled with a biohazard sign and carries the UN 3291 number. Bins are stored in a locked, brick store with concrete floor until collection by Grundons Waste Ltd. Grundons Waste Ltd are certified to handle and dispose of level 2 waste, which once collected is incinerated ensuring 100% kill. Grundons Ref: BIOF001.
3. Tips and other plasticware which may contain a small amount of liquid after use, will be placed in Phoraid disinfectant overnight before being treated as solid waste.
4. A biohazard spill kit will be available close to hand.

CU2 Project Title  1) BV-2 Cell based Luciferase assay 2) BV-2 Cell based TNF (Tumour Necrosis  
Class  2  
CultureVolClass2  < 1 Litre  
CultureVolumeClass3-4
Project Additional Information

Purposes of the contained use

Recipient or parental organism

BV-2 cells (Mouse Microglial cell line)

Host/vector system

Replication defective J2 retrovirus (recombinant murine sarcoma virus 3611 containing viral oncogenes Myc and Raf).

Origin & function

This work was generated by Prof Rosario Donasto at the University of Perugia in Italy. BV-2 cells were originally transformed by infecting the primary cells with the J2 retrovirus. MSV-3611 (closely related to the M-Mulv) was originally isolated from chemically transformed mouse cells. MSV-3611 is replication defective due to deletion of the gag-pol replication genes and has acquired acute transforming properties due to incorporation of the oncogene v-raf into the proving genome (ref(1) PNAS.RAPP et al (1983) 80: 4218-4222

J2 was derived from MSV-3611 by incorporating a 2nd viral oncogene, V-MYC, into the viral genome (Ref (2) J virology (1985) SS (1): 23-33 Rapp et al) The function of J2 was to transform primary cells to obtain established cell lines. The presence of V-MYC in addition to V-raf removes1L-3 dependant for growth maintenance in culture (ref 2)

This transformed cell line and retrovirus are laboratory reagents for research, testing and evaluation purposes only. They are not for diagnostic or therapeutic use. The goods are classified as biological specimens category B (UN 3373) and are generated using cell culture techniques (they are not anti serum, blood fractions, nor a modified immunological product. They are not vaccine for human or veterinary use)

Evaluation of foreseeable effects

BV-2 cells transformed by replication defective J2 retrovirus (recombinant murine sarcoma virus 3611 containing viral oncogenes Myc & Raf). Other lymphoid cell lines transformed with J2 such as GG2EE have shown to produce viral particles due to the presence of endogenous virus.
Transformed cells and J2 virus have been shown to induce tumours when injected into mice, although the transforming efficiency of J2 is dependant to the pseudotype. Risk to the environment is minimal. Please see enclosed risk assessment. Bio-RA-0081

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

**Please enter comments on the GM safety committee on the risk assessment**

After lengthy discussion, the GMSC felt that all work undertaken for this project should be carried out in a Class 2 safety cabinet. That a thorough decontamination procedure should be strictly adhered to. Due to the space constraints in the level 2 laboratory, no other work should be carried out in the area during the running of this project. No other cell lines will be used or grown in the level 2 laboratory while working on this project. Staff working on this project should be thoroughly trained and have a full understanding of the possible risks involved.

Project Additional Information

Purposes of the contained use
To transfect mammalian cells for the purpose of drug discovery, including human ion channels, GPCR's or kinases. Various experimental techniques may be used including automated electrophysiology, radiochemical and biochemical assays using live transfected cells or cell lysates.

Recipient or parental organism
Mammalian cell lines including, but not limited to: HEK 293, CHO K1

Host/vector system
E1 replacement adenovirus serotypes vector with E2A gene deleted. Replication incompetent. Fiber protein pseudotypes include Ad5 and Ad50.

Origin & function
Recombinant adenovirus containing genes of interest will be produced in the PERC 6 E2A packaging cell line and purified by Biofocus DPI, Leiden, The Netherlands. The purified virus will be shipped to Biofocus DPI UK and used to overexpress the inserted genes in mammalian cells for the purpose of drug discovery research.

The fiber protein that interacts with the cell surface receptors and determines tissue tropism be either wild type Ad5 (coxsackie and adenovirus receptor dependent) or Ad50 pseudotype (SC46 dependent) which will be used to infect cell lines that are refractory to Ad5, e.g. colon tumor cell lines.

**Evaluation of foreseeable effects**

Due to the deletion of the E1 and E2A genes the virus is non-replicative human virus that can only propagate within the packaging cell line. Recombinant adenovirus may mimic wild type adenovirus with exposed individuals experiencing mild respiratory illness. The Ad50 pseudotype may also infect cells/tissues that are not normally infected by wild type Ad5, such as leukemic cells. The initial infection is unlikely to be sustained or spread via viral shedding since it is not replicative. Even if replication competent viruses were generated the risk is low since human adenovirus infection is very common and the majority of adults are immunised. Furthermore the inserted genes will not alter the pathogenicity, stability or immunotoxicity compared to wild type adenovirus.

Live adenovirus is relatively stable and may persist for long periods if released into the environment and may pose a low risk to animals/plants/humans. However, cross species transmission of human adenovirus is generally thought not to occur, so the greatest risk is to young children and immunocompromised patients. Transport of virus and waste will only be undertaken in appropriate UN certified containers.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity.  (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste collected from flasks and plastics is decontaminated overnight using phoraid disinfectant (validated). This is left in a sealed container overnight to ensure 100% kill. Solid waste is placed in a yellow biohazard bin. The bin is lined with two biohazard autoclave bags which, at the end of the working day, are sealed and the lid locked in position that the container cannot leak or the lid be removed. The bins are labelled with a biohazard sign and carries the UN 3291 number. Full bins are stored in a locked brick store with concrete floor until collection by Grundens Waste Ltd. Grundens Waste Ltd are certified to handle and dispose of level 2 waste, which once collected is incinerated ensuring 100% kill. Grundens ref:Bio001. Bins used are UN approved for hazard packing group 2.

Tips and other plasticware which may contain a small amount of liquid after use is placed in phoraid disinfectant (validated) overnight before being treated as solid waste. Level 2 waste bins are segregated from level 1 waste bins when stored. Disinfected liquid waste is removed from site for incineration by an approved contractor. Spill kits are available in all biology labs.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment
Members of the GMSC had access to written papers regarding the origins of the adenovirus and its modifications in advance of the meeting. They were given both risk assessments which accompany this form. After the meeting initial concerns were raised regarding the possible infection of other cell lines being cultured in the tissue culture laboratories and also the possible risk to the environment. Should there be an accidental spill or leak. Our molecular biologist gave a clear and informative presentation explaining how the virus is unable to replicate either in vitro or in vivo due to the deletion of both the replication incompetent E1 gene and the deletion of the E2 gene.

The GMSC were also informed that cells transfected with the adenovirus would be handled in isolation and away from wildtype or susceptible cell lines. The meeting was closed with all members happy that the risk assessments were thorough and that they had a full understanding of the theory behind the replication deficient adenovirus and that the risks are adequately controlled.

The article "Dominant phenotypes produced by the HD mutation in STHdh striatal cells" was given to all members of the GMSC 24 hrs before the meeting along with the risk assessment for the project.

Generally, the GMSC was happy that the risk assessment had highlighted areas of higher risk and steps were taken to try to reduce that risk. Unanimously, the GMSC felt that a commercially available kit (MSP18 Mitoprogile Rapid microplate assay kit for PDH activity - by Mitosciences) should be tried as this would eliminate the homogenization steps of freeze/thawing and high speed centrifugation, enabling the whole protocol to be carried out in one tissue culture laboratory and inside a class II cabinet. It will also require less protein and therefore less cells.

### Project Additional Information

**Purposes of the contained use**

Evaluation of 19 adenoviral shRNA-corrected Delta F508-CFTR variants for the purpose of drug discovery, techniques to include routine culturing of cells, transfection and conventional patch clamping.

**Recipient or parental organism**

Bronchial Epithelial cells

**Host/vector system**

pSVori-plasmid (replication defective SV40 virus)

**Origin & function**

The immortalized CFTR cell line originates from Dr. *****. California Pacific Medical Centre Research Institute. San Fransisco, CA, USA

CFBE41 cells are immortalized using the pSVori plasmid (replication defective SV40 virus). These cells will be transfected using 19 Adenoviral targets (see GM notification 680/08.1 entitled "Use of replication deficient adenovirus to transfect mammalian cells") previously shown to promote activity of the delta F508-CFTR. The transfected cells will then be evaluated by conventional patch clamp.

**Evaluation of foreseeable effects**

Exposure to the immortalized cell line has a low risk of foreseeable effects. No infective viral particles can be produced by pSVori. Co-infection of the cell line with another SV40 virus will not rescue pSVori because the origin of replication is non-functional. There may be a risk of rescue by recombination with replication competent SV40 virus but since the viral genome encoded by pSVori does not contain any heterologous genes the virulence or pathogenecity of the rescued virus would not differ from wild type SV40 virus.

If released into the environment, the cell line is not viable without the defined cell media. The cell line is transformed and therefore has the capacity to form tumors but would require oral or subcutaneous exposure.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste collected from flasks and plastics is decontaminated overnight using a validated disinfectant. 12 hour contact time ensures 100% kill. Liquid is held in sealed containers until discarded. Disinfected liquid waste is removed from site for incineration by an approved contractor.

Flasks, tips and other plastic consumables which may retain small levels of liquid are immersed in validated disinfectant overnight before discarding as solid waste.

Glass pipettes and coverslips are placed in a biohazard burn bin. This is disposed of as solid waste.

Solid waste is placed in biohazard bins which have been lined with two autoclave bags. At the end of the working day the bins are sealed and the lid locked in the position so that the container cannot leak or the lid be removed. The Bins are UN approved for the transport of packing group 2 substances and are labelled with a biohazard sign which carries the UN3291 number. Full bins are stored in a lockable brick store with concrete floor and are segregated from level 1 and other waste until collection by Grundons waste limited. Grundons Waste LTD are certified to handle and dispose of (by incineration) level 2 waste. Grundons GM centre number is 782.

### Project Additional Information

**Purposes of the contained use**

**Recipient or parental organism**

Uropathogen E coli wild type. Strain J96

**Host/vector system**

Luminescence genes from LuxCDABE from Potorhabdus luminescence

**Origin & function**

Antibacterial research and drug discovery

**Evaluation of foreseeable effects**

The wild type J96 strain is a known uropathogen. The insertion of the luxCDBE gene is unlikely to render this strain as non replicating and non infectious. With this in mind, all work will be carried out at BSL 2 and all contaminated wasle will be rendered inactive before leaving the premises (refer to waste risk assessment). Only trained and well informed personnel will be permitted to work on this project and occupational screening will be offered both at the start and end of the project. Therefore it is felt that the risk to both staff and the environment is low.
N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Grundons Waste LTD are certified to handle and dispose of (by incineration) level 2 waste. Grundons GM centre number is 782.

This uropathogen can sometimes be asymptomatic and therefore does not always show signs of urinary tract infection before causing infection to the kidneys. With this in mind the GMSC felt that screening should be offered to people working with this strain at both start and end point of the project. It was felt after much discussion that the screening should be made compulsory and that staff who were not happy to take the test should not be permitted to work with the organism.

Please enter comments on the GM safety committee on the risk assessment

Please enter comments on the GM safety committee on the risk assessment

Generally the members of the GMSC were satisfied with the current risk assessment in place, however it was decided that due to the fact that the supplier of the cells could not guarantee the cells did not carry other infectious material, that this should be better highlighted on the risk assessment (now in place) and should also be taken into account when training staff on the project. It was also acknowledged that the risk assessment may change slightly as the work develops and that the risk assessments would be updated accordingly, although the actual risk to staff should not be higher than currently declared.

### Project Additional Information

**Purposes of the contained use**

Section 17 refers

**Recipient or parental organism**

Opportunistic pathogenic Pseudomonas aeruginosa wild type strain PA14

**Host/vector system**
Section 17 refers

Origin & function

The recombinant derivative and wildtype strain of Pseudomonas aeruginosa (PA14) are to be supplied by our US Client to enable us to perform the services described in Section 5. Strain PA14 is a human clinical isolate strain that displays a highly virulent phenotype against broad spectrum of organisms.

The "Purpose of the contained use" is research (biological screening) aimed at identifying new chemicals that control the virulence of P. aeruginosa and thus have the potential to act as therapeutic agents.

Section 17 refers with respect to non-disclosure

Evaluation of foreseeable effects

The wild type PA14 strain is a known opportunistic pathogen: it is present in the environment.

The modified strain of the pathogen is not expected to be more virulent than the wild type strain; however due to it being resistant to tetracycline, additional vigilance would be assigned to working with this strain. As first aid treatments for Pseudomonas infections include third generation cephalosporins, aminoglycosides and carbapenems, then resistance to tetracycline is not expected to incur further hurdles for its treatment should a worker become infected (ie. It is unlikely that the modified strain would pose a greater threat to human health or the environment than the wild type strain).

All open work will be carried out at BSL 2 and all contaminated waste will be rendered inactive before leaving the premises (refer to waste risk assessment). Only trained, competent and well informed personnel will be permitted to work on this project and health screening for P. aeruginosa infection would be undertaken should workers show signs of chest, eye, intestinal, or urinary tract infections.

Any employees who are assigned to the following categories would not be allowed to work with this organism: immunocompromised, diabetics, anyone with cuts and/or burns, anyone with an existing illness/infection and/or are known to have an allergy to antibiotics (see risk assessments).

By ensuring that we work within the guidelines described in our risk assessment we believe that the risk to both staff and the environment is low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste collected from plastic flasks and other open plastics is decontaminated overnight using a validated disinfectant. 12 hour contact time ensures 100% kill. Liquid is held in sealed containers until discarded. Disinfected liquid waste is removed from site for incineration by an approved contractor.

Flasks, tips and other open plastic consumables which may retain small levels of liquid are immersed in validated disinfectant overnight before discarding as solid waste.

Solid waste is placed in biohazard bins which are lined with two autoclave bags. All solid waste will be autoclaved and then placed back into the burn bins which are then sealed and the lid locked in the position so that the container cannot leak or the lid be removed. The bins are labelled with a biohazard sign, carries the UN3291 number and are UN approved for packing group 2. Full bins are stored in a lockable brick store with concrete floor and are segregated from level 1 and other waste until collection.
by Grundons Waste Limited. Grundons Waste LTD are certified to handle and dispose of (by incineration) level 2 waste. Grundons GM centre number is 782.

The GMSC were given procedure protocols and risk assessments prior to the meeting.

The following points were raised:

1. Investigations to be made to determine if the absorbance read could be done using sealed plates as opposed to lidded plates, thus reducing the risk of spill. This investigation was carried out and it was concluded that this indeed could be done. The protocol has been changed accordingly.

2. Concerns raised about the amount of equipment the protocol was suggesting to be placed in the class 2 safety cabinet at any one time. This would affect the flow and reduce the safety efficiency of the MBSC. The first point now means that there is no need for the reader to be placed in the MBSC. The protocol has been changed accordingly.

3. The GMSC also discussed the number of plates to be run at any one time. It was decided that the work should be comfortably managed in one day, that the MBSC should not be overfilled and that movement around the MBSC should be minimal so as not to disrupt airflow. Batches of 5-10 plates seemed to be the ideal.

4. It was decided that emergency clothing should be available inside the ante-room. Should clothing become contaminated it would be autoclaved to ensure contamination did not infect the environment.

5. It was suggested that swabbing was carried out on door handles, taps and benches to ensure there was no breach of containment. This should be done at the end of each phase of the project. As this would be easy to carry out, there seemed no good reason not to do it as a "belt and braces" exercise.

The GMSC were comfortable in assigning the strain of P. aeruginosa to Biohazard Level 2.

Although P. aeruginosa is an opportunistic pathogen (i.e. more likely to infect individuals who are sick or immunocompromised, as opposed to healthy individuals), it can cause a wide range of infections, particularly among immunocompromised people (HIV or cancer patients) and persons with severe burns, diabetes mellitus or cystic fibrosis. Consequently, only trained, competent and well informed personnel will be permitted to work on this project. Any employees who are in the following categories would not be allowed to work with this organism: immunocompromised, diabetics, have cuts and/or burns, have an existing illness/infection and/or are known to have an allergy to treatment antibiotics. Health screening for P. aeruginosa infection would be undertaken should workers show signs of chest, eye, intestinal, or urinary tract infections.

Animal Units  Large Scale Activities  Human Clinical Applications

02/03/2022  Page 10639 of 15326
The aim of the project is to use small molecule libraries and RNAi using non viral transfection vectors, for functional screening of Pu.1 activity.

Non-viral the pu.1 containing cDNA expression vector comprises an expression plasmid (pGL4.23) with a 5X lambdaB reporter. A neomycin resistance cassette is included in the targeting vector.

Viral: the murine cell line (BV-2) was generated by infecting primary microglial cell cultures with a v-raf/v-myc oncogene carrying retrovirus (J2) described by Blasi et al, in J Neuroimmunol. 1990 May;27(2-3):229-37.
Pu.1 transcription factor. Luciferase is a naturally occurring oxidative enzyme that catalyses the conversion of luciferin to oxyluciferin and light.

**Evaluation of foreseeable effects**

The BV-2 cell line produces an enveloped recombinant ecotropic murine retrovirus such virus is known for its in vitro transforming ability and in vivo tumorigenic potential. It should be capable of infecting murine cells only and therefore presents a risk from accidental release into the environment.

There is also a minor risk of the J2 virus infecting human lymphocytes following prolonged (24 hour) exposure as described by Peppoloni et al (Experientia. 1988 Dec 1;44(11-12):1013-5) which should be evaluated as a potential risk to the operator.

BSL 2 containment and control measures as described in the risk assessment, handling within class II biological safety cabinet, wearing personal protective equipment and treating all contaminated waste with validated disinfectant will minimise both of these risks to very low.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

n/a

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

All BV-2 cells are lysed as part of the luciferase assay protocol. All category 2 waste from both the screening assay and tissue culture activities is first treated with validated disinfectant overnight to ensure no viable material remains, then double biohazard bagged and disposed for incineration by an approved contractor. Transport to the incinerator is undertaken in UN approved packaging.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All BV-2 cells are lysed as part of the luciferase assay protocol. Please enter comments on the GM safety committee on the risk assessment
The prolonged exposure required for infection of human lymphocytes is not tenable under the conditions of use.
We have sufficient pest control measures in place on site so that even in the case of an unexpected failure of containment during the experiment there would be no murine exposure to the wild population.
Following disinfection, the packaging used in transport to the incinerator is designed to prevent any escape to the environment, even though what is being transported is not viable.

Date of Significant Change

Project Additional Information
### Purposes of the contained use

Cell lines containing either wild-type or gene-edited versions of the human Huntingtin (HTT) gene will be supplied by the Rockefeller University, New York. Cell lines will be grown and differentiated into neuronal cells via characterized small-molecule induction protocols. Samples will be taken at defined points in the process in order to examine differences among the lines (which contain gene-edited alterations of the human HTT gene), using immunohistochemistry and quantitative methods of mRNA determination (e.g. branched DNA assay or qPCR). No further genetic modification is anticipated with these cell lines. Both of these techniques result in the chemical destruction of the cells and removing the potential biological hazard. Identification of differences in the lines may lead to potential new HD therapies or biomarkers to assess the effects of HD treatments.

### Recipient or parental organism

Human embryonic stem cells (RUES2) were derived from a de-identified frozen embryo that was originally generated for reproductive purposes and later donated with informed consent for research purposes. RUES2 cells are sourced from The Rockefeller University, New York. These cells are unscreened for adventitious pathogenic viruses—therefore they are treated as potentially infectious and handled at BioSafety Level 2. In addition, RUES2 cells are totipotent with the potential to form teratomas in immunosuppressed individuals.

### Host/vector system

Non-mobilizable, non-episomal, pUC based plasmids were introduced into the supplied cells by electroporation.

### Origin & function

1. **Homologous Recombination (HR) Targeting Vector.** The vector comprised a synthetic left and right homology arm against the human HTT gene that flank a donor sequence. The donor sequence contained the first exon of the human HTT gene with either normal or expanded lengths of CAG repeats and viral Inverted Tandem Repeats (ITRs) flanking a Puromycin-Thymidine Kinase (TK) positive-negative selection cassette; the HTT exon1 was obtained by PCR from genomic DNA extracted from fibroblasts or iPSCs derived from human HD patients.

2. **Cas9 plasmid contained a synthetic Cas9 endonuclease; codon-optimized for human expression, and a synthetic sequence for the guide RNA targeting the human HTT gene.**

3. **Transposase Plasmid expressing integration-deficient PiggyBac transposase.**

How the supplied cells were generated

The HR targeting vector and Cas9 plasmids were designed to replace the parental HTT exon 1 CAG repeat with a normal or expanded length of CAG repeats to create either a null hESC cell line or a mutant HTT hESC cell line. The inserted Puro-TK selection marker was used to isolate cells that have undergone homologous recombination by positive selection with puromycin. The Transposase plasmid was then used to excise the Puro-TK selection marker without leaving behind any residual residues of the targeting vector. Cells that did not have the Puro-TK marker excised were killed by negative selection with ganciclovir (a pro-drug that is converted into a DNA synthesis inhibitor by TK).

### Evaluation of foreseeable effects

The supplied GMM will possess either a wild type and/or a mutant HTT gene. The presence of an extended CAG repeat in the mutant HTT gene results in mHTT protein aggregates which are toxic to cells, particularly neuronal cells. Plasmid reagents used for the gene editing (Cas9 & Transposase) are not transmissible, do not integrate and are not maintained episomally; they will have been removed from the supplied cell lines through prolonged culturing. The
completed gene editing process will also leave no extraneous residues, such as DNA regulatory sequences or antibiotic selection markers, present in the vectors.

Foreseeable effects from GM.

RUES2 cells are unscreened for adventitious I pathogenic viruses and are therefore treated as being potentially infectious. The supplied genetically modified cells will be handled under BSL2 conditions. As RUES2 cells are totipotent with the potential to form teratomas in immunosuppressed individuals no such individual will be allowed to culture these cells. Non-immunosuppressed individuals would clear the cells rapidly and as such they are not at risk.

Very low risk to human health from the genetic modification. WtHTT/mHTT is not an oncogene, tumor suppressor, hormone, cytokine or involved in the immune system. The genetic modification was conducted in the suppliers laboratories and no further modification is anticipated. Although mHTT protein aggregates are toxic within a cellular context they are non-transmissible and will therefore pose negligible risk.

Very low risk to environment since there are no antibiotic resistant genes or viral/plasmid sequences present and the cells cannot survive outside of defined culture media used within a laboratory environment. Although cells can form teratomas when injected in nude mice there is no chance that this can happen.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We wish to request derogation from the need to autoclave solid waste material. All material (solid and liquid) will be chemically inactivated for 24hrs prior to it being stored securely before being taken away for incineration by an authorised waste disposal contractor. This is sufficient for the level of hazard posed by the materials in question.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste is placed in biohazard bins which are lined with two autoclave bags. Flasks, tips and other plastic consumables which may retain small levels of liquid are immersed in validated disinfectant for 24 hrs before being discarded as solid waste.

At the end of the working day solid waste is sealed in double bags which are then placed in lockable wheelie bins (supplied by Grundons, an external waste disposal contractor (GM Centre number 782)). These are stored in a locked brick waste store with concrete floor until collection by an authorised contractor. Waste is then incinerated ensuring 100% kill.

Only containers certified to UN packing group* or better are used. Solid waste is sealed and the contents and bags incinerated without being opened.

Liquid waste is chemically inactivated for 24hrs with a validated disinfectant prior to disposal. Chemically inactivated liquid waste is decanted into 10 litre waste containers where it remains until removal from site for incineration by an authorised contractor, ensuring 100% kill. Due to site rules, there is no disposal to drains.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
The RUES2 embryonic cell line was initially derived from unscreened human material. As such it is treated as potentially infectious. These cells have been genetically modified in the laboratories of the Rockefeller University, New York, to introduce gene sequences encoding mHTT via homologous recombination. The techniques used result in the removal of any extraneous regulatory sequences and selectable markers. The genetic modification does not increase the risk posed by the cells to humans or the environment. Cells cannot survive outside of the laboratory. It is noted that there is a small risk of tetraomas forming in immunosuppressed individuals if injected with RUES2 cells. Such individuals will not work with this material and no sharps will be used.

The main risk comes from the presence of adventitious human pathogens and it is appropriate for the cells to be classified as level 2 and handled as such.

**Project Additional Information**

### Purposes of the contained use

Human Embryonic Stem Cells containing either wild-type/endogenous or gene-edited versions of the human Huntingtin (HTT) gene will be transfected or transduced in order to identify or validate gene targets which will modify or counteract the effects of the CAG expansion in the HTT gene. This may lead to the identification of druggable targets which could be used as potential HD therapies.

### Recipient or parental organism

Human embryonic stem cells (RUES2) were derived from a de-identified frozen embryo that was originally generated for reproductive purposes and later donated with informed consent for research purposes. RUES2 cells are sourced from The Rockefeller University, New York. These cells are unscreened for adventitious / pathogenic viruses - therefore they are treated as potentially infectious and handled at BioSafety Level 2. In addition, RUES2 cells are totipotent with the potential to form teratomas in immunosuppressed individuals.

Human Embryonic Stem Cells (hES cells) (either with a normal HTT gene or with a CAG expansion in the HTT gene in chromosome 4 (mHTT) that is associated with HD disease) will also be used. These cells are ethically sourced from donated human embryos resultant from IVF treatment. There is no information available about whether the parental hES cells have been screened for any pathogens. It is assumed however that there is no previous known history of infectious disease and donors are from epidemiologically low-risk populations. Cells may still contain adventitious / pathogenic viruses and will be treated as potentially infectious. Parental hES cells are totipotent with the potential to form teratomas in immunosuppressed individuals.

### Host/vector system

**Generation of RUES2 Cells**

Non-mobilizable, non-episomal, pUC based plasmids were used in the generation of the supplied RUES2 cells by electroporation.

**Expression of Exogenous Genes**

Commercially available expression vectors will be used to introduce genes to act as reporters or involved in differentiation and/or disease pathogenesis. Random stable integration may be desirable and vectors may contain a selectable marker to enable this activity. The use of these sorts of vectors represents a minimal hazard because they are non-mobilisable, lack a eukaryotic origin of replication and can not enter cells easily.

In some cases very efficient delivery of a gene is required. In this case viral delivery methodologies (e.g. lentivirus) could be used. Viral systems represent a higher risk due to their ability to transduce quiescent cells and subsequently integrate into the host genome. This integration may potentially inadvertently activate or inactivate genes with deleterious consequences. The risk of this happening will be mitigated by obtaining small aliquots of pre-prepared packaged viral particles that lack the necessary genes for replication. Any transduction or subsequent transduction will only occur once the GMSC has given approval and is satisfied that in the case of an additional transduction there is a lack of sequence homology between the viral systems being used to decrease the chance of recombination.

**Knock-down of Gene Expression with shRNA**

Lentiviral particles used for either delivery of shRNA constructs for 'knock down' of target gene expression or overexpression of a particular gene will be obtained from commercial sources. Viral particles will be generated using third or fourth generation viral packaging systems. These systems have the following safety features:
1. Viruses produced using third or fourth generation systems are unable to replicate. They have been attenuated in several ways. The gene required to produce viral packaging proteins (en v) is absent from the packaged viral genome. The genes required for viral replication gag, pol, and accessory genes, tat, rev, vif, vpr, vpu, and nef, are also absent from the packaged genome. The env, gag and pol genes (which are sufficient and necessary for viral production) are provided transiently on three separate expression vectors that lack homology during viral particle production. The genetic material to be packaged is supplied on a forth plasmid that is the only vector to contain a packaging motif. The lack of homology essentially prevents recombination in the packaging cell line and hence the chance that genes required for virus replication are packaged into lentiviral particles is minimal.

2. The vectors are self-inactivating. This means that upon integration into the genome of a target cell the Long Terminal Repeats (LTRs) are truncated and this prevents mobilisation of the introduced genetic material.

3. It is noted that nearly all viral delivery systems contain the Woodchuck Hepatitis Post-Transcriptional Regulatory Element (WPRE) to enhance transgene expression. It is known that the WPRE contains an oncogenic sequence unless it has been specifically deleted. The increase in risk due to the ability to infect a wide variety of cell types, including quiescent cells, and the potential presence of an oncogenic sequence in the WPRE is mitigated by using small aliquots of virus. There will be no in-house production of lentiviral particles and the use of sharps is prohibited when using this material to prevent inadvertent percutaneous inoculation.

4. There remain the risk of insertional mutagenesis/inappropriate (in)-activation of a gene. This is reduced by the use of small, single use aliquots and that the material will be handled in a Class II MBSC. Sharps are banned in the tissue culture labs which will prevent the risk of sharps injuries during routine work.

To increase tropism these viruses contain the protein product of the VSV-G gene from Vesicular Stomatitis Virus in their envelope. This increases the hazard but not significantly as a worker is unlikely to be exposed to a sufficient dose to lead to a transformation of cells.

When using lentivirus oral ingestion will be prevented by standard laboratory safety practices. Aerosol formation resulting from an accident outside of the safety cabinet and involving lentivirus particle-containing liquid may lead to transduction of a limited number of the laboratory worker's skin or mucosal cells with modified viruses. However, these modified virus particles carry an extremely low safety risk for human health, as they are replication-incompetent, and also because the particles carry an extremely low infection potential via the mucosal/skin routes, due to the inherent properties of the viral vectors. Moreover, the programmable nucleases and shRNA that will be expressed or targeted will not be designed to disrupt any growth factors, trophic factors, quiescence factors, confirmed oncogenes, tumour suppressors or immunomodulators. In the unlikely event of accidental transduction of a laboratory worker's skin or mucosa by lentivirus particles, this will be self-limited, due to natural shedding of superficial epithelial skin and mucosal cell layers.

The most likely route of accidental infection with a lentivirus or with human ES cells will be via inadvertent percutaneous inoculation. The likelihood of this occurring will, however, be minimised by not using sharps in the lab and adhering to other appropriate risk management measures.

Targetted Gene Modification by CRISPAI-Cas9

hES cells will be transiently transfected (e.g. lipofected or nucleofected) with plasmids D010400-hCas9 v1 or D010400-hCas9_T2A_ZsGreen1. Nucleofection is an electroporation-based transfection method that enables the DNA to enter directly the nucleus. Vectors have a pcDNA3.1 backbone and express codon optimized RNA-guided DNA endonuclease enzyme Cas9 from Streptococcus pyogenes under the control of the CMV promotor. The Neomycin mammalian selectable maker is included. The D010400-hCas9_T2A_ZsGreen1 vector additionally expresses the GFP. In order to deliver the guide RNA (gRNA) the plasmid G150300 will be transiently nucleofected into the cells. G150300 is based on the gWIZ vector with Kanamycin resistance. The gRNA is expressed under the
control of the RNA polymerase III promoter U6. The vector additionally encodes a gRNA scaffold necessary for correct functioning of Cas9. Cells will be cloned by FACS sorting individual cells into separate wells of a 96-well plate. The plan is to knock out a gene in hES cells by inducing two Cas9 mediated DNA double-strand breaks by transfecting Simultaneously with two gRNAs targeting the same gene. The endogenous non-homologous end joining (NHEJ) pathway will repair the DNA double-strand breaks and destroy the mRNA integrity and therefore the protein production.

To deliver the guide RNA (gRNA) the plasmid G150300 will be nucleofected into the cells. Additionally cells will be nucleofected with another commercial available vector in order to provide the template for the homology directed repair. The plan here is to introduce one gRNA directed Cas9 mediated DNA double-strand break but this time we will provide a DNA template encoding our tags and on both sides homology arms for the homology directed repair (HDR) to introduce well-characterised protein tags such as, but not limited to, GFP, FLAG or luciferase.

It is not expected that this work will increase the hazard already associated with the human derived ES cells.

Origin & function

RUES2 Cells

1) Homologous Recombination (HR) Targeting Vector. The vector comprised a synthetic left and right homology arm against the human HTT gene that flank a donor sequence. The donor sequence contained the first exon of the human HTT gene with either normal or expanded lengths of CAG repeats and viral Inverted Tandem Repeats (ITRs) flanking a Puromycin-Thymidine Kinase (TK) positive-negative selection cassette; the HTT exon1 was obtained by PCR from genomic DNA extracted from fibroblasts or iPSCs derived from human HD patients.

2) Cas9 plasmid contained a synthetic Cas9 endonuclease; codon-optimized for human expression, and a synthetic sequence for the guide RNA targeting the human HTT gene.

