**Project Additional Information**
Purposes of the contained use

In order to study the genes involved in symptom induction in the tuber necrotic strain of Potato virus Y (PVY), a clone containing a full-length genome copy of a UK isolate of PVYNTN will be constructed from which infectious RNA transcripts can be synthesised in vitro. The transcripts will be established by mechanical inoculation to tobacco and be transferred by mechanical inoculation to potato. Gene swap experiments will then be conducted between the clone isolate and isolates, which are unable to cause necrotic tuber symptoms.

Recipient or parental organism

PVY. This is a single stranded, monopartite RNA virus, belonging to the Potyvirus genus. PVY is naturally transmitted in a non-persistant fashion by aphids and can be mechanically transmitted, the host range is generally limited to the Solanaceae and it is distributed. The initial clone should produce wild-type necrotic symptoms on potato tubers, the subsequent modifications are expected to make an isolate that causes less damaging symptoms on potato, with no tuber necrosis. The changes are not expected to alter the host range nor the survivability of the modified virus compared to the wild type.

Host/vector system

The host plants will be Nicotiana spp and Solanum tuberosum. The plants will be mechanically inoculated with the in vitro RNA by rubbing the leaves with a mild abrasive (eg celite).

Origin & function

The isolate of PVY that will be used to make the infectious clones is called v942490 and originated from symptomatic potatoes grown in the field in the UK in 1998. The clone will contain the whole of the genome of the isolate, which is translated in the plant into a single polyprotein; the polyprotein is cleaved into 9 gene products, which allow full systemic infection of the plant. The plasmid will contain the PVY genome cloned adjacent to an RNA polymerase (T7 and SP6) promoter sequence. Prior to use the plasmid will be purified, cut using a restriction enzyme to linearise the plasmid at the 3' end of the PVY genome insert. This plasmid will then be used to make in-vitro RNA transcripts (using T7 or SP6 RNA polymerase) of the PVY genome which should be infectious when mechanically inoculated to host leaf.

Evaluation of foreseeable effects

It seems unlikely that the cloned PVY genome will have any effect on the E. coli strain used; it is unlikely that it will complement any of the disabling mutations. Full-length clones of potyviruses are difficult to establish due to the length of the genome (10kb) and the established plasmids are often found to rearrange within the bacterial clones, thus it is unlikely that the plasmid will persist in E. coli. The PVY transcripts from the initial clone will have the same sequence as PVY isolate V942490; an isolate found within the UK. This isolate belongs to the tuber necrotic strain (NTN), which is the causal agent of potato tuber necrotic ringspot disease (PTNRD) and is able to cause superficial necrotic rings on the surface of the tubers of susceptible cultivars. The genome of these strains is recombinant containing regions of other PVY strains (PVY-N and PVY-O). Future genome rearrangements will aim to deconstruct the recombinant genome and aim to 'knockout' the ability of this isolate to cause tuber symptoms. Thus the aim of the project is to modify the isolate to generate less damaging symptoms.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The GMOs in use are the transformed E. coli and the modified PVY isolates, the plants will not be transformed.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste material will be in the form of liquid cultures and agar plates (and the associated lab ware that will have come into contact with the modified organisms), and in addition, there will be infected plant material and the soil/pots in which the material was grown. Prior to autoclaving, all plastic ware and glassware for reuse will be soaked for 24 hours in 3% Virkon. All contaminated material will be autoclaved at 121 degrees C for 20 minutes using a machine (which is serviced annually on contract and for which there is validation data) situated within the facility. Work surfaces will be wiped down with 3% Virkon after procedure has been completed (eg inoculating plants) and
any spills will also be treated with 3% Virkon. The treatments described have been shown to achieve 100% kill (see attached documents). The material used to wipe down surfaces and clear up spills will also be autoclaved as above before disposal. Treated waste will then be disposed of by incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The attached risk assessment and operating procedures have been examined and discussed by members of CSL Genetic Modification Biological Safety Committee. They reached agreement that the work could proceed under the conditions stated.

Project Ref 448/06.1

Date Ackn’d 04/01/2006

CU2 Project Title

The aim of the study is to investigate the genes involved in symptom induction in the pathogen Pepino mosaic virus (PepMV) in the tomato host and indicator hosts.

Date Project Ceased 02/08/2019

Class 2

Culture Volume

< 1 Litre

Non-GMM Not Applicable

Consent Granted

Project notified under transitional arrangements N
The study aims to produce clones from which full-length infectious transcripts can be generated for PepMV. These transcripts will be inoculated to tomato, Nicotiana benthamiana, N. glutinosa, N. tabaccum and Datura stramonium to investigate symptom induction. Subsequently the clone will be altered by removing the tomato strain (causes symptoms in tomato) sequences and systematically replacing it with corresponding pepino strain (no symptoms in tomato) sequence. These new clones will be inoculated as before and symptoms on tomato and other indicator hosts will be investigated. The aim is to identify which regions of sequence are involved in symptom induction.

Pepino mosaic virus (PepMV) belongs to the genus potexvirus, it was first described infecting pepino (Solanum muricatum) plants in Peru. In 1999 the virus was found in tomato (Lycopersicon esculentum) crops in Europe. It has filamentous particles of around 510 nm in length that contain one genomic ssRNA molecule (6410 nucleotides). It is transmitted readily by inoculation of sap to many solanaceous species. No vector is known but the virus is easily transmitted from plant to plant through contact.

The host plants will be Lycopersicon esculentum, Nicotiana benthamiana, N. glutinosa, N. tobacco and Datura stramonium. The plants will be mechanically inoculated with the in-vitro synthesised RNA (from the plasmid) by rubbing the leaves with a mild abrasive (eg celite). One of the JM series of E. coli strains will be used. These are laboratory-adapted strains, and have biological limitations which mean they are unlikely to survive in the gut, lung or elsewhere. These strains have a history of safe use. A non-mobilisable plasmid vector (pUC 19) will be used which is defective in one or more functions required to transfer to other hosts.

The isolates of PepMV that will be used to make the infectious clones are from tomato in UK, tomato in North America and pepino in Peru. The clone will contain the whole of the genome of the isolate, which is translated in the plant into 5 gene products, which allow full systemic infection of the plant. The plasmid will contain the PepMV genome cloned adjacent to an RNA polymerase (T7 and SP6) promoter sequence. Prior to use the plasmid will be purified, cut using a restriction enzyme to linearise the plasmid at the 3' end of the PepMV genome insert. This plasmid will then be used to make in-vitro RNA transcripts (using T7 or SP6 RNA polymerase) of the PepMV genome, which should be infectious when mechanically inoculated to host leaf.

It seems unlikely that the cloned PepMV genome will have any effect on the E coli strain used; it is unlikely that it will complement any of the disabling mutations.
Full-length virus clones are often difficult to establish due to the length of the genome (6kb). The established plasmids are often found to rearrange within the bacterial clones, thus it is unlikely that the plasmid will persist in E. coli. The transcripts from the initial clone will have the same sequence as the PepMV isolates found within the UK. This isolate belongs to the tomato strain. Future genome rearrangements will aim to deconstruct the genome and aim to 'knockout' the ability of this isolate to cause foliage symptoms on tomato. Thus the initial aim of the project is to modify the isolate to generate less damaging symptoms. To carry out reciprocal modifications to prove which genes modulate symptoms it will be necessary to modify the Pepino strain to enable it to generate symptoms, but these symptoms are likely to be identical to those caused by the tomato strain.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

The GMOs in use are the transformed E. coli and the modified PepMV isolates, the plants will not be transformed.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste material will be in the form of liquid cultures and agar plates (and the associated lab ware that will have come into contact with the modified organisms), and, in addition, there will be infected plant material and the soil/pots in which the material was grown. Prior to autoclaving, all plastic ware and glassware for reuse will be soaked for 24 hours in 3% Virkon. All contaminated material will be autoclaved at 121 degrees C for 20 minutes using a machine (which is serviced annually on contract and for which there is validation data) situated within the facility. Work surfaces will be wiped down with 3% Virkon after a procedure has been completed (eg inoculating plants) and any spills will also be treated with 3% Virkon. The treatments described have been shown to achieve 100% kill (see attached documents). The material used to wipe down surfaces and clear up spills will also be autoclaved as above before disposal. Treated waste will then be disposed of by incineration.

## Project Ref 448/13.1

### CU2 Project Title
- **Use of Mengovirus vMC0 (ATCC-VR-2310) as a sample process control for detection of enteric viruses in food and environmental samples**

### Purposes of the contained use
- For use as a sample process control when detecting enteric viruses in food and environmental samples

### Recipient or parental organism
- We do not possess the parental organism

### Host/vector system
- N/A

### Origin & function
- vMC0 mengovirus (ATCC-VR-2310). This virus has been modified by the removal of the poly(c) tract

### Evaluation of foreseeable effects
- Exposure of experimenters to mengovirus vMC0 could occur during its use as a process control. There is no available information on the infectivity of this strain for humans.

Project notified under transitional arrangements N
Project Additional Information

Purposes of the contained use

The fish pathogen Yersinia ruckeri is the causative agent of Enteric Redmouth (ERM) disease in salmonids, known as Yersiniosis, and can cause losses in aquaculture. However, only few pathogenic mechanisms of Y. ruckeri have been described. Previous work by Dr Deng's research group has shown that Y. ruckeri produces several small organic molecules that may have a role in virulence, and will be the subject of these studies.

Goals of the project:
1. to determine the structures of these small organic molecules;
2. to understand how these molecules are biosynthesised;
3. to understand the impact of these molecules on Y. ruckeri pathogenicity.

Recipient or parental organism

The wild-type Y. ruckeri strain is not a human pathogen but is a fish pathogen and therefore it is handled at Containment Level 2. This project will generate several mutant strains in which various genes involved in the biosynthesis of the potential virulence factor(s) will be knocked out. In some cases, the genes knocked out will be reintroduced into the mutant strains, in knockin experiments, to help verify the functions of the encoded proteins in vivo.

Host/vector system

The vectors used to knockout the target genes in Y. ruckeri will be pK18mobSac and pK18mobGII. The vector used to knockin the target genes into Y. ruckeri will be pRK404. These three vectors are well described and (i) are either non-mobilisable (e.g. pUC series and their derivatives) or mobilisation-defective (e.g. pBR322 and its derivatives) in bacteria; (ii) contain only selective markers that are already in routine use in standard cloning vectors; or (iii) contain no recognisable harmful sequences.

Origin & function

We will generate knockout mutant strains of Y. ruckeri. The deleted or modified genes will be those associated with the biosynthetic pathways which direct the biosynthesis of small molecules that may be involved in virulence. In some cases the genes will be re-introduced into the mutants to verify function.

Evaluation of foreseeable effects

Yersinia ruckeri is a Containment level 2 fish bacterial pathogen, not known to cause disease to humans.

In this study the focus is on the biosynthetic pathway of siderophores as virulence factors in Y. ruckeri, which will be studied initially by knockout mutagenesis. Genetic manipulation of secondary metabolism in Y. ruckeri is expected to decrease virulence compared with the wild-type strain. Precedents to support this conclusion can be found in the literature, where knockout mutants of different genes in Y. ruckeri relating to biosynthesis result in significant reductions of virulence (Appl Environ Microbiol. 70, 5199-5207. Microbiol. 2007, 153.483.489. J Bacteriol. 2011, 193, 944-951).

The genes inserted as selection markers will confer resistance to the antibiotics kanamycin and tetracycline, which are not commonly used to treat Y. ruckeri infections in fish, for which there is an effective vaccine used in aquaculture.
The genetic insertions for the knock-ins are stable in the genome and plasmid maintenance is not required. The knock-in mutant strains of Y. ruckeri may revert or partially revert to a virulent phenotype. Whilst the risks of the knock-ins generating a more virulent phenotype seem very low, this cannot be completely excluded and therefore whilst likely negligible it cannot be stated there is no risk.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste: 2% Trigen/Distel (active ingredient = TM307).
Glassware: soaked with 2% Trigene/Distel or autoclaved.
Plasticware: autoclaved.
Sharps: contaminated sharps are placed in CinBins, bagged and incinerated.

Liquid waste, after inactivation, will be disposed of down the drain. Solid waste, after inactivation will be sent off site for incineration.

In the event of spillage, the contaminated area will be flooded with concentrated Trigene/Distel (to 2% final concentration), mopped up with paper towels, and reswabbed with 2% Trigene/Distel. Contaminated material will be autoclaved.

The use of Trigene/Distel has been validated experimentally to kill > 99.99% of cells.

The autoclave in the Chemistry section is validated at least annually by means of biological indicators. On a daily basis, when in use, monitoring is by thermocouple temperature recordings and autoclave strips included in the loads.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

This application was approved at Containment Level 2 by the local Genetic Modification Safety Committee. They were satisfied that generally the knock-out mutants were likely to be less virulent than wild type strains and potentially this work could be at Containment Level 1, but that it was not possible to be sure there was no risk associated with the knockin mutants, in terms of reversion to virulence.

Historical Date of Additional Info

This project has transferred to GM391

Significant Change ID

Date of Significant Change
### Purposes of the contained use

Evaluation of poxvirus vectored feline viral antigens for vaccination of cats.

### Recipient or parental organism

Non-modified poxvirus with no markers or attenuations prior to use. Biological Hazard and MAFF hazard group 1.