3) Transposase Plasmid expressing integration-deficient PiggyBac transposase.

How the RUES2 cells were generated

The HR targeting vector and Cas9 plasmids were designed to replace the parental HTT exon 1 CAG repeat with a normal or expanded length of CAG repeats to create either a null hESC cell line or a mutant HTT hESC cell line. The inserted Puro-TK selection marker was used to isolate cells that have undergone homologous recombination by positive selection with puromycin. The Transposase plasmid was then used to excise the Puro-TK selection marker without leaving behind any residual residues of the targeting vector. Cells that did not have the Puro-TK marker excised were killed by negative selection with ganciclovir (a pro-drug that is converted into a DNA synthesis inhibitor by TK).

Expression of Exogenous Genes

For systems to monitor the promoter activity of genes involved in differentiation and/or the causative disease gene; two options will be used:

- Direct expression of well characterised reporter genes such as but limited to luciferase or GFP.
- Expression of the gene fused with a reporter gene.

Genes which may be involved in the pathogenesis of HD may be over-expressed either as full length or truncated proteins. Fusions with epitope tags or reporter proteins will also be viewed as an option to enable monitoring of the location and effect of the protein in a cellular environment.

Commonly used reporter genes represent a minimal hazard. Expression of genes involved in disease pathogenesis are unlikely to pose a significant risk because expression would need to be in the brain and in normal epidemiology is present from birth. If the expression of confirmed oncogenes, growth factors, tropic factors or immunomodulators is required this will be via non-viral methodologies. The expression of other genes will have the oversight and require approval from the GMSC.

Knock-down of Gene Expression with shRNA
shRNA constructs will be selected based on project needs to 'knock-down' gene expression of a target gene. This will be subject to oversight by the GMSC. Particular attention will be made to avoid the use of shRNA towards known tumour suppressors, trophic factors and growth factors. Targetted Gene Modification by CRISPAICas9
gRNA sequences will be designed to drive specific targetted modifications in response to project requirement. In the case of knock-outs and fusion proteins the GMSC will have oversight to check that there is no inadvertant introduction of an oncogene or suppression of a tumour suppressor.

**Evaluation of foreseeable effects**

**Foreseeable Effects on Human Health**
The cells to be used are deemed to have been unscreened for adventitious / pathogenic viruses and will be treated as being potentially infectious and handled BSL2 conditions. In deed this is the biggest risk associated with the proposed work. Workers are immunised against HepB. The cells are totipotent with the potential to form teratomas in immunosuppressed individuals; no such individual will be allowed to culture these cells. Non-immunosuppressed individuals would clear the cells rapidly and as such they are not at risk.
The cells possess either a wild type and/or a mutant HTT gene. The presence of an extended CAG repeat in the mutant HTT gene results in mHTT protein aggregates which are toxic to cells, particularly neuronal cells.
For RUES2 cells the plasmid reagents used for the gene editing (Cas9 & Transposase) are not transmissible, do not integrate and are not maintained episomally; they will have been removed from the supplied cell lines through prolonged culturing. The completed gene editing process will also leave no extraneous residues, such as DNA regulatory sequences or antibiotic selection markers, present in the vectors.
In addition cells may also express exogenous proteins, shRNA or additional targetted gene modifications to allow evaluation of effects of interesting genes upon disease pathogenesis.
There is a very low risk to human health from genetic modifications in the WtHTT/mHTT gene. HTT is not an oncogene, tumor suppressor, hormone, cytokine or involved in the immune system. Although mHTT protein aggregates are toxic within a cellular context they are non-transmissible and will therefore pose negligible risk.
Subsequent modifications will be unlikely to increase the hazard associated with working with the cells. Increases in viability or fitness will not be an issue for non-immunosuppressed individuals.

**Environmental Considerations**
Very low risk to environment since plasmid sequences are non-mobilisable. Gene sequences required for viral replication will not be present. All cell lines cannot survive outside of defined culture media used within a laboratory environment. Although cells can form teratomas when injected in nude mice these are only present within a laboratory environment and there is no chance that this can happen.
In the case of viral particles: the chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as the viral vector studies that will be undertaken have been classified as biosafety level 2, and effective containment procedures will be adhered to. In the unlikely event that active viral vector particles do accidentally get released into the environment, the safety risks posed by such an event is considered to be low due to the vectors being self-inactivating and non-replicative, and also due to the poor ability of the vectors to survive outside of their host systems.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
We wish to request derogation from the need to autoclave solid waste material. All material (solid and liquid) will be...
Chemically inactivated for 24hrs prior to it being stored securely before being taken away for incineration by an authorised waste disposal contractor. This is sufficient for the level of hazard posed by the materials in question.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste is placed in biohazard bins which are lined with two autoclave bags. Flasks, tips and other plastic consumables which may retain small levels of liquid are exposed to validated disinfectant for 24hrs before being discarded as solid waste.

At the end of the working day solid waste is sealed in double bags which are then placed in lockable wheelie bins (supplied by Grundons, an external waste disposal contractor (GM Centre number 782). These are stored in a locked brick waste store with concrete floor until collection by an authorised contractor. Waste is then incinerated ensuring 100% kill.

Only containers certified to UN packing group II or better are used. Solid waste is sealed and the contents and bags incinerated without being opened.

Liquid waste is chemically inactivated for 24hrs with a validated disinfectant prior to disposal. Chemically inactivated liquid waste is decanted into 10 litre waste containers where it remains until removal from site for incineration by an authorised contractor, ensuring 100% kill. Due to site rules, there is no disposal to drains.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The GMSC has considered the above proposal. The work focuses on efforts to understand the molecular basis for HD pathogenesis with an aim to identify potentially new targets for therapeutic intervention. The cell lines are derived from human materials from reputable sources and as such will be regarded as medium risk requiring containment level 2. The introduction of genetic material, either with the aim to over-express or suppress gene expression, by physical methodologies does not increase the risk associated with the original cell lines. In a similar way the editing of genes by CRISPRiCas9 techniques will not increase the hazardous nature of the original material. The use of lentiviral delivery systems is a convenient means to efficiently deliver genetic material to cells. The commercial products being considered predominantly contain WRPE which contains an oncogenic sequence unless specifically deleted. This represents a hazard to workers which is controlled by the use of small aliquots of virus sufficient for one transduction at a time. To increase tropism the VSV-g envelope protein is used. As a result the deliberate introduction of oncogenes, hormones, hormone receptors, inhibition of tumour suppressor genes or modulation of immune regulators should not be conducted by this methodology if deemed essential to the project. Any use of viral material runs the risk of inadvertent recombination events occurring. There is an assumption that donors have no known medical history of infectious disease which would significantly reduce the chance of recombination leading to the generation of active viral particles. The risk is further reduced because the viral particles lack any of the essential and necessary genes for viral replication and are self-inactivating. So even if the cells did contain an adventitious virus the chance that the introduced material could be mobilised and packaged into active virus is minimal. It is the view of the GMSC that this work can be safely conducted at containment level 2. Proposed genes covered under this RA will be submitted to the GMSC for approval first.

### Project Additional Information

#### Purposes of the contained use

molecular genetic study of S. aureus to gain an understanding of its virulence, pathogenesis, & drug resistance leading to the discovery of new therapies for treatment of S. aureus infections.

#### Recipient or parental organism

The parental host strain Staph. Aureus ATCC 25923 is well characterised, and the culture conditions coupled with good microbial practise will prevent any release of either recombinant or host Staph aureus, the host is susceptible to most antibiotics, the Psd1 shuttle plasmid confers constitutive expression of the guide RNA (SgRNA) which is specific to the target gene & only in the presence of tetracycline is there expression of the recombinant Cas9 protein which forms a complex with the SgRNA, physically blocking the RNA polymerase from binding to the promotor (resulting in highly selective reversible transcriptional repression). Due to the small scale of the experimental processes & existing good microbial practises. It is highly unlikely that there would be any significant release of viable recombinant Staph aureous into the environment

#### Host/vector system

This work is to form part of a feasibility study to determine if it is possible to knock-down gene expression in Staphylococcus aureus. It is proposed to use a CRISPR-based transcription repression system that has been modified from the pSD1 CRISPR plasmid described in a publication by Zhao et al (https://www.ncbi.nlm.nih.gov/pubmed/28411216). The CRISPR sequence has been modified to incorporate a ccdB cassette between the SapI restriction sites to enable easier cloning of gRNAs into the vector.

#### Origin & function

pSD1 was constructed in-house in accordance with Zhao et al final construct was sequence verified and published on Pub Med

#### Evaluation of foreseeable effects

determine if it is possible to knock-down gene expression in Staphylococcus
aureus. It is proposed to use a CRISPR-based transcription repression system that has been modified from the pSD1 CRISPR plasmid described in a publication by Zhao et al (https://www.ncbi.nlm.nih.gov/pubmed/28411216). The CRISPR sequence has been modified to incorporate a ccdB cassette between the Sapi restriction sites to enable easier cloning of gRNAs into the vector.

Expression of the guide RNA (SgRNA) which is specific to the target gene & only in the presence of tetracycline is there expression of the recombinant Cas9 protein which forms a complex with the SgRNA, physically blocking the RNA polymerase from binding to the promoter (resulting in highly selective reversible transcriptional repression). Due to the small scale of the experimental processes & existing good microbial practises, it is highly unlikely that there would be any significant release of viable recombinant Staph aureous into the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All Staphylococcus aureus work will be done in a BSL2 designated laboratory. Cultures will be treated to create electrocompetent cells and then transformed with the pSD1 CRISPR plasmid. Any unused cultures or waste material generated during these experiments will be disposed of via approved disposal methods for BSL 2. Specifically, bacterial cultures will be destroyed by autoclaving at 103KPa for 15 mins; equipment contaminated with S. aureus will be soaked in 1% w/v Vircon for 30mins prior to autoclaving at 103KPa for 15 mins. Disposables items will be removed from the site by a reputable waste disposal contractor (Grundons) materials will then be destroyed by incineration. Exposure to any aerosols will be prevented by containment in certified biological level 2 safety cabinets e.g. during centrifugation.

Project Ref 680/18.2

Identification of Sting dimerization modulators

Date Ackn’d: 10/08/2018

Date Project Ceased:

Class 2

Cultures Volume Class 2: < 1 Litre

Non-GMM Consent Granted

Tick if notifying a connected programme of work: N

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use

Stable expression of stimulator of interferon genes (STING) -232R & ISRE driven luciferase in

Recipient or parental organism

HEX293T cells

Host/vector system
STING: pMSCVpuro (Clontech, cat# PT3303-5)
LUCIFERASE: pGL4.45[luc2P/ISRE/HYGRO] (Promega, cat# E414A)

Origin & function
STING 232R variant derived from human origin (verified by sequencing)

Evaluation of foreseeable effects
stable expression of STING & luciferase (STING will be measured by luminescence) expression products have been assessed to be non-hazardous to human health or the environment

greatest theoretical risk is from the HEX293T cells which because of the SV40 large antigen warrant BSL2 containment

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

recombinant cell will be inactivated with 10% vircon & then destroyed by incineration by a registered contractor (Grundons)

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The presence of the SV40 large antigen in the HEK293T cells, does present a very low theoretical risk to human health & as such warrants BSL2 containment

Project Additional Information

Purposes of the contained use
Identify inhibitors or activators of an orphan nuclear receptor (NR2F2)

Recipient or parental organism
HEK293T

Host/vector system
HEK293T pLVX-TETOne-Puro plasmid expressing Dox inducible NR2F2

Origin & function
Sequence verified by client ChromaCure

Evaluation of foreseeable effects
The expression product is a transcriptional activator of gene expression & might play a role in angiogenesis & might trigger tumour growth, the expression host HEK293T warrants BSL2 containment because of the SV40-
T antigen, which according to The National Academy of Sciences has a moderate association of causing cancer in humans.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Biological cultures & contaminated consumables will be treated with 10% vircon prior to destruction by incineration by licenced contractors (Grundons).

Project Additional Information

Purposes of the contained use

Stable expression of SLC6A8 P544L mutant in KO HEK 293T cell line

Recipient or parental organism

HEK293T

Host/vector system

The human SLC6A8 gene encodes the sodium- and chloride-dependent creatine transporter 1. This is a HEK 293T cell line in which endogenous SLC6A8 expression has been knocked out using the ThermoFisher Cas9 Blast gene editing system in conjunction with CRISPR targeting SLC6A8 gene following expression of SLC6A8 P544L mutant within a pcDNA6.2 vector.

Origin & function

The human SLC6A8 gene encodes the sodium- and chloride-dependent creatine transporter 1. to identify correctors of SLC6A8 trafficking function.

Evaluation of foreseeable effects

HEK-293T cell line is a highly transfectable derivative of HEK293 cells and contains the SV40-T antigen. The hypothesis that SV40 might cause cancer in humans has been a particularly controversial area of research, notably, a 2002 study performed by The National Academy of Sciences Immunization Safety Review committee that stated, "The committee concluded that the biological evidence is moderate that SV40 exposure could lead to cancer in humans under natural conditions.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Project Ref 680/18.5

Date Ackn'd 20/12/2018

CU2 Project Title

Transient expression of zinc finger transcription factors (ZFPs) have been designed to specifically repress huntingtin HTT gene expression

Date Project Ceased

Class 2 CultureVolClass2 < 1 Litre

Class CultureVolumeClass3-4

Non-GMM Consent Granted

Project notified under transitional arrangements N
Project Additional Information

Purposes of the contained use
To investigate the use of targeted ZFPs as a therapeutic tool for the study and treatment of Huntingdon's disease

Recipient or parental organism
RUES CAG56 cell line

Host/vector system
pAAV-6P-SEWB

Origin & function
Rockefeller University Institute for Stem cells

Evaluation of foreseeable effects
The parental UES cells are unscreened for adventitious/ pathogenic viruses, & should be treated as potentially infectious, the cells are totipotent with the potential to form teratomas in immunosuppressed individuals, the transient expression of the targeted ZFPs, have been assessed to be of low risk

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
All level 2 waste is chemically treated using validated disinfectants and ensuring 100% kill. All solid and liquid waste is housed in sealed containers and collected for incineration by approved contractor(Grundons). The building does have an autoclave, due to the bulky nature of the waste. Derogation requested for omission to autoclave waste. The chemical disinfection regime has been assessed to be sufficient to prevent any exposure to infectious biological waste

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All liquid waste collected from flasks & plastics is decontaminated overnight using a validated disinfectant. 12 hr contact time ensures 100% kill. Liquid is held in sealed containers mixed with a validated disinfectant disinfected liquid waste is removed from site for destruction by incineration by an approved contractor (Grundons). Contaminated plastic consumables are immersed in validated disinfectant overnight before discarding as solid waste. Solid waste is placed in dedicated biohazard bins which have been lined with two autoclave bags at the end of the working day, the bags are sealed and then placed into lockable biohazard waste bins (UN approved for the transport of packaging group 2 substances with a biohazard sign which carries the UN3291 number. Full bins are stored in a secure brick store with bunded concrete floor. And then collected for incineration by approved contactor (Grundons).

### Project Additional Information

**Purposes of the contained use**

The aim of the project is to identify compounds that would inhibit biological activity of ADAR1 in cells. The potential ADAR1 inhibitors would be identified in the cell line overexpressing ADAR1. The mechanism of action for any active compounds is expected to be direct inhibition of editing activity of cellular ADAR1 protein.

**Recipient or parental organism**

HEK298T A549 cells

**Host/vector system**

The client, Agios have cloned ADAR1 variants in lentiviral vector system (commercially available from Addgene https://www.addgene.org/guides/lentivirus/) At CRL the vectors carrying gene of interests will be transfected in the 293T (packaging cells) along with packaging and envelope plasmids. The Lentiviruses produced from this experiment will be used to generate stable A549 cells. In A549 cells, the modifications include stable expression of ADAR1 variants and in addition cell line will also expresses reporter constructs carrying ADAR1 substrate to be edited and hence allowing expression of Nanoluciferase as a reporter gene. The cell line clone showing optimal results will be chosen for screening compounds and potential HTS in agreement with the client.

**Origin & function**

The client, Agios have cloned ADAR1 variants in lentiviral vector system (commercially available from Addgene https://www.addgene.org/guides/lentivirus/)
expression studies will be done using HEK293T cells. HEK-293T cell line is a highly transfectable derivative of HEK293 cells and contains the SV40-T antigen. The hypothesis that SV40 might cause cancer in humans has been a particularly controversial area of research, notably, a 2002 study performed by The National Academy of Sciences Immunization Safety Review committee that stated, "The committee concluded that the biological evidence is moderate that SV40 exposure could lead to cancer in humans under natural conditions. It is for this reason that the GMSC has assessed this program of work as BSL2.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All level 2 waste is chemically treated using validated disinfectants and ensuring 100% kill. Purposes of the contained use

Multispan HEK293T cells expressing human GPR55

Recipient or parental organism
proprietary expression system (Multispan) the present invention provides a vector for facilitating high levels of expression of GPCR proteins in a cell line. The vector includes components such as a cytomegalovirus (CMV) promoter, a signal peptide, and epitope tag, a Kozak sequence, a poly-A site, and a viral origin of replication.

Full-length Human GPR55 cDNA (GenBank Accession Number NM_005683.3) with FLAG-tag sequence at the N-terminus is inserted into the HEK293T host cells and is stably expressed with selection by puromycin. The cloning vector used is the proprietary Multispan vector and the cell line is commercially available only from Multispan.

the overexpression of the intended GPCR would not present a significant risk to human health or the environment however the expression host HEK293T does present a risk HEK-293T cell line is a highly transfecatable derivative of HEK293 cells and contains the SV40-T antigen. The hypothesis that SV40 might cause cancer in humans has been a particularly controversial area of research, notably, a 2002 study performed by The National Academy of Sciences Immunization Safety Review committee that stated, "The committee concluded that the biological evidence is moderate that SV40 exposure could lead to cancer in humans under natural conditions.

Purposes of the contained use

To study the role of MAPT in frontotemporal dementia and parkinsonism

Recipient or parental organism

axolGEM iPSC-Derived Neural Stem Cells MAPT P301L HOM (Product Code: ax0324)

Host/vector system

axolGEM iPSC-Derived Neural Stem Cells MAPT P301L HOM (Product Code: ax0324)

Origin & function

The cell line cannot survive outside of the laboratory environment and therefore poses no hazard to the wider environment. Small spills will be treated with Virkon and absorbed onto paper. The area will then be treated with 70% IMS.

Evaluation of foreseeable effects

The cell line cannot survive outside of the laboratory environment and therefore poses no hazard to the wider environment. Small spills will be treated with Virkon and absorbed onto paper. The area will then be treated with 70% IMS.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

axolGEM iPSC-Derived Neural Stem Cells MAPT P301L HOM (Product Code: ax0324) are commercially available from Axol Bioscience. The human iPSCs used to derive this cell line were generated by reprogramming of dermal fibroblasts from a female donor and present normal karyotype. Reprogramming was performed using episomal vectors, which are non-integrating vectors used to introduce reprogramming factor into somatic cells. Using a chemically defined neural induction medium, these iPSCs have been used to generate iPSC-Derived Neural Stem Cells.

Human iPSC-Derived Neural Stem Cells that have been genetically edited using CRISPR-Cas9 technology to introduce the P301L mutation (CCG>CTG) into the MAPT gene. This line is homozygous for the P301L mutation so both alleles contain the mutation.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

02/03/2022
The cells will be used to identify compounds which inhibit the VPS4A gene. Inhibition of VPS4a will cause apoptosis of the cells which will be quantified using cell viability assays.

Recipient or parental organism

ATCC CT 1® CCL-247™

Host/vector system

Vector: Edit-R All-in-one lentiviral (knockout) Human VPS4B sgRNA-mCMVCas9-Puro (Horizon VSGH11937-248432319)

The vector above was delivered by lentiviral transduction and cells were selected with puromycin. The puromycin resistant population was subsequently single-cloned and the VPS4B KO clone was identified.

Origin & function

The cells will be used to identify compounds which inhibit the VPS4A gene. Inhibition of VPS4a will cause apoptosis of the cells which will be quantified using cell viability assays.
Evaluation of foreseeable effects

Based on supplied information this cell line has been categorised as BSL level 2 (i.e. UN3291) and will be disposed of in that waste stream. And treated with Virkon prior to disposal. The genes affected by the genetic manipulation are to our knowledge not proto-oncogenes or tumour suppressor genes. Cells can only exist in a laboratory environment and require continued selective pressure to maintain the genetic manipulation. There is negligible risk to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Purposes of the contained use**

A2a (Adenosine receptor 2a) is a G-protein coupled receptor (GPCR) implicated in a large number of disorders including cancer and neurodegenerative diseases.

**Recipient or parental organism**
Parental Cell Line: CHOZN (CHO K1 adapted to chemically defined suspension culture)

**Host/vector system**

Produced with pLenti viral vector from Origene. The pLenti expression vector is replication deficient as it contains SIN (Self Inactivation), a deletion in the 3' LTR (ΔU3). This SIN deletion does not affect lentiviral packaging, yet results in "self-inactivation" after integration into the transduced cell. The integrated lentiviral genome is no longer capable of self replication. Expression of the transduced target gene is driven either by a cytomegalovirus (CMV) promoter, vector contains blasticidin and ampicillin antibiotic-resistance genes.

**Origin & function**

A2a (Adenosine receptor 2a) is a G-protein coupled receptor (GPCR) implicated in a large number of disorders including cancer and neurodegenerative diseases.

**Evaluation of foreseeable effects**

The foreign DNA (A2a) and antibiotic-resistance genes represent a very low risk to environment since the vector is non-mobilizable. The CHOZN cells are expected to have limited survivability in the environment as the cells only survive in defined cell culture media in a laboratory environment and they are non-colonizing.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

- All level2 waste is chemically treated using validated disinfectants and ensuring 100% kill. All soil and liquid waste is housed in sealed containers and collected for incineration by approved contractor (Grundons). The building does have an autoclave, due to the bulky nature of the waste. The chemical disinfection regime has been assessed to be sufficient to prevent any exposure to infectious biological waste.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- All liquid waste collected from flasks & plastics is decontaminated overnight using a validated disinfectant.
- 12hr contact time ensures 100% kill. Liquid is held in sealed containers mixed with a validated disinfectant. Disinfected waste is removed from site for destruction by incineration by an approved contractor (Grundons).
- Contaminated plastic consumables are immersed in validated disinfectant overnight before discarding as solid waste. Solid waste is placed in dedicated biohazard bins which have been lined with two...
autoclave bags at the end of the working day, the bags are sealed and then placed into lockable biohazard waste bins (UN approved for the transport of packaging group 2 substances with a biohazard sign which carries the UN3291 number. Full bins are stored in a secure brick store with bunded concrete floor, and then collected for incineration by approved contractor (Grundons).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Collective agreement of BSL2 to prevent any possibility of creating replicative competent lentivirus this recombinant cell line must NOT be exposed to any further modification with Lentiviral vectors.

Project Ref 680/21.3

Date Ackn'd 30/07/2021

CU2 Project Title Identification of compounds modulating PKD2 for the treatment of Autosomal dominant polycystic kidney disease (ADPKD)

Class CultureVolClass2 CultureVolumeClass3-4

Class 2 < 1 Litre

Non-GMM Consent Granted

Tick if notifying a connected programme of work N

Project notified under transitional arrangements N
**Project Additional Information**

**Purposes of the contained use**

Identification of compounds modulating PKD2 for the treatment of Autosomal dominant polycystic kidney disease (ADPKD)

**Recipient or parental organism**

Human Embryonic Kidney 293T cells (HEK293T), originally from American Tissue and Cell Culture Inc.

**Host/vector system**

Hemagglutinin (HA) tagged full length PKD1 (PKD1-HA) and FLAG-tagged full length PKD2 (PKD2-FLAG) transgenes stably overexpressed using third generation lentivirus expression systems in the HEK293T cells. Packaging plasmids were made with one encoding Gag and Pol and another encoding Rev. Envelope plasmid contained VSV-G. Cell lines are replication incompetent after deletion in the 3'LTR, rendering the virus self-inactivating after integration. Expression of the PKD1 and PKD2 genes is induced by the addition of doxycycline to the growth media.

**Origin & function**

There is no serious hazard to the environment as this cell line would not survive outside of a lab environment. Small spills will be treated with validated disinfectant & absorbed onto paper then discarded as UN3291 BSL2 waste.

HEK-293T cell line is a highly transfectable derivative of HEK293 cells and contains the SV40-T antigen. The hypothesis that SV40 might cause cancer in humans has been a particularly controversial area of research, notably, a 2002 study performed by The National Academy of Sciences Immunization Safety Review committee that stated, "The committee concluded that the biological evidence is moderate that SV40 exposure could lead to cancer in humans under natural conditions.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All level 2 waste is chemically treated using validated disinfectants and ensuring 100% kill, All solid and liquid waste
is housed in sealed containers and collected for destruction by incineration by an approved contractor (Grundons).

The building does have an autoclave, due to the bulky nature of the waste.

Derogation is requested for omission to autoclave waste, the chemical disinfection regime has been assessed to be sufficient to prevent any exposure to infectious biological waste

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste collected from flasks & plastics is decontaminated overnight using a validated disinfectant.

12hr contact time ensures 100% kill. liquid is held in sealed containers mixed with a validated disinfectant disinfected

Liquid waste is removed from site for destruction by incineration by an approved contractor (Grundons)

Contaminated plastic consumables are immersed in validated disinfectant overnight before disacarding as solid waste. Solid waste is placed in dedicated biohazard bins which have been lined with two autoclave bags, at the end of the working day the bags are sealed and then placed into lockable biohazard waste bins (UN approved for the transport of packaging group 2 substances with a biohazard sign which carries the UN3291 number).

Full bins are stored in a secure brick store with bunded concrete floor, and then collected for destruction by incineration by approved contractor (Grundons)

HEK-293T cell line is a highly transfectable derivative of HEK293 cells and contains the SV40-T antigen. For activities involving GMMs, describe the waste management measures which will apply to the activity

The maximum culture volume that could be released at any one time (breakage of flasks or shaking incubator) would be 250 ml. Surface inactivation of such spillages would involve use of 1% Virkon medical disinfectant.

All other waste both liquid and solid is made safe by autoclaving at 136.4 degrees C for 106 minutes at 2.37 bar. Chart recorder records all autoclave runs.

Validation of autoclaving is carried out using DRG test packs. Autoclave is under a standard manufacturer's maintenance and calibration regime.

---

**Project Ref 686/01.1**

**CU2 Project Title:** AN INVESTIGATION INTO THE ROLE OF DNA METHYLATION IN MURINE EMBRYONIC STEM CELLS VIA INDUCIBLE EXPRESSION OF RELEVANT GENES

**Date Ackn'd:** 30/04/2001

**Date Project Ceased:** 17/02/2004

**Withdrawn:** N

**Historical Significant Changes:** Transferred to GM207 on 17/02/2004

**Class:**
- CultureVolClass2
  - Class 2
  - < 1 litre

**Consent Granted:**
- Non-GMM: not applicable

**Project notified under transitional arrangements:** N
**Project Additional Information**

**Purposes of the contained use**

Introduction of methyl transferase genes, via retrouiral infection, into murine ES cells.

**Recipient or parental organism**

Murine embryonic stem cells, E14 line.

**Host/vector system**

DH5x: Host

Non mobilisable plasmids, pLNCX-Derives: vector.

Replication - incompetent retrouirus production in PT67 cells.

**Origin & function**

Genetic material derived from non-mobilisable pLNCX plasmids and containing commonly used reporter and marker genes together with one of the following three genes.

1. De Novo Methyltransferase 3A.
2. De Novo Methyltransferase 3B.
3. Methyl Binding Domain 2B.

The vectors enable study of these gene functions in cell culture.

**Evaluation of foreseeable effects**

The genetic elements and vector system are well characterised and frequently employed. The proximal aim is to generate replication. Incompetent viral particles for the purpose of infection of murine ES cells and the study of the phenotypic effects of the above-named genes. Since the viral particles will be incapable of autonomous propagation (due to the absence of structural genes) and since the plasmids themselves are non-mobilisable, there are no significant foreseeable environmental or health concerns arising from this experiment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Effective containment and control measures:

1. Non-mobilisable plasmids.
2. Replication - incompetent viral particles.
3. Use of a Level 2 containment facility.
4. Use of a Level 2 tissue culture hood.
5. Chemical and heat inactivation of waste material.
6. Confirmation of inactivation using appropriate methods.
7. Autoclaving of all equipment before removal from facility.
9. Regular inspection of facility and hood.
10. Regular confirmation of satisfactory autoclaving.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
None.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste management measures:
1. Pipette aspiration of biological cell culture material.
2. Chemical and heat neutralisation of cells and viral particles.
3. Chemical and heat neutralisation of bacterial cultures.
4. Confirmation of 100% neutralisation by demonstration of absolute sterility post treatment.
5. Monitoring of methods using Browne's steriliser tubes.
6. Removal from facility in appropriate labelled bags for incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
Discussed fully.
Satisfactory risk assessment.
Recorded in safety committee minutes.

**Historical Significant Changes**
Transferred to GM207 on 17/02/2004

**Project Additional Information**

**Purposes of the contained use**
Introduction of Epsien-Barr virus genes into human antigen presenting cells using Vaccinia virus as a vector.
### Recipient or parental organism

Recombinant Vaccinia viruses are thymidine kinase negative and consequently less virulent than wild type Vaccinia. Manipulated human antigen presenting cells are not known or thought to be any risk to the operator of the environment.

### Host/vector system

<table>
<thead>
<tr>
<th>DH 5a Host</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vectors will be non-mobilisable plasmids.</td>
</tr>
<tr>
<td>Vaccinia virus will be propagated in TK-143 cells.</td>
</tr>
</tbody>
</table>

### Origin & function

All Epstein-Barr virus genes are derived from the phototype B95.8 strain of EBD. The gene products will be used to stimulate an immune response against cells latently infected with EBV, as with some tumour cells.

### Evaluation of foreseeable effects

EBV is carried out by nearly all individuals in any community, therefore, the effect of any exposure to a single EBV gene product is likely to be effective zero. Vaccinia virus has been used on a wide scale to immunise people. Vaccinia virus Recombinant strains carrying Rabies Virus genes have also been used in non laboratory settings, notably in Belgium where virus infected meat was used to immunise foxes in the wild. Plasmid vectors are of the non-mobilisable type. Thus, these should be incapable of passing genetic material to wild-type bacteria.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- All cultural aspirates pass into concentrated Presept. Aerosols will be contained with an 'in line' 0.22mu filter.
- All solid and liquid waste will be autoclaved after chemical inactivation.
- All bacterial cultures will be chemically treated and its effectiveness monitored by regular culturing to test for viability.
- The autoclave is regularly monitored by use of Browne's tubes and a temperature recorder.
- Removal of waste after treatment to the clinical waste stream.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The maximum volume which could be released at any one time is 250 mls. The waste is deactivated by autoclaving, which ensures that all the material is microbiologically inactivated. The autoclave is calibrated and procedures are in place to ensure that autoclave cycles are monitored for their correct performance.

Genetically modified clones, class 1, are grown at < 31 scale in fermenters and at < 11 scale in flasks. Cultures and waste material are killed by sterilisation at 121 degrees C for 20 minutes for all flasks and for 40 minutes for fermenters. The autoclave is routinely serviced by the manufacturer. Alternatively cultures and waste material may be killed by use of a disinfectant (Virkon from Antec International). All killed liquid waste is then disposed of down the drains.

**Project Ref** 691/05.1

**Date Ackn'd** 13/04/2005

**CU2 Project Title** Introduction of a cloned modified oncogene into primary cultures of human cells using replication defective retroviruses for the purposes of cell immortalisation

**Class** Class 2

**Culture Volume Class 2** < 1 Litre

**Non-GMM Consent Granted** Not Applicable

**Date Project Ceased**
### Project Additional Information

**Purposes of the contained use**

The generation of replication incompetent retroviruses carrying an immortalising gene including variants of the myc oncogenes. The packaging line will be the TeFLY A-(amphotrophic) and TeFLY-RD cell lines. Harvested virus will be used to transduce primary cultures of human cells for the purpose of immortalisation and cell line generation.

**Recipient or parental organism**

1. TeFLY packaging cells. These are a third generation, multiply replication-disabled packaging line containing Moloney leukaemia virus-encoded retroviral gag/pol proteins from one plasmid and viral envelope genes (MLV-A (amphotropic and feline virus from a second plasmid). Details of the constructs and evidence that they do not give rise to replication competent viruses have been published (Cossett et al., J. Virol., 69:7430-7436, 1995). The original Te671 line (Takeuchi et al., J Virol., 67: 8001-8007, 1994) from which the lines were derived are a human rhabdomyosarcoma line. TeFly packaging cells are obtained from Genethon 11, Paris. These lines were realised under GMP conditions and are clean. 2. Human neural, retinal, pancreatic or hepatic cells in primary culture will be infected with retrovirus harvested from TeFLYA producers.

**Host/vector system**

The cMyc/mycER constructs are cloned into retroviral plasmids including pLNCX-cmycER, pBabe-puro and pLHCX and used to generate amphotrophic, replication incompetent retroviruses using TeFLY producer cells. Cell lines infected with these retroviruses will be screened for the absence of replication-competent retroviruses by transfer of neomycin resistance to human TE671 cells following 3 to 5 passages; infection of susceptible cells then selecting for transfer of G418 resistance.

**Origin & function**

The cMyc/mycER is a recombinant fusion protein of human cMyc and the binding domain of the mouse estradiol receptor. The plasmids carrying the cMyc or cMycER have been prepared by Dr. Z Dong (formerly of ReNeuron). These will be used to transfect TeFLY-RD packaging cells. A transient viral harvest will be collected to infect TeFLY-A cells. Producer lines will be selected and those producing stable, full insert viruses and free of replication-competent retroviruses will be expanded. Retroviral vectors from these lines will be used to infect and immortalise primary cultures of human cells.

**Evaluation of foreseeable effects**

This project involves the infection of human foetal cells in primary culture using a retroviral vector system with amphotropic potential to introduce the cMyc construct. Transfected TeFLY lines will produce retrovirus carrying the cMyc construct capable of transducing human cells in culture. The cMyc gene in viral state is infectious but has a very short half life, is not replication competent and is used in ACGM containment level 2. Following infection of human cells, the cMyc construct is inserted in the eukaryotic genome and so may be considered non-mobilisable. cMyc transfection ensures genetically stable long term proliferation of infected cells. Following transduction with pLNC-cmycER or pBabe-puro-cmycER, immortalisation is inducible by the presence of tamoxifen. The cells stably expressing it have no mechanism to release it into the environment. Myc is a normally expressed protein in human cells although it is
upregulated in cancers.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1. Oncogenic DNA will be treated overnight with quaternary ammonium compound Barrycidal 36 before being autoclaved and discarded down the drains (all within CL2 laboratory).
2. Liquid waste (viral supernatants and culture media) will be treated with >1% Virkon solution (Antec International) overnight then discarded down the drains.
3. Solid waste is treated with a 1% Virkon solution overnight then sent for incineration where there has been contact with culture media (e.g. pipettes, culture flasks, media bottles). Other solid waste is inactivated with heat treatment (decontaminating autoclave) to give 100% kill and then sent for incineration. The decontaminating autoclave includes a high temperature step of 126.5 Celsius held for 15 minutes. The temperature of the autoclave cycle is printed out in real time.

Is an emergency plan required according to regulation 20? N

Project Ref 692/02.1

Date Ackn'd 25/07/2002
CU2 Project Title GENERATION OF DEFINED DELETIONS IN PASTURELLA MULTOCIDA
Class 2
CultureVolClass2 < 1 litre
CultureVolumeClass3-4

02/03/2022 Page 10729 of 15326
Purposes of the contained use
Construction of a live attenuated Pasteurella vaccine strains for the prevention of disease in meat turkey and chicken layers and breeders.

Recipient or parental organism
Pasteurella multocida.

Host/vector system
Disabled E. coli K12 strains will be used for intermediate cloning steps.

The vector PCVD442 will be used to transfer the genetic material to the Pasteurella multocida chromosome.

The vector PCVD442 is mobilisation defective and unable to replicate in Pasteurella and is therefore integrated into the chromosome along with the genetic material suitable to generate defined deletions by homologous recombination.

Following homologous recombination, there will only be a small fragment of additional DNA sufficient to allow diagnostic restriction enzyme digests.

Origin & function
The material originates from commercial sources or collaboration laboratories and will function to generate defined deletions in certain genes, which will be tested as live attenuated vaccines.

Evaluation of foreseeable effects
The intermediate GMMs will be disabled E.coli K12 strains containing genetic material from P. multocida.

The plasmid vector is unstable in the absence of selective pressure and the recombinant genetic material would be rapidly lost.

It is unlikely that the cloned DNA would offer any advantage to the survival of the E. coli strains in the environment.
The final resulting GMMs will represent vaccine strains of P. multocida. Genes required for virulence will have been deleted and steps will have been taken to prevent any alteration of gene expression.

No genetic material will be included that would provide the recombinant Pasteurella with a selective or pathogenic advantage.

The mutants are likely to be attenuated in humans as well as in animals. Any hazard that is likely to occur in the unlikely event that these mutants become established in the environment is likely to be much less that wild-type strains. The consequences of the hazard is therefore considered low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid cultures are chemically inactivated prior to disposal. Chemical inactivation is performed using Virkon which has been validate for treatment of E. coli and Pasteurella bacteria. Following treatment at 3% for 14 hours, liquid waste is disposed of by dilution via the normal sewage waste drain.

All other contaminated materials are inactivated via autoclaving prior to disposal. A dedicated waste autoclave is used for these activities. This autoclave is serviced and validated annually to ensure proper function. Following inactivation by autoclaving, all waste is then removed by a private contractor for incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment

This risk assessment has been carried out by the personnel who will carry out the work and reviewed by the Microscience GMSC. It has been given a class II, containment level 2 classification.

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

The aim of this project is to delete the gene encoding the heat stable toxin from Enterotoxigenic Escherchia coli (ETEC) for use as a challenge strain in clinical trials.

**Recipient or parental organism**

Escherchia coli E24377A which is a Clinical ETEC isolate and has been used previously as a clinical trial challenge strain. It is serogroup 0139:H28 and it expresses LT, ST, CS1 and CS3.

**Host/vector system**

Initial manipulations will be carried out in pUC or similar non-mobilisable vectors in E. coli Top10. The suicide vectors for introducing the deletion region to the chromosome will be pCVD442. These vectors will be manipulated in E. coli PIR1 which does not apply any plasmid transfer machinery, rendering the host vector combination mobilisation defective.

The suicide vector will be delivered by E. coli S17.1 Apir which supplies the Tra functions required to mobilise the plasmid into the ETEC recipient.

**Origin & function**

The material originates from commercial sources or collaboration laboratories and will function to generate defined deletions in certain genes.

**Evaluation of foreseeable effects**

The intermediate GMMs will be disabled E. coli K12 strains containing genetic material from ETEC.
The plasmid vector is unstable in the absence of selective pressure and the recombinant genetic material would be rapidly lost.

It is unlikely that the cloned DNA would offer any advantage to the survival of the E. coli strains in the environment.

No genetic material will be included in the final strain that would provide the recombinant ETEC with a selective or pathogenic advantage.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid cultures of small volumes less than 1L are chemically inactivated prior to disposal. Chemical inactivation is performed using Virkon which has been validate for treatment of E. coli. Following treatment at 3% for 14 hours, liquid waste is disposed of by dilution via the normal sewage waste drain. Liquid cultures of more than 1L are inactivated by autoclaving prior to disposal via the normal sewage waste drain.

All other contaminated materials are inactivated via autoclaving prior to disposal. A dedicated waste autoclave is used for these activities. This autoclave is serviced and validated annually to ensure proper function. Following inactivation by autoclaving, all waste is then removed by a private contractor for incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

This risk assessment was reviewed by Microscience's GMSC and given a classification as containment level 2.

Expression of Neisseria meningitidis serogroup B genes in Escherichia coli.

Disabled non-colonising strains of E. coli will be used for all cloning and expression steps. It is intended to use the following strains; TOP10, HMS174(DE3), BL21(DE3), Tuner(DE3), Rosetta(DE3), Origami2(DE3), HMS174(DE3) pLysS and BL21(DE3)pLysS.

Cloning vectors pCR2.1-TOPO and pCRXL-TOPO from Invitrogen will be used for initial cloning. The genes will then be transferred to pET26b (Novagen) or pNET(E1) (derivative of pET27b) for expression (T7 expression system).

The N meningitidis genes will be PCR amplified from N. meningitidis genomic DNA or alternatively may be chemically synthesised. The genes are to be expressed in E. coli with the aim of purifying the resultant proteins. The list of genes and their putative functions are included in Section 17.

The host strains to be used are deficient in a number of traits required for pathogenicity and it is therefore unlikely that a single gene would compensate for this. However, a number of the genes are predicted to encode proteins with outer membrane location. Their expression may therefore increase the pathoenicity of the E. coli host strain eg by altering tissue tropism.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be autoclaved or alternatively small volumes (<1L) may be inactivated overnight by addition of hycolin to 3%. Chemical inactivation with hycolin has been test in our laboratory and shown to result in a greater than 7 log reduction in viable E. coli (no viable organisms were detected after overnight inactivation). Liquid waste will then be diluted and disposed of via the normal sewage system. Solid waste will be autoclaved and then removed from site for incineration by a commercial contractor. A dedicated waste autoclave is used for these purposes. The autoclave is serviced and validated annually to ensure correct function.

Is an emergency plan required according to regulation 20? N

**Project Additional Information**

**Purposes of the contained use**

Preparation of full-length functional C. difficile toxins for use as reagents in various immunoassays.

**Recipient or parental organism**

Disabled non-colonising strains of E. coli will be used for all cloning and expression steps. It is intended to use E. coli TOP10 during the cloning stages. E. coli BL21 (DE3) and HMS174(DE3) will initially be used for protein expression. Other E. coli expression strains may also be used. A study of the pathogenicity of laboratory-adapted E. coli showed that these organisms did not contain the well recognised pathogenic mechanisms required by strains of E.coli causing the majority of enteric infections (Chart et al., 2000. J Appl. Microbiol. 89: 1048-1058).

**Host/vector system**

The C. difficile toxin genes will be amplified by PCR in two halves, cloned separately into pCRXL-TOPO (Invitrogen), and used to transform E. coli TOP10 (Invitrogen). Full length genes or gene halves may also be cloned directly into pET26b (Novagen) without the intermediate pCRXL-TOPO steps. These steps will add on a 6 x histidine tag but not incorporate the pelB leader which is also possible with this vector. The toxins will be under the control of T7lac promoter and expressed in E. coli (DE3) hosts. Other host/vector systems, with the same characteristics may also be used.

**Origin & function**

The C. difficile toxin genes will be PCR amplified from C. difficile genomic DNA. The genes will be expressed in E. coli (DE3) hosts with the aim of purifying full-length functional toxin. Purified toxin will be used in various immunoassays to test sera generated from immunisation of animals/humans with an experimental vaccine.

C. difficile toxins A and B are high molecular weight glucosyltransferases that inhibit members of the Rho family of GTPases. Toxin A, historically referred to as the enterotoxin, has a molecular weight of 300kDa and an isoelectric point (pI) of 5.3. Toxin B, known as the cytotoxin, has a molecular weight of 270 kDa and pI of 4.1. These toxins are produced by C. difficile, the causative organism in antibiotic-associated diarrhoea and pseudomembranous colitis and the toxins play a key role in the pathogenesis.

**Evaluation of foreseeable effects**

The most hazardous GMMs to be constructed will be DE3-containing expression hosts with either toxin gene cloned in the pET26b(+) expression plasmid. The host strains to be used are deficient in a number of traits required for pathogenicity (Chart et al., 2000) and it is unlikely that the expression of a single C. difficile toxin gene would...
compensate for this. The toxins are secreted in C. difficile by an unknown mechanism though it may be mediated by the action of a holin-like protein. They are unlikely to be secreted through the Gram negative E. coli membrane. In the event of a laboratory-acquired infection occurring any unregulated expression of the toxin could lead to increased toxin effects compared to the parent strain. Theses strains have therefore been designated as Class 2; this is consistent with C. difficile and clinical isolates of E. coli.

All other strains constructed are considered as Class 1, as they will lack the ability to express the full length toxins. F strains expressing these toxins were to be ingested this could give rise to biological effects such as diarrhoea. Both toxins are also known to cause irritation following skin contact. It is unlikely that these strains would show altered host range, tissue tropism mode of transmission or resistance to killing by the immune system. However, expression of the toxins would be expected to increase the ability of the host E. coli strains to cause disease compared to the E. coli host strains used.

The following antibiotic resistances will be conferred, Zeocin (to E. coli TOP10 only) and kanamycin (to all E. coli strains used). Zeocin is never used to treat human infections and kanamycin is very rarely used to treat humans. As the plasmids used are all mobilisation defective it is highly unlikely that they would be transferred. If they were to be transferred then dissemination of the antibiotic resistance determinants would be of concern.

It is possible that aerosols could be generated by pipetting.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste will be disposed of according to the Emergent BioSolutions Laboratory Code of Practice. Briefly, all solid waste and large batches of liquid waste (maximum 2L) will be autoclaved and disposed of appropriately. A serviced and validated autoclave is used at all times. Alternatively small volumes of liquid waste are treated with 1% FAM30 or 1% virkon prior to disposal to drain. 70% ethanol, 1% FAM30 and 1% virkon have been tested on site against representative strains of Streptococcus agalactiae, Neisseria meningitidis, E. coli and Salmonella spp. and were found to be effective.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

This risk assessment has been reviewed by the Emergent GMSC and classified as Class 2.

02/03/2022
The largest single culture which could be released is 400 ml. Biological waste generated in the lab can be treated in one of two ways dependent on the physical nature of the waste. Liquid waste is treated with freshly prepared Virkon solution and left overnight prior to being washed down the sink with copious amounts of water. Solid waste (Agar plates) as autoclaved at 136 degrees C for 75 minutes.

The maximum culture volume that could be released at any one time is 50 ml.
Any waste generated is disposed into Dispo Safe containers containing Virkon. The containers are then autoclaved in a Denley BA852 Sovereign Portable Autoclave for 15 minutes at 121 degrees C. The autoclaves are regularly serviced. Successful decontamination is monitored using autoclave marker tape.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The maximum culture volume which could be released in any one incident is one litre.
All microbiological waste is autoclaved at 121 degrees C for 15 minutes before disposal by the waste contractors.
The satisfactory completion of the autoclave cycle is validated by the use of autoclave tape on all items or bags of waste autoclaved.
The autoclave is maintained under a service contract from the autoclave manufacturer and the service records are available for inspection as required.

The maximum culture volume that may be released at one time is 500-1000 ml. All liquid waste is deactivated using an approved method (1% Virkon for at least 2 hours) prior to disposal. Solid waste is deactivated by autoclaving prior to disposal or washing. This is monitored by a probe in the autoclave.

02/03/2022
All containers which have been in contact with GMM are immersed in Presept at 4.5g/L for a minimum of 1 hour. Available chlorine is 2,500ppm and % kill is 99.999 (data from manufacturer). Alternatively waste is autoclaved for 15 minutes at 121°C. After treatment, materials going to waste are consigned to yellow bags or sharps boxes for incineration.

Spent tissue culture medium is either treated with a 1:1 volume of Presept at 9g/L for volumes up to 100ml or Presept tablet(s) are added directly to the media for volumes over 100ml to give a final concentration of 4.5g/L. Available chlorine is 2,500ppm and the % kill with 10% serum is 99.999 (data from manufacturer). After a minimum of 1 hr the liquid waste is disposed of down the sink. A maximum of 1L of culture medium will be released at any one time.

All Presept solutions are made fresh daily.

Used bacteriological plates and spent bacterial broth are autoclaved for 15 minutes at 121°C before being consigned to yellow bags for incineration (plates) or disposed of down the sink (broth).

The autoclave is serviced twice a year at which a NAMAS one point calibration is carried out.

### Project Additional Information

#### Purposes of the contained use

The cell lines are infected with Epstein - Barr virus so therefore work using the cell lines should be carried out under level 2 conditions.

### Recipient or parental organism

Mammalian cells: B-Lymphoblastoid cell lines such as DK0064, GM14680, GM01526. These cell lines are well characterised mammalian cells which have been immortalised through infection with EBV. The cells will not be modified by KuDOS in anyway.

### Host/vector system

N/A

### Origin & function

DK-0064 cells have been derived from a Parkistani family (family 1) with Seckel syndrome (ref Goodship). The FO2-98 cells are primary fibroblasts from this family (ref Stiff). The DK-0064 LBL cells have been derived from the same patient and infected with EBV to immortalise them.

- Stiff et al EMBO 2005
  - "DK0064 is an ATR defective LBL derived from the same patient as FO2-98 cells"

- O'Driscoll et al Nature Genetics 2003
  - "FO2-98 is a fibroblast line established from an individual from family 1 affected with Seckel syndrome". Ref Goodship et al Am J Hum Genet 2000.

The cells will be used in growth inhibition and cytotoxicity assays as well as in western blotting, flow cytometry and FACs to look for ART signalling and identify possible biomarkers.

### Evaluation of foreseeable effects

The cell lines are well characterised mammalian cells which contain EBV. KuDOS has not modified the cell lines in anyway and they are the wild type. The cell lines could survive in the environment however there is a low risk of any adverse consequences to the environment arising from their release.

- Possible routes of transmission to humans would be via exposure to culture medium. The likely routes of transmission would be inoculation by contaminated sharps, contact with open wounds. Therefore no sharps or glass should be used in conjunction with this project, work should be carried out in the designated class II biological safety cabinet and the general rules and procedures outlined in the local GMO rules adhered to.
- Possible route of transmission to the environment would be through the waste disposal. All waste will be processed under level 2 conditions and decontaminated prior to leaving the company by a validated means so therefore the risk to the environment will also below.
- The cells have been classified as containment level 1 however as they are infected with EBV the overall containment level for the project is classified as 2. Therefore the project will be carried out under class 2 containment conditions.
- All users are aware of the risks and are competent at working at a class 2 level.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All infected waste material is disposed in a safe manner. All level 2 GMO waste is required to be inactivated by validated means prior to disposal (Virkon and autoclaving). The autoclave is situated in the same laboratory suite and suitable containers are used to transport the waste material to the autoclaves so ensuring that the waste is contained. Any waste that cannot be autoclaved on site (waste that is too large for the autoclave, such as pipettes) is disinfected using Virkon and then sent for incineration in UN approved containers using an approved external waste management company. The autoclaves are serviced on a 6 monthly basis and inspected annually.

Is an emergency plan required according to regulation 20?  N

Tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

The genetic modification sub-committee requested justification for the use of the EBV infected cell lines.

Response of user: The DK64 Seckel (ATR mutant) cell lines are the most relevant cell lines for the work that needs to be undertaken. All other Seckel cell lines are either fibroblasts or poorly characterised in terms of protein levels and functional assays. Other cell lines have been investigated but there are no other cell lines with the same characteristics which are not EBV transformed. Similarly, B-cell lines such as GMO 1526 which harbour ATM.

Committee response: Justification accepted.

The maximum culture volume that could be released at any one time is less than 1 litre. All waste is deactivated in an autoclave, with a 15 minute cycle at 121 degrees C. Each load has autoclave tape on it, which turns black after 15 minutes at 121 degrees C. The autoclave is under a service contract and is thoroughly checked/serviced every 6 months. Documented record of service contract and each service is available.
# Project Additional Information

## Purposes of the contained use

To culture and propagate the above class II cell lines and carry out various cell biological assay procedures on these lines. Such studies will include microscopic imaging, fluorescent immunoassay development for researching cellular processes (e.g. secretion of an endogenous/transfected protein of interest, expression of endogenous/transfected receptors or bio-markers of interest, etc.), expression and reporter gene function. The GMOs will only be used for research and cell based assay validation purposes.

## Recipient or parental organism

Mammalian cell lines including Jurkat, Human leukaemic T-cell (SupT1), A431, Calu-6, B13 Chinese Hamster Ovary cells, HEK293 cells.

These are immortalised cell lines maintained in sterile cell culture. They are handled by authorised, trained operators only in a contained environment. Gloves, howie-style lab coats and shoes are worn at all times within the lab and are kept in a separate area.

## Host/vector system

HEK293 cell have been stably transfected with a multi-vector non-replicative lentiviral vector system.

DNA plasmid (E.coli based origin) purified and transfected into cells to express human proteins and selectable resistance gene.

B13 CHO cells are transfected with plasmids containing both cytomegalovirus (CMV) and SV40 viral sequences.

## Origin & function

In the case of antibody production, the DNA was generated by taking mouse B cells and fusing them with myeloma cells to immortalise them, selecting the specific clones required and isolating the DNA. The gene of interest is then integrated into a plasmid as described above and transfected into the cell. Other proteins can be isolated from RT-PCR from Human RNA/cDNA samples.

The function of the genetic material in the cells can be to generate sufficient quantities of a therapeutic protein.

Many of the cell lines in question are used for analysis of samples for cell surface markers for identification of genotypes. These have not had any DNA inserted into them.

In the lentiviral system, cells are transfected with multiple vectors expressing components of a lentivirus, including a gene-of-interest. This system is used to produce non-replicative viral particles able to infect cell lines, which then express the gene-of-interest.

## Evaluation of foreseeable effects

Cells stably transfected with lentiviral vector system produce viral particles able to infect human cells and therefore could integrate into the host cell genome, potentially leading to insertion of oncogenic sequences or inactivation of host-cell tumour suppressor function. However, exposure of the operator to quantities of virus high enough to cause such effects would be very unlikely during standard laboratory-based manipulations.

Protective clothing is worn at all times within the lab. Apart from cells transfected with the lentiviral system, the agent is not considered contagious and even though the cancer cells are human, they are still 'non-self'. The only potentially dangerous route of exposure is via injection or sharps injury (broken contaminated cover slips etc) and the effect to the lab staff would at worst be a strong immune response/inflammation to the Cat II agent. Although no infection/tumour would be able to take hold, a sufficiently high 'dose' could trigger an immune response as the cells/virus like particles are rejected and cleared.
Since both cells and sub-genomic VLPs are not infectious there would be no risk to the wider population of the business or to the general public if a lab worker was exposed to these materials.

Measures are in place to ensure that with good laboratory practice this does not happen. It should not be the case that syringe needles are being used with these cell lines, but they may be used by others in the lab for different cell lines. These are deposited in sharps bins immediately after use.

Since the GMOs are considered incapable of survival in the environment no effects on the physical environment are expected

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Mammalian cell lines are maintained in sterile culture on a small scale (no more than 50ml).

The lab is a contained single purpose environment separated from the rest of the building by a semi-sterile lobby area and two sets of doors.

Access is by authorised, trained users only.

All new users are introduced to the safety measures in place in the lab and supervised initially.

Howie style lab coats, protective shoes and gloves are used at all times by anybody entering the lab. These garments are used only for this lab and are kept in the lobby area. At no time are they used for any other purpose.

All lab coats and shoes are changed weekly and subjected to a hot wash to kill any remaining material.

Cell culture work is carried out in laminar flow hoods with all waste disposed of in biohazard bins. Liquid waste is treated with Virkon to destroy any live material. Waste is double bagged in red biohazard bags before removal for autoclaving on site and incineration off site.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disposal of any waste which has come into contact with the cells is disposed of in biohazard bins. Waste is double bagged before removing from the lab for autoclaving. Waste is then incinerated off site by Veolia Environmental Services Birmingham Ltd, James Road, Tyseley, Birmingham, B11 2BA. This method gives 100% kill. Liquid waste is treated with Virkon and left for >8 hours. This method is sufficient to kill any living material left in contact with it (100% kill).

For activities involving GMMs, describe the waste management measures which will apply to the activity

i) solid material - double bagged including an outer yellow bag marked with biohazard symbol that is held in rigid plastic theatre bins. When full, the bags are sealed, removed from the bins and collected by a waste management company for incineration.

ii) Contaminated glasswear/lab equipment and liquids - these are cleaned/disposed of in one of 2 ways:
1. Soaking in a 1% Virkon solution for a minimum of 2 hrs, after which the equipment can be rinsed and where appropriate transferred to dishwasher and then drying oven.
2. Autoclave at 121 degrees C for 20 minutes to remove the biohazard risk. When cool, the equipment is washed by hand or in the dishwasher, then placed in the drying oven.

**Other(s)**

For activities involving GMMs, describe the waste management measures which will apply to the activity

The maximum culture volume that could be released at any one time is 6 litres (from 12 one-litre flasks half filled with culture medium).

Waste is deactivated either by autoclave (plates etc.) or by treatment with strong hypochlorite (media etc.), 2500 ppm using presept tablets.

1 x 5g Presept tablet in 1 litre water  
1 x 2.5g Presept tablet in 500 ml water  
1 x 0.5g Presept tablet in 100 ml water

Surfaces are treated with hypochlorite (1000 ppm) 1 x 2.5g tablet in 1 litre water.
In the case of autoclaving, the deactivation is validated and monitored by internal temperature probes.

The maximum active culture volume that could be released at one time shall not exceed 20 litres. All cell culture liquid waste is autoclaved using a set autoclave programme giving a holding temperature of 125 degrees C for 15 mins. Bottles containing bacterial liquid waste additionally receive Virkon powder to generate a 1% Virkon solution. Solid waste is placed into autoclavable bags and autoclaved using the same conditions as above. Reusable glassware is treated by pouring 1% Virkon solution into the glassware, rinsing and pouring into an autoclavable waste bottle. Waste bottled are autoclaved at 125 degrees C for 15 mins.

The maximum culture volume will be approximately 5 litres.

1. Liquid Waste: All liquid culture waste is disinfected using by adding VIRKON powder to a final concentration of 1% followed by standing for 20 minutes before being disposed to drains.

2. Solid Waste: All solid waste is autoclaved at 121 degrees C for 15 minutes and then disposed by incineration through a clinical waste stream using off-site contractors.

Autoclave activity is monitored using "Sterikon Bioindicators" (Merck) in which the growth of spores from Bacillus stearothermophilus after autoclaving is monitored. This effectively monitors bacterial activity after sterilisation. In addition, all waste is incinerated through a clinical waste stream.

### Project Additional Information

#### Purposes of the contained use

The scientific aim is to investigate in vitro the mechanisms of CNS pathology in autoimmune disorders such as multiple sclerosis or in conditions with an inflammatory component such as Alzheimer's disease. In this context, cultures of three types of brain resident cells, namely microglia, astrocytes and brain endothelial cells, will be transduced with replication-deficient lentiviruses containing specific genes or small RNAs which are thought to be involved in the control of inflammatory processes within the CNS.

The genes under investigation will be amplified in bacteria (step 1)

Lentiviral particles containing the genes will be assembled in a packaging cell line (HEK 293). (step 2)

The human cell lines will be transfected with the genes under investigation using the lentiviral particles. (step 3)

The vectors will be generated using a Lenti virus kit available from Systems Biosciences

#### Recipient or parental organism

Step 1: Standard laboratory K12 derivatives of E. coli (DH5alpha, MC1061/P3) will be used to produce plasmids carrying genes that allow expression of small RNAs. The cloned DNA fragments will be used as reagents for introduction into mammalian cells (see below).

Step 2: A packaging cell line HEK293 will be transiently transfected with plasmids. Since the DNA introduced in the transfection process is usually not integrated into the nuclear genome, the foreign DNA will be diluted through mitosis or degraded and hence transfected HEK293 will not itself be permanently modified.

Step 3: Recipient cells for transduction with lentiviral particles will be primary human cells and human cell lines originating from: 1) human brain tissue: primary brain astrocytes, microglia, neurons, ependymal cells, and endothelial cells, and established glioma, microglial and endothelial cell lines (U373-MG, CHME3, hCMEC/D3); 2) blood and lymphoid tissue: PBMCs, human lymphoblastoid T cell lines (CEM, Jurkat, H9) and monocytic cell lines (U937, THP-1).

#### Host/vector system

Steps 1-3

We will use two commercially available lentiviral systems provided by Thermo Scientific and SBI that will allow us to produce lentiviral particles in-house by transfection of packaging cell lines. This will require transformation of bacteria with the same vectors for amplification (step 1). Lentiviral particles will then be used as vehicles for transducing and expressing different effector molecules or reporter constructs into cells (step 3). Below is a list of all vectors necessary to produce viable lentiviral particles and these have been separated into: A) transducing lentiviral vectors whose genomic sequence contained within the LTR will be integrated into human cell lines; and B) Lentiviral packaging vectors necessary for lentiviral production by the packaging cell lines. Frozen stocks of lentiviral particles containing reporter genes with the 3'UTR of
the gene of interest are also available commercially (Sigma-Aldrich; MISSION® 3’UTR Lenti GoClone). Although in this case, the original vectors will be neither amplified in bacteria nor transfected into packaging cells, the description of the original transducing lentiviral vector has been induced below in the transducing lentiviral vector category as it is relevant for step 3 (transduction of human cell lines).

A) Transducing lentiviral vectors:
1) pTLA1-Pak: Components of the plasmid are: Human cytomegalovirus (Tre-CMV) RNA polymerase ll promoter that permits high-level expression of the lentiviral gag and pro genes in mammalian cells; gag, virion structural proteins for forming the virion core and ribonucleoprotein complex within the core; pro, aspartyl-protease that cleaves the Gag, Gag-Pro-Pol polyproteins to produce viral proteins in their mature forms; rev, viral protein that binds to the RRE and facilitates the transport of unspliced and incompletely spliced mRNAs to the cytoplasm; tat, transcriptional activator of lentiviral gene expression, enhancing LTR-directed transcription; polyA, allows transcription termination and polyadenylation of the mRNA; Ori, permits high-copy replication and maintenance in E. coli; Amp, allows selection of the plasmid in E. coli.

2) pGIPZ (Thermo-Scientific): Lentiviral vector mainly used for transducing small RNAs (microRNAs, shRNAs) that contains; CMV RNA polymerase ll promoter that permit high-level expression of the lentiviral gag and pro genes in mammalian cells; Ψ (Psi), region of viral RNA responsible for directing packaging; PPT, purine-rich sequence cleaved during reverse transcription to produce the RNA primer for synthesis of viral DNA; wpre, post-transcriptional regulatory element derived from the woodchuck hepatitis virus to increase vector independent expression levels of the transgene; 3’ & 5’ LTR with deletion of the transcriptional enhancers & promoter in the U3 region of the 3’ LTR; GFP Green fluorescent protein utilized to track shRNAmir expression; Puro, puromycin-N-acetyl transferase, mammalian drug selectable marker; shRNAmir, microRNA flanking a stem-loop-stem structure; polyA, allows transcription termination and polyadenylation of the mRNA; Ori, permits high-copy replication and maintenance in E. coli.

3) SBI Lentiviral expression vectors that contain Hybrid RSV-5’LTR promoter; cPPT, GAG. LTRs which are genetic elements necessary for the packaging, transduction, and stable integration of the viral expression construct into genomic DNA, the 3’ LTR is a self-inactivating long terminal repeat that results in replication-incompetent particles; SV40 origin, provides stable propagation of the lentiviral plasmid in 293 producer cells; pUC origin, ensures high copy replication and maintenance of the plasmid in E. coli cells; Ampicillin resistance, used for selection in E. coli cells; WPRE element, enhances stability and translation of the lentivector-driven transcripts; SV40 polyadenylation signal. These plasmids also contain a promoter that drives the expression of the gene (CMV, EF1alpha) or small RNA (H1) and reporter genes such as GFP, RFP, Puromycin, Hygromycin, Neomycin or Zeocin selection.

4) pLSG_UTR_RenSP (Sigma-Aldrich) contains Constitutive human RPL10 promoter; RenSP Optimized Renilla luciferase gene; XbaI, NheI, AvrII, Xhol, FseI, Multiple Cloning Site for human 3’UTR insertion; PGKprom Human phosphoglycerate kinase eukaryotic promoter; Puro Puromycin resistance gene for mammalian selection; LTRs Long terminal repeats; Amp, Ampicillin resistance gene for bacterial selection; ori, Origin of replication; RRE, Rev response element.

B) Trans-Lentiviral Packaging Vectors: are an optimized mixture of packaging plasmids to facilitate viral packaging of the transfer vector following co-transfection into HEK293T producer cells. These plasmids supply the helper functions as well as structural and enzymatic proteins in trans required to produce the lentivirus. The plasmids are:

Thermo-Scientific Open Biosystems:
1) pTLA1-Pak: Components of the plasmid are: Human cytomegalovirus (Tre-CMV) RNA polymerase ll promoter that permits high-level expression of the lentiviral gag and pro genes in mammalian cells; gag, virion structural proteins for forming the virion core and ribonucleoprotein complex within the core; pro, aspartyl-protease that cleaves the Gag, Gag-Pro-Pol polyproteins to produce viral proteins in their mature forms; rev, viral protein that binds to the RRE and facilitates the transport of unspliced and incompletely spliced mRNAs to the cytoplasm; tat, transcriptional activator of lentiviral gene expression, enhancing LTR-directed transcription; polyA, allows transcription termination and polyadenylation of the mRNA; Ori, permits high-copy replication and maintenance in E. coli.