Only produces disease in it's natural host. Is not known to produce disease in humans.

### Host/vector system

Host is poxvirus as described above.

### Origin & function

Inserted gene sequences derived from a feline virus, feline genes from feline peripheral blood mononuclear cells and marker genes derived from E. coli. The genes and their regulatory elements are not known to affect virulence, survival in the host, survival in the environment or increase resistance to therapeutic agents. The donor genes are not known to be involved in host range, virulence or expansion of tissue tropism.

Insertion of the genes into the parental viruses confers an attenuated plaque phenotype.

The inserted genes are intended to induce protection against the parental organism following vaccination of cats with the GMM.

### Evaluation of foreseeable effects

The GMM is only known to cause disease in it's natural host. The inserted sequences are not expected in increase the survivability of the GMM in the environment or increase its host range of tissue tropism. The use of category 2 containment reduces any risk to the environment and therefore exposing the natural host to effectively zero. The GMM is not known to cause disease in humans and category 2 containment reduces any risk of exposure to effectively zero.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not claimed.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not claimed.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste will be decontaminated by autoclaving using a validated temperature cycle designed to achieve 100% killing.

Liquid waste will be heat treated using a validated temperature cycle designed to achieve 100% killing.

No waste will be disposed off containing any live organisms.

Is an emergency plan required according to regulation 20? **N**

If yes, tick to confirm that it is attached to this form **N**
The risk assessment and notification form was reviewed by the GMM Safety Committee on 15/12/00. All elements were debated and the committee found that the information provided was in accordance with the 2000 regulations. The containment level applied was deemed to be appropriate for the activities and scale in order to reduce all risk to effectively zero.

Please enter comments on the GM safety committee on the risk assessment

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Project Ref 456/05.1

Date Ackn'd 29/04/2005

CU2 Project Title

Storage of seed materials and associated laboratory work targeted at formulating an experimental vaccine.

Date Project Ceased 17/04/2009

Class 2

Culture Vol Class 2 1-50 Litres

Non-GMM Consent Granted Not Applicable

Tick if notifying a connected programme of work N

Historical Significant Changes

This project has transferred to GM391

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

02/03/2022
Project Additional Information

Purposes of the contained use
To provide vaccine for potential evaluation in controlled laboratory studies or in the field.

Recipient or parental organism
a) The parental Mannheimia haemolytica is a field isolate originally cultured from bovine pneumonic lung tissues.
B) The parental Pasteurella multocida is a field isolate originally cultured from pneumonic lung tissue. This strain is highly virulent and is capable of replication in the bovine lung.

These are both classified as ACDP hazard group 2 and had no genetic modifications carried out prior to the production of the deletant strains.

Host/vector system
Not applicable.

Origin & function
Attenuation of the virulence of Mannheimia haemolytica and Pasteurella multocida by virtue of gene deletions, whilst maintaining a suitable immune response in the host animal.

Evaluation of foreseeable effects
The deletant strains are likely to retain the features of the parental organism with respect to host range, tissue tropism and mode of transmission. They will however be significantly attenuated with respect to virulence.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
The level of attenuation of these organisms is such that the measures applicable to containment level 1 are appropriate. However, since the mode of transmission is unlikely to have been affected, work with open vessels where there is a risk of aerosol generation will be carried out within a microbiological safety cabinet.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All solid waste will be decontaminated by autoclaving using a validated temperature cycle designed to achieve 100% killing.
Liquid waste will be heat treated using a validated temperature cycle designed to achieve 100% killing.
No waste will be disposed of containing any live organisms.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

02/03/2022
The risk assessment and notification form were reviewed by the GMSC on 31 January 2005. All elements were debated and the committee found that the information provided was in accordance with the 2000 regulations. The containment level applied was deemed to be appropriate for the activities and scale in order to reduce all risk effectively to zero.

### Historical Significant Changes

This project has transferred to GM391

### Project Additional Information

Purposes of the contained use

Evaluation of immunogenicity, potency and safety in chickens.
The construct is a novel avian herpesvirus, consisting of regions of herpesvirus of turkeys (HVT) and of Marek’s disease virus (MDV).

A. The parental HVT is ubiquitous in domestic turkeys and widespread in chicken populations where vaccination with HVT has been practiced since the early 1970s. It is not considered to be pathogenic for turkeys or chickens (Cainek BW HW Jr. Iowa State University Press, Ames, Iowa pp342-385).
B. The parental MDV causes a lymphoproliferative disease that affects the peripheral nervous system and other organs.

Project Ref 456/07.1

CU2 Project Title
The development of a vaccine to provide passive protection to the new born calf against clinical disease caused by Cryptosporidium parvum.

Date Ackn'd 13/04/2007
Date Project Ceased 17/04/2009

Non-GMM Consent Granted Not Applicable
Project notified under transitional arrangements N

Withdrawn N
Tick if notifying a connected programme of work N

Historical Significant Changes
This project has transferred to GM391

Project Additional Information

Purposes of the contained use
Evaluation of potential constructs for the expression of the gene of interest, process development and scale up to 40L.

Recipient or parental organism
The recipient E. coli strain is a weakened laboratory adapted mutant and is regarded as non pathogenic. It is expected that the survivability of the bacterial host in the environment will be poor.

Host/vector system

02/03/2022 Page 7414 of 15326
The plasmid comprises a heat-inducible expression plasmid with a pUC origin of replication and tetracycline resistance gene plus the coding sequence for the gene of interest. The plasmid is non-conjugative and there is therefore minimal risk of transfer to other micro-organisms.

### Origin & Function

The gene sequence has been obtained from Cryptosporidium parvum and codes for a structural protein. It is not a known virulence determinant.

### Evaluation of foreseeable effects

As discussed.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste will be decontaminated by autoclaving using a validated temperature cycle designed to achieve 100% killing.

Liquid waste will be heat treated using a validated temperature cycle designed to achieve 100% killing.

No waste will be disposed of containing any live organisms.

Withdrawn [N] 

Tick if notifying a connected programme of work [N]
The overall objective of this project is to determine genetic loci in Salmonid Alphavirus RNA virus genomes which determine the phenotypic properties of these viruses in cell cultures and in vivo models. Such properties include, for example, ability to infect cells, ability to stimulate interferon and to activate other cellular genes, ability to trigger apoptosis, and ultimately ability to cause disease. These properties can be assessed both in vitro by infection of cells in culture and in established salmonid infection models. One key approach to be used will be to compare viruses with specific genetic modifications to parental virus. This will involve swapping sequences between strains which are known to exhibit different virulence properties and by deleting/mutating specific areas of sequence. Another key approach will be to insert reporter genes into the virus genome. In all cases, this work will involve engineering complete or partial cDNA copies of the viral genome. The virus to be used is salmonid pancreas disease virus (SPDV). This virus is the most significant viral disease of Atlantic salmon aquaculture in Scotland where it is responsible for considerable economic losses. The ubiquity of the pathogen, impact of the disease and lack of official control measures render it a threat to the long term sustainability of salmon aquaculture, in addition to raising welfare issues. This work will contribute to understanding the fundamental biological processes influencing the outcome of SPDV infection which is key to developing control and mitigation strategies that underpin a sustainable industry that can coexist with ubiquitous pathogens.

The alphavirus genome consists of a single strand of positive sense RNA of around 12 kb. This RNA codes for two open reading frames. The first codes for the non-structural viral replicase proteins (nsP1, 2, 3 & 4), the second for the viral structural proteins (C, E1, E2 & E3). Expression of the replicase proteins is under the control of a promoter (P) in the 5’ non-coding region of the virus. Expression of the structural proteins is under the control of a subgenomic promoter (SP) which is activated later in infection and leads to a high level of expression from this second open reading frame. The full genome sequence of SAV isolates is available and a strategy for generation of recombinant Sleeping Disease Virus (SDV) has previously been reported (Moriette et al 2006). The recovery of recombinant virus from cDNA is usually based on the transfection of cells with positive stranded RNA generated in vitro from SP6 or T7 driven full length cDNA transcripts. An alternative approach is to transfect cells with plasmids and provide T7 polymerase in situ by eg infecting cells with a recombinant vaccinia viral strain which expresses the T7 viral polymerase.

A similar strategy to those previously reported is planned for generation of recombinant SPDV. A plasmid will be generated that encodes the entire SAV genome under the control of a T7 promoter. Plasmids will be used to generate positive sense genome copies using T7 polymerase that will be used to transfect permissible cell lines. This is expected to result in the generation of infectious virus.

Recipient or parental organism

The GMM recipient organisms generated in this project include:
I) E.coli host cells transformed with plasmid DNA.
II) Eukaryotic cell lines transfected with plasmids for the purpose of virus expression.
III) Recombinant viruses in some cases bearing reporter genes as described above.
GMM type I risks

Only disabled E. coli K12 strains as defined in the ACGM Compendium of Guidance will be used as hosts. The project and risk assessment explicitly excludes use of other host species and other non-K12 strains of E. coli, including E. coli B strains such as BL21 and its derivatives. E.coli K-12 derivative strains may be considered as equivalent to ACDP hazard group 1 and are not considered pathogenic to humans or animals. They are expected to have limited survival in the environment and often have auxotrophic requirements unlikely to be satisfied outside of laboratory culture. None of the genes intended for expression encode any protein of detriment to human health nor derive from any organism known to cause a human health risk. Proteins will not be expressed in E.coli which in this instance is being used purely for the generation of plasmid DNA.

GMM type II risks

Generation of replicating virus is not considered to pose any greater risk to the recipient cell line than routine characterisation and isolation of fish alphavirus. Both fish and mammalian derived cell lines (eg BHK) may be used as host cell lines for initial generation of recombinant viruses, but this will occur at temperatures permissive for SPDV infection (<25ºC). These cell lines are well characterised and in routine laboratory use for isolation of viruses. No known human health or environmental hazards associated with the proposed cell lines has been identified.

GMM type III risks

Recombinant viruses will be used to re-infect cell lines for the purposes of studying viral pathogenesis as described above. Risks to the recipient cells will be no greater than those incurred in the primary generation of infectious virus described above. Recombinant viruses may also be used to infect live fish in established SPDV challenge models. Atlantic salmon are susceptible to SPDV. The focus on use of only naturally occurring and identified gene changes in generated viruses coupled to the fact that other changes are unlikely to dramatically increase the fitness of the virus will likely result in no dramatic increase in the pathogenicity of viruses above that of the wild type isolates.

GMM Risks type II

Inserted genes will be derived from SPDV. The intention is to generate replicatively active virus in cell lines. Generation of replicating virus is not considered to pose any greater risk to the recipient cell line than routine characterisation and isolation of fish alphavirus. Furthermore, virus will be replicated at temperatures below 25ºC will be used as host cell lines for generation of recombinant viruses: no fish viruses adapted to these lower temperatures are known to cause any hazard to humans.

GMM Risks type III

No risks beyond those described above are anticipated in infection of tissue cultured cells or live fish with recombinant SPDV.

Host/vector system

GMM type I risks

The only vectors that will be used will be well-characterised vectors that (i) are either non-mobilisable (eg pUC series and their derivatives) or mobilisation-defective (eg pBR322 and its derivatives) in bacteria; and (ii) contain only selective markers that are already in routine use in standard cloning vectors; and (iii) contain no recognisable harmful sequences. The primary purpose of this part of the work is to generate plasmids from which proteins will not be expressed in host E.coli strains used for propagation of plasmid. Fish pathogens are generally adapted to low temperatures and their proteins are often rendered inactive at the elevated temperatures associated with E.coli culture (37ºC). In the unlikely event that biologically active inserted proteins are produced, consequences for human health are not anticipated since gene products or indeed wild type SPDV are not known to cause any hazard to humans.

Origin & function

02/03/2022
The intention is to generate recombinant SAV viruses using a reverse genetics approach. Using this, SPDV will be genetically modified to identify and characterise genetic loci that determine the phenotypic properties of this important virus of Atlantic salmon. Specific gene loci will be targeted. Sequences may be swapped between different natural isolates that have varying phenotypes or they may be mutated or deleted. The only foreign genes that will be inserted are non-harmful marker or reporter genes. Changes in phenotypes will be assessed both in vitro and in vivo.

Recombinant viruses will be used to re-infect cell lines for the purposes of studying viral pathogenesis as described above. Risks to the recipient cells will be no greater that those incurred in the primary generation of infectious virus described above. Recombinant viruses may also be used to infect live fish in established SPDV challenge models. Atlantic salmon are susceptible to SPDV. The focus on use of only naturally occurring and identified gene changes in generated viruses coupled to the fact that other changes are unlikely to dramatically increase the fitness of the virus will likely result in no dramatic increase in the pathogenicity of viruses above that of the wild type isolates.

Evaluation of foreseeable effects

Virulent viruses will be selected for study. It is unlikely that any significant increase in virulence will be observed in this study since most changes would be expected to reduce virulence of the wild type virus strain.