2) pTLA1-Enz: Human cytomegalovirus (CMV), RNA polymerase ll promoter that permits high-level expression of the lentiviral RT and IN genes in mammalian cells; Vpr Viral protein that shuttles the RT and IN into the viral particle; RT Reverse Transcriptase, DNA polymerase that copies RNA and DNA; IN Integrase, Enzyme responsible for inserting he linear double-stranded DNA copy of the lentiviral genome into host cell DNA; RRE, binding site for the Rev protein that aids in the transport of unspliced and singly-spliced RNAs from the nucleus to cytoplasm; polyA, as above; Ori, as above.

3) pTLA1-Env: In addition to CMV, polyA and Ori, as above, it contains VSV-G Envelope G glycoprotein from Vesicular Stomatitis Virus to allow production of a pseudotyped lentivirus.

4) pTLA1-Rev: In addition to CMV, polyA and Ori, as above, it contains tat and rev, as above.

5) pTLA1-TOFF: In addition to CMV, polyA and Ori, as above, it contains tTA, a transactivator protein that binds to the TRE in the absence of doxycycline and allows
transcription through the minimal CMV promoter.

System Biosciences (SBI):
1) In addition to CMV, polyA and Ori, as above, the pPACKH1-GAG plasmid (SBI) contains the structural (gag), and replication (pol) genes which code for some of the proteins required to produce the lentivirus. It also encodes the viral env gene, which encodes the envelope protein that defines the tropism (i.e. the range of infectable cells).
2) In addition to CMV, polyA and Ori, as above, the pPACKH1-REV plasmid (SBI) contains the regulatory protein rev that is required for HIV replication.
3) In addition to CMV, polyA and Ori, as above, the pVSV-G plasmid (SBI) expresses the envelope glycoprotein of vesicular stomatitis virus (VSV-G) from the CMV promoter.

The lentiviral particles will be used to directly transfect the primary cells and cell lines (see above), to stably integrate the genes of interest and allow their expression.

Origin & function

Genes to be transduced will be
a) microRNAs or shRNAs under an H1 promoter, in order to knockdown expression of cellular genes which have appropriate microRNA targetting sequences
b) reporter genes such as luciferase with the 3' UTR of the target gene to test microRNA target specificity,

Evaluation of foreseeable effects

Step 1: DNA amplification in bacteria.
E. coli derivatives are non-colonising and disabled, considered non-pathogenic to humans (ACDP hazard group 1). Transformed bacteria will be grown at a scale of a maximum 2 litres/amplification step. The vectors used are well characterised standard non-mobilisable plasmids. Although the cloned fragments may have biological effects as explained above, they have been cloned into sites which are not engineered to drive expression in prokaryotic cells. For the purposes of risk assessment, the cloned gene products may be considered non-harmful. No significant hazards have been identified above. Therefore, the assigned provisional containment level is 1.

Step 2: Transient transfection of vectors into packaging cell lines to produce viable lentiviral particles
Vectors: All plasmid vectors are based upon bacterial replicons and hence cannot be stably maintained as extra chromosomal elements in mammalian cells. Thus, the risk of transfer to humans is extremely low. Stably integrated plasmids are very unlikely to excise from their integration site. Therefore, the potential for horizontal gene transfer is negligible.
Expression: In packaging cells, constructs will drive the expression of pseudoviral RNA by LTR or hybrid RSV/LTR and enzymatically active mRNA or small RNA by the CMV, EF1 or H1 promoters. It is anticipated that the expression of these will be high enough to produce high pseudoviral titres in the supernatant. In packaging cells, constructs will also drive expression of an enzymatically active mRNA or small RNA. The CMV, EF1alpha and H1 promoters driving expression are strong promoters. It is therefore expected expression levels to be high.
Product: The expression of RNA and protein products such as VSV-G and accessory viral proteins from the different plasmids in the packaging cells will result in the production of viable pseudoviral particles which could potentially infect the worker and the potential hazard to human health is high. However, these particles are replication-defective as they do not carry the env gene necessary for viral replication and cannot propagate within the newly infected cell. In target cells, RNA gene products alone will be very unstable outside the cell and are very unlikely to have any biological effect. The protein products, if released outside cells, will be subject to protease degradation, which will greatly reduce the likelihood of hazard.
Recipient cells: The packaging cell line like all human non-tumorigenic cells can be considered as especially disabled host as they are unlikely to colonize the worker and do not contain any adventitious agents. Increased infectivity or pathogenicity of the GMMs is extremely unlikely, especially following transient transfections. Expression lentivectors together with the packaging plasmids from both companies comprise the third-generation lentiviral expression system. The SBI HIV-based lentivectors are based on the vectors developed for gene therapy applications by Dr. J (US patent #5,665,577 and #5,981,276). The Trans-LentiviralTM GIPZ Packaging System uses a replication-incompetent lentivirus based on the trans-lentiviral system developed by Kappes et al. (2001). However, both SBI's and Thermo-Scientific HIV-based lentivector systems are designed to maximize their biosafety features, which include:
• A deletion in the enhancer of the U3 region of 3′LTR ensures self-inactivation of the lentiviral construct after transduction and integration into genomic DNA of the target cells.

02/03/2022 Page 10802 of 15326
In the SBI system, the CMV and RSV promoters upstream of 5'LTR in the lentivector allow efficient Tat-independent production of viral RNA, reducing the number of genes from HIV-1 that are used in this system.

In both systems, the number of lentiviral genes are necessary for packaging, replication and transduction; corresponding proteins are expressed from different plasmids lacking packaging signals and share no significant homology to any of the expression lentivectors, pVSVG expression vector, or any other vector, to prevent generation of recombinant replication-competent virus.

In both systems, none of the HIV-1 genes (gag, pol, rev) will be present in the packaged viral genome, as they are expressed from packaging plasmids lacking packaging signal therefore, the lentiviral particles generated are replication-incompetent.

Pseudoviral particles will carry only one copy of the expression construct.

Therefore, even though the genetic manipulation of packaging cell lines in step 2 may be considered as level 1, and despite the above safety features, the production of HIV-based particles falls within Containment Level 2 criteria due to the potential biohazard risk of infection of the worker and hence the potential hazard to human health being high.

Step 3: Transduction of target cells with lentiviral particles
Vectors: Replication-defective lentiviruses will be able to transduce and integrate the genomic sequence flanked by the LTR sequences into most eukaryotic cells.
Expression: In transduced cells, constructs will drive the expression of enzymatically active mRNA or small RNA by promoters are strong and it is therefore expected expression levels of transcripts to be high.
Product: In target cells, transcribed small RNAs are biologically active and will be able to modulate the expression of not only a single gene but also many other putative target genes. Although the transgenes in themselves will not be harmful to the host cells, they may regulate their proliferative ability or induce apoptosis as a consequence of endogenous gene regulation. Outside the cell, RNA gene products alone will be very unstable and are very unlikely to have any biological effect. The protein products, if released outside cells, will be subject to protease degradation which will greatly reduce the likelihood of hazard.
Recipient cells: All established human cell lines can be considered as especially disabled hosts as they are unlikely to colonize the worker and do not contain any adventitious agents. Increased infectivity or pathogenicity of the GMMs is extremely unlikely. Primary human cells are unscreened and can potentially contain adventitious agents.

Recombinations between integrated sequences with endogenous viral sequences resulting in more pathogenic or replication-competent viral particles is extremely unlikely especially due to the transient nature of experiments. In the context of insertional mutagenesis, all transducing lentiviral vectors used are self-inactivating systems where the virus is deleted in the 3' LTR thereby reducing the potential for transactivation of cellular genes as a result of insertion. Also the risk of rescue of such vectors by wild type HIV is significantly reduced. However, the risk of insertional mutagenesis from disruption of genes following insertion although remote must still be considered.

Therefore, the genetic manipulation in step 3 may be considered as level 2, due to the potential remote biohazard risk of possible recombination with endogenous viral sequences to form self-replicating virus, or the possibility of insertional mutagenesis. Measurement of virus titre (e.g. p24 levels by ELISA) should be monitored if any Class 1 GM activity is performed subsequently with the GMM.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste will be autoclaved in the LTE Autoclave followed by disposal as clinical waste for incineration. All liquid waste will be inactivated in 1% Virkon overnight and flushed away down the sink.
The autoclaves are tested and validated twice a year.
The committee was concerned that the original application included potential oncogenes and the combination of potential oncogenes with the host/vector systems given confused the risk assessment. The committee requested that these inserts should be deleted or submitted as a separate more closely defined project with a more limited range of host cells. This has been done.

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

02/03/2022
**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

The goal of this work is to validate PKCq as a drug discovery target by investigating in vitro the effects of the disruption of PKCq signalling on the function of cultured primary human T Cells. The aim is to transiently transfect primary T cells with a DNA construct expressing kinase-inactive human PKCq in order to interfere with PKCq-dependent signalling (transfecting wild-type human PKCq as a control), and to assess the consequences using standard measures of T cell function such as inflammatory cytokine production and T cell adhesion.

**Recipient or parental organism**

The ultimate recipient strain will be primary human T cells (routinely purified in the laboratory according to standard procedures). Cultures of these cells will be transduced with lentiviruses carrying the pLenti4/TO/V5-DEST, pLenti4/TO/V5-DEST-PKCq, pLenti4/TO/V5-DEST-PKCqK409R or pLenti4/TO?V5-GW/ICNe expression vectors, which is predicted to induce constitutive transient expression of no protein (negative control), PKCq, PKCqK409R or b-galactosidase (positive control), respectively. Full details of all recipients are included in the attached RA.

**Host/vector system**

The ViraPower Lentiviral Expression System will be used. The supplied human 293FT packaging cell line will be transfected with both the Packaging Mix (containing the pLP1, pLP2 and pLP/SVG packaging vectors) and one of each of five expression vectors: pLenti4/TO/V5-DEST, pLenti4/TO/V5-DEST-PKCq, pLenti4/TO/V5-DEST-PKCqK409R, pLenti4/TO/V5-GW/ICNe and pLenti6/TR. This will generate five different replication-incompetent lentiviruses, carrying one of each of the expression vectors. The numerous safety features of this system are detailed in the RA.

**Origin & function**

The pENTR™ 221-PKCq vector is an entry vector containing the PKCq cDNA sequence and will be purchased from Invitrogen Life Technologies. This vector will be mutated (using a standard commercially available kit) at a single codon in the PKCq cDNA to generate pENTR9™ 221-PKCqK409R, which is an identical entry vector containing the cDNA sequence for kinase-inactive (K409R) PKCq.

The PKCq and PKCqK409R cDNAs will then be cloned (using standard techniques) into the pLenti4/TO/V5-DEST lentiviral destination vector (suppliedwith the kit), to generate pLenti5/TO/V5-DEST-PKCq (encodes wild-type human PLCq) and pLenti/TO/V5-DEST-PKCqK409R (encodes kinase-inactive human PKCq). A control destination vector encoding bacterial b-galactosidase, pLenti4/TO/V5-GW/ICNe is also supplied with the kit.

The supplied human 293FT packaging cell line will then be transfected with both the (supplied) ViraPower Packaging Mix (containing the pLP1, pLP2 and pLP/SVG packaging vectors) and one of each of five expression vectors: pLenti4/TO/V5-DEST, pLenti4/TO/V5-DEST-PKCq, pLenti4/TO/V5-DEST-PKCqK409R, pLenti4/TO/V5-GW/ICNe and pLenti6/TR. pLenti6/TR is a vector that encodes the bacterial Tet repressor in mammalian cells and provides the option of Tetracycline-regulated expression of the gene of interest (PKCq) if co-transduced with the pLenti4/TO/V5-DEST expression vectors. This will generate five different replication incompetent lentiviruses, carrying one of each of the expression vectors: pLenti4/TO/V5-DEST, pLenti4/TO/V5-DEST-PKCq, pLenti4/TO/V5-DEST-PKCqK409R, pLenti4/TO/V5-GW/ICNe and pLenti6/TR.

The final recipient strains will be primary human T Cells (routinely purified in the laboratory according to standard procedures). Cultures of these cells will be transduced with lentiviruses carrying the pLenti4/TO/V5-DEST, pLenti4/TO/V5-DEST-PKCq, pLenti4/TO/V5-DEST-PKCq K409R, pLenti4/TO/V5-GW/ICNe expression vectors, which is predicted to induce constitutive transient expression of no protein (negative control), PKCq, PKCqK409R or b-galactosidase (positive control), respectively. Co-transduction of cells with lentiviruses carrying any of these vectors plus lentiviruses carrying the pLenti6/TR plasmid provides the additional option of tetracycline-regulated expression of the gene of interest from the expression vectors. This is because the pLenti6/TR plasmid encodes the bacterial Tet repressor, which inhibits gene expression from pLenti4/TO/V5-DEST derived vectors due to the presence of Tet operator (TetO2) sequences in the pLenti4/TO/V5-DEST promoter.

Finally, the transduced cells would be assayed for PKCq expression and the effects of transduction with the various constructs on T cell function.
Evaluation of foreseeable effects

The most noteworthy GMMs resulting from this work are lentiviruses harbouring the pLenti4/TO/V5-DEST-PKCq and pLenti4/TO/V5-DEST-PKCqK409R vectors generated using the ViraPower lentiviral expression system. This lentiviral system includes a substantial number of safety features designed to enhance its biosafety and minimize its relation to wild-type human retroviruses. It is clear from the safety features incorporated into this lentiviral system (see attached RA) that in this case the recipient microorganism (the lentivirus generated) is extremely unlikely to cause disease and could not spread to the human community or organisms in the environment. We are confident that there are no harmful properties associated with the (third generation) vectors to be utilised in this work, with the inserted material (the PKCq and the PKCqK409R genes) or with the resultant pLenti4/TO/V5-DEST-PKCq and pLenti4/TO/V5-DEST-PKCqK409R expression vectors. There is no evidence indicating that these sequences are inherently biohazardous i.e. there is no evidence that expression of PLCq or the disruption of PKCq signalling in a small subset of human cells is per se oncogenic. Toxic or in any way harmful, despite intensive worldwide research into PKCq signalling using these sequences. It is clear that none of the vectors to be used in this study encode potential pathogenicity determinants such as surface components nor harbour genes predicted to modulate the resistance of the lentivirus to disinfection procedures. Nor do any of these vectors encode animal toxins or any other products representing a specific risk to any organisms in the environment, and we are confident that there is negligible potential for the alteration of the existing traits or ViraPower lentiviruses by the packaging of any of the vectors used in this study. Similarly, the risks of sequences within the GMMs being transferred to related microorganisms are extremely low. The viruses produced in this work could not survive in the external environment, would be extremely unlikely to come into contact with related viruses and are engineered using vectors designed not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus. Nonetheless, the fact remains that replication-incompetent lentiviruses retain the ability to infect primary mammalian cells (by definition) and therefore pose some (albeit low) biohazardous risk. For this reason alone, we believe that the cautionary approach of the assignment of a provisional containment level of biosafety level 2 is preferable, and consistent with the supplier's recommendations.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

This work will only involve the transient modification of cultured human cells; no other non-microorganisms will be modified. Purified primary human T cells will be incubated for 24 hours in an isolated 37°C incubator in sealed tissue culture flasks in the presence of lentiviral stocks titrated in tissue culture medium. Subsequently, the virus-containing supernatants are destroyed and the cells are incubated for a further 48 hours in fresh clean medium. Finally, the cells would be assayed for PKCq expression and the effects of transduction with the various constructs on T cell function. Primary T cells are unable to survive in the absence of specific well-defined growth media and cell culture conditions provided by the researcher. In accordance with the industry standard and the recommendations of the suppliers of the ViraPower Lentiviral Expression System (Invitrogen Life Technologies), all manipulations potentially involving infective (mature) lentivirus will be carried out in a certified class II safety cabinet and all medium and plasticware potentially coming into contact with lentivirus will be treated overnight in undiluted bleach (5.28% Sodium hypochlorite) in a certified class II safety cabinet, before disposal by off-site incineration. Upon completion of the experiment, mammalian cells incubated in medium potentially containing lentivirus will be inactivated and disposed of in an identical manner. Numerous studies, most notably by Robert Heimer, have shown that undiluted bleach is an effective and rapidly acting disinfection solution for retroviruses. For this reason alone, we believe that the cautionary approach of the assignment of a provisional containment level of biosafety level 2 is preferable, and consistent with the supplier's recommendations.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

In accordance with the industry standard and the recommendations of the suppliers of the ViraPower Lentiviral Expression System (Invitrogen Life Technologies), all manipulations potentially involving infective (mature) lentivirus will be carried out in a certified class II safety cabinet and all medium and plasticware potentially coming into contact with lentivirus will be treated overnight in undiluted bleach in a certified class II cabinet, before disposal by off-site incineration. Upon completion of the experiment, mammalian cells incubated in medium potentially containing lentivirus will be inactivated and disposed of in an identical manner. Numerous studies, most notably by Robert Heimer, have shown that undiluted bleach (5.28% Sodium hypochlorite) is an effective and rapidly acting disinfection solution for retroviruses. However, upon production of the first lentivirus batch, we will confirm experimentally that this disinfection procedure is effective under the actual conditions of use.
A comprehensive risk assessment. The committee asked for further details to be included regarding the suitability of bleach for inactivation of waste. This has been included in the attached risk assessment. We will conduct in-house experiments to confirm this. The committee also discussed procedures to minimise the creation of aerosols, such as the use of sealed buckets during centrifugation. Again, this has been incorporated into the risk assessment.

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

To use the mouse micoglial BV-2 cell line as a model system to investigate the role of microglia in neurodegenerative disorders. Conventional laboratory techniques will be used to assess the production of cytokine / chemokines / ROS in response to various stimuli.

**Recipient or parental organism**

Mouse micoglial cells. Primary cells have previously been infected with the J2 virus to generate the BV-2 cell-line. (Blasi et al. J Neuroimmunol. 1990 27 (2-3) p229-37)

**Host/vector system**

**Origin & function**

MSV-3611 (closely related to the Mo-MLV) was originally isolated from chemically transformed mouse cells. MSV-3611 is replication defective due to deletion of the gag-pol replication genes and has acquired acute transforming properties due to incorporation of the oncogene v-raf into the proving genome (Rapp et al Proc Natl Acad Sci U S A. 1983 Jul;80(14):4218-22). The function of J2 was to transform primary cells to obtain established cell lines. The presence of v-myc in addition to v-raf removes the dependence on IL-3 for continued growth in culture (Blasi et al J Neuroimmunol. 1990 27 (2-3) p229-37).

The J2 virus was subsequently reported to be capable of replication and the BV-2 cell line was reclassified as Biosafety Level 2 by the ATCC (http://atcc.custhelp.com/app/answers/detail/a_id/550/~/biosafety-level-change-for-cells-carrying-mlv-or-j2).

**Evaluation of foreseeable effects**

The BV-2 cell line releases an ecotropic oncogenic retrovirus (J2) into the culture media that could potentially infect mice or other murine cell-lines if released into the environment.

The expressed gene products are the oncogenes v-raf and v-myc. v-myc is the viral homolog of c-myc. The v-myc oncogene can transform several lineages of cells either alone or in co-operation with other oncogenes. v-raf is a murine leukemia viral oncogene homolog 1, also capable of transforming cells.

There are no obvious hazards to human health. This cell line has been successfully cultured for over 20 years with no reported incidents of human infection. The use of the cell line for research purposes should not represent a risk to humans as the retrovirus from the BV-2 cells is ecotropic, that is only capable of infecting murine cells (http://bioinformatics.istge.it/cldb/cl7130.html).

If the J2 virus came into contact with other virally infected cells it may become amphotropic (able to infect non-mouse cells). The chance of this happening is negligible since none of the cell-lines currently handled in our laboratories are knowingly infected with viruses capable of infecting humans. However, work with this cell line will be done in a separate quarantined laboratory away from other activities.

In addition, retroviruses are highly susceptible to dehydration and are rapidly inactivated outside of the host, as illustrated by the fact that close contact, e.g. injection, ingestion, etc, is required for successful transmission.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not Applicable
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not Applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste (culture media etc.) will be disinfected using >1% solution of Virkon for at least 30 minutes following manufacturers instructions. It will then be poured down the sink and flushed with copious amounts of water.

Virkon is specifically designed for inactivating virus (>99.99% reduction in virus titre) when used following the manufacturers instructions, i.e. soaking in a 1% solution for ≥ 30 minutes (DuPont Technical bulletin K09006-Disinfectant).

Solid waste including culture flasks, tubes, contaminated pipette tips and other lab consumables will be decontaminated by soaking in 1% Virkon for at least 30 minutes before being transferred to BioHazard bins. These bins will be sealed with a self-locking lid at the end of the working day. The bins are labeled with a biohazard sign that displays UN 3291. Bins are stored in a locked brick store with concrete floor until collection by our licensed waste contractor. They are certified to handle and dispose of Class 2 GMO waste, which once collected is incinerated ensuring 100% kill.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The committee considered that the risk to HUMAN HEALTH was NEGLIGIBLE, as it is extremely unlikely that the virus could become amphoteric and thus capable of infecting human cells, but that risk to the ENVIRONMENT is LOW and so assignment to Risk Class 2 is appropriate.

Project Ref 713/17.1
Investigations into the function of genes linked to polycystic kidney disease using lentiviral transfection of a human kidney in vitro model

Polycystic kidney diseases are the most prevalent inherited kidney diseases yet the molecular basis of the role of PKD-associated genes is poorly understood. The aim of this work is to determine how mutations in genes such as Polycystin-1 (PC1) and Polycystin-2 (PC2) contribute to cyst formation in kidney cells. Like most primary cells, primary kidney cells are difficult to transduce with exogenous DNA. To circumvent this problem, replication incompetent lentiviruses will be used to deliver exogenous DNA sequences to mammalian cells. Advantages over other transduction techniques include the ability to transduce a wide-range of different cells types that are both dividing and non-dividing. Primary kidney cells will be transduced with a DNA construct expressing either wild-type or mutant forms of PKD relevant genes e.g. PC1 and PC2 in order to determine their effects on in vitro cystogenesis. As controls, primary kidney cells will also be transduced with constructs encoding no protein product (vector only).

Recipient Organisms and evaluation of foreseeable effects
A. Cloning of DNA using Stbl3 chemically competent E. coli (Designated a Class 1 activity)
Stbl3 chemically competent E. coli with genotype: F−mcrB mrrhsdS20(rB−, mB−) recA13 supE44 ara-14 galK2 lacY1 proA2 rpsL20(StrR) xyl-5 λ−leumt1-1. These cells will be transfected with and used to propagate the pLenti6.3 vectors. The plasmids do not contain bacterial promoters so no expression of target protein will take place. Stbl3 is derived from HB101 which is a K-12 derivative of E. coli. This strain is non-colonizing, disabled and considered class 1, due to the lack of pathogenicity in humans or animals

B. Generation of Lentiviral expressing 293FT cells (Class 2 activity)
This is a clonal isolate derived from primary embryonal kidney cells transformed with sheared human adenovirus type 5 DNA and stably express SV40 large T antigen from pCMVSPORT6Tag.neo plasmid under the control of the human CMV promoter. 293T will be transfected with both the Virapower Packaging Mix (containing the pLP1, pLP2 and pLP/VSVG lentivial packaging vectors) and one of each of the pLenti6.3 plasmids described above. 293FT is a commonly-used cell line with a history of safe use and 293FT cells are unable to survive in the absence of specific well-defined growth media and cell culture conditions provided by the researcher. Consequently, these cells can be considered as especially disabled.

C. Transduction of primary human kidney cells and analysis of cyst formation (Class 2 activity)
The final recipient strains will be primary human kidney cells. These cells have been screened for the presence of HIV, Hep B and C infections. Cultures of these cells will be transduced with lentivirus carrying the pLenti6.3 vectors, which is predicted to induce constitutive expression of no protein (negative control), or wild-type PKD gene
products and mutants thereof. Primary kidney cells are unable to survive in the absence of specific well-defined growth media and cell culture conditions provided by the research. These cells can be viewed as being especially disabled.

Conclusion
We are confident that no hazards to the environment are associated with the recipient Stbl3 (bacterial) strain, 293FT (mammalian) cell line or primary human kidney cells when transformed/transfected/transduced with any of the vectors described below. There are no harmful properties associated with these recipient strains in the absence of the vector sequences. The vectors to be transformed/transfected/transduced are not predicted to give rise to a harmful phenotype either directly (genes themselves do not encode for harmful proteins products (oncogene/toxins)) or when acting in concert with existing recipient characteristics (genes do not encode products predicted to alter pathogenicity in normal cells). These GMMs would not be expected to cause any serious harm to humans and/or the environment in the event of a failure of containment and control measures (regulation 21).

The most hazardous GMMs resulting from this work are lentiviruses harboring the pLenti6.3 vectors generated using the ViraPower lentiviral expression system (Thermo Fisher). This lentiviral system, which is based on the HIV-1 virus, includes a substantial number of safety features designed to enhance its biosafety and minimize its relation to wild-type HIV1. Wild type HIV1 is listed as a Hazard Group 3 agent in the ACDP approved list. However, there are a number of safety features built into this third-generation viral system. These include:

- The pLenti6.3/TO/V5-DEST and pLenti6/TR vectors contain a deletion in the 3'LTR (ΔU3) that does not affect the generation of the viral genome in the producer cell line, but results in “self-inactivation” of the lentivirus after transduction of the target cell. Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing a package-able viral genome.
- The number of HIV-1 genes that are used in the system has been reduced to three (gag, pol, and rev), thus reducing the genetic similarity to HIV-1.
- The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 envelope, thus further reducing the relation of the viral particles to HIV-1.
- Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids (i.e., three packaging plasmids and pLenti6.3/TO/V5-DEST or pLenti6/TR). All four plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus.
- Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny in the 293FT producer cell line, none of them contain LTRs or the Ψ packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication competent virus can be produced.
- The lentiviral particles produced in this system are replication incompetent and only carry the gene of interest. No other viral species are produced.
- Expression of the gag and pol genes from pLP1 has been rendered Rev dependent by virtue of the HIV-1 RRE in the gag/pol mRNA transcript. Addition of the RRE prevents gag and pol expression in the absence of Rev.
- A constitutive promoter (RSV promoter) has been placed upstream of the 5’LTR in the pLenti6.3/TO/V5-DEST and pLenti6/TR expression vectors to offset the requirement for Tat in the efficient production of viral RNA.

It is clear from the safety features incorporated into this lentiviral system that in this case the recipient microorganism is “unlikely to cause disease” and thus is best categorized as a Hazard Group 2 agent.

Conclusion
These viruses are “defective retrovirus produced from a packaging line in which the helper genes are located in three separate blocks of DNA (thus eliminating the possibility of a reversion to replication competence by a single recombinant event) and which self-inactivated to prevent ‘insertional activation’”. Thus, these viruses are an example of an “inherently safe recipient microorganisms which, depending on the nature of the insert, would in most cases are expected to form the basis of extremely safe GMMs”. In this way, these viral particles are extremely unlikely to cause disease and could not spread to the community.

Origin & function
The goal of this study is to understand the function of genes involved linked with the development of polycystic kidney disease (e.g. PKD1 and PKD2) as much of their function is unclear. Polycystin-1 (PC1), encoded by PKD1, is a large glycoprotein (4,303aa) with an approximately 3,000aa N terminal ectodomain, anchored to the membrane by 11 transmembrane helices with a short C terminal cytoplasmic tail. Polycystin-2 (PC2) encoded by PKD2 is believed to be a member of the transient receptor potential (TRP) ion channel family, a large group of six-trans membrane cation channels that play crucial roles in sensory physiology. PC1 and PC2 form a receptor/ion channel complex through association of their C-terminal coiled-coil domains. Certain mutations in PC1 and PC2 can cause autosomal dominant polycystic kidney disease
ADPKD. Polycystin proteins may participate in many different signaling pathways and regulatory processes, for instance PC1 shares similarities with both adhesion GPCRs and TRP family ion channels. We are confident that there are no harmful properties associated with the vectors to be utilized in this work. The DNA will be synthesized by Genewiz. The lentiviral and packaging vectors supplied with the ViraPower lentiviral system are third-generation vectors and include a substantial number of safety features designed to enhance their biosafety (see above). Regarding the polycystic kidney disease related DNA sequences e.g. (PC1 and PC2) to be inserted into the vectors, there is no evidence indicating that these sequences are inherently biohazardous. We acknowledge that overexpression of even a normal human gene may be harmful, especially if the overexpression is in tissues that do not normally express the protein. However, there is no evidence, to our knowledge, that over-expression of PC1 or PC2 in cell types other than cells of kidney origin is likely to have an effect on cell physiology. The cellular functions of PC1 and PC2 are detailed above. It is not apparent from these functions how overexpression of PC1 or PC2 or the disruption of PC1/PC2 signaling in this setting could be inherently harmful to human cells if the lentiviruses carrying the pLenti6.3 vectors were to accidentally infect living cells from a human worker.

Evaluation of foreseeable effects

From the list of functions of PC1 and PC2 (listed above), it is not clear that the widespread infection of human beings with the pLenti6.3 vectors (details outlined below) or sequences derived therefrom would present a matter of significant concern. Although loss of PKD1/PKD2 may result in ADPKD, there is no evidence to our knowledge that PKD1/PKD2 or the disruption of PC1/PC2-dependent mechanisms in a subset of human cells is per se oncogenic, toxic, or in any way harmful outside the context of the kidney. Regarding the roles of PC1 or PC2 in normal primary human kidney cells, it is almost inconceivable that PC1/PC2 signaling could be disrupted using lentivirus in a sufficiently large number of human kidney cells to affect human health. There is little evidence of potential harmful effects realized as consequence of exposure to lentivirus from the ViraPower system. However, despite enhanced biosafety using replication incompetent viruses and separating viral proteins across numerous packaging constructs, the lentiviruses still harbor the potential to infect mammalian cells. We acknowledge that overexpression of even a normal human gene may be harmful, especially if the overexpression is in tissues that do not normally express the protein. This risk is associated with lentiviruses in general: there is no evidence to our knowledge that PKD1/PKD2 or the disruption of PC1/PC2-dependent mechanisms in a subset of human cells is per se oncogenic, toxic, or in any way harmful outside the context of the kidney. It is not clear that any one of the specific lentiviruses to be generated in this study will be significantly more hazardous than the others. Although it is presumed that lentiviruses harbouring the pLenti6.3 vectors can be slightly more hazardous since they can induce the ectopic expression of a wild-type, gain-of-function, and loss-of-function protein in human cells. It is for this reason that we have considered the lentiviruses harbouring pLenti6.3 vectors to be slightly more biohazardous than the other control lentiviruses to be generated in this work.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment will be used. No derogation required

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

In accordance with the industry standard and the recommendations of the suppliers of the ViraPower Lentiviral Expression System (Invitrogen Life Technologies, UK), all contaminated solid waste (e.g. plasticware including pipettes and flasks) and liquid waste that has potentially come into contact with lentivirus will be treated overnight in 2% Virkon (Fisher Scientific, UK) in a certified class II safety cabinet prior to disposal. Solid waste is disposed by off-site incineration and inactivated liquid waste will be disposed via sewerage. Virkon has the widest proven spectrum of any disinfectant - proven effective in independent tests against all 18 virus families affecting man and animals, including AIDS (HIV) and Hepatitis B. Upon completion of the experiment, mammalian cells incubated in medium potentially containing lentivirus will be inactivated, and disposed of, in an identical manner.

None of the work proposed in this study requires the use of sharp materials (metal, glass or otherwise). Only standard blunt plastic ware will be necessary.
There was some discussion over whether this work should be categorized as low risk (requiring level 2 containment); other sites have assessed the use of kit-based lentiviral transduction to be effectively controlled through the use of Level-1 containment (negligible risk). However, the committee was satisfied with the assessment of low risk (class 2) containment considering both the use of lentiviral transduction capable of transducing human cells and the expression of novel proteins (including PC1 and PC2).

The committee also recommended using Virkon instead of 5% bleach in order to decontaminate both plasticware and liquid waste. The assessment has been amended to reflect this.

It was unanimously agreed that the work should be carried out under the Level 2 containment procedures outlined in the risk assessment. The HSE should be notified of our intentions.

Action: CU2 form to be completed and the HSE informed of our intended usage with £981 notification fee (MG).

For activities involving GMMs, describe the waste management measures which will apply to the activity

Maximum culture volume = 8000 litres.
Deactivation methods: Bacteria are retained for further processing which involves breakage at high pressures. Culture broth is filtered away from the bacterial cells through a 0.2 um membrane. Fermentation vessels are sterilised by steam at 121 degrees C. Auxiliary equipment which may have been in contact with bacterial cells are disinfected with hypochlorite. Smaller cultures are autoclaved. Solid waste also autoclaved.
All deactivation methods are standard microbiological methods, no culture is discarded directly to drain.

For activities involving GMMs, describe the waste management measures which will apply to the activity

**Background** - Work involving Class 1 genetically modified bacteria and fungi is conducted at the premises from which waste materials are generated. These materials are decontaminated by autoclaving or by chemical deactivation prior to discard.

**Decontamination procedures - Autoclaving** - Waste fluids and materials are autoclaved inside perforated metal bins at 134°C for 20 minutes, well in excess of the minimum sterilisation conditions. Fermenters and supporting peripherals are autoclaved in situ or in a separate autoclave at 121°C for 20 minutes. The building possesses 2 autoclaves, both of which are equipped with alarms and data log print-out facilities which give details of each autoclave cycle. An audible alarm is activated should an autoclave run fail. Autoclaves are serviced every 3 months and probes calibrated every six months by a competent contractor. 100% Kill

**Chemical Deactivation** - Some waste material may be chemically deactivated prior to discharge if autoclaving is not a practical alternative. This is accomplished using total immersion in Virkon disinfectant at concentrations between 0.4% and 1% for 60 minutes, as per the manufacturers recommendations. An evaluation testing the effectiveness of Virkon for chemical deactivation of microorganisms has been performed and is recorded in lab book KC46, experiment number KC010/29/09/95, pages 168-172. 100% Kill.

For activities involving GMMs, describe the waste management measures which will apply to the activity

As the activity to be undertaken comprises receipt, storage and distribution of material in pre-packaged vials, the only waste that should be produced will be that arising from any breakages, spillages or reject stock. Since the material is supplied in liquid form contained in unbreakable vials, and will be maintained frozen at all times while on site, it is anticipated that little (if any) waste will be produced.

Any such waste arising from the work will be inactivated by off-site incineration. This will provide 100% inactivation of the GMMs. The waste will be consigned as genetically modified clinical waste for incineration at a site notified to the HSE under the Contained Use Regulations. Such waste will be transported in single-use "one way" UN approved sealed waste units. A copy of the incinerator's HSE authorisation will be held by Quintiles. All clinical wastes will be handled in accordance with the "safe Disposal of Clinical Waste" (HSAC 1999).

Spillage

Any spillage of Ad5/FGF-4 will be inactivated by use of Virkon, used in accordance with the manufacturer's instructions. These will specify the concentration to be used and the acting time. Virkon is a broad-spectrum disinfectant with proven efficacy against adenoviruses, and manufacturer's data on the disinfectant and its method of use will be kept in the area spillage kits.

The maximum culture volume that is released at any one time is 10 litres. The waste is deactivated by a Virkon soak and autoclaving. The deactivation method is validated by colour coded tape, i.e. tape changes black when reaches required temperature. The deactivation method is monitored by a computer in the autoclave which warns of a cycle fail (e.g. if the autoclave hasn't reached the required temperature or length of time for deactivation of waste).

All liquid and solid waste (maximum total volume 5 litres) will be deactivated by autoclaving at 125 degrees C for 20 minutes. Deactivation will be monitored by using 3M comply indicator tape for steam. In addition, small amounts of liquid waste may be deactivated using Chloros solution (concentrated sodium hypochlorite solution, equal or greater than 10% w/w active chlorine).

### Project Ref 720/01.1

**CU2 Project Title**

CLONING OF GENES INVOLVED IN BIOSYNTHESIS OF POLYKETIDES FROM ACTINOMYCETES INTO E. COLI AND OTHER ACTINOMYCETES TO PRODUCE NOVEL POLYKETIDE DERIVATIVES

**Date Ackn’d**

Project Additional Information

Purposes of the contained use
biosynthesis of novel polyketides of industrial interest.

Recipient or parental organism
Actinomycetes:-
Streptomyces lividans, albus, cinnamomensis, coelicolor, fradiae, avermitilis, rimosus, rochei Saccharopolyspora erythraea, spinosa.
E. coli:-
K-12 strains TG1 recO, DH1OB, XL1-Blue, S17-1, TB1. ET12567, TOP10.

Host/vector system
E.coli vectors will be derivatives of the following plasmids:
Non-mobilisable bacterial plasmids:-
Mobilisation deficient and integrative bacterial plasmids:-
Actinomycete vectors will be derivatives of the following plasmids:-
Non-mobilisable and self-replicating plasmids:-
pCJR29 (pUC19 based) & pWHM3.
Mobilisation deficient and integrative (all pUC19 based) plasmids:-

Origin & function
The genes that will be expressed encode enzymes that cannot conceivably cause harm or disease or affect the environment adversely.
DNA from various Actinomycetes including Nocardia sp. will be cloned into K-12 strains of E. coli and other Actinomycetes. The DNA will contain polyketide synthase genes or portions thereof, as well as auxiliary genes involved in polyketide synthesis (activator genes, methylases, oxidases, hydroxylases, glycosyltransferases, holosynthases, genes for the production of co-substrates for polyketides synthases, genes for the production of sugars).
Those expressed in E. coli under the Tac, Trc and T7 promoters will be expressed at levels between 0 - 50% of total cell protein.
Those expressed in Streptomycyces or Saccharopolyspora under the ActI, ActIII, ErmE, PTR, Spn and TipA promoters will be expressed at levels between 0 - 2% of total
cell protein.

**Evaluation of foreseeable effects**

New GMMs will be created which will produce novel polyketides. These Actinomycete GMM strains should have the same characteristics as wild-type strains being naturally occurring soil bacteria which are not aggressive colonisers, and are generally found in small patches which do not proliferate. They are not human or animal commensals. They are therefore completely safe for humans, animals or plants. E. coli strains created all contain non-reversible disabling mutations and could not infect animals or humans.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All liquid and solid waste (maximum total volume 20 litres) will be deactivated by autoclaving at 125°C for 20 minutes. Deactivation will be monitored by using 3M comply indicator tape for steam. In addition, small amounts of liquid waste may be deactivated using RBS (final concentration of 5% v/v). There is therefore no possibility that bacteria will escape from the laboratory. Where possible the use of sharps is avoided and plastic pipettes are used. However, any sharps used are always placed in a Cin-Bin and disposed of through licenced contractors according to the Company’s Waste Disposal Procedure. A kill curve disinfection test versus time is performed on all organisms.

Is an emergency plan required according to regulation 20?  
If yes, tick to confirm that it is attached to this form  
Tick to confirm that you have attached a risk assessment to this form  
Tick if you are claiming exemption from disclosure for section of the risk assessment

Maximum culture volume that could be released at any one time: 100 ml.

All solid waste will be autoclaved, before disposal. All liquid waste will be autoclaved, or if appropriate disinfected with Virkon (peroxyxgen compound) before disposal.

All non disposable items (glassware, non disposable plastic containers and contaminated equipment) used with the GMOs will be autoclaved or disinfected with Virkon as appropriate.

The autoclave will be serviced and the in load probe calibrated regularly (using a representative load). The in load probe temperature will be recorded for each batch of waste autoclaved.

The maximum culture volume which could be released at one time is less than 20L. The waste is deactivated by autoclaving for 40 minutes at 121 degrees C or, treated with presept (Dichloroisocyanurate, Sodium Salt 50%), the minimum contact time being 1 hour.

Validation of the deactivation processes are supplied by the manufacturers and the recommendations are adhered to. Monitoring the deactivation by presept is currently being undertaken in-house.

Autoclaving is monitored by timer and pressure regulation. The autoclave is regularly checked under a service contract.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Maximum waste volume is 1 litre. In practice waste volumes, at a given time, are likely to be less than this.

* Waste will be deactivated by autoclave processing.
* A dedicated autoclave is reserved for inactivation of microbiological wastes.
* GMMs will be deactivated separately from other micro-organisms.
* A high temperature regime [124 degrees C for at least 30 minutes] is used.
* The deactivation regime is monitored by chart recorder [NAMAS accredited] and also by steam sterilisation integrator indicator [Thermalog S] incorporated into the autoclave load itself.
* The above procedures have been previously shown to achieve deactivation of the GMMs.
* Standard microbiological procedures will also be used to confirm sterilisation.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The maximum culture volume that could be released at any one time is 20 cm cu.
Deactivation: All waste cultures and contaminated materials to be deactivated by autoclaving at 121 degrees C for 15 minutes. Benches to be wiped down with 60% propan-2-ol after use.
Validation: Indicator strips to be included in the centre of each load to ensure temperature of 121 degrees C for 15 minutes is achieved.
Monitoring: Disposal record of all cultures kept in log book maintained in the Biotechnology Prep room.

02/03/2022
Waste Disposal:
* The anticipated maximum culture volume is 2 - 3 litres per week.
* Cultures will be inactivated with a concentrated solution of Hibicet or Virkon.
* Liquid will be absorbed onto tissue paper.
* Tissue paper, flasks, stripettes etc. will be double-bagged for collection and incineration.

Validation:
* Because all waste will be incinerated, there is no anticipated need for validation of the deactivation.
* If required, random samples of deactivated cells could be cultured to ensure there are no viable cells present.

For activities involving GMMs, describe the waste management measures which will apply to the activity

We grow HeLa cells for our research work; approximately half to one litre per week. These cells are killed by using "Promega lysis buffer" which we understand is a proprietary buffer which will disrupt and render harmless enveloped cells and viruses. Secondly, we either (i) autoclave such material (after treatment with said lysis buffer), or (ii) send this in a sealed container to a specialist contractor for incineration.

For activities involving GMMs, describe the waste management measures which will apply to the activity

---
**Project Additional Information**

**Purposes of the contained use**
expression of proteins which may have oncogenic potential. Contained use is therefore required.

**Recipient or parental organism**
Human immortalised cell lines HeLa, HT29, HCT116

**Host/vector system**
Mammalian expression vectors pcDNA3 and pcDNA4

**Origin & function**
Human gene sequences which code for potentially oncogenic proteins have been obtained from various institutional sources and cloned into mammalian expression vectors. The GMM (human immortalised cell lines expressing these gene sequences) will be used in cell-based assays of protein function.

**Evaluation of foreseeable effects**
The proposed modification to the recipient organism is not anticipated to alter infectiousness, allergenicity or host range. The recipient organisms will carry heterologous gene sequences which may confer a growth advantage to that organism when compared to the parental cell line in a laboratory setting. None of the expressed proteins are toxic or pathogenic in the environment. The recipient organism has strict media requirements that cannot be met outside of the laboratory. Survivability is effectively zero.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
Not applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
The general principles of Good Laboratory Practice and Good Occupational Health and Safety will be applied to this activity. All manipulations involving the modified cell line will take place in a Class II safety cabinet. All GMM material will be autoclaved for 20 minutes at 121°C in a regularly maintained autoclave or will be disinfected using Virkon S (shown to achieve 100% killing of HeLa cells). Disinfected waste will then be disposed of by WasteCare clinical waste management contractors.

**Is an emergency plan required according to regulation 20?**

<td>Fluorescent tagging of the nucleus in Ramularia collo-cygni, a fungal pathogen of barley</td>
<td>Class 2</td>
<td>&lt; 1 Litre</td>
<td>Non-GMM</td>
<td>Consent Granted</td>
<td>N</td>
</tr>
</tbody>
</table>

- Project notified under transitional arrangements: N

**Project Additional Information**

- **Purposes of the contained use**
  - To visualise nuclei of Ramularia collo-cygni in the investigation of possible sexual reproduction in this fungus

- **Recipient or parental organism**
  - Isolates of Ramularia collo-cygni endemic to Scotland
**Host/vector system**

Bacterial Plasmid pMF357 (Ishikawa et al. 2010), in which the green fluorescent protein gene is expressed from the N. crassa ccg-1 promoter and which contains the hygromycin resistance gene.  

Bacterial plasmid pGR02 (Freitag and Selker, 2005), in which the red fluorescent protein gene is expressed under control of the N. crassa ccg-1 promoter and which contains the phleomycin resistance gene.  

Both plasmids also contain the ampicillin resistance gene for selection and propagation in E. coli.

**Origin & function**

Green fluorescent protein (GFP) gene from jellyfish Aequorea victoria. Function: to confer green fluorescence on transformed nuclei.  

Red fluorescent protein (RFP) gene from the coral Discosoma. Function: to confer red fluorescence on transformed nuclei.

**Evaluation of foreseeable effects**

It is not anticipated that the expression of fluorescent protein genes in Tamularia collo-cygni would result in any change in the host range or aggressiveness of this plant pathogen. However, as barley, the natural host for Ramularia, may be cultivated in the vicinity of the laboratory, it is considered that the activity is Class 2. It is not anticipated that E. coli strains used to propagate the plasmids would present a risk to the environment or to human health, primarily as the fluorescent protein genes will not be expressed in the bacterium.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

The waste generated will compromise aqueous fungal spore suspensions and fungal mycelium growing on agar plates. Waste E.coli, both intact and fragmented cells, will be generated during propagation and isolation of the plasmids. All waste will be inactivated by heat treatment at 121 degrees Celsius for 15 minutes in an autoclave to give 100% kill. The autoclave is fitted with a data monitor to verify correct temperature and duration. Any spillage of liquid containing GMMs will be treated immediately with Trigene disinfectant.

The maximum liquid volume containing the GMOs to be handled at any one time is 1 litre. Contaminated waste to be decontaminated by autoclaving at 134 degrees C for a minimum of 12 minutes, or by neutralisation with appropriate sterilising agents (e.g., sodium hypochlorite). The autoclave validation is by thermocouples embedded in typical loads; monitoring via integral time/temperature printout, which is checked by laboratory management. Sterilising agents validated by compliance with national NHS standards, and/or in-house testing for neutralisation of the vector. Monitoring via records kept in accordance with procedural documentation.

For activities involving GMMs, describe the waste management measures which will apply to the activity.

**Project Additional Information**

**Purposes of the contained use**
Clinical testing of gene therapy agents based on herpes simplex virus, with the aim to develop and validate improved treatments for cancer.

**Recipient or parental organism**
The gene therapy agents are modified versions of herpes simplex virus, which are modified to be non-pathogenic in normal tissues, but retain the ability to undergo lytic replication in cancer cells. Similar viruses have already been tested in human clinical trials and found to be safe, even when administered intracranially.

**Host/vector system**
The ultimate hosts in these clinical trials are human cancer patients. The modified herpes virus vectors used are able to replicate and spread within cancerous tissue, but are unable to replicate in normal tissues.

**Origin & function**
The vectors are intended to replicate in cancer tissue, spreading through the cancer and killing the cancer cells. Because the vectors are unable to replicate in normal tissues, they are non-pathogenic and should not harm normal tissues, and would be unable to spread in the population. In order to increase their anticancer activity, the vectors may contain additional therapeutic genes, such as genes encoding human cytokines. These may enhance the generation of immune responses against the cancer cells, which would help to eliminate cancer cells from the patient.

**Evaluation of foreseeable effects**
The virus vectors are expected to replicate in cancer cells, killing them by lysis and releasing identical progeny virus, which can infect surrounding cells. Thus the vectors should spread progressively through a tumour, killing the cancer cells. Although some normal cells, e.g., at the tumour margins, may become infected, the vectors should be...
unable to replicate in these, and spread of the virus should cease. Transmission from the cancer patient to other humans will be prevented, by covering the injection site with occlusive dressings, and retaining the patient in a containment suite until virus shedding has ceased.

In the unlikely event that persons other than the cancer patient become contaminated with the vector, it will be unable to replicate and so it is most likely that no significant effects would be observed. The vectors are unable to generate the "cold sore" lesions associated with the natural herpes simplex virus, because these result from virus replication in the normal skin, whereas the vectors are unable to replicate in normal tissue. A high proportion of the population has been naturally exposed to herpes simplex virus, and has a pre-existing immune response to the virus. If seronegative individuals are contaminated with high doses of the vector (e.g. through inadvertent self-inoculation at the time of administration), then seroconversion may occur. The production of cytokines by the GM vectors may be expected to cause an increased inflammatory response and enhance the generation of immune responses.

Thus the effects of the vector in normal individuals are expected to be minimal. As an additional safety feature, the vectors retain the viral thymidine kinase gene in the virus, and thus infection could be controlled with acyclovir.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste materials contaminated with the GMM will include the vials in which it is supplied, the syringe and needles used for injection, contaminated dressings, latex/vinyl gloves with a risk of contamination. These will be placed into a sharps bin within the containment facility. These are decontaminated by autoclaving within the Microbiology Department, using fully validated and documented procedures, providing 100% kill. The waste is transported to the Microbiology autoclave by knowledgeable, responsible individuals associated with the trial, e.g. research nurses, using specified, appropriate secondary containers showing specific biological hazard labels. These arrangements have been discussed with the HSE, who advised that this complies with the standard level 2 provisions.

We have also validated disinfection with 1% Virkon, 0.5% Chloroclean, and Klercide B to provide complete inactivation of the vector.

Following autoclaving, the decontaminated waste is disposed as clinical waste, being removed by contractors for high temperature incineration off-site.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment
The GMSC agreed that Oncovex-GM-CSF is appropriately classified as Class 2; noted that this is the first class 2 GMM to be used within the Trust, and agreed that the containment facilities and procedures are suitable.

The GMSC recommended that in view of the increased hazard of WT HSV in persons who are immunosuppressed, pregnant, or have active eczema, as a precaution healthcare workers who fall into any of these categories should be excluded from possible contact with Oncovex-GM-CSF, by exclusion from the area when the virus is dispensed or administered, and while the patient is shedding the virus.

Purposes of the contained use

In the first instance, Pexa-Vec will be used in the clinical trial, "A Phase 3 Randomized, Open-Label Study Comparing Pexa-Vec (Vaccinia GM CSF I Thymidine Kinase-Deactivated Virus) Followed by Sorafenib Versus Sorafenib in Patients with Advanced Hepatocellular Carcinoma (HCC) Without Prior Systemic Therapy". Pexa-Vec is currently in clinical development for the treatment of Hepatocellular Carcinoma. The proposed contained use will be the administration of the investigational product, in a hospital or clinic setting, by intratumoral (IT) injections to patients as part of an international, multicenter clinical trial. This clinical trial is a Phase III trial in patients with Advanced Hepatocellular Carcinoma (HCC) without prior systemic therapy. Results from this pivotal trial will determine whether Pexa-Vec followed by sorafenib increases survival duration in advanced HCC patients compared to treatment with sorafenib alone, and whether sequential dosing with Pexa-Vec followed by sorafenib has a favourable safety profile.

Approximately 40 clinical sites in the EU will enroll patients in the JX594-HEP024 (PHOCUS) study. Additional clinical sites in Australia, Canada, China, Israel, Korea (Republic of), New Zealand, Singapore, Taiwan, Thailand and the USA will also participate in the study. A total of 600 patients will be recruited in this clinical trial with an expectation to enroll 200 patients in EU countries. In the control arm, the 300 patients will not receive Pexa-Vec. After study completion, all patients will be followed up for survival. Among them, 300 patients (i.e. approximately 100 patients in EU) will receive Pexa-Vec by IT injections.

This is being submitted as a Connected Programme Notification, to facilitate the possibility of conducting other, future clinical trials of the same product, e.g. in patients with other cancers or in combination with other treatments.

Recipient or parental organism

Pexa-Vec is a replicative oncolytic recombinant vaccinia virus (W) derived from the commonly used vaccine Wyeth strain, DryvaxTM. W is a member of the Poxviridae family (genus Orthopoxvirus). Multiple strains of W exist that have different levels of virulence for humans and animals. The New York City Board of Health (NYCBOH) strain, from which the Wyeth strain of the Dryvax® vaccine was derived, has low pathogenicity in humans (Fenner F. et al., 1988). W has a long and extensive history of use in humans. Following injection into the skin, the virus typically establishes only a brief and limited subcutaneous (SC) infection. As W contains antigens that stimulate an immune response that are cross-reactive with smallpox antigens, the vaccine thereby confers protection from the human smallpox disease. W may cause local reactions including erythema, edema and systemic reactions such as fever and malaise, as has been observed with conventional vaccination to smallpox. During the smallpox vaccination campaign, serious complications had occurred in less than 1 in 4,000 individuals, mainly in immunosuppressed and extremely young individuals. Pexa-Vec is even further attenuated as the thymidine kinase gene has been disrupted which makes replication in normal cells more difficult than the smallpox vaccine. Rare complications included eczema vaccinatum (patients with eczema), disseminated vaccinia rash, progressive vaccinia (in T-cell-deficient individuals) and encephalitis (1-2 per million vaccinated) (Fields B.N., 1996). Recent studies of smallpox vaccines have identified cardiac injury including pericarditis and myocarditis as a potential risk (Halsell J.S. et al., 2003). W replication exclusively occurs in the cytoplasm thus eliminating any risk of integration of the viral DNA into the host genome (Moss B., 2007).

In terms of classification of hazard, W is considered as a Group 2 biological agent as per Directive (2000/54/EC). W is also classified as a Biosafety Level 2 (BSL-2) infectious substance by the US Centers for Disease Control and Prevention (CDC) (CDC, 2009) and as a risk group 2 organism by the US NIH Guidelines (NIH).

Host/vector system
Pexa-Vec was generated by co-transfection of CV-1 cells (Monkey kidney cells) with W (Wyeth strain obtained from the Center for Disease Control, Atlanta, Georgia) and the plasmid pSC65/hGM-CSF. The vector pSC65/hGM-CSF contains DNA sequences coding for the hGM-CSF and β-galactosidase proteins and for their respective promoters. In addition, the transgene sequences are flanked by two W genomic regions (TKL and TKR) that allow homologous recombination between the transfer plasmid and W.

The plasmid pSC65/hGM-CSF is generated from the plasmid pSC65 which was provided by Dr. B. Moss, National Institute of Allergy and Infectious Diseases, Bethesda, Maryland (Chakrabarti 1997). The plasmid pSC65/hGM-CSF is inserted into W. The insertion of pSC65/hGM-CSF into W can be detected by using colorimetric identification of plaques containing recombinants expressing β-galactosidase.

The pSC65 vector when provided by Dr. B. Moss contains the LacZ gene. The LacZ gene is a reporter gene, under control of the W p7.5 earlylate promoter. The additional donor gene (i.e. gene coding for hGM-CSF) is inserted in pSC65 as follows.

The plasmid pCSF-1 (No. 39754) was obtained from American Type Culture Collection and comprises the full-length cDNA for hGM-CSF (Wong 1985). The hGM-CSF gene was cloned first into the EcoR1 site of pBLUESCRIPTSK (Stratagene, La Jolla, California), generating plasmid pBLUE/hGM-CSF, and providing restriction enzyme sites to allow cloning of the hGM-CSF gene into the SalI and BgiII sites of pSC65. This positioned the hGM-CSF gene downstream of a synthetic promoter (PsE/L) designed by Dr. Moss’ laboratory to give maximal levels of transcription during both the early and late phases of vaccinia infection (Chakrabarti 1997).

Pexa-Vec contains three genetic modifications compared to the wild type Wyeth strain: 1) disruption of the viral thymidine kinase (TK) gene by 2) insertion of the human granulocyte macrophage-colony stimulating factor (hGMCSF) gene and 3) insertion of the LacZ gene. Due to the insertion of the transgenes, the TK gene is inactivated. This decreases W virulence (Buller R. et al. , 1985) by restricting viral replication to proliferating cells. This also targets dissemination of the virus to tumors (Puhlmann M. et al. , 2000).

The LacZ gene is contained in the pSC65 plasmid which was provided by Dr. B. Moss, National Institute of Allergy and Infectious Diseases, Bethesda, Maryland.

The LacZ gene encodes for β-galactosidase which is a hydrolase enzyme that catalyzes the hydrolysis of 13-galactosides into monosaccharides.

Of note, following recombination between the W and pSC65/hGM-CSF, the antibiotic resistance gene contained in pSC65 is not part of the insert. The final GMO does thus not contain any genes conferring resistance to antibiotics.

Origin & function

Pexa-Vec is non-integrative, and replicative and propagative characteristics of W have been attenuated in Pexa-Vec, which makes the virus replication dependent on actively dividing cells such as cancer cells. Therapy with a replicating virus can theoretically lead to shedding of the virus into the environment, and potentially to the public, although controls are used in this trial to minimize this occurrence. The clinical information available to date
suggests that Pexa-Vec is safe at the clinical dose of 1 x 10^9 pfu (10,000-fold higher than smallpox vaccine dose) and has not spread to caregivers in contact with the treated patients. Should shedding occur, the level of exposure would be predicted to be low compared to the doses received by patients in the proposed trial, and extremely low compared to doses of non-attenuated vaccines administered to the public (e.g. vaccines against smallpox). In addition, exposed individuals over the age of 35 will likely have been previously immunized with vaccinia. In the highly unlikely event that an exposed individual were to demonstrate virus-associated toxicity, therapy could be initiated with VIG and/or cidofovir. Therefore, public health risks with this virus are extremely low and in fact should be lower than with standard vaccination procedures. To date, no reports of transmission to health care personnel from vaccinia recipients have been published. Routine barriers nursing approaches should be used per institutional guidelines for infectious organisms (e.g. such as for M. tuberculosis, Pseudomonas).

The information regarding the risk to patient contacts and guidelines for reducing the risk of viral transmission is contained within the Participant Information Sheet and Consent Form (PISCF) and the Pexastimogene Devacirepvec (Pexa-Vec) Guidelines (provided in Appendix B of Pexa-Vec Investigator's Brochure). The PISCF will be reviewed with the patients, and their written consent will be obtained, before they undergo any study-specific procedures. A signed copy of the PISCF will be given to the patients so that they can come back to the guidelines at any time. Pexastimogene Devacirepvec (Pexa-Vec) Guidelines will be given to investigators, pharmacists, and all personnel involved in the handling of the product.

The genetic modification of the virus is not expected to result in any post-release shift in biological interactions or host range or in any known or predictable effects on non-target organisms in the environment. It is also not expected that the release of the recombinant virus would result in any increase in pathogenicity as compared to the parental virus strain and/or in any increase in the capacity to recombine with other related viruses.

Therefore, under the conditions for use in the proposed clinical trial, Pexa-Vec is not considered to represent a risk for the environment and for the public health.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Used vials, needles, gauze and syringes will be discarded into a designated, autoclavable sharps bin. This will be closed (but not locked, so as to permit steam penetration), and placed into an autoclave bag. Disposable gowns, gloves and other PPE will be discarded directly into an autoclave bag. These are labelled to indicate GM waste, and placed in a rigid, lockable container for temporary storage and transport. The research nurses associated with the trial transport the waste on a trolley to Clinical Laboratory Services, floor -1, QEHB, at a pre-arranged time, where it is decontaminated by autoclaving. Autoclaving is assumed to provide 100% inactivation of the GMM.

Is an emergency plan required according to regulation 20?

Y
The GMSC discussed the risk assessment at a meeting held on 17th May, 2016. The committee noted that the virus is based on the replication-competent, Wyeth strain of vaccinia, although the thymidine kinase deletion results in restricting virus replication to proliferating cells, such as cancer cells. It additionally expresses the human cytokine GM-CSF, which promotes immune responses, as well as bacterial beta-galactosidase. The proposed use of the virus in the trial was outlined. It was noted there was considerable experience from previous clinical trials with the agent. The virus is not shed orally or in urine. A small proportion of treated patients develop up to about 5 pustular lesions typical of vaccinia, however control procedures are in place, involving covering any lesions with dressings. Although transmission to staff has not been observed, the committee agreed that staff in identified risk groups (including pregnancy, immunosuppression, severe eczema) should be excluded when the virus is handled, and from contact with potentially contaminated materials, e.g. skin pustules. The committee agreed the risk assessment could be approved, subject to provision of some missing (non-critical) information, review and if necessary updating of SOPs, and the agreement of the consultant virologist absent from the meeting. Each of these conditions was subsequently met, and further reassurance was provided regarding exclusion of staff in risk groups when there is a risk of infection, and that the Sponsor has procedures in place to follow up and cases of potential transmission to healthcare personnel or other contacts. The BSO and Chair of the GMSC confirm approval of the risk assessment, subject to completion of Notification requirements.

Soft waste is double bagged as per infectious clinical healthcare waste guidelines, sharps waste is disposed of in plastic sharps containers which are then sealed. All waste is labelled and tagged and held in a temporary segregated waste store until removed from the relevant clinical area to the external waste store to await subsequent removal by a waste contractor. There is full traceability of the waste. For modified vaccinia virus/adenovirus/adeno-associated virus, Virkon is used according to the manufacturers guidelines which for general virus inactivation is 2%w/v. In validation studies two representative examples from the poxviridae have been tested (vaccinia and pseudocowpox virus). For vaccinia, a 10 min exposure to both 0.5% and 1% solutions of Virkon caused a 1000 folds reduction in infectious titre with complete deactivation being demonstrated at 30 minutes. For pseudo cowpox virus a greater dilution range was explored and completely deactivation was demonstrated at 30 mins exposure to 1:300 w/v solution.

Virkon is used following manufacturers guidelines. There is a colour indicator which facilitates monitoring the deactivation efficacy of the solution in use.

For activities involving GMMs, describe the waste management measures which will apply to the activity.
**Project Additional Information**

**Purposes of the contained use**

TK-8001 is a cellular therapy which is able to detect MAGE-A1 on the surface of cancer cells and destroy it. TK-8001 is created from special white blood cells, so called T cells, which are collected from a patient’s own blood and which are then being processed in a laboratory and genetically modified to recognize the tumor protein MAGE-A1. When the T cells have been modified, they will be called TK-8001, which represents the medicine. TK-8001 is a personalized drug and can only be given to the person from which the T cells derived.

The study is a combined Phase I and II clinical trial. The purpose of this trial is to test in the first (Phase I) part of the trial different dose levels of TK-8001 for the treatment of advanced-stage cancer. In the second (Phase II) part of the trial, TK-8001 is then tested at the dose identified during the Phase I part. The overall aim is to test the safety, and efficacy against cancer of TK-8001.

**Recipient or parental organism**

- human T cells

**Host/vector system**

- **Gene insert:** self-inactivated gammaretroviral-derived genome carrying as transgene the MAGE-A1 specific TCR.
- T cells get transduced with a retroviral vector particle composed of Moloney Murine Leukemia Virus (MMLV) structural proteins, pseudotyped with GaLV glycoproteins. The vector genome construct contains MMLV derived self-inactivating long terminal repeats (LTRs), as promoter driving the expression of the encoded TCR the short version of human Elongation factor 1alpha promoter (EFS), the TCR, and the posttranscriptional regulatory element of Woodchuck hepatitis virus with deleted sequence of the viral X-protein.

**Origin & function**

The anticipated mode of action of TK-8001 is to bind to MAGE-A1-expressing tumor cells and, by exploiting their cytotoxic properties as well as their ability to secrete cytokines, lead to tumor cell destruction and reduction and potential elimination of the tumor.

**Evaluation of foreseeable effects**

The expected mode of action of TK-8001 is to bind to MAGE-A1-expressing tumor cells and, by exploiting their cytotoxic properties as well as their ability to secrete cytokines, lead to tumor cell destruction and reduction and potential elimination of the tumor.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

- Not Applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

- Not Applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Culture Volume.
The maximum culture volume that could be released is one litre.

Waste Deactivation
Liquid waste will be deactivated by autoclaving (at 126 degrees C for 20 minutes), in a waste only autoclave situated in the building in which the work is carried out. Reusable materials (ie. glassware) and solid waste (ie. disposable plasticware) will be autoclaved as above.

Validation of Deactivation
After receipt of approval to start work, any liquid waste produced will not be disposed of until it has been shown that the organisms being used, E.coli (which is not genetically modified) and bacteriophage cannot be cultured from a sample of waste that has been deactivated as above.

Monitoring of Deactivation.
At periodic intervals (as deemed appropriate by the GMSC), samples of waste will be checked for deactivation as above.

Additional information.
A solution of Chloros will be kept available for dealing with any liquid spillage that may occur. The solution will be used at the concentration, and left for the time, indicated by the manufacturer, prior to the spillage being cleared up.

Project Additional Information

Purposes of the contained use
Personal protection from contamination of workers handling the transfected cells.