RNA viruses exist as populations of genotypes and are selected for fitness by the systems in which they replicate. The predominant genotype in an RNA virus population is that most fit to survive the selective pressures encountered during virus replication and dissemination. Genotypes with all possible base changes at all possible positions are likely to be generated naturally in the course of replication of RNA viruses. The cDNA clones of the laboratory strains of SPDV to be used in this project represent single genotypes selected from natural isolates by molecular cloning. It is likely that these cDNAs represent genotypes abundant in the original natural virus isolate and therefore genotypes most fit for replication. Most point mutations or deletions introduced into such viruses can be expected to attenuate fitness. However, base changes in the structural, replicase genes or non-coding sequences of avirulent virus cDNAs which change the sequence to that of a more virulent virus cDNA would be expected, at least in some cases, to increase virulence but only to a level seen in wild type isolates. With the exception of reporter genes, known to be harmless to humans, the engineered recombinant viruses to be generated will either contain only sequences found in natural virus isolates or specific point mutations or deletions; they are therefore likely to remain non-infective for humans. Any transfer of genetic material will only be between different strains of naturally occurring viruses. The studies in this project are therefore unlikely to change the host range or tropism of these viruses.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment and Control Measures

Aquarium Control Measures

The waste water treatment system provides treatment of waste water from the disease aquarium facility. It caters for a flow of up to 10m3/hour of freshwater and sea water. The treatment is Ozone and there is a sodium hypochlorite solution standby dosing system and generator in the event of a plant failure or power failure which automatically activates on plant failure. Once the water has passed through the system it leaves the degassing tank and flows to the domestic sewage works at Nigg Bay. Once at Nigg Bay sewage works the sludge is removed and incinerated to produce electricity and the waste water is then treated by UV irradiation. However this supplementary treatment process is not considered as part of the treatment system.

Entry to the aquaria facility is highly controlled and monitored. Specific documented procedures exist for entry/exit and disinfection of all material originating from the
aquarium. This includes onsite autoclaving and subsequent incineration of all potentially infectious material generated within the facility. Specific risk assessments are generated for all planned experiments. These are scrutinised and signed off by a local bio-security officer. Additional precautions to be taken in the aquaria during experimentation with GMMs would include collection of all waste water and chemical treatment (eg hypochlorite) in the aquaria prior to discharge of waste via the effluent treatment plant described above.

Laboratory Control Measures

Standard tissue culture protocols will be used to grow and maintain stocks of viruses and to assay for virus infectivity. These involve typical volumes of infectious material of <500 ml. All tissue culture work will be carried out in a microbiological safety cabinet. In other procedures where aerosols may be generated, for example homogenisation of tissues, a microbiological safety cabinet will also be used. Laboratories are designed to comply with ACDP containment level 2. All surfaces (benches, walls, floors) are impervious to water, easy to clean and resistant to acids, alkalis, solvents and disinfectants. All tissue culture procedures are conducted within contained laminar flow hoods to minimise risk to fragile cultures. All GMM solid waste is collected and autoclaved prior to incineration. All liquid waste is chemically disinfected with Microsol prior to autoclaving.

Building Physical Measures

Laboratories are designed to comply with ACDP containment level 2. All surfaces (benches, walls, floors) are impervious to water, easy to clean and resistant to acids, alkalis, solvents and disinfectants. All tissue culture procedures are conducted within contained laminar flow hoods to minimise risk to fragile cultures.

Inactivation and disposal

All contaminated material solid and small quantities of sealed liquid waste, will be placed in identifiable biohazard (blue) autoclave bags, transferred securely to the autoclave and inactivated on site by autoclaving prior to incineration by a third party. Reusable laboratory equipment, such as glassware will be soaked in Microsol (10%) immediately after use, prior to washing and drying. Liquid waste will be treated with Microsol (10%) or Virkon and autoclaved prior to disposal down the sink. Sharps (in sharps bin, eg needles, syringes, scalpels) – will be autoclaved and disposed of via the clinical waste stream for incineration. All solid waste from the aquaria is autoclaved and disposed of via the clinical waste stream for incineration.

Validation and Monitoring of control methods

The waste autoclave is monitored under the UKAS quality system and is serviced and calibrated annually. Individual run data is recorded to ensure the appropriate temperature is reached (121°C) for each run.

Aquarium

Previous experimental work to determine the efficacy of aquaria ozone disinfection system demonstrated that a single pass through the ozone system produced a 3.75 log reduction of IPNV isolate 975/99. This virus represents one of the hardiest viruses known in terms of its ability to persist in the environment.

The plant is checked twice daily and measurements taken for the following:-

-Ozone alarm system (daily check recorded)
-Ozone Redox Potential (ORP), (daily check recorded). FRS Standard Operating Procedures (SOP’s) state that ORP readings must be above 700mV. Fraser D.I., Munro P.D. and Smail D.A. (2006) Fisheries Research Services Internal Report No 13/06 DISINFECTION GUIDE VERSION IV PRACTICAL STEPS TO PREVENT THE
INTRODUCTION AND MINIMISE TRANSMISSION OF DISEASES OF FISH, recommend that a ORP of between 600-750mV is used to disinfect effluent water.

-Ozone generator flows daily (the generator that is running should have the float at the red line).
-Generator pumps daily
-Ambient and exhaust generator readings daily (below 0.1ppm)

These records are kept in the Ozone plant room.

There are 2 ozone generators one duty and one standby in case of failure etc., both generators are serviced on a 6 monthly basis.

The sodium hypochlorite dosing pumps are tested every month when the ozone system is shut down to change the activated carbon. Fraser D.I., Munro P.D. and Smail D.A. (2006) Fisheries Research Services Internal Report No 13/06 DISINFECTION GUIDE VERSION IV PRACTICAL STEPS TO PREVENT THE INTRODUCTION AND MINIMISE TRANSMISSION OF DISEASES OF FISH, recommend that processing plant effluent is treated with a dose of 1000ppm sodium hypochloride solution for 10min to disinfect the effluent. At FRS the sodium hypochlorite standby dosing pumps 1000 ppm sodium hypochloride solution, minimum contact time 12 hours.

There are 2 pumps with auto change over one duty and one standby, that pump the waste water through the contact chamber.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

Comments from the GMSC were included in the risk assessment. The GMSC comprises Senior management, Union and Biosecurity experts. External advice was also sought from Prof ********* (university of Edinburgh), a collaborator and acknowledged alphavirus expert. Most comments were minor edits and did not fundamentally change the scope or outcome of the assessment. The GMSC and Prof ********* agreed the risk assessment was suitable and categorisation of the work as class 2.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Site 1: Maximum culture released at any one time is one litre. Supernatant is treated with bleach, left for 2 hours then disposed to drain with copious amounts of water. Approximately one bacterial transformation and one large scale probe preparation is performed each year.

Site 2: All waste autoclaved @ 121 deg c for 15 minutes. Autoclave is serviced every six months. Thermocouple testing is done. Autoclave log kept and autoclave tape used.

Project Additional Information

Purposes of the contained use

During the trial we will be delivering genetically modified virus vaccines to human volunteers to try to stimulate their immune system to fight off any residual cancer cells. We will be specifically delivering the virus vaccines, PANVAC-V and PANVAC-F to patients who have had an operation to remove a colorectal cancer.

Recipient or parental organism

Human volunteers (cancer patients).

The viruses have been grown in chick embryo dermal cells at the provider company in the USA.

Host/vector system

The genetically modified viruses that we will use will be PANVAC-V and PANVAC-F. The virus backbones used are a) a vaccinia virus derived from the Syeth vaccination strain (class 2 containment) and b) a fowlpox virus (class 1 containment). Vaccinia has been found to be an excellent primer of the immune system but cannot be used repeatedly because of the antibody response against the vaccinia's own proteins. However experiments have determined that using repeated fowlpox vaccinations after the vaccinia prime leads to repeated boosting of the primary response with continuing increases in specific immune activity to at least five boost injections.

The virus vaccines will be administered by injection under the skin of cancer patients that have had their primary cancer removed.

Origin & function

Each of these viruses has been modified so that they also contain the genes of five human proteins: carcino-embryonic antigen (CEA), mucin-1 (Muc-1), lymphocyte function antigen 3 (LFA3), ICAM-1 and B7.1.

CEAcand MUC-1 are over-expressed in solid cancers but are not carcinogenic in their own right. The remaining three proteins are natural human co-stimulatory molecules, which allow maximum activation of the immune system.

The intended functions are to stimulate the immune system to fight residual cancer cells that carry the proteins CEA and MUC-1.

Evaluation of foreseeable effects

The main foreseeable event is stimulation of the immune system. Volunteers may experience reddening at the site of inoculation and mild flu-like symptoms for 24-48 hours.

The fowlpox virus is unable to replicate in human hosts and for this particular strain is no longer capable of replicating effectively even in fowl hosts. Therefore we do not anticipate any problems with PANVAC-F.

The vaccinia backbone has a slight risk of vaccinia-related illness as recognised during the worldwide smallpox eradication program. However the incidence of these effects were in the order of 14 per million vaccinations.

The vast majority of people accidentally or, in the case of the trial, intentionally infected with vaccinia will suffer very few ill effects because of the effectiveness of the antibody response in humans against this organism. However the patients that are immunosuppressed and those with a history of severe eczema there is an increases risk of vaccinia related illnesses including generalised vaccinia and vaccinia eczematum (a skin condition associated with vaccinia which can be serious). For this reason we will exclude patients that are HIV positive and we will screen patients for immunoglobulin status. An occupational health assessment will also be performed so that workers can be screened to ensure that they are not put at risk of problems in the unlikely event of accidental infection.
The inserts are human proteins whose functions are well characterised. Modification by insertion into the viral vectors is not expected to change their biological activities.

Stringent procedures under clinical trial conditions have been designed to prevent any release into the environment. The virus does not appear to spread effectively by aerosol spray and there is no evidence of shedding of virus from vaccinated individuals. Stand operating procedures (SOPs) have been set up within the unit for all activities surrounding the trial from receipt of the material, storage, administration, clean down in the lab, disposal of contaminated waste, and what to do in the event of any incident. The unit has experienced in gene therapy trials using class I organisms.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Class II containment requires disposal by validated means and an autoclave sited in the building where the waste is generated. The unit where this work is to take place (Cancer Research UK, Churchill Hospital) do not have an autoclave. Currently class I waste is placed in sealed bins and collected as soon as possible for offsite disposal by an independent contractor approved for disposal of GM waste. Separating class I waste (fowlpox derived) from class II (vaccinia) for this trial would not be practical.

Derogation is requested so as to allow this route of disposal to be extended to class II waste from clinical trials. Autoclave facilities on the Churchill site are located some distance from the Unit. Transport of waste across site would be difficult with inherent risk of delays and errors. It would require transport across areas used by staff, patients and hospital visitors. We believe in current system of off-site disposal in sealed robust bins, which works well for class I waste to date, is the safest route of disposal at this time.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste contaminated with vaccine will be disposed of according to the local SOP ie transferred immediately into robust bins, sealed and collected by an approved external contract for off site incineration (subject to approval of the derogation requested above). Waste material will include the vials in which the vaccines arrive, syringes and needles used for injection and the dressings applied to the injection site. Expected degree of kill: effectively 100%.

Preparation areas will be cleaned with 2% Virkon according to local SOPs. Should any spills occur volumes will be very small, inactivation will be with Virkon. Absorbant materials used in cleaning will then be disposed of as above. Expected degree of kill: Effectively 100%.

Maximum culture volumes are 1000 ml (routinely only 10-15 ml) and all organisms are destroyed by autoclaving at 121 degrees C for 15 mins. Genetically modified micro-organisms are typically more fragile than wild type organisms and are rendered non-viable at temperatures well below this value. The effectiveness of the procedure will be monitored at monthly intervals using steriliser control tubes ("Browne Tubes") suitable for autoclaves operating at up to 126 degrees C.

Purposes of the contained use

The aims of this work are to transfect exogenous DNA into Plasmodium falciparum for in vitro studies to:

1. Provide for reporter gene studies on the (i) structure and function of nucleic acid regulatory sequences and (ii) action of antimalarial agents
2. Label genes with tags to provide for isolation of interacting proteins, cell localisation and trafficking studies
3. Explore the function of genes through knock-out and knock-in studies

Recipient or parental organism

The recipient organism is Plasmodium falciparum (ACDP hazard group 3*), the aetiological agent of malaria in humans. The * refers to this organism being listed in the Certificate of Exemption accompanying the ACDP Approved List for the classification of microorganisms – this organism is not transmissible though aerosol routes.

Host/vector system

Plasmid vector- these are members of the pUC series plasmids (eg pBluescript SK+). Novel sequences introduced are listed below. Otherwise no other modifications to the ampicillin or kanamycin selection cassette, multiple cloning site and bacterial origin of replication are made to this plasmid.

Origin & function

a) Plasmodium coding or non-coding sequences:

(i) P. falciparum coding sequences

Full (or partial) open reading frames would be derived from P. falciparum, and therefore would not increase level of risk of the GMO. Of the P. falciparum sequences to be used, the functions of only a few are linked to virulence (e.g. several naturally occurring variants of the PfEMP1 protein are known to bind to human endothelial receptors CD36 and ICAM-1) but since these forms exist in nature, they would not increase the level of risk of the resultant GMO. Some constructs designed for stable integration are, by design, incomplete open reading frames. Such constructs would not alter the pathogenicity of the final GMO because they aim to delete or disrupt the target gene, causing loss of function. Knock-in of endogenous sequences to complement loss-of-function produced by these knock out experiments will be required to replace an existing function and therefore are unlikely to affect pathogenicity.