Recipient or parental organism
HeLa cells are derived from a human cervical adenocarcinoma. The cell line is obtainable from cell culture collections such as the American Type Culture Collection (ATCC) who advice the cell line to be handled as potentially biohazardous material under at least Biosafety Level 2 containment.

Host/vector system
The plasmid used is pIRES (described and sold by Clontech). It contains a ColE1 origin of replication for propagation as a low copy number plasmid in E. coli, the B-lactamase gene for ampicillin selection in E. coli, and the f1 origin of replication for production of single stranded DNA in E. coli. It contains the immediate early promoter of Cytomegalovirus (CMV) driving transcription of a bi-cistronic transcription unit that translates into two separate proteins by means of an internal ribosome entry site (IRES) from encephalomyocarditis virus (ECMV). An SV40 polyadenylation site directs proper processing of the resulting mRNA. Flanking the multiple cloning sites of the vector are bacteriophage T7 and T3 promoters. For G418-selection in cell cultures the plasmid holds the Neomycin resistance gene (NEO) expressed from an SV40 promoter/enhancer and 3-processing of this transcription unit is mediated by an artificial polyadenylation signal. The SV40 origin allows replication of the plasmid in mammalian cells expressing the SV40 T antigen.

Origin & function
One insert codes for human beta 2-microglobulin in its native form or in a form mutated to express a protein that will inhibit natural cytotoxic T cell responses. The second insert codes for human HLA-A*02011 in its native form. The genetic material is to be used in experiments intended for proving a principle and for patent exemplification.
The naturally occurring wild type proteins are highly unlikely to have implications for human health. Mutant B2-microglobulin is likely to have an immune suppressive effect by inhibiting CTL activity against human cells expressing the gene.

If transfected HeLa cells infect the worker handling the cells by accidental needle stick, or similar injury, and these cells evade the worker's immune system the infection may develop as a metastatic cancer and be fatal. The workers humoral immune system, however, will in all likelihood pick up and destroy these cells based on differences in the repertoire of surface proteins expressed by the HeLa cells and the cells of the worker. As an additional precaution the worker handling the cells must be tissue typed and have a significantly different tissue type from the HeLa cells being transfected.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMOs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid, and in some cases liquid, GMO contaminated waste is collected in special containers and sterilised by autoclaving at 121 degrees C for 40 minutes to give 100% kill. Autoclaved liquid waste is disposed of through the sink to public sewer. Solid waste is hereafter treated as contaminated laboratory waste and disposed through a specialist waste management company (Grundon).

The performance is monitored by labelling material with indicator tape. On a routine basis the general performance of the autoclave is monitored by its ability to sterilise multiple 1 litre batches of media used for bacterial growth. Sterilised batches of media are routinely kept at room temperature to facilitate growth and detection of contaminating microorganisms if any.

As a minimum the autoclave is checked and serviced annually by an authorised service contractor. A temperature mapping analysis of the autoclave is carried out as part of the annual service.

Liquid waste which is not autoclaved is inactivated by addition of Virkon to 1% and incubation at room temperature for at least 1 hour.

The method gives a bacterial degree of kill of 99.999%. The performance is monitored by re-plating bacterial samples and comparing scores against non-treated samples. Inactivated liquid waste is disposed of through the sink to public sewer.

CU2 Project Title
PRODUCTION OF VACCINIA VIRUS FOR EXPRESSION IN HUMAN CELL LINES OF PROTEINS INVOLVED IN IMMUNE RESPONSES

Class Class 2
Culture Volume Class 2 < 1 litre
Consent Granted not applicable

Non-GMM
Project notified under transitional arrangements N

Project Additional Information

Purposes of the contained use
Personal protection from contamination of workers handling the virus and prevention of spread to the environment.

Recipient or parental organism
In addition to endogenous proteins the parental and recipient human cell lines involved in the study will express viral proteins as well as proteins involved in immune responses.

Host/vector system
Vaccinia virus has been used for many years as a vaccine against smallpox and the possible effects of infection are well documented. The recombinant virus will be propagated in a human cell line.

**Origin & function**

The genetic material involved derive from human cell lines and represent human leukocyte antigens molecules in their native form or in a form mutated so as to have impaired CD8 binding capabilities. Expression of mutated HLA should render the infected cells less sensitive to the effect exerted by CD8-dependent cytotoxic T lymphocytes (CTLs) specific for that particular HLA molecule.

**Evaluation of foreseeable effects**

No additional hazards are envisaged by accidental infection with virus expressing wild type HLA molecules. A slight increase in immunological resistance may be observed for viruses expressing a mutated HLA molecule in individuals expressing the wild type HLA molecule from which the mutant HLA derive. Since each individual express HLA class 1 molecules from three different loci and thus between three and six different class 1 molecules depending on their degree of heterozygosity the virus will eventually be eradicated by CTLs with specificity for alternative HLA molecules and by the humoral branch of the immune system.

### Project Additional Information

- **Purposes of the contained use**: Personal protection from contamination of workers handling the transfected cells.

- **Recipient or parental organism**:

---

Page 10913 of 15326
The recipient cells to be used in these procedures will be established mammalian cell lines and will have the following characteristics: they will be negative for the SV40 large T antigen, they will be non-EBV transformed, and to the best of our knowledge, they will be free of adventitious agents.

Indirect hazards to human health associated with possible adventitious agents have been considered separately.

### Host/vector system

Gene expression for pEE14, pCDNA, pCI-neo, plRES, plRES-blasticidin, plRNEB, pCDNA6.2/GFP DEST and pGFP2 is controlled from the immediate early Cytomegalovirus (CMV) promoter. In plRES the gene transcript is translated into two distinct proteins by means of an internal ribosomal entry site (IRES) from encephalomyocarditis virus (ECMV). The pGFP2 and pCDNA6.2/GFP DEST vectors contain the green Fluorescent protein which can be fused to the C terminus of the gene to be transfected.

All eight vectors contain the SV40 origin which enables episomal replication in mammalian cells that contain the SV40 large T antigen. The recipient cells to be used in these procedures will be established mammalian cell lines and they will be negative for the SV40 large T antigen.

### Origin & function

The genetic material will be derived from tumour cell lines. The desired genes code for proteins that are expressed in tumour cells but will not include defined oncogenes. It is envisaged that the inserts will enable expression of cancer antigen proteins and result in the transfected cell presenting fragments of antigen on its surface by means of the major histocompatibility complex (MHC). The presented antigen complex would then serve as a target in cellular and/or biochemical assays.

### Evaluation of foreseeable effects

In the extremely unlikely event of the cells gaining entry to the worker via a needle-stick type injury, they would in all likelihood be rapidly destroyed by the workers’ immune system by virtue of the differences in cell surface proteins between those of the worker and the transfected cells. It is extremely unlikely that the inserted genes will endow the cells with the ability to evade the workers’ immune system.

Indirect hazards to human health associated with possible adventitious agents have been considered separately.

Mammalian cells are considered especially disabled and are unlikely to survive in the environment in the absence of strict osmotic, buffering, and nutrient conditions.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid, and in some cases liquid, GMO contaminated waste is collected in designated containers and sterilised by autoclaving at 121 degrees C for 40 minutes to achieve 100% kill. Autoclaved liquid waste will be disposed of down a sink to the public sewer. Autoclaved solid waste is hereafter treated as contaminated laboratory waste and disposed through a specialist waste management company (Grundon).

Autoclave performance is monitored by the use of autoclave indicator tape included in every run. On a routine basis the general performance of the autoclave is monitored by its ability to sterilise multiple 1-litre batches of bacterial growth media. Sterilised batches of media are routinely kept at room temperature to facilitate growth and to detect contaminating microorganisms.

On an annual basis, the autoclave is checked and serviced by an authorised service contractor. A temperature mapping analysis of the autoclave is carried out as part of...
Liquid waste which is not autoclaved is inactivated by the addition of Virkon to a final 1% concentration followed by incubation at room temperature for at least one hour. This treatment gives a bacterial kill of 99.999%. Performance is monitored by replating bacterial samples and comparing scores against non-treated samples. Inactivated waste is disposed of through the sink the public sewer.

Project Ref 742/08.1

Date Ackn'd 15/05/2008

CU2 Project Title
Retrovirus carrying genes encoding for human telomerase reverse transcriptase (hTERT) and enhanced Green Flourescent Protein (GFP).

Class 2
Consent Granted Not Applicable

Non-GMM

Consent Granted

Project notified under transitional arrangements N

Tick if notifying a connected programme of work N

Withdrawn N

Tick if notifying a connected programme of work N
Project Additional Information

Purposes of the contained use

The purpose of the contained use is to infect human cancer specific T cell clones with retrovirus containing a mini gene construct that encodes for the human telomerase reverse transcriptase protein and enhanced Green Fluorescent Protein (GFP). The introduction of human hTERT cDNA into a human T cell clone extends the life span of the clone in vitro. T cell clones containing the hTERT minigene will be used in cellular assays to test the efficacy of biological reagents.

Recipient or parental organism

The recipient cells will be human cancer-specific T cell clones and as such fall into the “Especially Disabled Hosts” category as defined in Part 2A ANNEX II of the ACGM Compendium of Guidance. These T cell clones will not be derived from the blood of any personnel working in MediGene’s cell biology laboratories. The work involving these cells will be undertaken in a Containment Level 2 facility. The cells used are to the best of our knowledge, free of adventitious agents and will be non-self cell lines that will not be able to colonise those involved with the work. Indirect hazards to human health associated with possible adventitious agents have been considered separately in a general Risk Assessment relating to work with human derived materials. All human derived samples are treated as though capable of causing disease.

Host/vector system

The MMLV vector is based on the moloney murine leukaemia virus. The amphotropic form of the virus will be used, meaning that the virus can infect mammalian cells but is replication defective and lacks more than two thirds of the viral genome. In the absence of wild type virus or gene products that provide the functions of the missing genes, the vector is unable to generate a productive infection once introduced into the cell. In addition the MMLV virions are particularly sensitive to human complement. The vector containing a mini gene construct that encodes for the human telomerase reverse transcriptase protein and enhanced Green Fluorescent Protein (GFP). Any T cell clones that are immortalised using this vector will only present a hazard to the original cell donor. T cell clones will not be derived from the blood of any personnel working in MediGene’s cell biology laboratories thus removing this potential hazard. The hTERT protein produced within infected cells can immortalise those cells. If a worker does accidentally infect themselves with the virus in all likelihood the particles will be rapidly destroyed by the workers’ immune system. Any infected cells will appear altered due to the expression of GFP or will be perceived as virally infected and destroyed by the immune system.
The aim of this work is to infect human cancer specific T cell clones with retrovirus containing a mini gene construct that encodes for the human telomerase reverse transcriptase protein and enhanced Green Fluorescent Protein (GFP). The introduction of human hTERT cDNA into a human T cell clone extends the life span of the clone in vitro, T cell clones containing the hTERT minigene will be used in cellular assays to test the efficacy of biological reagents. The GFP gene assists in the selection of positive transfectants. The inserts will confer the T cells with the ability to produce hTERT protein which can potentially render them immortal.

Evaluation of foreseeable effects

The hazards to workers and the environment posed by the vector with insert are considered negligible due to the containment level II measures employed. Skin contact with the organisms or the transfected cells will be avoided by minimizing aerosols (by working in a Class II biosafety cabinet), and by the use of gloves and safety glasses. If a worker does accidentally infect themselves with the virus, in all likelihood it will be rapidly destroyed by the workers’ immune system. MMLV virions are particularly sensitive to human complement.

Should the virus gain entry to a worker, any infected cells will appear altered due to the expression of GFP or will be perceived as virally infected and rapidly destroyed by the immune system. The routine procedures employed (i.e., autoclaving/chemical inactivation of all cellular material prior to disposal) will ensure an adequate level of safety. In the extremely unlikely event of transfected T cell clones gaining entry to the worker, the cells in all likelihood would be rapidly destroyed by the workers’ own immune system by virtue of being “non-self”. Transfected mammalian cells are considered especially disabled and are unlikely to survive in the environment in the absence of strict osmotic, buffering, and nutrient conditions.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The solid waste and the majority of the liquid waste generated during this procedure will be collected in specialised containers and sterilised by autoclaving at 121°C for 25 minutes to give 100% kill. Thermal mapping of the autoclave cycles and the use of chemical indicator strips will be used as methods of validating the autoclave sterilisation cycles. Autoclaved solid waste will be treated as Hazardous Waste under MediGene Limited’s Environment Agency Waste Registration Number; NAAOSO. The autoclaved solid waste will be disposed of via incineration through an appointed specialist waste management company; Grundon Waste Management Limited. Autoclaved liquid waste will be disposed of through a sink to public sewer. Any remaining liquid waste will be treated with an over-kill concentration of VirkonTM (2% fmal w/vol) according to the manufacturers instructions (DuPont) for which independent validated efficacy against retrovirus exists.

**Project Additional Information**

**Purposes of the contained use**

The aim of the contained work is to generate T cells with specificities to the following cells:
1. Cells expressing cancer antigens such as NY-ESO, gpIOO, MAGE A3, WT-1, p450, p53 & survivin.
2. Cells expressing viral epitopes from viruses such as human immunodeficiency virus (HIV), cytomegalovirus (CMV), Epstein Barr Virus (EMV) & human papilloma virus.
3 Cells expressing putative-immune disease antigens or in graft rejection antigens. The auto-immune diseases to be studied include but are not limited to diabetes mellitus type 1, rheumatoid arthritis, autoimmune hepatitis, & multiple sclerosis. The T cells will also express reporter genes that allow for the selection of transformants and subsequent detection in immunological assays. These include but are not limited to: Green Fluorescent Protein (GFP), Red Fluorescent Protein (RFP), dsRED and/or Luciferase genes.

The T Cell Receptors (ICR) would be either the wild type form or an isoform with one of various affinities. The Lentivirus system would allow us to derive T cell clones stably expressing the TCR of interest, or T cells transiently expressing these genes. T cell clones expressing ectopic TCR would be used in cellular assays to test antigen specific response.

Recipient or parental organism

The recipient cells will be
- a Human T cells not derived from the blood of the user
- or
- b. Fully characterised cell lines such as HT1080 fibrosarcoma cell line.

The work involving these cells will be undertaken in a Containment Level 2 facility. The cells used are to the best of our knowledge, free of adventitious agents and will be non-self cell lines that will not be able to colonise those involved with the work. Indirect hazards to human health associated with possible adventitious agents have been considered separately in a general Risk Assessment relating to work with human derived materials.

All human derived samples are treated as though capable of causing disease.

Host/vector system

Two types of vectors will be used:

Type A. Commercially acquired vectors, typically third (or even fourth) generation Lentivirus systems

Including but not limited to:
- ViraPower Lentiviral Expression systems sold by Invitrogen Ltd. The vectors are: pLenti6iVs-Directional TOPO, pLenti6.2-GW/EniGFP, pLP1, pLP2, and pLP/VSVG plasmids.
- Lenti-X Lentiviral Expression systems sold by Clontech Laboratories, Inc. The vectors include: pLVX-Puro, pLVXDsRed-Monomer-CI, Lenti-X FIT packaging system

Type B. Vectors constructed by our academic collaborators e.g. Cardiff University & University of Pennsylvania (UPenn).

These will typically be second or third generation type systems and so may lack the additional safety features of the commercially acquired systems.

Including but not limited to:
- Vectors obtained from (CardiffUniversity): pUC19-x-SQSG-2A-y shuttle plasmid, pLenti-SxW, pMD2G (VSVG envelope) and p8.91 (gag/pal/rev/tat) plasmids
- Vectors obtained from (University of Pennsylvania; UPenn): Lentiviral vector derived from the ‘Dull’ vector (Dull ci a?, J Viral 1998), and 3 packaging plasmids (gag/pal, rev, VSVG envelope) similar to that used by Zufferey (Zufferey eta?, Nat Biotech 1997)

These Lentiviral Expression Systems are second, third or fourth generation lentivirus systems. The lentiviruses can infect manirnalian cells but cannot replicate in these cells. These systems include some or all of the following safety features:

1. Expression vectors containing a deletion of the 3’ LTR (AU3) that does not affect generation of the viral genome in the producer cell line, but results in “self-inactivation” of the lentivirus after transduction of the target cell. Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing a viral particle.
2. The number of HIV-1 genes that are used in the system has been reduced to three or four only: gag, pal, tat and rev.
3. The VSV-G gene from Vesicular Stoniatitis Virus is used in place of the HIV-1 envelope protein (env).
4. Genes encoding the structural and other components required for packaging the viral genome are separated onto multiple plasmids. These plasmids have been engineered not to contain any homology regions to prevent recombination events.
5. Although the plasmids allow expression in trans of proteins required to produce lentivirus progeny in producer cell lines, none of them contain LTRs or the ‘1’ packaging sequence. This means that none of the MV-I structural genes are present in the packaged viral genome and are thus never transduced in the target cell. No new replication-competent virus can be produced.
6. The lentiviral particles produced in these systems are replication-incompetent and only carry the genes of interest.
7. Expression of the gag and pol genes has been rendered Rev-dependent by virtue of the HIV-I RRE in the gag/pol mRNA transcript.
Any T cells transduced using these vectors will only present a hazard to the original cell donor. Transduced T cells and derived T cell clones will not be derived from the blood of any personnel working in MediGene’s cell biology laboratories thus removing this potential hazard.

Origin & function

Reporter genes such as GFP, RFP and luciferase reporter genes have been used in various transgenic animal systems and have been shown to have no harmful effects on the organisms.
The TCR gene inserts encode for proteins known to be clonally expressed by T cells only. Expression of TCR by cells other than T cells renders the TCR non-functional. In the case of cancer and viral epitope-specific TCR genes, their expression in T cells would induce a response to cells expressing tumour antigens or viral antigens (including virally infected cells).
TCR genes specific for putative auto-antigens or self antigens do present a hazard to the worker performing the work but only if the worker’s own T cells were transfected to express the genes. This could result in T cells that would target normal tissue and would not be recognised by the worker’s immune system as non-self. For this reason, the use of self cells is strictly prohibited.

Evaluation of foreseeable effects

The hazards to workers and the environment posed by the vector with insert are considered negligible due to the containment level II measures employed. Skin contact with the organisms or the transfected cells will be avoided by minimizing aerosols (by working in a Class II biosafety cabinet), and by the use of gloves and safety glasses. If a worker does accidentally infect themselves with the virus, in all likelihood it will be rapidly destroyed by the worker’s immune system. MMLV virions are particularly sensitive to human complement.
Should the virus gain entry to a worker, any infected cells will appear altered due to the expression of GFP, RFP, OsRed or luciferase, or will be perceived as virally infected and rapidly destroyed by the immune system. The routine procedures employed (i.e., autoclaving/chemical inactivation of all cellular material prior to disposal) will ensure an adequate level of safety.
The extremely unlikely event of transfected T cell clones gaining entry to the worker, the cells in all likelihood would be rapidly destroyed by the worker’s own immune system by virtue of being “non-self”.
Transfected mammalian cells are considered especially disabled and are unlikely to survive in the environment in the absence of strict osmotic, buffering, and nutrient conditions.
Lentiviruses are highly susceptible to dehydration. However, they can survive for long periods in high protein media. Lentiviruses are rapidly inactivated outside the host, as illustrated by the fact that close contact is required for transmission. The lentivirus cannot replicate and so the consequences of escape are considered negligible.
Risk is effectively zero. Infected mammalian cells are not able to establish themselves and spread in nature and the vectors selected are either disabled or attenuated.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**Purpose of the contained use**

Mammalian cells are genetically modified to express full length, truncated or modified proteins of mammalian, viral or bacterial origin for use in cell-based assays or in order to purify recombinant proteins as part of the development and testing of TCR-based therapeutic proteins.

**Recipient or parental organism**

The recipient organisms are mammalian cells that can be subcategorised as either:

1. Well characterised, widely used cell lines of mammalian origin with a low risk of endogenous infection with a biological agent and that present no apparent harm to laboratory workers and which have been tested for the most serious pathogens.
2. Cell lines that harbour endogenous biological agents (including agents classified as hazard group 1 or 2) or cells that have been deliberately infected with hazard group 1 or 2 organisms.
3. Primary cells including cells isolated from blood or lymphoid cells of human origin.

**Host/vector system**

Recombinant proteins will be expressed in mammalian cells from commercially available and non-mobilisable mammalian expression plasmid vectors including but not limited to:

- pIRES/FRT Hyg, pCEP4, pCDNA3.1, pMAX, pEE14, pLRNEB, pGFP2, pEE14, pCI-neo, pIRES, pIRES-blasticidin, pIRES, and pCDNA6.2/GFP DEST.

These vectors typically consist of some or all of the following elements:

1. Antibiotic resistance genes for example genes that confer resistance to zeomycin, hygromycin and puromycin.
2. Sequences derived from viral genomes, for example gene expression may be driven by immediate early Cytomegalovirus (CMV) promoter, the gene transcript may be translated into two distinct proteins by means of an internal ribosomal entry site (IRES) from encephalomyocarditis virus (ECMV). Vectors may contain the SV40 origin to enable episomal replication in mammalian cells that contain the SV40 large T antigen.
3. Peptide or proteins tag for example vectors may contain sequences that encode Fc molecules, Green Fluorescent Protein (GFP) or to antigenic peptide sequences by means of a flexible peptide linker such as FLAG or myc-peptide which can be fused to the N or C terminus of the exogenous gene to be expressed to produce a fusion protein product.

**Origin & function**

Inserted DNA sequences covered by this risk assessment encode proteins that can be functionally categorised as:

1. Cancer antigens
2. Antigens derived from microbes such as bacteria or viruses
3. Normal and variant leucocyte proteins including but not limited to T cell receptors (TCRs), Human leucocyte antigens (HLAs), beta 2 microglobulin (β2m), and other proteins likely to be immunomodulatory.
4. Gene products with oncogenic properties (for example that has been reported in the scientific literature to confer anchorage independent growth) or oncogenes.
5. Label probes such as GFP, RFP or luciferase. Inserts that encode genes expected to confer additional hazardous properties on the GMO will be considered in detail as an additional risk assessment by the GMO committee. Inserts which are deemed to raise the class of the GM activity above 2 will not be permitted.

**Evaluation of foreseeable effects**

Primary T cells will be transfected exclusively with genes encoding TCR alpha and beta chains. These genes are known to be expressed on T cells. Although inserted TCR chains could mis-pair with endogenous TCR chains, the consequence of this are unlikely to endow transfected T cells with harmful properties.

For other cell lines, the inserted gene products also include oncogenic and immunomodulatory proteins and toxins. Although some of the proteins produced have the potential to confer harmful properties to recipient cells, these cells would in all likelihood be rapidly destroyed by the workers’ immune system, in case of accidental exposure. The constructs are incapable of infecting human cells.

The hazards related to the release of toxins and proteins with immunomodulatory properties from transfected cells is considered. Appropriate control measures will minimise the risk of worker exposure to these proteins (containment level 2, good microbiology practice, avoid the use of sharp).

The majority of the recipient mammalian cells used are to the best of our knowledge, free of adventitious agents, are purchased from reputable sources (ATCC and DSMZ). However, some of the cell lines may harbour adventitious agents such as viruses (e.g., EBV, Hazard Group 2) or mycoplasmas (Hazard group 2), resulting in some shedding into the culture medium. Indirect hazards to human health associated with possible adventitious agents are mitigated by work in containment level 2 laboratories with good microbiological safety.

These cells are non-self cell lines and targets of immune rejection of non-self tissue. It is therefore highly improbable that accidental exposure would result in survival and replication in normal healthy individuals.

Primary cell cultures are the greatest risk for human health. The potential for contamination of cells with blood-borne viruses including hepatitis B, hepatitis C, HIV, SIV and HTLV will be considered and screened for, where possible.

Workers will not conduct genetic modification work with their own cells or cells derived from other laboratory workers.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Biologically/GMO contaminated solid waste:
- Waste from class 1 activities (e.g. used agar plates), are collected in designated containers and if possible autoclaved at 121 °C for at least 20 minutes.
- If autoclaving is not possible then solid waste from class 1 activities is collected and sealed in designated bags. These bags are placed in a sealable, designated container on site and collected for proper disposal.
- Waste from class 2 activities is treated with a final concentration of 1-10 % virkon for at least 10 minutes before being drained and placed in designated containers for disposal. Virkon is drained into the public sewer via the sink.
- All solid waste incinerated by validated means through a licensed contractor.

Biologically/GMO contaminated liquid waste:
- All liquid waste (e.g. culture medium, phage supernatants, contaminated assay materials) is deactivated before disposal. This is achieved by autoclaving at 121 °C for at least 1 hour or by treatment with disinfectant.
(including but not limited to Virkon, ChemGene HLDL4, Surfamios) according to the manufacturer’s specifications. Autoclave performance is monitored by the use of autoclave indicator tape included in every run. Autoclaves are serviced annually by an authorised service contractor, as part of this service temperature mapping analysis is carried out.

**Project Ref** 742/18.2

**Date Ackn’d** 05/01/2018

**CU2 Project Title** Use of lentivirus and lentiviral vectors for expression of novel molecules in both E. coli and Mammalian cells of both primary and established cell lines.

**Class** Class 2

**Culture Vol** 1-50 Litres

**Consent Granted** Not Applicable

**Project notified under transitional arrangements** N

**Withdrawn** N

Tick if notifying a connected programme of work N

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

The use of Lentivirus transduction technology to generate cell lines, reagents, and develop assays and tools to help in screening for novel TCR molecules with high-affinity and restricted specificity. Ultimately, this will help in the generation of immunotherapeutic biologicals affecting the fields of oncology, autoimmunity, and infectious diseases.

**Recipient or parental organism**

Non-colonising/disabled *E. coli* K-12, *E. coli* B or k-strain derivatives including and not limited to: DH5alpha (NEB5alpha, Zymo 5-alpha, etc), Stbl3. Various established Mammalian cell lines as well as primary cell lines isolated from whole blood and human tissue either made in-house, or sourced from a commercial approved supplier.

**Host/vector system**

Multiple sources of vectors will be used: purchased commercially, made by collaborators, or made in-house.

Commercially acquired *E. coli*/mammalian shuttle vector plasmids, typically 3rd and 4th generation lentiviral systems, including but not limited to: ViraPower (Invitrogen), MISSION (Sigma).

*E. coli*/mammalian shuttle plasmid vectors constructed in-house or by our academic collaborators.

These will be typically 3rd generation type systems and so may lack some additional safety features of the commercially acquired systems.

Including but not limited to: plasmid vectors obtained from Andy Sewell, Cardiff University and derived from the “Dull” vector (Dull et al, J Virol 1998)

Lentiviral packaging: 3 separate packaging plasmids: (gag/pol, rev, VSVG envelope) similar to that used by (Zufferey et al, Nat Biotech 1997). Packaging envelope plasmid can alternatively express the measles F and H gene products.

In-house vector pCluedo-Lenti which is compatible with all 2nd and 3rd generation packaging vectors

**Origin & function**

The inserts (under constitutive or inducible promoters) fall into various categories and include but are not limited to:

- Native TCR molecules
- Variant TCR molecules (chimeras or containing point mutations that improve the stability and surface expression)
- Marker and reporter molecules. Including but not limited to: fluorescent proteins, luminescent proteins, antibiotic resistance proteins, and inert surface markers
- Genome editing molecules. Including but not limited to: safe integrases and recombinases, CRISPR proteins, TALEs, ZFNs
- Individual or libraries of silencing/upregulating strategies' components (siRNA, shRNA, gRNA)
- Human cancer-associated and lineage-specific genes, collectively referred to as ‘target antigens’. Inserts can include whole genes, regions of a gene, or gene fusion products. Inserts will be deemed suitable for lentiviral transduction by individual consideration.
- Genes from viruses including but not limited to hepatitis B virus, collectively referred to as ‘viral target antigens’. Inserts can include whole genes, regions of a gene or gene fusion products. Inserts will be deemed suitable for lentiviral transduction by individual consideration.
- Genes from bacteria including but not limited to Mycobacterium tuberculosis, collectively referred to as ‘bacterial target antigens’. Inserts can include whole genes, regions of genes or gene fusion products. Inserts will be deemed suitable for lentiviral transduction by individual consideration.
- Human genes associated with immune-modulation, collectively referred to as ‘immunomodulators’. Inserts can include co-stimulatory receptors, inhibitory receptors, receptor agonists, and cytokines. Inserts will be deemed suitable for lentiviral transduction by individual consideration.
- Large scale expression of excreted protein as means for production.
- Native TCR, antibodies, effector molecules; and other membrane-displayed libraries for protein selection and affinity maturation
- Cell-fate genes (aka “suicide genes”).
- Human leukocyte antigens (HLAs). Including but not limited to: classical and non-classical HLA class I, beta-2 microglobulin, HLA class I-like molecules (e.g. CD1 molecules, MR1) and HLA class II molecules. Inserts can include whole genes and gene-fusion products
- Inserts encoding short regions of viral, bacterial and human genes, including genes with oncogenic potential, collectively referred to as ‘immunogenic epitopes’
- The GMO committee will advise on which inserts will require additional risk assessment, considering of all existing control measures and whether any additional control measures are required prior to conducting work. Inserts which are deemed to raise the class of the activity above 2 will not be permitted. These are assessed and monitored on a regular basis.

**Evaluation of foreseeable effects**

**Vectors:**
Lentiviruses can infect human cells but cannot replicate in humans. The lentivirus genome randomly integrates into its host genome. This event could transactivate or alter the gene expression in the host at the site of integration. However a number of disabling mutations in the lentiviral system add to a number of safety features outlined in the section below.

**Recipient cells:**
Mammalian cells in general are considered as especially disabled hosts provided they are unable to colonise the worker (i.e. non-self) and to the best of our knowledge they contain no adventitious agents which are potentially harmful. Mammalian cells that are known to be infected with adventitious agents represent additional safety concerns. In particular the interaction of retrovirus with other members of the lentiviral family of with viruses that have different tropisms of transmission properties will be avoided.

**Marker/reporter inserts:**
Reporter genes such as GFP, have been proven to have no hazardous properties to organisms it is used in.

**Lineage-associated genes:**
Genes associated with distinct cell lineages that are not known to alter the growth status of the cell or confer any cytotoxic property are unlikely to pose a significant hazard to human health. This assertion will be supported by relevant knowledge of the function of the gene, including extensive literature review, and will not be inferred.

**Viral genes:**
Several hazards need to be considered when evaluating the risk of introducing genes from a virus into retroviral vectors. Third generation lentiviral systems are designed to be replication incompetent through the removal of non-structural components of the virus and separation of the material to be integrated from the structural components of the virus. Any gene inserted into a lentiviral system that originates from a retrovirus presents a risk of disrupting this system by effectively removing inbuilt safety features. This would increase the risk of generating replication competent virus (RCV). Genes originating from lentivirus will therefore never be used in this system.
Genes from other viruses that do not use the same mechanisms of host integration can represent significant hazards through the increased risk of altering the phenotype of
In particular, incorporation of envelope glycoproteins associated with viral entry represents an increased risk of generating virus with altered tropism and/or transmission properties and should be avoided. Viral gene base pair sequences can encode regions associated with recombination events and transcriptional control elements. This will be considered when designing viral inserts and in particular wherever possible native viral base pair sequences will be avoided. Alternative codon usage at the stage of synthesis will highlight and remove sequences prone to secondary structures and recombination events.

**Toxins, mitogens and superantigens:**
Insertion of genes that are known to produce toxins, mitogens or superantigens represent a risk to human health. These will be considered on an individual basis by additional (part B) risk assessment, inserts which are deemed to increase the class of the activity above 2 will not be permitted.

**Cancer-associated genes:**
Insertion of human, viral or bacterial genes that are known to be involved in the deregulation of cell growth or survival (proto-oncogenes and/or oncogenes) into broadly tropic retroviral systems represent a significant hazard to human health over and above the hazards associated with the recipient strain. Cancer-associated gene inserts will be carefully assessed on an individual basis, particularly for genes that have demonstrable oncogenic properties, for example src or c-myc. The risks associated with exposure to multiple oncogenes is significantly higher than that associated with a single gene, and so under no circumstances will multiple oncogenes be inserted into one vector, and multiple vectors encoding different oncogenes will not be used at the same time. Many proteins have undefined oncogenic properties and in this case will be assumed to have capacity to act directly as an oncogene.

**Immunomodulators:**
Any gene inserted into broadly tropic retrovirus that is able to modulate the immune system represents an increased risk to human health. Recipient strains that contain immunoinhibitory molecules may be able to circumvent the immune system of someone exposed to them, although the broad nature of immune defense against foreign antigen makes this unlikely. A greater risk lies in exposure of the operator to the system itself, where the likelihood of the insert contributing to systemic toxicity or autoimmune reactivity will be considered carefully. The risks associated with exposure to multiple immunomodulatory genes is likely to be higher than that associated with one gene, and so multiple genes will not be inserted into one vector, and multiple vectors encoding different immunomodulatory genes will be used at the same time with caution.

**TCR gene inserts:**
TCR genes that have been transfected into a donors T cells represent a hazard toward that donor. For this reason, scientists are strictly prohibited from working with their own cells.

**Immunogenic epitopes:**
Immunogenic epitopes do not contain sufficient genetic information to impart and altered phenotype on the recipient strain or represent a significant hazard to human health. Epitopes derived from viruses, and in particular retroviruses, will not use viral base pair sequences where possible, to reduce the risk of altering the safety systems of the lentiviral system in any way.

**Human leukocyte antigens:**
Human leukocyte antigens are essentially polymorphic (classical) and nonpolymorphic (non-classical) variants of genes expressed ubiquitously within the body and as such are unlikely to pose a significant risk to human health.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Biologically/GMO contaminated solid waste:

- Waste from class 1 activities (e.g., used agar plates), are collected in designated containers and if possible autoclaved at 121 °C for at least 20 minutes.
- If autoclaving is not possible then solid waste from class 1 activities is collected and sealed in designated bags. These bags are placed in a sealable, designated container on site and collected for proper disposal.
- Waste from class 2 activities is treated with a final concentration of 1-10 % virkon for at least 10 minutes before being drained and placed in designated containers for disposal. Virkon is drained into the public sewer via the sink.
- All solid waste incinerated by validated means through a licensed contractor.

Biologically/GMO contaminated liquid waste:

- All liquid waste (e.g., culture medium, phage supernatants, contaminated assay materials) is deactivated before disposal. This is achieved either by autoclaving at 121 °C for at least 1 hour or by treatment with disinfectant (including but not limited to Virkon, ChemGene HLDL4, Surfanios) according to the manufacturer’s specifications.

Autoclave performance is monitored by the use of autoclave indicator tape included in every run. Autoclaves are serviced annually by an authorised service contractor, as part of this service temperature mapping analysis is carried out.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

The risk assessment was reviewed by the GMO committee on 11/10/2017. It considered that the risk assessment contained sufficient risk management to justify classification of the project as class 2. It was therefore approved without additional changes.

## Project Additional Information

### Purposes of the contained use

To use the cells for cellular and molecular applications to test or carry out research activities on our novel biological molecules.

### Recipient or parental organism

The recipient organisms are mammalian cells that can be subcategorised as either:

1. Well characterised, widely used cell lines of mammalian origin with a low risk of endogenous infection with a biological agent and that present no apparent harm to laboratory workers and which have been tested for the most serious pathogens.
2. Cell lines that harbour endogenous biological agents (including agents classified as hazard group 1 or 2) or cells that have been deliberately infected with hazard group 1 or 2 organisms.
3. Primary cells including cells isolated from blood or lymphoid cells of human origin

### Host/vector system

Vector systems include but are not limited to: plasmids such as pLXSN which encode ampicillin and neomycin resistance markers and allow for stable constitutive expression of retroviral genetic material.

### Origin & function

Inserts used by different suppliers include but are not restricted to: human papillomavirus type E6 gene, HPV-16 E6/E7 or SV40 large T-antigen.

### Evaluation of foreseeable effects

The modification causes the cells acquire immortal properties by modulating a variety of pathways including but not limited to:
1) EBV transduced cells: activation of TERT, binding TNF, upregulation of anti-apoptotic pathways, promotion of cell adhesion,
2) HPV transduced cells: E6 and E7 oncogenes targeting p53 and Rb tumour suppressor proteins respectively,
3) SV40 T antigen transduced cells: inactivation of tumour suppressor genes such as p53 and Rb.

The resulting GMOs are not expected to pose any additional risks compared to wild type, as described above, and may therefore be handled at the same containment level.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Biologically/GMO contaminated solid waste:
- Waste from class 1 activities (e.g. used agar plates), are collected in designated containers and if possible autoclaved at 121 °C for at least 20 minutes.
- If autoclaving is not possible then solid waste from class 1 activities is collected and sealed in designated bags. These bags are placed in a sealable, designated container on site and collected for proper disposal.
- Waste from class 2 activities is treated with a final concentration of 1-10 % virkon for at least 10 minutes before being drained and placed in designated containers for disposal. Virkon is drained into the public sewer via the sink.
- All solid waste incinerated by validated means through a licensed contractor.

Biologically/GMO contaminated liquid waste:
- All liquid waste (e.g. culture medium, phage supernatants, contaminated assay materials) is deactivated before disposal. This is achieved either by autoclaving at 121 °C for at least 1 hour or by treatment with disinfectant (including but not limited to Virkon, ChemGene HLDL4, Surfanios) according to the manufacturer’s specifications.

Is an emergency plan required according to regulation 20? N

Tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

The risk assessment was reviewed by the GMO committee on 11/10/2017. It considered that the risk assessment contained sufficient risk management to justify classification of the project as class 2. It was therefore approved without additional changes.
**Project Additional Information**

**Purposes of the contained use**

The aim of this project is to generate Hepatitis B viral stocks which will be used to infect either cell lines or primary hepatocytes, and enable screening of Immune Mobilising Monoclonal T cell receptor against virus (ImmTAV) molecules.

**Recipient or parental organism**

Human hepatocellular carcinoma cell line HEPG2.

**Host/vector system**

Plasmid ptetHBV was created by removing the cytomegalovirus immediate-early (CMV-IE) promoter from pCMVhbv and replacing it with the tetracycline-responsive CMV-IE promoter (CMVtet) from pUHD10-3.
pCMVhbv was created by fusion of the sequence corresponding to the cDNA of pregenomic (pg) RNA of HBV, subtype ayw, to the CMV-IE promoter.

Origin & function

The Hepatitis B virus genome that has been used to stably transfect HepAD38 cells was isolated from patient serum of HBSAg sub type ayw.
Plasmid ptetHBV, which contained this construct, was co-transfected with plasmid pUHD15-1neo, which encodes the trans-acting transcriptional regulator of the tetracycline-responsive promoter and neomycin resistance. The resulting cell line was called HepAD38.

Evaluation of foreseeable effects

Insertion of the HBV genome confers harmful properties to the cell line by allowing for production of infection competent HBV. The resulting viruses are not expected to pose any additional risks over wild type HBV and may therefore be handled at the same containment level.
The tasks that will be undertaken as a part of this project are:
1. Handling of infectious cell cultures: HBV is typically transmitted via infectious fluids. The highest risk route of exposure is via percutaneous injury. The use of sharps, or working with an open wound, could allow exposure directly to the blood. Absorption/ingestion could occur following splash injuries to mouth/nose/eyes; however, infection is less likely via this route. Infection is also less likely via intact skin.
2. Centrifugation of viral material: Collapse of a tube or container during centrifugation could lead to aerosol formation due to the rapid motion inside a centrifuge. Broken plastic resulting from any such collapse may also present a sharps hazard, increasing the risk of percutaneous injury.
3. Movement of infectious material within the laboratory: Samples being moved around the laboratory pose a risk of exposure if they are dropped and their containers break. As with centrifugation, broken plastic resulting from any such collapse may also present a sharps hazard, increasing the risk of percutaneous injury.
4. Storage of infectious material: Viral stocks will be stored at -80 °C in a dedicated freezer within the Containment Level 3 (CL3) lab. Exposure to infectious virus is less likely from frozen stocks as the risk of splashing is negligible. Freezer failure could lead to thawing of the samples, which increases the risk of exposure in the event of a tube failure.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The Control of Substances Hazardous to Health (COSHH) Regulations (2002), require that CL3 laboratories are sealable in order to permit disinfection. The most common method used for such disinfection is fumigation with gaseous formaldehyde. However formaldehyde is flammable, corrosive, carcinogenic, mutagenic, and toxic and is covered by 10 hazard statements. Due to these characteristics, the Workplace Exposure Limit is 2 parts per million (2.5 mg/m3). The reclassification of formaldehyde as a carcinogen has led to its use being discouraged by the Health and Safety Executive (see Biological Agents eBulletin Special Edition, July 2015).
A common alternative to formaldehyde is hydrogen peroxide. Used either as a "wet" or "dry" fumigant, it has been commonly used in pharmaceutical environments for disinfecting clean environments, but little data exist on the efficacy of hydrogen peroxide when disinfecting areas spoiled with contaminating material. Hydrogen peroxide is also corrosive, harmful, and can cause serious eye damage. Further, as a vapour it is potentially explosive. The Workplace
Exposure Limit is 1 part per million. Although the laboratory is sealable for fumigation, the facility is derogated from room fumigation due to the following considerations:

- The inherent risks associated with fumigation using either formaldehyde or hydrogen peroxide
- Infection with HBV is less likely via the aerosol route
- No scenario exists in which routine or emergency fumigation (and the associated risks of exposure to the fumigant) is considered to be safer than appropriate spill treatment and surface disinfection.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste from the CL3 laboratory must be treated prior to final disposal. An autoclave for making waste materials safe is located in the laboratory. Robust leakproof containers will be used for storage and transport of waste for autoclaving. The autoclave is serviced every 6 months, and calibrated annually or following any maintenance work to check performance. The autoclave sterilisation cycle will be validated with biological indicators.

Disinfectants:
Sodium hypochlorite is the only disinfectant approved for use in the CL3 laboratory. Residual disinfectant is cleaned up with 70% ethanol (which is not to be considered a disinfectant). No other disinfectant should be used without seeking approval from the CL3 manager. Validation experiments of viral killing will be performed based on validation described in the literature.

Extensive literature evidence is available to support killing of HBV by ClO2:
HBV and DHBV (Duck HBV - a commonly used substitute virus), in the presence of plasma, were inactivated by 3,600 ppm NaOCl. Tsiquaye, K.N. and Barnard, J., “Chemical Disinfection of Duck Hepatitis B Virus: A Model for Inactivation of Infectivity of Hepatitis B Virus,” J. Antimicrob. Chemother. 32(2), 313–323
HBV-infected plasma samples were treated with 4,700 ppm NaOCl and a 3-4 log10 reduction was seen. Payan, C. et al., “Inactivation of Hepatitis B Virus in Plasma by Hospital In-Use Chemical Disinfectants Assessed by a Modified HepG2 Cell Culture,” J. Hosp. Infect. 47(4), 282–287 (2001).
0.1% NaOCl has been shown to deactivate HBV after 10 minutes. Memarian, M., et al., “Disinfection efficiency of irreversible hydrocolloid impressions using different concentrations of sodium hypochlorite: a pilot study.” J Contemp Dent Pract. 2007 May 1;8(4):27-34.
1% NaOCl was compared to 70% ethanol and no viral DNA was found after NaOCl treatment, but there was viral DNA found after ethanol treatment. Ito, K., et al., “Effect of ethanol on antigenicity of hepatitis B virus envelope proteins” Jpn J Infect Dis. 2002 Aug;55(4):117-21.
The use of a 1:100 and a 1:10 dilution of 5% NaOCl was tested against HBV and it was found that a 1:10 dilution (0.5% final) destroyed all viral DNA. Some viral DNA was found after treatment with the 1:100 dilution. Arami, S., et al., “Evaluation of the effect of three disinfectants on removing HBV contamination” J Dent Med. 2006 Spring;19(1):84-90

Non-contaminated general waste:
A bin or autoclave tin fitted with an autoclave bag must be used for depositing non-contaminated waste (e.g. paper towels, tissues, plastic wrapper etc.). When the bin is two-thirds full, detach the autoclave bag from the rim and place loosely inside an autoclave tin (if using a bin). Ensure that the bag is only loosely closed to admit steam freely during autoclaving. Replace the used bin with an empty one containing an autoclave bag.

Contaminated liquid waste:
Decontaminate liquid waste by adding sodium hypochlorite to a final concentration of 10,000 ppm free chlorine and leave overnight before disposal via the sink within the CL3 facility. Ensure that the solution is equilibrated before leaving it for its contact time. Label all waste with the start date and user initials to ensure all waste is appropriately decontaminated.
Contaminated solid waste:
Solid waste generated inside an MSC (such as tissue culture flasks, centrifuge tubes, microtitre plates, pipette tips, cryovials, stripettes etc.) can be disposed of either in the autoclave bag or solid container within the MSC. Once full (or when work has been completed) close the container, spray with sodium hypochlorite, and leave in the MSC for the specified contact time. Once the disinfectant contact time is over, place the waste in an autoclave tin and dispose of by autoclaving. Clean up any sodium hypochlorite residue with 70% ethanol.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The genetic modification safety committee reviewed the risk assessment and deemed it sufficient for the planned scope of the work in the project. The committee identified no further risks to consider that are not covered by the risk assessment and the control measures detailed by the risk assessment are sufficient to mitigate these risks to a reasonable level. The committee agreed with the designation of the work as requiring containment level 3.

Project Ref 742/18.5

Date Ackn’d 21/06/2018

Generation of recombinant Human Immunodeficiency Virus (HIV) containing specific mutations to develop and test engineered immune-mobilizing monoclonal T cell receptor against virus (ImmTAV) technology against HIV

Date Project Ceased

Class 3

CultureVolClass2 < 1 Litre

Consent Granted Yes
The aim of this project is to facilitate generation of HIV specific ImmTAV molecules effective against a wide range of potential viral escape variants. This will be achieved in this project by generating tools for characterisation of candidate ImmTAV molecules.

The construction of recombinant HIV variants (pre-existing and/or archived intra-patient viral variants) will allow us to test a wide range of ImmTAV molecules and enable us to investigate their respective selection pressures on virus.

From the data obtained we hope to be able to identify ImmTAV molecules of sufficient efficacy that can specifically target the regions of the viral genome least likely to induce escape mutation variants.

For cloning to generate plasmid expression clones:

Non-pathogenic laboratory E. coli strains such as DH5α (B or K12 strain derivatives) cells will be used as the cloning host to generate plasmid expression clones. These strains are disabled non-invasive bacteria that have a history of safe use and may be considered equivalent to ADCP hazard group 1.

For generation of infectious HIV particles and infection with infectious HIV particles a range of mammalian lymphocytic cells will be used. These include, but are not restricted to:

- CEM4 cells: CEM derived clone with high level of surface CD4 expression, originating from lymphoblasts isolated from peripheral blood of a female child with acute leukemia. These are well characterised and available from a commercial source.
- HEK293 cells: Primary human embryonic kidney cells transformed by sheared human adenovirus type 5 DNA. These are well characterised and available from commercial sources.
- C8166: Clone of C63/CRII-4 derived by fusion of primary umbilical cord blood cells with HTLV-1 producing line from adult T cell leukaemia lymphoma patient. Contain defective HTLV-1 genome. The cells should be handled at laboratory containment level 2. These are well characterised and available from commercial sources.
- Jurkat cells: Human T cell line isolated from an adolescent with T cell leukemia. These are well characterised and available from commercial sources.
- H9: Cutaneous T lymphocyte cell line derived from 53 year old male lymphoma patient. Clonal derivative of Hut78 cells. These are well characterised and available from commercial sources.
MOLT4/CCR5 T lymphoblast line derived from 19 year old male acute lymphoblastic leukemia patient. These are well characterised and available from a commercial source.

Primary cells, such as peripheral blood mononuclear cells (PBMCs) and subsets thereof such as CD4+ T cells and CD8+ T cell depleted PBMC.

**Host/vector system**

Standard expression plasmids will be used such as, but not restricted to, pUC18 and PDR8.

pUC18: E. coli plasmid containing the pMB1 replicon rep and the AmpR gene which confers ampicillin resistance. It also contains a fragment of the LacZ gene.

pDR8: E. coli plasmid containing the pMB1 replicon rep and the AmpR gene which confers ampicillin resistance. pDR8 is derived from pUC19, however the LacZ and LacI genes have been removed.

**Origin & function**

Multiple different plasmids will be used which contain genomic DNA encoding the HIV genome. These plasmids include, but are not restricted to:

- pNL4-3 (termed pRG1): Plasmid backbone = pUC18. Insert is a full length, replication- and infection-competent chimeric DNA derived from NY5 (5’) and LAV (3’) provirus strains. This is a widely used and well characterised molecular clone of B Clade HIV (Adachi et al. 1986). Sourced from NIBSC AIDS reagent repository.

- pNL4-3 Ba-L Env (termed pRG2): Plasmid backbone = pUC18. Plasmid is derived from pNL4-3. The insert is a full length replication- and infection competent molecular clone of HIV-1 NL4-3 with wild type envelope sequence derived from Ba-L HIV (B clade RS-tropic strain). Sourced from NIBSC AIDS reagent repository.

- pRG3: Plasmid backbone = pDR8. Derived from pNL4-3. The insert is a 5747bp fragment consisting of 155bp of cellular flanking DNA and 5592bp of DNA from HIV-1NY5 containing the 5’LTR, gag, pol and vif coding regions, and part of the vpr gene cloned into pDR8 (a derivative of pUC19). These were synthesised as whole plasmids by a commercial supplier.

- pRG4: Plasmid backbone = pDR8. Derived from pNL4-3. The insert contains a 4002bp fragment with the LAV vpr (partial), tat, rev, vpu, env and nef coding regions, 3’ LTR and 34bp of cellular DNA cloned into pDR8 (a derivative of pUC19). Green fluorescent protein (GFP) cloned in frame. These were synthesised as whole plasmids by a commercial supplier.

Transfection with both pRG3 and pRG4 is required to produce infectious virus.

Mutations and insertions will be introduced into these or similar HIV producing plasmids in order to generate infectious virus containing the relevant modifications.

**Evaluation of foreseeable effects**

The inserted genes within the generated plasmids allow the generation of infectious HIV particles when transfected into mammalian cells. The pRG3 and pRG4 plasmids must be transfected together to generate infectious virus and thus, by themselves, do not confer harmful properties. The transformation of the plasmids into E. coli will not convey harmful properties as viral protein expression does not occur in E. coli cells.

The mutations that will be introduced into the plasmids will largely be those that have been found in viral sequences in naturally infected populations and would not be expected to increase viral fitness in a human host. It is highly unlikely that genetic modification would produce variants with a higher viral fitness/replicating capacity in humans than variants from naturally infected populations. The mutation rate of the virus means that the individual changes that are deliberately introduced will almost certainly have already been present in nature. The resulting GMOs are not expected to pose any additional risks compared to wild type HIV and may therefore be handled at the same containment level.
The tasks that will be undertaken as a part of this project are:

1. Handling of infectious cell cultures: HIV is typically transmitted via infectious fluids. The highest risk route of exposure is via percutaneous injury. The use of sharps, or working with an open wound, could allow exposure directly to the blood. Absorption/ingestion could occur following splash injuries to mouth/nose/eyes; however, infection is less likely via this route. Infection is also less likely via intact skin.

2. Centrifugation of viral material: Collapse of a tube or container during centrifugation could lead to aerosol formation due to the rapid motion inside a centrifuge. Broken plastic resulting from any such collapse may also present a sharps hazard, increasing the risk of percutaneous injury.

3. Movement of infectious material within the laboratory: Samples being moved around the laboratory pose a risk of exposure if they are dropped and their containers break. As with centrifugation, broken plastic resulting from any such collapse may also present a sharps hazard, increasing the risk of percutaneous injury.

4. Storage of infectious material: Viral stocks will be stored at -80 °C in a dedicated freezer within the CL3 lab. Exposure to infectious virus is less likely from frozen stocks as the risk of splashing is negligible. Freezer failure could lead to thawing of the samples, which increases the risk of exposure in the event of a tube failure.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The Control of Substances Hazardous to Health (COSHH) Regulations (2002), require that CL3 laboratories are sealable in order to permit disinfection. The most common method used for such disinfection is fumigation with gaseous formaldehyde. However formaldehyde is flammable, corrosive, carcinogenic, mutagenic, and toxic and is covered by 10 hazard statements. Due to these characteristics, the Workplace Exposure Limit is 2 parts per million (2.5 mg/m3). The reclassification of formaldehyde as a carcinogen has led to its use being discouraged by the Health and Safety Executive (see Biological Agents eBulletin Special Edition, July 2015).

A common alternative to formaldehyde is hydrogen peroxide. Used either as a “wet” or “dry” fumigant, it has been commonly used in pharmaceutical environments for disinfecting clean environments, but little data exist on the efficacy of hydrogen peroxide when disinfecting areas spoiled with contaminating material. Hydrogen peroxide is also corrosive, harmful, and can cause serious eye damage. Further, as a vapour it is potentially explosive. The Workplace Exposure Limit is 1 part per million.

Although the laboratory is sealable for fumigation, the facility is derogated from room fumigation due to the following considerations:

• The inherent risks associated with fumigation using either formaldehyde or hydrogen peroxide
• Infection with HIV is less likely via the aerosol route
• No scenario exists in which routine or emergency fumigation (and the associated risks of exposure to the fumigant) is considered to be safer than appropriate spill treatment and surface disinfection.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste from the CL3 laboratory must be treated prior to final disposal. An autoclave for making waste materials safe is located in the laboratory. Robust leakproof containers will be used for storage and transport of waste for autoclaving. The autoclave is serviced every 6 months, and calibrated annually or following any maintenance work to check performance. The autoclave sterilisation cycle will be validated with biological indicators.

Disinfectants:
Sodium hypochlorite is the only disinfectant approved for use in the CL3 laboratory. Residual disinfectant is cleaned up with 70% ethanol (which is not to be considered a disinfectant). No other disinfectant should be used without seeking approval from the CL3 manager. Validation experiments of viral killing will be performed based on methods described in the literature.
Extensive literature evidence is available to support killing of HIV by ClO2:

Cell-free HIV-1 in cell culture medium containing 10% FCS was inactivated in 1 minute by 2,500 ppm NaOCl. No p24 was found in the cell culture supernatant. Druce, J.D. et al., “Susceptibility of HIV to Inactivation by Disinfectants and Ultraviolet Light,” J. Hosp. Infect. 30(3), 167–180

Cell-associated HIV-1 in cell culture medium containing 10% FCS was inactivated in 1 minute by 2,500 ppm NaOCl. Druce, J.D. et al., “Susceptibility of HIV to Inactivation by Disinfectants and Ultraviolet Light,” J. Hosp. Infect. 30(3), 167–180

Cell-free HIV was reduced by 3-4 log10 using 50 ppm NaOCl when no plasma was present, and 2,500 ppm NaOCl in the presence of 10% plasma. Equal volumes of 10,000ppm NaOCl and whole blood produced total killing within 2 minutes. Bloomfield, S. F., et al., “Evaluation of hypochlorite-releasing disinfectants against the human immunodeficiency virus (HIV),” J Hosp Infect. 1990 Apr;15(3):273-8.

Non-contaminated general waste:
A bin or autoclave tin fitted with an autoclave bag must be used for depositing non-contaminated waste (e.g. paper towels, tissues, plastic wrapper etc.). When the bin is two-thirds full, detach the autoclave bag from the rim and place loosely inside an autoclave tin (if using a bin). Ensure that the bag is only loosely closed to admit steam freely during autoclaving. Replace the used bin with an empty one containing an autoclave bag.

Contaminated liquid waste:
Decontaminate liquid waste by adding sodium hypochlorite to a final concentration of 10,000 ppm free chlorine and leave overnight before disposal via the sink within the CL3 facility. Ensure that the solution is equilibrated before leaving it for its contact time. Label all waste with the start date and user initials to ensure all waste is appropriately decontaminated.

Contaminated solid waste:
Solid waste generated inside an MSC (such as tissue culture flasks, centrifuge tubes, microtitre plates, pipette tips, cryovials, stripettes etc.) can be disposed of either in the autoclave bag or solid container within the MSC. Once full (or when work has been completed) close the container, spray with sodium hypochlorite, and leave in the MSC for the specified contact time. Once the disinfectant contact time is over, place the waste in an autoclave tin and dispose of by autoclaving. Clean up any sodium hypochlorite residue with 70% ethanol.

Is an emergency plan required according to regulation 20? [N]  
If yes, tick to confirm that it is attached to this form [N]  
Tick to confirm that you have attached a risk assessment to this form [Y]  
Tick if you are claiming exemption from disclosure for section of the risk assessment [N]  

Please enter comments on the GM safety committee on the risk assessment
The genetic modification safety committee reviewed the risk assessment and deemed it sufficient for the planned scope of the work in the project. The committee identified no further risks to consider that are not covered by the risk assessment and the control measures detailed by the risk assessment are sufficient to mitigate these risks to a reasonable level. The committee agreed with the designation of the work as requiring containment level 3.

**Project Ref** 742/21.1

- **Date Ackn’d**: 09/07/2021
- **CU2 Project Title**: Use of mycobacterium bovis BCG-GFP to assess TCR potency against infected monocytic cells

**Class Culture**

- **Class**: 2
- **Culture Volume**
  - **Class 2**: ≤ 1 Litre
  - **Class 3-4**: Non-GMM

**Consent**

- **Consent Granted**: Yes

**Historical Significant Changes**

- **Historical Date of Additional Info**: N

**Project Additional Information**

**Purposes of the contained use**

Mycobacterium bovis BCG-GFP will be used to infect monocytic cells and test whether TCRs recognise these antigen presenting cells. A strain of the mycobacterium bovis BCG with a GFP reporter will be used to measure uptake of the organism by monocytic cells and evaluate BCG infection efficiency.

**Recipient or parental organism**
Mycobacterium bovis BCG vaccine strain.

Host/vector system

Plasmid pSMT1 carrying the gfp gene of jellyfish, cloned under the control of the BCG heat shock protein-60 (hsp60) promoter on a mycobacterial shuttle vector (pOLYG) BCG that has had HspR gene, or other genes, replaced with a defective copy of the gene using a non-replicating “suicide” vector. Selection of mutants is using the hygromycin gene from Streptomyces hygroscopicus that replaces the HspR gene and allows selection of recombinants in which a double cross over event has resulted in exchange with the wild type gene (Husson et al 1990, J. Bacteriol 172: 519-24: Garbe et al Microbiology 140: 133-8).

Origin & function

M. bovis BCG is the vaccine strain that has been used extensively in humans. This BCG-GFP strain we intend on using was developed by Professor Young (https://www.ncbi.nlm.nih.gov/pmc/articles/PMC96782/). We will be using it as received and not be modifying the strain any further. Inclusion of GFP into M. bovis-BCG has been shown not to increase their virulence or effects on how they effect cytokine production or surface molecule expression by antigen presenting cells in vitro (Luo et al 1996 Clin Diag Lab Immunol 3: 761-8).

Evaluation of foreseeable effects

BCG as the established vaccine strain for human use is avirulent and no effect on virulence is foreseen.

The production of BCG-GFP will be at other establishments as detailed by Professor Young (https://www.ncbi.nlm.nih.gov/pmc/articles/PMC96782/). Inclusion of GFP into M. bovis-BCG has been shown not to increase their virulence or effects on how they effect cytokine production or surface molecule expression by antigen presenting cells in vitro (Luo et al 1996 Clin Diag Lab Immunol 3: 761-8).

The organisms will be handled as ACDP category 2 pathogens for all experiments thus reducing the potential of environmental exposure to negligible.

They will be handled in the tissue culture hoods and no procedures have the potential to generate aerosolised bacteria. The risk of inhalation therefore is extremely low.

A Code of Practice for working within the CL2 laboratory at IMC has been written. It details protective and containment measures, including general working arrangements, access controls, training procedures, emergency procedures, health surveillance, disinfection and waste management and decontamination processes.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste (mainly plastic disposable) will be placed in burn bins and incinerated using a licensed incineration facility.

All liquid waste resulting from bacteriological procedures involving the propagation, disruption and analysis of the GMO will be treated with Virkon tablets to a final concentration of greater than 1% (weight/volume). Virkon is recommended by the manufacturer for the treatment of liquid waste. Detailed information is available at www.antechh.com. Laboratory benches and equipment will be wiped down with 1% (weight/volume) Virkon solution or where this is inappropriate a solution of 70% ethanol in water on absorbent paper and then paper will be disposed of as solid waste. Spills will be treated with Virkon as above and soaked up on absorbent paper, and treated as solid waste.
Pipettes and similar objects, as well as work surfaces will be disinfected, and surfaces wiped, with virkon disinfectant and ethanol.

The reporter gene (GFP) is well-characterised with no known associated health hazards.

M. bovis BCG is a difficult strain to maintain in the laboratory, with very specific culture methods. Mycobacteria are also sensitive to UV light. If inadvertently M. bovis BCG is introduced to the environment, it is unlikely that the organism will survive.

- **Tick if confidential**
Liquid waste is inactivated by Precept or Lifeguard diluted and used in accordance with the manufacturer's instructions. Information indicates that these treatments result in a kill of greater than 5 log10 for bacteria and greater than 99% kill for mammalian viruses. Taking into account the disabled nature of the hosts and vectors used, it is considered that these treatments are effective in providing a high level of protection to humans and the environment. The maximum culture volume used at any time is normally < 1 litre but will not exceed 10 litres. Solid waste is autoclaved at 121°C, 1 bar for 30 mins. The autoclave is serviced and validated at least once per year. Equipment and benches are decontaminated with Precept, Lifeguard or 70% ethanol.
Replication-defective adenovirus type 5 (Ad5) based vectors will be used to deliver genes of interest to mammalian cells in tissue culture and their expression will be studied in order to determine their possible roles in immune cell regulation.

The inclusion of marker genes (such as GFP or lacZ) in the constructs will principally permit the efficiency of virus infection to be evaluated, and enable the sorting of populations of cells expressing the immune regulatory genes.

Gene sequences from both human and murine sources will be cloned into the virus vectors.

Recipient or parental organism

Recipient or parental organism

Host/vector system

Human adenovirus type 5 vectors, constructed in *Escherichia coli* K12 using the commercially available AdEasy system, will contain the gene sequences of interest cloned behind the cytomegalovirus (CMV) or Ubiquitin (UB-C) promoters. These promoters are not active in bacterial hosts. Adenoviral vector DNA will be isolated and used to transfect mammalian 293 cells (human embryonic keratinocytes which have been transformed with the adenoviral E1 gene). Virus plaques will be picked and virus released into tissue culture media by repeated freeze/thawing. Virus titres will then be amplified by re-infection of 293 cells and purified before being used to infect a number of both primary and established mammalian cell lines. Gene expression will be transient since the vector is replication-defective. The effect the gene of interest has on cell function and the expression of cellular genes will be evaluated by analysis of cellular protein and RNA.

The adenovirus vectors to be used are replication-defective by virtue of the deletion of E1 and E3 genes. The replication of such adenovirus vectors is supported only by certain specifically engineered cells lines, such as 293 cells (the propagating cell line), which have been transformed to express the E1 gene product, and thus complement the virus replication in trans. However, other cell lines do not express this E1 gene product naturally, and thus do not support the replication of the virus. This substantially reduces any risk of infection posed by this virus, and thus will limit any potential damage that could be caused to human health by this virus. Additionally, should the adenovirus vectors enter the body, a high percentage of the population have a pre-existing anti-adenovirus humoral response which would prevent the virus from infecting cells, but should cell infection occur, an immune response would be mounted against viral-encoded proteins that should eliminate the infected cells.

It is known that the viral DNA cannot integrate into the genome of human cells.

Human adenovirus type 5 does not naturally infect wild animals or plants. It is pathogenic to cotton rats and mice only when delivered at very high doses via the intravenous, intraperitoneal or intranasal route. The inclusion of either the reporter gene or the immune regulatory genes is not expected to alter the tropism or infectivity of the virus.

Origin & function

Genes encoding Notch receptors, ligands and other related genes of interest will be derived from human and murine genomic DNA or CDNA sources. These genes are
widely expressed in mammals and are involved in cell signaling pathways, particularly in embryonic and adult immune tissues, such as thymus and cellular components of bone marrow. The exact roles of these genes in immunological tolerance remain to be elucidated. We therefore intend to express these genes in mammalian tissue culture systems with the aim of investigating their function within immune cell regulation, with a specific interest in understanding the induction of the state of tolerance.

We initially intend also use the marker gene encoding green-fluorescent protein (GFP), originally derived from the anthazoan Renilla reniformis, and sub-cloned from a commercially available source (pIRES-hr-GFP-1a, Stratagene). This reporter gene will be co-expressed with the immunological regulatory genes of interest during transfection, and will be used as an indicator of transfection efficiency. Additionally, under some circumstances, the GFP construct may be used as a reporter gene to quantify the effect of the test gene product on certain target sequences. Other marker genes, such as beta-galactosidase (lacZ) or luciferase, may also be used.