(ii) Non-coding regulatory sequences:

These are necessary for expression of the selectable marker or inserted coding sequence, and are not likely to alter the pathogenicity of the final GMO, since they are not translated. These sequences may be transcribed (e.g. 5’ and 3’ untranslated regions of genes), but their transcription will lead only to the expression of genes that naturally occur in the parasite, or of non-pathogenic reporter genes, so the pathogenicity of the resultant GMO is not considered likely to be increased.

b) Reporter genes/tags:

Coding or flanking sequence of genes will be placed up or downstream from reporter genes/tags. None of these reporter genes are likely to affect the virulence or therapeutic drug sensitivity of the transfected organisms, since the altered proteins thus expressed will either contain portions of proteins normally expressed by the parasite and/or reporter gene proteins which are not hazardous (eg. luciferase and GFP). The reporters are standard, used in many different experimental systems and are highly unlikely to affect the pathogenicity of an organism. Specifically, for each reporter gene:

(i) HA epitope tag: a short (10-12 amino acid) epitope derived from influenza haemagglutinin. It is highly immunogenic and therefore easily detected with commercial
antibodies. In itself it has no biological function.

(ii) Myc epitope tag: a short (10 amino acid) epitope from human c-myc, detected with commercial antibodies as for the myc tag. In itself it has no biological function.

(iii) LUC: Phontinus pyralis (firefly) luciferase (or derivatives) is an enzyme which catalyzes production of light from luciferin and ATP; the light produced is used as a measure of gene activity. The enzyme has no other biological function.

(iv) GFP and derivatives: Aequorea victoria (jellyfish) green fluorescent protein emits green light when excited by blue/UV light, and has no other known biological function. Its derivatives emit other colours of light, and again, have no other known functions.

c) Drug resistance genes and other selectable markers: P. falciparum sequences will be inserted alongside one or more drug selectable markers. Parasites expressing the transferred genes can then be selected in vitro by addition of the appropriate drug to the culture medium.

(i) The human dihydrofolate reductase (DHFR) gene provides resistance to pyrimethamine or antifolate analogues (e.g. WR99210). The resultant parasites will by definition be resistant to pyrimethamine, but since (a) the P. falciparum pyrimethamine-resistant DHFR is a naturally occurring mutation and (b) for this reason pyrimethamine is not used as a treatment for infection in the UK (and most regions globally), this does not affect the therapeutic drug sensitivity of the organism. Note also that transfected drug resistant genes confer a less-resistant folate-resistant phenotype than naturally occurring resistant alleles. Reduced levels or altered timing of gene expression are the probable cause (Lakshmanan et al (2005) EMBO 24(13):2294-305 and Crabb and Cowman (1996) PNAS 93(14):7289-94)

(ii) Other selectable markers: Genes from various bacteria confer resistance to: bleomycin, phleomycin, neomycin (geneticin, G418), tetracycline, blasticidin. In all cases, the drug used for selection would never be used for treatment of an unlikely accidental infection with the GMO, so these would not alter the ability to treat disease.

Evaluation of foreseeable effects

P. falciparum is one of five Plasmodium spp. aetiological agents of human malaria - left untreated, human malaria can cause a life-threatening illness.

The genetic modifications proposed (see previous section) specifically outline our risk evaluation with respect to any potential alteration to the hazards to human health of this organism. This, and the attached risk assessment, lead us to conclude that the transgenic Plasmodium falciparum pose no more of a hazard to human health and the environment than an unmodified Plasmodium falciparum. Given known issues with plasmid loss following genetic modification and often reduced replication rates following transfection, realistically these GMOs are actually considered less likely to be a hazard.

Presented below is information that considers effects on the risk of genetic modification to alterations to host range/tropism, altered interactions with a human host immune system and susceptibility to antimalarial therapy. These will outline our basis for an evaluation that insertion of these exogenous sequences will not affect the interaction with the human host. We do not outline here the issue of transmission. Our studies will not explore the transmission of the parasite by the mosquito vector - a risk analysis is thus primarily centred around the extant risk of the unmodified parasite - and as advised in note 6 is considered fully in the attached risk assessment.

a) Alterations to host range and tissue tropism
The inserted genes will not alter the host range of the transfected P. falciparum populations. Any genes inserted which could possibly affect tissue tropism (specifically, var genes encoding members of the clonally variant Plasmodium falciparum erythrocyte membrane protein 1, PfEMP1) are naturally occurring P. falciparum genes, and therefore do not change the tissue tropism.

b) Altered interactions with host defences
No alterations in the interaction of genetically manipulated P. falciparum with host defences are anticipated. Protein will be expressed in both transient and stable transfectants. To interact with the human immune system, these proteins must be exported to the host cell surface. Protein expressed here (such as PfEMP1) undergo clonal antigenic variation as a means of immune escape, and as such the expression of a constant epitope at the same site would only reduce virulence of the GMO.

c) Susceptibility to antimalarial drugs
Laboratory clones of P. falciparum will be rendered resistant to selection drugs: pyrimethamine (and antifolate analogues), bleomycin, phleomycin, neomycin (geneticin, G418), tetracycline and blasticidin. None of these drugs would be used for treatment in the event of accidental infection (HPA guidelines direct the use of quinine, and doxycycline/clindamycin or Malarone or an artemesinin combination therapy) The drug-resistance markers used to select transfected parasites will not therefore affect...
treatment of any accidental infections. Parasites in use within the laboratory are thus sensitive to standard chemotherapeutic treatment of malaria in the UK.

Pyrimethamine resistance will not compromise therapy as this would not be used as a first line treatment in this country in any case. Inserted sequences from other Plasmodium genes and reporter genes would not affect drug sensitivity, since these gene products are not involved in drug resistance.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable here.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The recipient organism is P. falciparum (ACDP Hazard Group 3). P. falciparum has a Certificate of Exemption accompanying the ACDP Approved List as this organism is not transmissible though aerosol routes. The secure cell culture facilities therefore do not include the following measures:

1. Laboratory sealable for fumigation.
2. Negative pressure relative to the immediate surroundings.
3. The naturally occurring organism does not represent any hazard of infection through aerosol transfer, therefore face masks are not required for this work.

The Code of Practice for use of the cell culture suite does, however, require the following control measures to be in place - based on the extant risk of the parasite to human health;

1. Use of regularly maintained and tested Class II microbiology safety cabinets (annual serice contract includes testing and validation of HEPA filters and KI dicus tests).
2. Use of microbiology jacket and non-latex gloves.
3. No sharps in the cell culture facility.
4. Safe and effective autoclave of materials within the cell culture facility (dedicated autoclave within the CL3 facility is subject to annual service contract with validation of both pressure and temperature).
5. Induction and probationary training supervised by experienced user.
6. All work is carried out in a secure cell culture facility, with access restricted to named individuals and swipe card access to the main laboratory and keypad access to cell culture suite.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Both solid and liquid waste are generated from work with transgenic P. falciparum.

Solid waste includes soiled plasticware/paperware and microscope slides. Soiled plasticware/paperware waste is treated with a 1-5% Virkon multi-purpose disinfectant solution for at least 10 minutes – this provides for complete lysis of the infected erythrocyte and parasite. This waste is secured in an autoclave bag loosely sealed at the neck, which is then contained in a second autoclave bag (left unsealed) to reduce risk of plasticware penetrating out of the bag. These are stored in an upright plastic bin (covered with a lid when not in use) until ¾ full. A trained user then takes the material into the cell culture lobby (no more than 5M) to the autoclave. The cycle employed is 121-125 degrees C for at least 15 minutes. The autoclave is regularly maintained and validated under an annual contract. Regular monitoring of activity using autoclave tape that changes colour on reaching the correct temperature for the appropriate time. The autoclaved material is then disposed of with other laboratory waste – this is removed for incineration via a commercial contract held by the University. Glass slides are air-dried and fixed with methanol – this kills the parasites. The slide is then disposed of via yellow hard sharps bins – again taken for incineration via a commercial contract.

Liquid waste is collected via vacuum into traps containing c 500mL of 10% Virkon. These are regularly changed (at least twice a week), with monitoring of effectiveness provided by changes from the pink/red colouring agent. Liquid waste is disposed of via drains with copious volumes of cold water.

An in vivo determination of the degree of kill after Virkon treatment is not possible as addition of Virkon to cultures of parasites congeals the lysed cells to a slurry. The only means of absolute detection of living parasites would require be injection of this slurry into a primate, and the Virkon itself would be toxic. By means of an in vitro assessment, no intact parasite or red blood cell is visible via light microscopy of a 5% haematocrit 2% parasitaemia culture (typically maintained in the laboratory) with an equal volume of 1% Virkon solution after 10 minutes treatment at room temperature. The stages of parasite used in this laboratory absolutely require a viable erythrocyte -
and under the conditions provided in our disinfectant procedures, these are not available.

The risk assessment (Project ID 54) was considered at a full meeting of the GMSSC on 3 February 2014. In advance of this meeting, drafts of the risk assessment were discussed informally with the Chair. For reasons of simplicity and clarity, it was agreed that the PI would remove those sections dealing with standard cloning in disabled E. coli strains through which transformation vectors for use in P. falciparum were generated. These activities, which are clearly Class 1 and do not require notification to HSE, are covered in a separately approved risk assessment (Project ID 41). Based on a discussion of the P. falciparum risk assessment (Project ID 54) it was agreed that this work should be notified to HSE as a Class 2 activity, supported by the risk assessment and full Codes of Practice. The committee approved the risk assessment and felt that the codes of practice for working with P. falciparum within the secure culture facility were both well-considered and appropriate. Within the codes of practice, some modifications to the training records were requested so that it could be clearly identified what competences had been achieved by registered workers following training. I can confirm that the necessary changes have been made to the codes of practice. The membership of the GMSSC includes a representative of the trades union recognized by Keele University and I can confirm that the outcomes of the meeting on 3 February 2014 have been disseminated to all applicable unions (UCU, UNITE and UNISON). The GMSSC also includes representatives of the Joint Workplace Safety Committee and I can confirm that the outcomes of the GMSSC meeting will be reported appropriately at the next meeting of the JWSC. (Paul Eggleston, Chair - GMSSC).

Please enter comments on the GM safety committee on the risk assessment

Project Ref 463/14.2

Date Ackn'd 18/03/2014

CU2 Project Title Molecular cell biology of Leishmania and Trypanosoma brucei

Class 2

CultureVol Class 2 1-50 Litres

CultureVolume Class 3-4 < 1 Litre

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
Purposes of the contained use

- To target specific genes for disruption by RNA interference or by homologous recombination to generate null, loss-of-function or gain-of-function mutants for phenotypic analyses, by the introduction of antibiotic resistance genes into chromosomal sites in the genomes of Leishmania or T. brucei.
- To clone Leishmania and Trypanosoma brucei genes into plasmid vectors engineered for prokaryotic expression: to express and purify the target proteins for further analyses.
- To evaluate the ability of compounds to kill parasites in vitro, towards development of new drugs

Recipient or parental organism

- Leishmania major MHOM/IL/81 Friedlin
- Leishmania mexicana
- Leishmania donovani MHOM/SD/62/IS-CL2D
- Leishmania infantum MCAN/es/98/LLM-724
- Leishmania (Viannia) braziliensis MHOM/BR/75/M2904
- Leishmania amazonensis
- Trypanosoma brucei brucei Lister 427 and GVR35
- Trypanosoma brucei rhodesiense

Host/vector system

Non-mobilisable plasmid shuttle vectors: pUC based such as the pBS or pSK series including eukaryotic sequences to allow chromosomal integration or expression of introduced genes. Plasmid vector p2T7Ti will be used for RNA interference in T. brucei.

Origin & function

The sources of the genetic material are as follows:

i) Genomic DNA from Leishmania spp. or T. brucei e.g. the BBS1 gene which encodes a component of the flagellum-associated BBSome complex. Leishmania and T. brucei genomic DNA and parasite lines will be obtained from Prof. D. F. Smith and Prof. Paul Kaye at the University of York, UK.
ii) Reporter genes or tagging epitopes: Parasite sequences may be placed adjacent to these to study expression or to create tagged proteins. Standard reporter genes and epitope tags (functions as indicated by names) include:
- c-myc epitope [Myc tag], human
- luciferase [LUC], firefly (Phontinus pyralis)
- green fluorescent protein [GFP and derivatives], jellyfish (Aequorea victoria)

iii) Drug resistance and selection markers: these permit the maintenance of transfected plasmids
- E. coli tetracycline repressor gene (TET) -- confers regulatable gene expression
- Hygromycin phosphotransferase (HYG) – hygromycin resistance
- Bleomycin resistance gene (BLE) – phleomycin resistance
- Puromycin acetyltransferase (PAC) – puromycin resistance
- Bacterial neomycin phosphotransferase (NEO) -- neomycin resistance

**Evaluation of foreseeable effects**

Species of Leishmania are causative agents of human leishmaniasis; the parasite species L. donovani, L. infantum, L. braziliensis are designated hazard group 3 (ACDP categorisation). The remaining species covered by this notification, L. major and L. mexicana, are hazard group 2 (ACDP categorisation). The trypanosome subspecies Trypanosoma brucei rhodesiense is a causative agent of human African trypanosomiasis, while T. brucei brucei is non-infective to humans but is listed by DEFRA as a Specified Animal Pathogen (cattle), therefore a SAPO licence is required. For susceptible individuals, both leishmaniasis and African trypanosomiasis are treatable (as detailed in the Keele University Code of Practice, Dec 2013). The pathogenicity of Leishmania and T. brucei species and the hazards these impose to experimental work in the School of Life Sciences are covered by the Keele University Code of Practice.