**Evaluation of foreseeable effects**

Cells expressing full-length Notch ligands could potentially deliver a tolerogenic signal to the immune system, particularly if MHC molecules are being expressed by the same cells and are thus capable of antigen presentation. Transplantation models have shown that the development of tolerance to foreign cells requires the processing of target cells and indirect antigen presentation, as opposed to direct presentation of antigen from transplanted cells. Therefore, since cells used for in vitro infection experiments will not be histocompatible with the operator, it is very unlikely that the tolerant phenotype would develop without the processing of cellular antigens and a high dose of soluble Notch ligand. This risk is further reduced by the use of replication-deficient adenovirus vectors, which are considered to be unable to deliver a pharmacologically relevant dose, thereby further minimising the risk to human health.

Notch and its ligands are known to be important in embryonic development and thus consideration must be given with relation to the potential effects on the developing foetus. A limited amount of transgenic data has shown that the phenotypes of Notch and Notch-ligand-deficient mice are characterised by abnormal embryo development and death in utero. However, despite this, the moderate level of expression generated by the adenovirus vector systems described here, are considered to be unable to deliver a pharmacologically active dose, and no significant hazard is anticipated.

There is a minimal risk that the replication-deficiency could be complemented in vivo, should an accidental infection of the test Ad5 virus particles coincide in the same cell with a natural infection of wild-type adenovirus. As no wild-type adenovirus will be used or cultured in the laboratories, the changes of this occurring are considered to be very low. However, giving consideration to the fact that the exact function of some of the genes of interest is not fully understood, steps will be taken to minimise the exposure of operators to aerosols of Ad5 virus particles. This will entail concentrated suspensions of virus particles being contained within sealed tubes, which will be opened only inside a Class II Biological Safety cabinet, by using centrifuge rotors with sealed lids to contain any possible aerosols, and by limiting the personnel involved in the project only to those with relevant experience. When using diluted virus stocks, the risk of such coincident infect diminishes, and thus it is considered that work with diluted virus, such as analysis by ELISA, FACS or western blotting, could be carried out under Level 1 containment.

Marker/reporter genes will be moderately expressed and are not expected to be a hazard to health. If accidental user infection occurs, the virus would be unable to replicate unless the user is co infected with wild type virus. As wild-type virus is not used in the building the likelihood of co-infection is minimal, and would only occur from the wild-type virus present naturally in the atmosphere. The tropism of the virus will not be altered by inclusion of the reporter gene and it is not anticipated to affect the ability of the virus to infect cells. The reporter gene, is therefore not anticipated to pose any significant risk to human health.

Consequently, in terms of the general risk to human health, the use of replication-defective adenovirus vectors is considered to substantially reduce any significant risk, but that this will be further reduced by the containment measures proposed.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
Prior to disposal, all liquid waste, including mammalian cell culture media, will be decontaminated using a proprietary liquid anti-viral agent, such as Virkon or Trigene, used in accordance with the manufacturers instructions. Such products have been proven by independent studies to be highly virucidal against adenovirus, and are widely used in laboratories and health-care settings.

Small liquid spillages will be treated with a liquid anti-viral disinfect; larger spillages will be treated by applying solid and anti-viral disinfectant, in accordance with the manufacturers instructions, before cleaning.

Solid waste, including contaminated plastics, will be double-bagged in strong autoclave bags, placed in a leak-proof container with a lid and autoclaved at 121°C for 30 min. The autoclaved waste will then be sealed into a strong plastic bag and disposed of by incineration.

Re-usable items, such as glassware or centrifuge tubes and certain small equipment, will be swabbed down or soaked in a proprietary liquid anti-viral agent, as appropriate.

Should the use of any sharps by necessary, these will be placed directly in a sharps bin. Full bins will be sealed into a strong plastic bag prior to disposal by incineration.

Inner surfaces of safety cabinet will be cleaned with a proprietary liquid anti-viral agent after each use, and before commencing any servicing to the interior of the unit, the cabinet will be disinfected by formaldehyde vapour treatment.

No virus particles or cells are expected to remain viable after these treatments.

The circumstances under which replication-competent adenovirus might become infectious by fortuitous co-infection with wild-type adenovirus were discussed. Although considered to be highly unlikely, it may be possible that a pharmacologically-active dose of Notch or Notch-ligand could be delivered should such an infection occur. Since such co-infection would be most likely to result from inhalation of aerosols of concentrated virus suspensions, it is recommended that safety cabinets be used when handling open containers of concentrated virus samples, and that additional measures be taken to minimise aerosol generation during centrifugation. However, since the likelihood of co-infection will decrease with virus dilution, protocols such as ELISAs, FACS, Westerns etc using diluted or denatured virus may take place on the open bench, provided that appropriate disinfection measures are taken.

Where Level 2 containment is appropriate, the existing labs were confirmed as suitable for this level of containment, with the following actions: Access to be restricted to lab personnel, and a statement to be made to all staff making them aware that Level 2 work may be carried out in the laboratories; Existing disease control measures were considered adequate, as long as windows are kept shut - heat extraction for the FACS machine to be fitted; Written specific disinfection procedures to be drawn up and displayed in the lab.

ACGM training records should be established for all lab personnel, and that for new starters this should be included in the Starter pack. General Level 2 training will be given at a lab meeting. Individual personnel will be trained regarding the individual Risk Assessments are required when starting work on the individual projects.

<table>
<thead>
<tr>
<th>Purposes of the contained use</th>
</tr>
</thead>
<tbody>
<tr>
<td>To develop new purification strategies for retroviral gene therapy vectors.</td>
</tr>
</tbody>
</table>

**Recipient or parental organism**

- BL15 cell line: expressing non-viral protein LNGFR
- Bio-lentivir a second generation lentiviral packaging cell line
- K562 and TE671 cell lines (not GMOs)

**Host/vector system**

- Packaging plasmid (pCMV-deltaR8.91) which encodes structural proteins (not env gene)
- Envelope plasmid (pMD.G) which encodes envelope gene VSVg
- Replication deficient lentiviral expression vector with a GFP gene (pHR'SINctwSVGFP/LV.gfp)

**Origin & function**

**Vectors**

- Packaging plasmid (pCMV-deltaR8.91) encodes the genes for HIV structural proteins involved in vector packaging (except the env gene which encodes for the infection of T cells).
- Envelope plasmid (pMD.G) which encodes envelope gene VSVg. This enables the replication defective lentiviral vector to infect a range of cell lines beyond the capabilities of the HIV parent which is limited to T cells.
- Replication deficient lentiviral expression vector with a GFP gene (pHR'SINctwSVGFP/LV.gfp) does not contain the genes for HIV structural proteins and is unable to make virus particles without the packaging cell line.

**Recipients**

- K562 and TE671 cell lines are for infectivity testing but are not able to synthesise virus particles when infected with the replication deficient lentiviral expression vector.

**Packaging cell lines**

- BL15 cell line: expressing non-viral protein LNGFR encodes the non-viral protein LNGFR to assist co-pckaging lentiviral vectors. For use in synthesising the replication deficient lentiviral expression vector.
- Bio-lentivir a second generation lentiviral packaging cell line which contains no auxiliary genes. For use in synthesising the replication deficient lentiviral expression vector.

**Evaluation of foreseeable effects**

- Infection of a laboratory worker with the replication deficient lentiviral expression vector may result in incorporation of the green fluorescent protein (GFP) into the cells of the worker. This may cause localised fluorescence. If the insertion is into a part of the chromosome which encodes genes that control cancer cell proliferation it could feasibly lead to the formation of a tumor though the probability of this occurring is very low.

- There is a very low probability that the replication deficient lentiviral expression vector could incorporate the genetic material present in the packaging and envelope plasmids creating a replication competent lentivirus.

- Both of these low probability foreseen events require containment by the use of containment level 2 procedures.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

- Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All materials are steam sterilised in a calibrated autoclave for 20 minutes at 121 degrees C. Solid waste is then incinerated.

Please enter comments on the GM safety committee on the risk assessment

It was noted that the lentivirus carries a slightly higher risk than the retroviruses used previously. Philip Oliver advised the committee that this is a standard vector not thought to present any unusual problems, but that work should always need to be carried out in a microbiological safety cabinet as specified in the assessment documentation. The project was accepted by the committee as class 2.

**Project Ref** 747/08.1

**Date Ackn’d** 31/01/2008

**CU2 Project Title** Enhancing and scaling-up chromatography based purification technology and showing its utility for the manufacture of clinical lentivirus for gene therapy. The work will include cultivation of gene therapy vector, purification and subsequent infectivity testing in mammalian cell cultures.

**Class** Class 2

**CultureVolClass2** < 1 Litre

**Non-GMM** Consent Granted: Not Applicable

**Project notified under transitional arrangements** N
To develop new purification strategies for lentiviral gene therapy vectors by removing the biotin requirement as a tag, and instead using a precursor in E.coli 7,8-diaminopelargonate (7-DAPA) that does not bind streptavidin, but can be synthesised into a low-affinity desthiobiotin.

Recipient or parental organism

1. BL15 cell line: modified 293T (human embryonic kidney cell line)-derived cell line which expresses non-viral protein LNGFR-BAP.
3. Human chronic myeloid leukaemia cell line (K562) and human rhabdomyosarcoma cell line (TE671) (not GMOs).

Host/vector system

Lentiviral vectors based on replication disabled HIV.
1. Packaging plasmid (pCMV-deltaR8.91) which encodes structural proteins (not env gene).
2. Envelope plasmid (pMD.G) which encodes envelope gene VSVg.
3. Replication defective lentiviral expression vector with a GFP gene (pHR'SINctwSVGFP/LV.gfp.)

Origin & function

Vectors:
Packaging plasmid (pCMV-deltaR8.91) provides the elements required for vector packaging such as structural proteins, HIV genes (except the gene env which encodes for infection of T cells), and the enzymes that generate vector particles. Envelope plasmid (pMD.G) encodes the envelope gene VSVg. This increases the range of cells the replication-defective lentiviral vector can infect, beyond the capabilities of the HIV parent which is limited to T cells. Replication defective lentiviral expression vector with a GFP gene (pHR'SINctwSVGFP/LV.gfp) does not contain the genes for HIV structural proteins and is unable to make virus particles without the packaging cell line.

Recipient:
K562 and TE671 cell lines are for infectivity testing but are not able to synthesise virus particles when infected with the replication deficient lentiviral expression vector.

Packaging cell lines:
BL15 cell line: expressing non-viral protein LNGFR-BAP and metabolically producing ligand-tagged replication deficient virus that can be efficiently captured and eluted from an affinity absorbent in a concentrated, purified form. BL15 based lentiviral packaging cell line: constructed by insertion of a gene to express bacterial bioD into BL15. The desthiobiotin synthase bioD is naturally present in E.coli and simply allows a more practical route to the incorporation of desthiobiotin into the virus envelope than that permitted by BL15.
Infection of a laboratory worker with the replication deficient lentiviral expression vector may result in incorporation of the green fluorescent protein (GFP) into the cells of the worker. This may cause localised fluorescence. If the insertion is into a part of the chromosome which encodes genes that control cancer cell proliferation it could feasibly lead to the formation of a tumour though the probability of this occurring is very low.

There is a very low probability that the replication deficient lentiviral expression vector could incorporate the genetic material present in the packaging and envelope plasmids creating a replication competent lentivirus.

Both of these low probability forseen events require containment by the use of containment level 2 procedures.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None.

This project involves a new cell line currently being constructed at Kings College Hospital. The application papers for the project were discussed at a meeting of the Biological Safety Committee for the Department of Chemical Engineering. It was agreed that, although the disables virus has a negligibly small chance of re-acquiring replication competence by recombination with endogenous lentiviral elements, it might nevertheless be a sensible precaution to additionally ban the use of sharps in the CL2 laboratory. This measure will ensure that needle-stick injuries to any workers who may harbour lentiviral elements in their genome will be completely avoided. The Committee agreed to accept the project at GM Class 2, with the provision that sharps should not be used in the CL2 lab.

Page 10972 of 15326
Formulation of live bacterial vaccines for storage and delivery, using human live bacterial vaccine strains that have been previously tested in humans and shown to be safe, such as Salmonella Typhi CVD908-htrA and Shigella dysentariae SC599.

The attenuated bacterial vaccines to be used (e.g. Typhoid fever and Dysentery vaccines) are derived from parental organisms that were human pathogens. However, these parental organisms have already been disabled and attenuated by stable removal of two or more essential genes. Because the essential genes have been stably removed, there is no possibility of workers being exposed to the fully pathogenic parental organisms. Note that because stably attenuated non-pathogenic strains are to be used, Schedule 5 of the Anti-terrorism, Crime and Security Act 2001 does not apply.

No further genetic modification will be conducted in this work- only existing stably attenuated vaccine strains will be used. In cases where non-pathogenic experimental antigens are included, they will be contained within conventional plasmid systems such as the pUC bacterial plasmid vector.

Recipient or parental organism

The attenuated bacterial vaccines to be used (e.g. Typhoid fever and Dysentery vaccines) are derived from parental organisms that were human pathogens. However, these parental organisms have already been disabled and attenuated by stable removal of two or more essential genes. Because the essential genes have been stably removed, there is no possibility of workers being exposed to the fully pathogenic parental organisms. Note that because stably attenuated non-pathogenic strains are to be used, Schedule 5 of the Anti-terrorism, Crime and Security Act 2001 does not apply.

Host/vector system

No further genetic modification will be conducted in this work- only existing stably attenuated vaccine strains will be used. In cases where non-pathogenic experimental antigens are included, they will be contained within conventional plasmid systems such as the pUC bacterial plasmid vector.
No further genetic modification will be conducted in this work—only existing vaccine strains will be used. The host organisms will have genes deleted permanently to render them attenuated. Polypeptides may be included within some vaccine strains as experimental antigens, e.g. non-pathogenic protective antigens from pathogens. Only antigens already tested independently in humans and shown to be safe will be used.

**Evaluation of foreseeable effects**

The vaccine strains used will have been permanently genetically modified and attenuated by stable mutation of disease-causing genes. Subsequently, the strains have been tested in clinical trials in human volunteers and shown to be safe for oral infection as vaccines. Since there is no risk of reversion of the mutations to a pathogenic strain it is not possible for workers to be exposed to a disease causing strain. Vaccine strain samples will be obtained from reliable sources where the strain is stored in strictly defined and controlled stocks, and kept separately from the original pathogenic strain, to eliminate any possibility of obtaining a pathogenic sample.

One potential hazard would be accidental infection of workers; bacterial vaccine strains are infectious by the oral route. This is unlikely, since good microbiological practice and observation of containment level 2 procedures will prevent the exposure of workers to the live organism in any form. No work with sharps is permitted in the facility. Furthermore, the consequences of accidental infection are known to be low, since the strains have been tested previously in human volunteers and deliberate infection by oral administration of live vaccine to volunteers has been shown independently not to result in significant disease. Furthermore, should any unforeseen symptoms develop following accidental infection, bacterial vaccine infection can be treated with antibiotics.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Waste materials will be steam sterilised within the facility in a calibrated waste autoclave for at least 20 minutes at 121 degrees centigrade. This will achieve effectively 100% kill. Solid waste is then incinerated. Liquid waste will additionally be inactivated using the disinfectant Virkon-S in accordance with the approved written protocol within the facility.

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

All work approved subject to the following condition:

All work with dried vaccine samples must be conducted within the dedicated vaccine suite of the containment level 2 facility in the CUBE laboratory.

**Project Containment**
Transduction of mammalian neuronal cell line cultures (SH-SY5Y) and rat primary neuronal cultures (hippocampal, dopaminergic neurons by 3rd generation lentiviral vectors

Neuronal cells are difficult to transfect successfully, the lentiviral delivery system will increase transfection efficiency. In this work a 3rd generation lentiviral system will be used to deliver nucleic acids into cells for the expression of fluorescent probes for measuring intracellular molecules (ATP, H2O2, Ca2+ etc.) or processes (synaptic vesicle rupture/fusion), as well as expression of proteins involved in Alzheimers’ and Parkinsons’ diseases which include, but are not limited to, α-synuclein, tau, amyloid-β and their mutants. The transfected cells will be imaged for analysis of molecular pathways of disease.

E. coli Stbl3 (NEB) - for cloning genes of interest into transfer plasmids and plasmid purification.
Human embryonic kidney cells HEK-293T - cells to produce virus
Mammalian neuronal cell line SH-SY5Y - cells to transfect for experimental analysis
Primary neuronal cultures of hippocampal and dopaminergic cells from wildtype Sprague-Dawley rats - cells to transfect for experimental analysis
3rd generation lentivirus plasmids: Contain three of the nine essential genes for the replication of HIV-1 viruses in vivo split across three plasmids, therefore making the 3rd generation of lentivirus replication defective and self inactivating (SIN).

pMDLg/pRRE - contains gag and pol genes as well as the RRE recognised by the Rev protein. The gag genes encode proteins to form the matrix, capsid and nucleocapsid of the virus. The pol genes encode reverse transcriptase and integrase proteins.

pMD.2 - contains the genes encoding proteins to form the glycoprotein envelope of the virus.

Transfer plasmid based on pLJM1-EGFP containing the gene of interest.

All purchased from Addgene.

Genes of interest cloned into the transfer plasmid include:

- Fluorescent proteins (FP), including probes to measure intracellular molecules such as ATP, H2O2, Ca2+ or changes in cellular environments, such as pH.
- Genes involved in Alzheimers' and Parkinsons' including, but not limited to, α-synuclein, tau, amyloid-β and their mutants which are involved in disease.
- Optogenetic genes, such as channelrhodopsin, to allow light controlled activation of cellular processes in neurons.

No genes will be used that are oncogenic or can cause advantageous modifications to the transfected neuronal cells.

Evaluation of foreseeable effects

Risks include the potential to generate replication competent lentiviruses (RCL), however the genes required to make the viruses are split into four plasmids, greatly reducing the possibility of RCL occurring. To date no RCL have been reported for 3rd generation lentivirus vectors (Cornetta, et al., Mol Ther. 2011). To test for replication incompetent lentivirus, supernatant from the transduced cells will be taken and incubated with other non-virus infected cell lines to determine whether the lentiviruses are replication incompetent. The non-virus cell lines should not be transduced with the supernatant from the transduced cells.

No oncogenic genes will be inserted or used in the production of the lentiviruses.

The viruses formed using the 3rd generation lentivirus vector system are capable of infecting human cells, however with proper handling and correct PPE infection should not occur. The gene of interest delivered by the lentivirus would not have an advantageous effect on any infected cell. The viruses are not capable of replication therefore can not spread from person to person. No patient derived cells will be used, excluding the risk of vector recombination in cells of HIV-positive, virus-negative patients.

With correct disposal the lentiviruses pose no risk to the environment.

Evaluation of foreseeable effects

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste and solid waste will be decontaminated with 1% Virkon for at least 12 hours and liquid waste disposed of down the drain. 1% Virkon is commonly used as an effective disinfectant to inactivate viruses and bacteria (Hernandez, et al., J. Hosp. Inf. 2000). Solid waste will subsequently be autoclaved (126 degrees celsius, 30 minutes, >2 bars pressure) and disposed of. 70% ethanol will be used to clean metallic surfaces and and imaging equipment in contact with lentiviral contaminated supernatant. Both 1% Virkon and 70% ethanol have a 100% kill expectancy rate.
Project borderline GM Class 1/2, safer to be designated GM Class 2.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Waste Management: All waste is class 1. Media and plates containing GMM are inactivated by autoclaving in open bags at 123°C, 1 hour. This process has been validated by monitoring the penetration of steam using ‘safety strips’ and by taking autoclaved cultures and streaking onto non-selective plates to look for any surviving GMM. The kill rate for this process is 100%. Autoclaved waste is removed, in sealed bags, by S.Grundon (Waste) Ltd (Lakeside Road, Colnbrook, Berks SL3 0EG) and incinerated. Waste media, from which GMMs have been removed, is treated either by autoclaving as above, or by treatment with 2% w/v Virkon followed by overnight incubation, before disposal down the sink.

Culture volumes: Cultures are grown on a litre scale, with a maximum capacity of 30 litres. Release into laboratory areas is considered highly unlikely as the incubator is equipped with a drip tray to effectively contain spillages internally. Centrifugation is carried out in sealed bottles and again any spillages are effectively contained within the closed system. The most likely cause of release would be the dropping of flasks by personnel so making the maximum release likely to be one litre culture. This volume of culture would be decontaminated using 2% w/v Virkon followed by autoclaving all contaminated paperware. Personnel are required to wear a lab coat and gloves at all times which provides adequate protection against class 1 GMM. In addition a class 2 cabinet has been provided for additional safety. Release into the environment is considered to be highly unlikely when considering the procedure outlined above. In addition non mobilisable vectors and disabled host cells are used with expressed products not conferring a pathogenic phenotype, so accidental release would be unlikely to pose any environmental risk or risk to human health.

2022/06/22  10980 of 15326
so can be used to characterise FGF-induced effects and the modulation of these by potential FGFR inhibitors.

**Project Additional Information**

**Purposes of the contained use**
The constructs are oncogenes under control of mammalian promoters and will be stably expressed in NIH 3T3 lines. The cell line will be used to assess compound activity and mechanism of action.

**Recipient or parental organism**
Develop FGFR3 dependency, and analyse survival in the presence of FGFR3 inhibitors.
Activated fibroblast growth factor receptor 3 is an oncogene that contributes to tumour progression in multiple myeloma. Blood. 1 February 2001 729-736.

**Host/vector system**
PCI Neo is the mammalian expression vector.
The cells to be used for construct generation are XL1-Blue.
The NIH 3T3 cells are to be used for stable expression.

**Origin & function**
IMAGE clone of human origin provides the genetic material.
The function is to activate the ligand mediated and ligand independent activation of the MAP kinase pathway.

**Evaluation of foreseeable effects**
FGFR3 should lead to MAP Kinase pathway activation leading to increased proliferation.
DNA is a carcinogen under COSHH Regulations, therefore the DNA will be treated as a carcinogen. All work will be carried out by competent staff to class 2 regulations.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
DA is a carcinogen under COSHH Regulations, therefore the DNA will be treated as a carcinogen. All work will be carried out by competent staff to class 2 regulations.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be inactivated by chemical means, with 2% virkon. Validation of method will be continually assessed.
All solid waste will be autoclaved. Following sterilisation all waste will be disposed of in a sealed incineration bin to S. Grundon (Waste) Ltd.

**Project Additional Information**

### Purposes of the contained use

The purpose of generating cell lines which down-regulate the expression of genes linked to oncogenesis is for validating these gene products as potential targets for cancer therapeutics. Stable cell lines which express may also be used in screening assays to test the selectivity of small molecular weight compounds for a specific target.

### Recipient or parental organism

The lentiviral packaging cell line (293FT) distributed by Invitrogen will be used for the initial generation of Lentiviral pseudovirus particles. These particles will then be used to infect a variety of target relevant transformed mammalian cell lines e.g., A549, PANC1, BAF/3, Hek293, HCT-116, etc.

### Host/vector system

Generation of pseudovirus particles for the purpose of expressing gene fragments or shRNAs will be carried out using the pLenti (Invitrogen) vector system. Alternatively recombinant pseudovirus particles which code for specific gene products or shRNAs may be acquired commercially from Sigma-Aldrich, Invitrogen or Santa Cruz Biotechnology. Commercially available Lentiviral pseudovirus particles are derived from 3rd generation lentiviral vectors which cannot replicate within the target cells because the viral structural genes are absent and the LTRs are designed to be self-inactivating upon transduction. The expression of flag tagged gene products for reliable detection in mammalian cells as well as for functional analyses will be performed using the pLenti vector.

### Origin & function

The genetic material involved will be obtained through commercially available shRNA expressing clones from Sigma-Aldrich, Invitrogen or Santa Cruz Biotechnology. These clones should act to specifically down-regulate the gene transcripts to which they were designed. Alternatively gene fragments will be amplified from mammalian cDNA library I.M.A.G.E. clones, including clones for regulators of cellular proliferation and cell death. These gene fragments will be cloned and expressed using the pLenti vector.

### Evaluation of foreseeable effects

All mammalian cells transduced with the described lentiviral particles would not be immunologically compatible with a human host and as such there is no perceived threat in those cells colonizing a human host. Despite the inclusion of the safety features discussed above for the lentivirus particles, the lentivirus produced with these systems can still pose some biohazardous risk since it can transduce primary human cells. For this reason, lentiviral stocks generated will be used at Biosafety Level 2 (BL-2). Furthermore, we do not intend this risk assessment to cover the use of lentiviruses that express shRNA targeting human genes involved in negatively regulating cell division (e.g., tumour suppressor genes) Particular caution will be exercised with expression of gene fragments which are known to function in the regulation of cell proliferation or cell survival (e.g., cellular kinases activated through point mutations that stimulate pro-growth or pro-survival signal transduction pathways) using lentiviral vectors. While there are no known cases of cancer deriving from the usage of 3rd generation Lentiviral vectors, these agents will be treated as potentially oncogenic with regards to all handling and containment procedures.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All cultures are grown in appropriately stoppered flasks to minimize the risk of aerosols and are contained within a closed incubator. In the unlikely event that a spill should occur, or a flask break, it would be effectively controlled within the incubator. Local safety rules are in place for the safe handling and disposal of GMMs. When growing GMMs in culture eye protection is worn, lab coats and gloves are worn and for the disposal of GMMs and culture media either autoclaving at 123°C for 1hr or swabbing/soaking with Virkon (1%w/v) is carried out. No sharps or glassware will be used when working with these agents. If centrifugation of manipulated cell lines is required then sealed buckets will be used to avoid aerosols and allowing for appropriate decontamination. The decontamination methods will be validated by taking swabs of the treated material, followed by transfer to cells in culture. The ability to PCR amplify a lentiviral vector specific gene fragment will then be determined relative to a positive control over 40 PCR cycles.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

An enquiry was made concerning the negative pressure capabilities of the tissue culture suites. The capability exists for the rooms, but it was deemed unnecessary to bring this online for a class II GMO activity, since this is normally only a requirement for class III GMO activities, and there was little opportunity for the lentiviral particles to become aerosolized.

**Project Additional Information**

**Purposes of the contained use**
Generation of isogenic lines for mechanism of action studies

**Recipient or parental organism**
Mammalian cell lines e.g., A375, HCT116, SW48, etc.

**Host/vector system**
Mammalian cell lines e.g., A375, HCT116, SW48, etc./ geneart crispr vector

**Origin & function**
Geneart Crispr vectors are commercially available from Invitrogen. The isogenic cell lines derived from the use of this system will be used as screening tools to interrogate pathway dependence for cell survival and signalling

**Evaluation of foreseeable effects**
The system as described by Invitrogen allows for the inactivation or mutation of a specifically targeted gene.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
All handling of modified Crispr Vector DNA will occur in Class II laminar flow hoods with appropriate PPE protection. The ability for human cells to take up the modified DNA vectors will be negligible in the absence of specific transfection reagents which will only be mixed with the vector. All transfected cell cultures are grown in appropriately stoppered flasks to minimize the risk of aerosols and are contained within a closed incubator. In the unlikely event that a spill should occur, or a flask break, it would be effectively controlled within the incubator. Local safety rules are in place for the safe handling and disposal of GMMs. When growing GMMs in culture eye protection is worn, lab coats and gloves are worn.
worn and for the disposal of GMMs and culture media either autoclaving at 123^\circ C for 1hr or swabbing/soaking with Virkon (1%w/v) is carried out. No sharps or glassware will be used when working with these agents.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

In the unlikely event that a spill should occur, or a flask break, it would be effectively controlled within the incubator. Local safety rules are in place for the safe handling and disposal of GMMs. When growing GMMs in culture the disposal of GMMs and culture media will be accomplished either by autoclaving at 123^\circ C for 1hr or swabbing/soaking with Virkon (1%w/v). Either method should give a 100% kill rate.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMO committee were in agreement that the work entailed here using commercially available vectors posed no abnormal risks provided Class II GMO procedures were followed including posting signs that this work was ongoing.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The Almedica site at Unit 103 and Unit 107 on the Deeside Industrial Park are being used for receiving pre-packaged product containing genetically modified organisms for storage and distribution only. There will be no contact with the vials, and no waste will be generated except in the event of accidental damage resulting in a broken vial or vials. Each vial contains less than 1ml of vaccine in dry powder form, and a spillage situation would therefore only involve very small quantities of the product. Our emergency disinfection procedure requires the use of Hypochlorite in the form of Domestos on the recommendation of the HSE on the basis of the recognised efficiency of Hypochlorites in the deactivation of viruses. All disinfected materials will be sent for destruction, clearly marked: "Deactivated Genetically Modified Organisms - for destruction by high temperature incineration". As an emergency procedure, it is felt that monitoring of the disinfection procedure is not applicable. When the distribution process has been completed, any unused stock will be returned to the manufacturer.

Disposal of Genetically Modified Organisms - Contaminated waste generated will include syringes, needles and empty glass vials, there will be no significant liquid waste. All GM-contaminated material will be placed in a burn bin specifically designed for this purpose. When half full the slide lid will be pulled across leaving a small gap for steam penetration. The bin will be autoclaved and subsequently disposed of by incineration.

The used vial and syringe/needle will be deactivated prior to removal from the site for incineration. Deactivation will be carried out as follows:

1) Approximately 1ml of concentrated (neat) bleach (Domestos brand) will be injected into the vial to deactivate any residual GMO-containing material. The bleach will be left in the vial.
2) The syringe and needle used for the patient's injection will be placed in a small sharps container. Sufficient Domestos bleach will be poured into the container to cover the syringe and needle. The used vial (containing bleach) will then be placed in this same container.
3) The sharps bin will be sealed with adhesive tape and will be disposed of via our clinical waste contractors.

<tr>
<td>31/03/2003</td>
<td>ANGIGENIC GENE THERAPY PRODUCT FOR CORONARY ARTERY DISEASE</td>
<td>Class 2</td>
<td>&lt; 1 litre</td>
<td></td>
</tr>
</tbody>
</table>

02/03/2022
In the proposed clinical trial programme, angiogenic gene therapy product, consisting of a recombinant adenovirus (human serotype 5) containing the human gene for the fibroblast growth factor 4, and referred to as Ad5FGF-4, will be investigated as a treatment for patients with chronic stable angina due to coronary artery disease (CAD). Generation of new blood supply in the diseased heart by intracoronary administration of angiogenic gene therapy product represents a potential new therapeutic approach to relieve this condition.

Recipient or parental organism

see box below.

Host/vector system

The Ad5FGF-4 gene therapy product consists of a recombinant adenovirus vector (human serotype 5, Ad5) with a deletion in the E1 region; from map until 1.3 to 8.7 of wild-type virus (entire E1A and most of E1B are eliminated). The FGF-4 transgene is inserted, driven by CMV promoter.

Origin & function

The FGF-4 gene was originally isolated from a cDNA library which was constructed from mRNA of Kaposi's sarcoma DNA transformed NIH3T3 cells. The intended function is angiogenesis, the formation of new blood vessels.

Evaluation of foreseeable effects

The probability of adverse consequences resulting from deliberate or accidental release of the gene therapy product Ad5FGF-4 are minimal to nonexistent.

Hazards resulting from environmental release (viral shedding from treated persons, inadvertent contamination of the product prior to administration) are negligible or nonexistent for the following reasons: infection requires large numbers of infectious vectors, and transfection (expression of the inserted gene) requires a multitude of infectious particles.

Hazards associated with the adenoviral vector can be described as having low potential of adverse environmental consequences in humans or animals. The theoretical consequences to humans of several of the hazards associated with ectopic transgene expression, if they actually occurred, could be considered moderately severe (eg promotion of existent malignancy, unknown risk to foetus). However, since any unintended or accidental exposure would most likely be a fraction of the total dose being
administered to patients for therapeutic purposes, the relative risk of the occurrence of these types of adverse effects should be very low.

The possible risks to the environment could be assessed as low to effectively zero. This is based on the low probability of infectious adenoviral particles escaping into the environment either through viral shedding by patients that have received the product, or by incidental exposure during administration procedures. Even if viruses were shed or product spillage occurred the number of infectious viral particles would be too small to result in infection of exposed tissues. The risk to the non-human environment is extremely low to effectively zero because of the species specificity of adenovirus 5, which by natural exposure is only known to infect humans.

The above indicates that the product could be classified as Class 1. However, as a precautionary measure, due to the limited experience available, the product is currently being classified as Class 2. Reclassification into Class 1 may be considered if based on increased data and experience.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Inactivation by autoclaving and effectively 100% kill.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The Committee agreed with the assessment and the assignment of work to Class 2 and requiring the equivalent of Containment Level 2 facilities.