Genetically-modified and parental lines of Leishmania and T. brucei will be subject to the same safety protocols; the environmental risk is therefore no greater than with unmodified parasites. The life cycle of Leishmania involves transmission of extra-cellular parasite stages between hosts by a sandfly vector, followed by intracellular maintenance within macrophages in the mammalian host. No other organism is known to be at risk from infection. A sandfly colony is maintained in a different laboratory in the Huxley building and safety procedures are detailed in the Code of Practice to prevent accidental infection of the vector with Leishmania. Permission is not requested at the current time to undertake experimental infections of sandflies with Leishmania. The life cycle of T. brucei involves transmission of extra-cellular parasite stages between hosts by a tsetse fly vector. There are no tsetse fly colonies at Keele and the insect is geographically restricted to regions of sub Saharan Africa, therefore insect transmission of parasites from the laboratory is not possible.

Transgenic Leishmania and T. brucei will be resistant to one or more antibiotics used for selection (tetracycline, hygromycin, phleomycin, puromycin, neomycin). This is irrelevant to therapy against human disease where other drugs of choice (e.g. pentavalent antimonials, amphotericin B, miltefosine) are used for treatment.

The target genes for manipulation will be wild type Leishmania or T. brucei sequences that have been fully characterised by DNA sequencing. The products of these genes are not known to have a role in the progression of human disease but this possibility cannot be discounted for those genes coding for proteins of unknown function. The GMOs may express proteins at a level significantly higher than wild type parasites that have not been genetically-modified.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

The ACDP Approved List of biological Agents (2013) classifies L. donovani, L. braziliensis and T. brucei rhodesiense as CL3 species to which derogation can be applied, as these pathogens are not transmissible through the aerosol droplet route. This is also detailed in Appendix 3.2 of the HSE publication "Biological agents: managing the risks in laboratories and healthcare premises". The main physical control measures that are not required are:

i) Laboratory sealable for fumigation
ii) Negative pressure relative to the pressure of the immediate surroundings
iii) Extract and input air from the laboratory should be HEPA filtered
iv) Microbiological safety cabinet/enclosure

In practice, measures (iii) and (iv) will be in place in the CL3 laboratory. A Class II microbiological safety cabinet will be used in the dedicated laboratory for sterile culture of the organism but is not a requirement for operator safety. Activities will involve small scale, standard laboratory techniques with no aerosol generating procedures.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GM waste is of 2 types: liquid and solid.
Liquid GMM waste: is treated by chemical disinfection, using Distel detergent diluted 1:10 with contact time >12 hours. This gives 100% kill, as validated by testing described in the attached risk assessments.
Solid GMM waste: is autoclaved at 134 degrees C for 15 minutes at 27psi pressure. This gives 100% kill of Leishmania and Trypanosoma brucei, as validated by testing described in the attached documentation. All solid waste is sealed in bags and transported directly from the culture laboratory to the autoclave contained within the CL3 suite. This waste is handled by authorised personnel only. After autoclaving, the material is stored in a designated bin until collected for incineration.

Please enter comments on the GM safety committee on the risk assessment

The risk assessment (Project ID 57) was considered at a full meeting of the GMSSC on 3 February 2014. In advance of this meeting, drafts of the risk assessment were discussed informally with the Chair. Further clarification on various issues was also sought from experienced former colleagues of Dr Price at The University of York. Based on a discussion of the proposed work as a whole, it was agreed that it should be notified to HSE as a combination of Class 2 and Class 3 activities, dependent on the ACDP hazard group classifications of the relevant species, and supported by a copy of the approved risk assessment and full Codes of Practice. The committee approved the risk assessment and felt that the codes of practice for working with both Leishmania and Trypanosoma within the secure culture facility were both well-considered and appropriate. Within the codes of practice, some modifications to the training records were requested so that it could be clearly identified what competences had been achieved by registered workers following training. The GMSSC also noted that Dr Price will be submitting a COSHH CBA1 notification for first use of non-genetically modified parasites and a separate SAPO application to DEFRA covering the work with the cattle pathogen T. brucei. The membership of the GMSSC includes a representative of the trades union recognized by Keele University and I can confirm that the outcomes of the meeting on 3 February 2014 have been disseminated to all applicable unions (UCU, UNITE and UNISON). The GMSSC also includes representatives of the Joint Workplace Safety Committee and I can confirm that the outcomes of the GMSSC meeting will be reported appropriately at the next meeting of the JWSC. (Paul Eggleston, Chair - GMSSC).

Project Additional Information

Purposes of the contained use

The PI has 15 years experience working with CL2 viruses and 11 years working with CL3 viruses in containment.

The purpose of the contained use is several fold and described below. The research carried out focuses primarily on the interaction of virus minority variants with the host cell. We use RNA viruses as a model system, in particular we use positive stranded RNA viruses of the Togaviridae (Alphaviruses) and Flaviviridae family. These are of primary interest as they infect both arthropod and mammalian hosts, which allows us to study evolution and host adaptation during a transmission cycle. We will primarily use Semliki forest virus and Sindbis virus from the Alphaviruses and Zika virus from the Flaviviruses as our model organisms, but other ACDP2 alphaviruses may also be used as listed below.

1. To generate stocks of viruses from infectious clones.
   We use infectious clones electrophoresed into Vero cells to generate wild-type viruses as repeated cell culture passages of viruses can alter the specific infectivity of the viruses in certain cells. Therefore initially, stocks will be created from viruses that are generated using from plasmids using in vitro transcription and electroporation of the viral RNA. The resulting viruses will be stored at -80 degrees until used for viral infections.

2. To determine infection and replication competence of viruses in particular cell types.
   The viruses generated above are used to infect different cell lines including but not limited to the mammalian cell lines.
Infections will be used to measure replication and infection by using standard growth curves and measure virus titer using standard plaque assays. The RNA of viruses will also be used for next generation sequencing to determine the effect of different cell types on RNA secondary structure and the production of minority variants.

To determine the effect of RNA secondary structure on the generation of virus minority variants

Infectious clones will be modified to generate viruses that have the secondary structure altered while retaining the protein coding region of the viruses. These viruses will be used to generate infections in the cell lines described above to determine how the secondary structure affects the production of minority variants.

To determine the effect of changes in mutation rate/fidelity in the virus

Mutations identified in Venezuelan equine encephalitis virus and West Nile virus (Kautz et al. 2018, Van Slyke et al. 2015) that result in changes in replication fidelity or alterations in the mutation rate of specific mutations, will be introduced into the infectious clones. Our experience with such mutations indicates that they will result in attenuation of the viruses. We will investigate the method of attenuation and the effect of these mutations on virus replication and virulence as well as the interaction of these viruses with the host immune system.

To determine the effect of minority variants on host cell interactions

Specific mutations and deletions that are found during natural replication will be incorporated into the infectious clones. These altered viruses will be rescued and assessed for their ability to replicate and infect other cells. Our experience of such mutants is that many are not viable and those that are able to produce virus show evidence of attenuation.

To infect mosquitoes to determine competence for particular viral mutations

The specific mutations associated with minority variants and with replication fidelity/mutation change will be used to establish infections in Aedine and Culicine mosquitoes. The only GM organism will be the virus, the mosquitoes will be wild-type and not GMO modified. Experimental infections will be carried out in small containers within a biosafety cabinet and mosquitoes will only be manipulated when anaesthetized and on ice. Once the mosquitoes have been incubated for 12-21 days, mosquitoes will be dissected and the resulting tissues tested for the presence of virus using the appropriate cell culture assays.

Recipients or parental organisms

Viruses:
The alphaviruses are a diverse group of small, spherical, enveloped viruses with single-stranded, positive-sense, RNA genomes and have been isolated from all continents except Antarctica. They belong to the family Togaviridae, and include 29 recognized species.
The ACDP2 alphaviruses are all classed as arthralgic alphaviruses that cause mild to severe arthritis upon infection, sometimes accompanied by mild febrile illness with a maculopapular rash. The ACDP2 viruses that we propose to use are Sindbis virus, Semliki Forest virus, Ross River virus, O’nyong nyong virus and Bebaru viruses. These viruses are not responsible for significant illness or fatalities. In addition, these viruses are not easily aerosolized and the major route of transmission is mosquito bite. Infection routes in the laboratory are generally as a result of sharp exposure or mucosal infection. The two alphaviruses that will be worked with primarily will be Sindbis virus and Semliki forest virus. Semliki Forest (SFV) and Sindbis viruses (SINV) are arboviruses that were isolated from mosquitoes in Uganda and Egypt respectively. In humans these viruses generally cause a self-limiting mild febrile illness. SFV has only been identified as causing more than a mild self-limiting illness on two occasions. One was a lab infection, where the worker was found to be immune deficient. The second was when the serum samples of individuals having persistent headaches, fever, myalgia and arthralgia were found to have SFV. It is unclear why these strains of SFV had a different manifestation to most SFV strains. SINV causes a mild febrile illness, but has not been associated with any human disease. Of the other alphaviruses that are proposed to be used, Ross River virus
causes some mild arthralgic illness and O'nyong nyong virus has been associated with some outbreaks of mild arthralgic disease. Bebaru is a sub-type of SINV and is not generally associated with any human infections.

The only Flavivirus we propose to use is Zika virus. Flaviviruses, like Alphaviruses are enveloped viruses that are transmitted by a variety of species. Zika virus is found within the mosquito-borne group of flaviviruses and is typically transmitted by Aedine mosquitoes. Until 2014 Zika was considered an obscure virus in the Flaviviridae family. However, a large outbreak in Brazil resulting in serious birth complications associated with infection of Zika in pregnant women resulted in a concerted effort to understand the virus. Zika was first described in Uganda in 1947 and while there were numerous people with antibodies against the Zika virus, there was no evidence of significant outbreaks of the virus. The virus causes a mild febrile illness in adults and the major risk factor appears to be to the fetus if the mother is infected during pregnancy. Zika is transmitted by the Aedes aegypti mosquito and is primarily found in the Americas and Asia. Sporadic cases have been observed in Europe but these are a result of exposure during travel.

For all the above viruses, wild-type sequences of the viruses will be used to generate infectious clones, i.e. virus in the form of cDNA inserted into a bacterial plasmid with either a T7 or Sp6 bacterial promoter, or a CMV promoter. These full-length plasmids will be sequenced to confirm the genome of the virus and to ensure that no inadvertent mutations are included. Following confirmation of the correct sequence, the plasmid will be linearised, transcribed into RNA and electroporated into cells. To validate particular RNA secondary structures or mutations described above, deliberate mutagenesis will be performed using a variety of different protocols. All plasmids that are mutagenized will be sequenced to confirm that no other mutations are generated. These viruses containing specific mutants will be linearised, transcribed and electroporated into cells. Stocks of both wild-type and viruses containing mutations will be harvested and used for future work.

These viruses will be used to initiate cell infections with various cell types including but not limited to Vera cells, MRC-5 cells, U4.4 cells and C6/36 cells. In addition, some mosquito infections will be carried out. Mosquitoes will be infected with an artificial bloodmeal containing virus. Mosquitoes will be held for up to 21 days. Mosquitoes will be sampled by taking legs/wings, salivary deposit, midguts and salivary glands.

Host/vector system

Prokaryotic Hosts: All strains of E. coli used in this work are apathogenic, commercially available strains (e.g. Sure, JM109, DH-strains, Rosetta, TopTen etc.) classified as 'especially disabled hosts' by ACDP. These strains are only able to survive in the controlled environment of the lab and are used for propagation of the plasmids described above.

Eukaryotic hosts: Eukaryotic cells will be used to propagate the viruses, at no point will the introduction of the virus alter the host cell genome. These eukaryotic cells include cell lines of vertebrate or arthropod origin (for example, Vero cells (African Green monkey cells) or U4.4 cells (Aedine embryonic cells). Mosquito hosts such as Aedes aegypti and Aedes albopictus will also be used, once infected mosquitoes will be held for up to 21 days before being sampled. Once the mosquito tissue has been processed, the viral sample is handled as any other viral sample.

Origin & function

Viruses in plasmid forms will be obtained from collaborators at Leeds University and Glasgow University as well as from the WRCEVA reference collection at UTMB in Galveston, who already have the plasmids available. Prior to use the plasmids will be sequenced to confirm the sequence expected. The function of the genetic material is to produce viable virus for further study. These GMO organisms contain either the wild-type sequence, or mutations and deletions that are produced during normal viral replication, or mutations that our preliminary data shows cause attenuation of the virus. As these are transported in a DNA form there are no additional risks from transporting normal DNA samples.

The genetic material produced from this is designed to generate viral particles and these will function as viable virus once rescued.
The expected nature of this work is as described below. For all our experiments, any unexpected observations with viruses rescued from the plasmids will result in all work with that virus ceasing and a risk assessment being performed. As a routine measure all work will be carried out at containment level 2.

1. To generate stocks of viruses from infectious clones.

We do not expect any change from wild-type viruses during this portion of the work. Use of plasmids to generate viruses to create large scale stocks of particular strains of viruses is a common tool in virology. There have been no indications that this will lead to any change from that expected for wild-type viruses. Therefore this carries no more risk than working with wild-type viruses at CL2.

2. To determine infection and replication competence of viruses in particular cell types.

Although it is always possible that infection in different cell type could result in a change in the virus, our experience with both Alphaviruses and Flaviviruses is that in both mammalian and insect cell lines, infection is usually 2-3 days in length. Mammalian cells will produce observable cytopathic effect within 2-5 days, whereas infection with insect cells is asymptomatic and does not produce any overt sign of virus. It is not expected that there will be any changes from wild-type, therefore there this is a low risk procedure.

3. To determine the effect of RNA secondary structure on the generation of virus minority variants

RNA viruses have optimised their genome to maximise replication efficiency. We therefore expect that any mutation that alters the secondary structure of these viruses to attenuate the viruses. While we have no preliminary data to determine this, our hypothesis is that the secondary structure influences the production of specific minority variants. Therefore, it is likely that altering the secondary structure will impair the ability of the virus to generate minority variants, which has the potential to attenuate the virus by altering the distribution of important minority variants that are used to facilitate replication and transmission. Given that we expect this to attenuate the virus this aim is also low risk.

4. To determine the effect of changes in mutation rate/fidelity in the virus

Mutations identified in Venezuelan equine encephalitis virus and West Nile virus (Kautz et al. 2018, Van Slyke et al. 2015) will be introduced into the infectious clones. Our experience with such mutations indicates that they will result in attenuation of the viruses. This attenuation has been observed in many different systems including poliovirus, and influenza virus. Ultimately, it is likely that any change in the RNA-dependent RNA-polymerase from the wild-type will result in attenuation of the virus, as RNA viruses have optimised their RNA-dependent RNA-polymerase to maximise efficiency and replication. Given that we expect this to attenuate the virus this aim is lower risk than that in aim 1.

5. To determine the effect of minority variants on host cell interactions

Specific mutations and deletions that are found during natural replication will be incorporated into the infectious clones. These altered viruses will be rescued and assessed for their ability to replicate and infect other cells. Our experience of such mutants in Venezuelan equine encephalitis virus is that many are not viable and those that are able to produce virus show evidence of attenuation. Given these previous results we expect that any mutations incorporated will result in changes in the ability of the virus to infect cells. Similar results were observed in West Nile virus (personal communication) suggesting that these minority variants only function well when the wild-type virus is also present in the cell. Again given the expected attenuation of the viruses this is lower risk than that in aim 1.

6. To infect mosquitoes to determine competence for particular viral mutations

For wild-type viruses, it is expected that between 50-90% of mosquitoes will be infected with the virus, and while these viruses are transmissible following infection of mosquitoes, safe handling of mosquitoes and the use of primary containment and a glove box reduces the risk. For the viruses that have been modified from wild-type, we again expect that any modification will reduce the ability of the virus to infect mosquitoes. In our experience, mosquitoes will be infected in the midgut, but will be unable to disseminate to the rest of the body and therefore unable to generate virus to be transmitted to another host. Our data on Venezuelan encephalitis virus shows that any change to the RNA-dependent RNA-polymerase results in reduction of disseminated mosquitoes to 5-15% compared to 80-90%.
for wild-type (Warmbrod et al. submitted). Given this, we recognize that this may represent a slightly higher risk than wild-type if these results <;Ire not observed. However, our expectation is that any modification from wild-type generally results in attenuation in both in vitro and in vivo hosts. Therefore this aim is low risk, but any change from the expected risk will result in cessation of all work until a further risk assessment is carried out.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Mosquitoes will be maintained for up to 21 days following bloodmeals. Mosquitoes will be sampled by removing the legs/wings of mosquitoes. Salivation of the immobile mosquito into FBS and then removal of the salivary glands and the midgut. All manipulations prior to the removal of legs/wings will be done on ice to prevent mosquito movement. All manipulations will be performed in the glovebox. All samples will be put in individual tubes with safe-lock tubes including a stainless-steel ball for trituration.

The major risk is preventing mosquito escape once infected with the virus. All mosquitoes will be manipulated in a separate room with a double door and a net on the inner door. All manipulations of mosquitoes will be performed in a sealed glove box. Mosquitoes will be contained within primary containment with no more than 50 mosquitoes, which allows accurate counts to be maintained, in a sealed carton with a mesh lid. Mosquitoes will only be manipulated outside the primary containment when they are cold anaesthetized and cannot fly. They will also be manipulated on ice at all times to prevent recovery from the cold anaesthetization. Once the mosquitoes have been manipulated they will be placed back into the primary container where they are sealed. They are then placed in a secondary Tupperware container and placed in an incubator. Accurate counts of mosquitoes are maintained at all times. If any mosquito is missing, the person cannot leave the room until all mosquitoes are accounted for. An insectocutor can also be placed within the room or within the man trap if deemed necessary.

If a mosquito escapes outside the glove box, the user should call Dr. Forrester-Soto from the phone within the room. They must stay within the laboratory and try and catch the mosquito. No-one can enter or exit during this time. If after 3 hours the mosquito cannot be caught, a CO2 trap will be set up and left in the room for 24 hours. All captured mosquitoes will be killed following capture by the trap.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All alphaviruses and flaviviruses are killed when exposed to a 5% bleach solution or to the antimicrobials, cavicide or virkon. Specific protocols have been validated for killing of viruses and inactivation of viruses for further work. These methods have been validated for alphaviruses and published (Patterson et al. 2018). We have not validated these methods for flaviviruses, but prior to use, we will follow the same protocol to validate these methods.

Waste methods for the laboratory are described below.

All waste materials must be decontaminated prior to disposal from the cell culture virology room.

a. Paper waste generated in the MSC

   Paper waste generated in the BSC should be placed in a biohazard bag within the BSC. When the bag is 2/3 full, loosely tape, surface decontaminate, remove from BSC and place in biohazard bag located in the laboratory for further decontamination via the autoclave. .

b. Biological waste generated in the MSC

   Biological waste (pipette tips, serological pipettes, tubes, flasks and cell culture plates) must be placed in an autoclave-safe pan containing an appropriate disinfectant (CavicideNirkon, 5% Microchem or 5% freshly prepared bleach). All TLtubes, flasks and culture plates must be opened; pipette tips and serological pipettes must be rinsed (aspirate disinfectant and eject) so that the any virus within the pipette tip is also disinfected, prior to disposal in
autoclave pan. Do not overfill autoclave pans, the lid must close appropriately. 

i. Once work is complete all pans should be sealed with autoclave tape. Surface decontaminate the entire pan and remove from the BSC and store in a secured area for 24 hours.

ii. Following a 24 hour contact time; without opening the lid on the pan, drain the pan of all liquids down the sink in the laboratory. Discard solid waste in the biohazard bag located in the laboratory for autoclaving. Generally, 30 minutes is sufficient contact time for this concentration of bleach to kill alphaviruses and flaviviruses. However, 24 hours is used to ensure complete kill of any infectious material.

c. Vacuum traps
Vacuum traps must contain 10% fresh bleach (the bleach must be prepared daily). It must have a HEPA filter installed between the second flask (overflow flask) and the vacuum pump or in-house connection. At the end of the procedure the tubing must be rinsed with bleach followed by water. The waste must stand for at least 30 min in the flask before pouring it down the drain and cleaning the flask.

d. Waste generated in the Lab
i. All waste from the Lab must be considered infectious and therefore, must be decontaminated. Waste will be placed in autoclave bags in the laboratories prior to autoclaving. Autoclave bags must be loosely closed or taped when they are no more than 2/3 full. They must then be double bagged prior to autoclaving and placed in a lock-proof container such as an autoclave pan. Waste must not be left in the corridors.

ii. Autoclave waste must not be left in the autoclave. Users must ensure that waste is removed within 24 hours after the completion of the cycle.

e. Infected mosquitoes
i. All mosquitoes must be counted to ensure all infected mosquitoes are accounted for. As all mosquito manipulations should be performed in the glove box and the secondary container should only be opened in the glove box the most likely escape is in the glove box. Escaped mosquitoes in the glove box must be killed using paper towels present in the glove box for that eventuality. In the event of an escape outside of the glove box containment, personnel will not be allowed to leave the room until the mosquito is killed. As described above, in the event that the mosquito cannot be found after 3 hours, a CO2 trap will be placed in the room to collect the mosquito, after 24 hours, any mosquitoes will be killed. Mosquito tissues for processing are treated in the same way as the infected cell culture, inactivated using the correct buffer for downstream processing.

ii. The remaining mosquitoes are placed in 70% ethanol before being autoclaved to inactivate all viruses present in the samples.

Please enter comments on the GM safety committee on the risk assessment

Is an emergency plan required according to regulation 20? [N]  
If yes, tick to confirm that it is attached to this form [N]  
Tick to confirm that you have attached a risk assessment to this form [Y]  
Tick if you are claiming exemption from disclosure for section of the risk assessment [N]
Risk assessments have been written in consultation with (Chair of the Keele University Genetic Modification Safety Sub-Committee, GMSSC), (University Biological Safety Advisor) and (Head of Department of Occupational Health and Safety). As there is currently no virology work being carried out at Keele, an external academic with expertise in this area (University of Glasgow) was also consulted to ensure processes were suitable and robust. Full consideration has been given to any risks to human and animal health and release into the environment and the necessary containment measures needed to reduce risk to a negligible level. The notification documents have been approved by all members of the GMSSC which includes trade union representation.

### Project Ref 463/20.1

**Date Ackn’d**: 21/05/2020

**CU2 Project Title**: Production of SARS-Cov-2 virus like particles (VLP’s) containing a reporter system for initial screen of treatments and antivirals

**Class**: Class 2

**CultureVolClass2**: < 1 Litre

**CultureVolumeClass3-4**: Non-GMM

**Consent Granted**: Yes

**Project notified under transitional arrangements**: Yes

### Project Additional Information

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**
### Purposes of the contained use

The notifier has 15 years experience working with CL2 viruses and 11 years working with CL3 viruses in containment.

The purpose of the contained use is to identify compounds that prevent infection of cells and therefore infection of SARS-CoV-2. The VLP’s will be used to infect cells in the presence of different compounds and the degree of reporter gene recorded.

### Recipient or parental organism

**Viruses:**

The coronaviruses are a group of viruses that typically circulate within wild animals and occasionally emerge to jump into humans. There are 6 known human infecting coronaviruses, of which SARS-CoV-2 is the latest to emerge and has caused significant human infection. Coronaviruses are a group of RNA viruses, that unusually contain a proof-reading domain. This allows them to replicate their large genome with greater ease. Although SARS-CoV-2 is a relatively new addition to the list of human coronaviruses, we know that the virus has a propensity for ACE2 receptors on human cells. The virus causes a wide range of symptoms from severe to mild, with the worst being Severe Acute Respiratory (SAR) distress which requires hospitalization and a prolonged stay on a ventilator and may be fatal. Initial reports suggest that co-morbidities such as advanced age, obesity, cardiovascular and cerebrovascular disease as well as diabetes contribute to severe disease. However, it has become apparent that age is not a good predictor of severe disease. There is emerging evidence that the amount of virus the person is exposed to and potentially host genetics could play roles in determining the severity of disease.

All coronaviruses are transmitted through droplet transmission or aerosol transmission. The major route of transmission in the environment is contact with aerosols generated by an infected person. In the lab with wild-type virus the major source of infection would be any aerosol-producing technique. This includes but is not limited to, centrifugation, pipetting and vortexing. All of these will be done under conditions designed to reduce aerosol transmission and in a microbiological safety cabinet, or in the case of centrifugation in sealed buckets.

Recent work with the viruses has also identified that fomites can play a role in Coronavirus transmission. It appears that the virus is stable on metal and plastic surfaces for up to 3 days. All areas in contact with virus will therefore be wiped down with Virkon or Cavicide following any manipulations in the MSC.

### Host/vector system

**Prokaryotic Hosts:** All strains of E. coli used in this work are apathogenic, commercially available strains (e.g. Sure, JM109, DH-strains, Rosetta, TopTen etc.) classified as ‘especially disabled hosts’ by ACDP. These strains are only able to survive in the controlled environment of the lab and are used for propagation of the plasmids described above.

**Eukaryotic hosts:** Eukaryotic cells will be used to propagate the viruses and at no point will the introduction of the virus alter the host cell genome. These eukaryotic cells include but are not limited to cell lines of vertebrate origin (for example, Vero cells (African Green monkey cells) and 293T cells (kidney epithelial cells)).

### Origin & function

**Pseudoviruses** will be generated by the incorporation of the envelope and spike proteins into the plasmid pcDNA3.1 (commercially available from Invitrogen). A second plasmid pNL4-3Luc(env-) has been developed to have a reporter gene in conjunction with genes encoding the HIV proteins gag and pol. The plasmid is available on request from the NIH AIDS Institute and has been previously used with the H5 protein from avian influenza (Skidmore et al. Med. Chem. Commun. 2015, 6,640).

The plasmids will be transfected into cells together to produce a pseudotype virus with the luciferase reporter gene in complex with the HIV gag and pol proteins (the envelope protein has been replaced with the luciferase reporter gene). This pseudotype virus will produce envelope proteins consistent with the SARS-CoV-2 virus.

Once the pseudotype virus has been produced, it will be harvested, and titrated for luciferase expression in lieu of identification of virus titer.
The pseudovirus system will then be used to test agents that may prevent virus entry into cells and therefore the amount of luciferase expressed in cells. This will be used to validate the fractions of the heparin that have been identified as having potential to interact with the virus. Other promising compounds will also be tested using this system.

This system has been successfully used at CL2 level with Henipa and Nipah viruses as well as with SAPO agents such as Newcastle disease virus (NDV). (https://www.ncbi.nlm.nih.gov/pmc/articles/PMC2994542/, https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4061091/, ). Some concerns have been raised with the use of this system with HIV envelope proteins as to the possibility of recombinant (https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5372769/). However, as this system will be used in the absence of any HIV envelope proteins, this possibility is remote. To confirm that there is no possibility of revision, we will test the pseudotyped produced virus using Gag, Pol and Luciferase primers. We will also use SARS-Cov-2 non-structural and envelope primers, with the expectation that if the Gag, Pol, Luc and SARS-CoV-2 envelope proteins are PCR positive and the non-structural protein PCR is negative that there will be no issues with the safety of the virus. Due to the small potential of human infection in immunocompromised personnel, all procedures will be carried out at CL2 levels in a MSC.

**Evaluation of foreseeable effects**

The expected nature of this work is as described below. For all our experiments, any unexpected observations with viruses rescued from the plasmids will result in all work with that virus ceasing and a new risk assessment being performed. As a routine measure all work will be carried out at containment level 2.

1. To generate stocks of pseudotype virus.

   This has been used successfully in our collaborators’ laboratory in San Raffaele in Italy, and the plasmid contains no non-structural proteins that would facilitate viral replication. Initially we will verify that the pseudovirus has been generated as expected, and a set of PCR's that amplify the Coronavirus envelope protein, the HIV gag protein and the luciferase gene will be used to verify that this pseudotype virus is stable. At each infection a control infection will be carried out and RNA will be harvested and verified using these PCR's. We will also use PCR to amplify a gene encoding a non-structural Coronavirus protein to ensure that the circulating transmission in the human population is not impacting these studies.

2. Validation of compounds inhibiting pseudotype entry into cells.

   As most of these compounds already exist and have been well characterised there are few issues associated with this work. However, in the event that a compound causes an increase in reporter gene expression, all experiments with that compound would be stopped and an additional risk assessment performed.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Coronaviruses are killed when exposed to a 5% bleach solution or to the antimicrobials, caviocide or virkon. Specific protocols have been validated for killing of viruses and inactivation of viruses for further work. These methods have been validated for alphaviruses and published (Patterson et al. 2018), both the validation methods and confirmation of inactivation. We have not validated these methods for Coronaviruses, but prior to use, we will follow the same protocol to validate these methods for Coronaviruses.

Waste methods for the laboratory are described below.
All waste materials must be decontaminated prior to disposal from the cell culture virology room.

a. Paper waste generated in the MSC

Paper waste generated in the BSC should be placed in a biohazard bag within the BSC. When the bag is 2/3 full, loosely tape, surface decontaminate, remove from BSC and place in biohazard bag located in the laboratory for further decontamination via the autoclave.

b. Biological waste generated in the MSC

Biological waste (pipette tips, serological pipettes, tubes, flasks and cell culture plates) must be placed in a hard-sided autoclave-safe pan containing an appropriate disinfectant (Cavicide/Virkon, 5% Microchem or 5% freshly prepared bleach). All tubes, flasks and culture plates must be opened; pipette tips and serological pipettes must be rinsed (aspirate disinfectant and eject) so that the any virus within the pipette tip is also disinfected, prior to disposal in autoclave pan. Do not overfill autoclave pans, the lid must close appropriately.

i. Once work is complete all pans should be sealed with autoclave tape. Surface decontaminate the entire pan and remove from the BSC and store in a secured area for 24 hours.

ii. Following a 24 hour contact time; without opening the lid on the pan, drain the pan of all liquids down the sink in the laboratory. Discard solid waste in the biohazard bag located in the laboratory for autoclaving. Generally, 30 minutes is sufficient contact time for this concentration of bleach to kill alphaviruses and flaviviruses. However, 24 hours is used to ensure complete kill of any infectious material.

c. Vacuum traps

Vacuum traps must contain 10% fresh bleach (the bleach must be prepared daily). It must have a HEPA filter installed between the second flask (overflow flask) and the vacuum pump or in-house connection. At the end of the procedure the tubing must be rinsed with bleach followed by water. The waste must stand for at least 30 min in the flask before pouring it down the drain and cleaning the flask.

d. Waste generated in the Lab

i. All waste from the Lab must be considered infectious and therefore, must be decontaminated. Waste will be placed in autoclave bags in the laboratories prior to autoclaving. Autoclave bags must be loosely closed or taped when they are no more than 2/3 full. They must then be double bagged prior to autoclaving and placed in a leak-proof container such as an autoclave pan. Waste must not be left in the corridors.

ii. Autoclave waste must not be left in the autoclave. Users must ensure that waste is removed within 24 hours after the completion of the cycle.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Project Additional Information

The containment is required for the cultivation of erythrocytic stages of Plasmodium parasites. Parasites are maintained in in-vitro cell cultures by providing human red blood cells to support their growth. Erythrocytic stages are maintained in in-vitro cell cultures by providing human red blood cells to support their growth. Erythrocytic stages are used in the presented research project to study the biology of Plasmodium strains competent to infect humans. This project aims to discover and validate targets useful...
for malaria therapeutic interventions by applying genetic biochemical and cellular techniques presented.

Recipient or parental organism

Plasmodium is an apicomplexa parasite that completes its life cycle infecting alternatively mosquitoes (genus Anopheles) and vertebrates. In vertebrates it causes malaria. Human malaria is a deadly disease that affects about a half of the world population. The present project aims to study essential and critical genes for parasite asexual development and sexual differentiation. The strains under study are P. falciparum, vivax and knowlesi. In mosquitoes and humans Plasmodium respectively accomplishes sexual and asexual development. Plasmocium developmental stages used in this project are the erythrocytic stages and the initial phases of sexual development in absence of the vector. These stages are cultivated in vitro by providing human red blood cells (RBC), essential to support parasite growth. In fact Plasmodium is an obligate intracelular parasite.

Host/vector system

Since there is no way to maintain Plasmodium except inside red blood cells (RBCs), the parasites will be cultivated, transfected and stored inside RBCs. No forms/stages of erythrocytic parasite development can persist in the environment following RBC lysis. This project will use laboratory strains with known drugability and drug resistance. Genetic modification will be achieved by electroporation of purified plasmids constructed and analyzed in E. coli into RBCs. All the plasmids used in this project derive from pBlueScriipt and therefore are non-mobilisable.

Origin & function

Fragments of DNA that encode for fluorescent proteins such as GFP, yFP and RFP derivates will be used as probes for transfected parasites, for promoter functions, for protein tagging and for trafficking detection. These fragments originate from jellyfish and corals. They enable detection and visualization of parasites using fluorescence microscopy or flow cytometry. Fragments of DNA that encode for SB100x transposase, TALEN, endonucleases, recombinases, recombinin, will be used in this project. SB100X derives from Sleeping Beauty transposases and was produced and characterized by the Izsak's laboratory (Nat Genet. 2009 June; 41(6): 753-76L1). SB100X enables the insertion of a DNA fragment flanked by specific inverted repeats into the genome. TALEN is a chimera of TALE (Transcrition activator -like effectors from gene product recognizes specific DNA sequences and digests in the proximity of them. Homing endonucleases, such as Scel, specifically recognize and digest long stretches of DNA sequence (Gimble & Thorner, Nature, 1992, vol 35:35; hybridized short RNA molecule (Mali P. et al., Science, 2013, vol339, pp823-826). Cre recombinase is a tyrosine recombinase enzyme derived from the P1 Bacteriophage (Abreseth & Hoess Journal of Biological Chemistry 1984, 259: 1509-1514) and Flp is a recombinase enzyme derived from Saccharomyces cerevisiae (Broach & Hicks, Cell 1980, vol 21: pp. 501-508). These recombinases excise and insert DNA fragments flanked by specific DNA sequences called Lox and Frt, respectively. All these gene products enable genome editing and recombinaton. These molecules will be used to generate parasites that are defective in metabolic functions. Other fragments of DNA included in our plasmids encodes for specific drug resistance, such as human dihydrofolate reductase (hDHFR), yeast dihydroorotate dehydrogenase (yDHOXD) and blasticidin-S deaminase (BSD); Tetracycline transactivator proteins, and specific Plasmodium proteins or protein fragments under biochemical characterization. Accessory DNA fragments are used for optimal plasmid segregation and Plasmodium expression, as minimal centromer, Rep20, Promoters and 3’ untranslated regions.

Evaluation of foreseeable effects

There is no risk in the genetic modificatons included in this project for multiple reasons (1) The modifications will not cause a gain of function, or increase the wildtype danger, infectivity, virulence and environment or disinfectant resistance. In fact, used approaches aim to disable paraites in any of their vital functions and virulence, in order to gain access to unknown gene functions. (2) drug resistance genes (above listed), used to select transfected parasite, will be the only gain of functions. Nevertheless, despite the introduction of drug resistance genes, strains used in the present project will remain pharmacologically treatable, if therapeutic intervention is needed for accidental events. (3) There is no possibility to spread the modified parasite, wild type or mutant can survive in the environment. In fact, minimum changes is salts concentration of the media or air exposure will result in hemolyzed or dried RBC with consequent death of parasites (i.e. tap water kills parasites by RBC lysis). In order to reduce the risk of accidental injuries (like cuts or punctured wounds) that may expose to infection, glassware will be avoided as much as possible (details in the code of practice), and sharps (blades or needles) must not be used during Plasmodium culturing.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We request some derogations to CL3 containment level in accordance to the fact that cultivated stages cannot cause airborne transmission and the vector is absent from the natural environment in the United Kingdom. In particular, the requested derogations regard the following CL3 requirements: sealable laboratory for fumigation (M2), entry to laboratory via airlock (M4), negative pressure relative to the pressure in the immediate surroundings (M5) and HEPA filtered air from the laboratory (M6)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Treatment of contaminated items.
- Pippette tips and Graduated Pipettes: Place into polypropylene jars containing 2% Virkon. Incubate for 24 hours and then Virkon solution will be poured down the sink and solid waste disposed into autoclavable 'clini' bags.
- Microfuge tubes, Disposable cuvettes, Electroporation cuvettes, flasks and plates: they should be placed in a separate autoclavable 'clini' bag within the microbiological safety cabinet.
- 'Clini' autoclavable bags: When 3/4 full the neck of the autoclavable bag is loosely tied and moved into the autoclave tins and autoclaved within the suite. After autoclaving it is sent off site for incineration.
- Glass slides used in preparing blood smears of Plasmodium-infected red blood cells: they should be placed in a sharps bin. Plasmodium in blood smears on glass slides is inactivated by means of the fixative used to fix the blood film to the slide prior to staining. Because of this inactivation the glass slides can be disposed of by placing in a sharps bin and entering the clinical waste route.
- Liquid Waste: Cuvettes, glasks and universal/falcon tubes containing liquid waste are to be emptied or aspirated into jars containing 2% Virkon and after 24 hours incubation disposed down into the sink.

Disinfection procedures.
- Surface sterilisation; Hard surfaces such as the work surface of the safety cabinet or benches must be disinfected with 70% Ethanol.
- Equipments and their parts must be disinfected with 1% Distel.
- Spillages: Suspected contamination on hands, gloes or work surfaces must be disinfected immediately with 70% Ethanol. Minor spillages (up to ~ 10 ml) should be treated with 70% Ethanol and wiped with towels. Large spillages (>10ml) must be treated with Virkon powder and then wiped with 70% Ethanol soaked towels.

### Purposes of the contained use

The biological function of the prion protein PrPC is not known. It is thought that the disease isoform of this molecule, PrPSc, may be the infectious agent for BSE in cattle and scrapie in sheep. We wish to produce recombinant truncated forms of ovine and bovine PrP. Once purified monomeric truncated PrP will be converted to the -form for use as a target for antibody isolation in order to produce -form PrP conformational specific antibodies. Such antibodies may also be specific for the disease isoform PrPSc.

### Recipient or parental organism

The proposed E. coli hosts Novablue DE3 and TG1 are routinely used lab strains of E. coli that are inherently safe K12 derivatives. The PrP gene inserts, from bovine or ovine source, are truncated and do not possess the GPI anchor domain or the export signal domain. The truncated versions would therefore be significantly different from the disease and are likely to pose a reduced risk to human or animal health.

### Host/vector system

The PTrcHis, pRSET, pET, pMal expression vector systems will be used in the K12 derived E. coli host strains Novablue DE3 and TG1.

### Origin & function

The truncated PrP genes are from bovine or ovine origin. These would be produced in the E. coli host cells using the expression vectors PTrcHis, pRSET, pET, and pMal which produce target proteins fused to either a poly-His tag or maltose binding protein, these tags would then be used to affinity purify the PrP-fusion proteins.

### Evaluation of foreseeable effects

Due to the truncated nature of the inserts in the constructs proposed here and that the expressed proteins are structurally distinct from the disease isoforms (they need prolonged incubation at low pH in vitro to produce the conformational change thought to be central to the propagation of PrPSc, i.e. from a predominantly a-helical structure to a predominantly -structure) the hazards to human health are low and containment level 2 is appropriate.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

**Solid waste:**

Disposable plastic ware will be used wherever possible, disposable solid waste (including E. coli plates) to be put in biohazard burn bins and sent for incineration (100% kill). Reusable contaminated solids (including E. coli growth flasks) to be soaked in 20,000 ppm available chlorine of sodium hypochlorite for at least 2 hours, except for contaminated metal equipment which will be soaked in 2m sodium hydroxide for at least 2 hours.

**Lique waste:**

All liquid waste (including E. coli cultures) will be treated with 20,000 ppm available chlorine of sodium hypochlorite for at least 2 hours. Spills would be cleaned up with paper towels which will be treated as solid waste, contaminated spill areas will be soaked in 20,000 ppm available chlorine of sodium hypochlorite for at least 2 hours.
except for contaminated metal which will be soaked in 2M sodium hydroxide for at least 2 hours. Where soaking is not possible, contaminated areas will be wiped down with one of the above disinfectants (as appropriate) at least 3 times allowing drying between applications for at least 1 hour. All work using the listed constructs in E. coli will be carried out in the BSE suite (biology Dept., University fo Leicester) and the SOP for this lab followed.

Disinfectant to be used, exposure time and working concentration:
2M sodium hydroxide or 40% (v/v) Haychlor industrial bleach (Chloros hypochlorite bleach). A 40% (v/v) solution of Haychlor industrial bleach contains 20,000 to 64,000 ppm available chlorine (manufacturers data). Decontamination procedures obtained from “transmissible spongiform encephalopathy agents: safe working and the prevention of infection. Advisory Committee on Dangerous Pathogens, Spongiform Encephalopathy Advisory Committee. ISBN 0-11-322166-5.

N.B. The above waste treatment/decontamination procedures are to ensure that contaminating recombinant PrP is destroyed, these procedures will also ensure that viable E. coli are unlikely to remain after treatment. For example University's guidelines from "Genetically Modified Organisms" and "Hazardous Biological Agents" state that solutions containing 1,000 ppm available chlorine (e.g 1% Chloros) are suitable for routine disingection of bench tops and other surfaces. 2.5% Chloros or equivalent is suitable for pipette jars and spillages of blood etc. 10% Chloros or equivalent should be used for blood and other materials with a high organic content if the presence of infectious agents is suspected.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y

Please enter comments on the GM safety committee on the risk assessment

Agreed:
1 That a designation of Class 2 is appropriate
2 That the risk assessment is sound and that work should be carried out at Containment Level 2
3 That the proposer should forward the proposal to HSE for prior approval of the project.

<td>INDUCIBLE EXPRESSION OF CELL SIGNALLING MOLECULES IN</td>
<td>Class 2</td>
<td>&lt; 1 Litre</td>
<td></td>
</tr>
</tbody>
</table>
This aim is to express cell signalling molecules in hormone-secreting cell lines, to examine their functional roles in hormone secretion in these cells. The tet-on inducible expression allows for control levels of expression, with activated transcription in the presence of tetracycline (Tc) or analogues.

The cell lines used for packaging of the replication deficient retroviral vectors and for the expression of signalling-molecule cDNAs have a history of safe use. Alterations in the properties of the cells used in this work as a result of expression of these cDNAs will be negligible if any. The genetically modified cells are very unlikely to pose more of a hazard than the parental cell lines.

Genes of interest will be inserted into the expression vector (pRev-TRE, Clontech). Both this and the pRev-TET-on (Clontech) vector are considered as non-mobilisable. Both these vectors will be propagated in a suitable E. coli strain (eg DH5alpha, XL-1 Blue), which are recognised as non-colonising and disabled. The pRevTRE vector and the pRevTET-on plasmid will be independently transfected into the packaging cell line (RetropackTM PT67, Clontech), which produces viral proteins from stably integrated genes. Viral lysates will be used to infect cultured mammalian cell (PC-12, alphaTC, RINm5F, INS-1E), which do not have the ability to infect or transfer the inserted DNA to other cells.

cDNAs for a number of cell signalling protein molecules, including GTP binding proteins, have been cloned. These will be inserted into the pRev-TRE expression vector (Clontech), into a site not specifically situated to facilitate expression in E. coli. It is highly improbable that the proteins will be expressed within the bacterial cells. The E. coli strains used for propagation are not considered pathogenic to humans or animals and they are expected to have a low probability of survival outside of the laboratory culture environment - they always have auxotrophic requirements which are unlikely to be satisfied outside the laboratory.

The pRevTRE vector and the pRevTET-on plasmid will be independently transfected into the packaging cell line PT67, which allows for the safe, efficient production of high titer, infectious replication-incompetent retrovirus.

Phage produced by the pRevTet-on vector will be used to establish stable Tet-On cell lines expressing the "reverse" tet repressor (rTetR). Once established, the cell line (hormone-secreting) will be infected with the pRevTRE phage containing the inserted gene sequence. Transcription of the gene will only begin upon integration into a
stable (r)TA expressing line and in the presence of Tc or the Tc derivative doxycycline (Dox).

Evaluation of foreseeable effects

The RetroPack PT67 packaging cell line provides the genes necessary for recombinant virus particle formation: gag (core structural proteins), pol (reverse transcriptase, integrase), and env (coat glycoproteins). The recombinant virus produced by this cell line contain the products of these genes but lack the genes themselves, thus these retroviral particles can infect target cells and transmit the gene of interest but cannot replicate (replication-ioncompetence) within these cells. Retroviral production from subsequently infected cell lines is prevented. All retroviral packaging cells from Clontech have been safety-tested for replication incompetence, and a product analysis certificate accompanies the RetroPack PT67 cells.

Retrovirus such as Moloney murine leukaemia virus (MoMuLV) do not naturally infect human cells, however recombinant virus packaged from the MoMuLV-based vector described here maybe capable of infecting human cells and therefore could have deleterious effect if they were to infect a laboratory worker. The viral supernatants produced could, depending on the gene insert, contain potentially hazardous recombinant virus. Users are advised not to create retroviruses capable of expressing known or potential oncogenes.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All transfections and manipulations of cells will be performed in a Class II biological safety cabinet (identifiable to other users), preventing release of aerosols. Protective clothing, double gloves to be worn at all times.

Because of viral nature of the work, no glassware or sharps will be used, only disposable plasticware. All potential infectious waste (solutions and microbiological plates) will be de-contaminated and autoclaved prior to disposal. Due to the labile lipid-derived nature of membranes of cells etc, the use of alcohol, detergents or bleach will be sufficient for decontamination. In the event of spillage, the area will be effectively disinfected.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The genetic modification safety committee considered that the molecules being expressed using the retroviral vectors pose no significant risk to the people carrying out the procedures or to the environment. However because the ACDP guidelines indicate that the minimum level of containment for the use of retroviral vectors is at level 2 this work has to be carried out at this level.

Project Containment

02/03/2022
Project Additional Information

Purposes of the contained use

The aim of this work is to knock down expression of genes by introducing synthetic "genes" (random DNA sequences less than 100bp), encoding shRNA, these are processed by the cell to generate silencing RNAs (siRNAs). The siRNA leads to the degradation of the targeted mRNA and hence knockdown expression of that gene. shRNA libraries will be used to carry out a genetic screens (when coupled with an intracellular fluorescent reporter system) in tissue cultured cell lines. The shRNA is delivered to the cells by transfection with eukaryotic expression vectors or infection with replication defective adenoviral or lentiviral vectors. This work is directed at identifying components of signal transduction pathways.

Recipient or parental organism

The shRNA library will be constructed in E. coli. The E. coli strain used for propagation are not considered pathogenic to humans or animals and they are expected to have a low probability of survival outside of the laboratory culture environment - they always have auxotrophic requirements which are unlikely to be satisfied outside the laboratory. They are considered to be ACDP group 1. shRNA libraries will also be constructed in commercially-available, replication-deficient adenoviral vectors and
relication-defective lentiviral vectors.

The cell lines used for packaging of the replication-deficient retroviral vectors and for the expression of signalling-molecule cDNAs have a history of safe use. Alterations in the properties of the cells used in this work as a result of expression of these cDNAs will be negligible, if any. The genetically modified cells are very unlikely to pose more of a hazard than the parental cell lines.

Host/vector system

The shRNA library will be constructed in E. coli (ACDP group 1 strains). Commercially available eukaryotic expression plasmids with optimal antibiotic selection will be used eg pSilencer (Ambion), pSiren (BD Biosciences), pSiEx(Novagen), psiStrike (Promega). These vectors are mobilisation defective.

Plasmid or virus will be used to infect transfect the cell line of interest (eg HeLa, HEK293, nB2A, IN157, MCF-7, PC12, ES cells, and primary cells such as human macrophage and fibroblasts) (ACDP group 2).

Origin & function

The shRNA genes are small oligonucleotides synthesised invitro. The shRNA genes (small, random DNA sequences) are cloned downstream of a eukaryotic RNA polymerase III promoter consequently they cannot be expressed in E. coli and not affect their pathogenicity. DNA from the shRNA libraries generated will be used to transfect/infect eukaryotic cells to carry out genetic screens. Using a promoter-specific intracellular fluorescent reporter system in eukaryotic cells, changes in the level of expression from that promoter (detected by a change in fluorescence) will indicate that a component of the signal transduction pathway has been affected by the particular siRNA expressed in that cell.

Evaluation of foreseeable effects

The recombinant virus particles are capable of infecting human cells and could have a deleterious effect if delivered to a target tissue. However, as the virus is unable to replicate, only the initially infected cells would be affected, making serious effects very unlikely unless the infection was massive. The packaging cell lines to be used are supplied along with the commercially available vectors and contain the genes necessary for recombinant virus particle formation. Recombinant virus produced in the packaging cell lines contain the gene products provided in trans by the packaging cells, but they lack the genes themselves. The viral particles produced by the packaging cells can infect target cells and transmit the gene of interest but cannot replicate within these cells. Virus production from cells infected subsequently is therefore prevented. (The packaging cell lines provided by commercial suppliers are safety tested for replication incompetence, and a product analysis certificate is provided).

Primary human macrophage and fibroblast cells will be used in some experiments. These will be obtained from donors outside the school and grown to only low passage numbers to avoid any risk of transformation and accidental introduction into the original donor.

The Modified E. coli and viral vectors are not hazardous to the environment and in the event of accidental release from containment are unlikely to survive and propagate.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All transfections and manipulations of cells will be performed in a Class II biological safety cabinet (identifiable to other users), preventing release of aerosols. Protective
clothing, double gloves to be worn at all times. Because of viral nature of the work, no glassware or sharps will be used, only disposable plastic ware. All potential infectious waste (solutions and microbiological plates) will be either disinfected [using 2% Virkon] or autoclaved, prior to disposal via drains or incineration as appropriate. Due to the labile lipid-derived nature of membranes of cells etc, the use of alcohol, detergents or bleach will be sufficient for decontamination. In event of spillage, the spill will be absorbed onto paper towel, the area will be effectively disinfected with Trigene (1:100 dilution) or Virkon (1:100 dilution). Towels to autoclaved prior to disposal. Disinfectants are effective against the organisms in question. Data on the appropriateness and effective degree of kill for these detergents are provided by Brindle Microbiological Consultants (Trigene) and Antek International; a subsidiary of Du Pont International (Virkon). The autoclave is subject to calibration and validation by a service company twice yearly.

Project Additional Information

Purposes of the contained use

The intention is to express proteins in mammalian cells and tissues, to achieve high levels of transfection (-100%). The adenovirus system achieves this high transfection efficiency.

For transfection of cultured cells, the retroviral system allows efficient selection, and low level constitutive expression of genes using the Tet-off system, thereby enabling much more representative data. The proteins which I will be using are non-toxic and not oncogenic.

Recipient or parental organism

Adenoviral systems: Overview of system.

Inserts are cloned into a shuttle vector in E.coli. The insert DNA is then recloned into a predigested plasmid containing the Adeno-X viral DNA, and DNA of successful recombinants cloned and purified. The DNA is then transfected into an amphototrophic packaging cell line, which provides E1 sequences in trans, enabling production of an 'infectious' virus. The cell supernatant is then used directly for infection of cells and organs.

This is the Adeno-X system from Clontech, based on disabled Adenovirus 5. The Adenovirus lacks E1 sequences and is hence replication incompetent, and these are provided in trans by the cell line. The virus is produced in the supernatant of the packing cell line, but is replication defective, hence an access factor of -3.

Retroviral system: Overview of system

Inserts are cloned into a shuttle plasmid vector in SE.coli. The resulting plasmid is then transfected into an amphotrophic packaging cell line (with or without the Tet-on or Tet-off plasmids), and virus is produced by the cell line. The supernatant, containing 'infectious' virus, is collected and can be used for transformation of cell lines. It is then possible to select for stable integration of the retroviral DNA into the genome of the cell line (which does not support viral replication) using antibiotic selection. The retroviral system is the Retro-X system, and Tetracycline-regulated derivatives available from Clontech, based on the MuLV retrovirus. These systems use defective virus DNA, with the gag, pol and env genes provided in trans from a packaging cell line; the gag, pol and env genes are the product of separate integrations into the packaging cell line; and so a functional virus cannot be produced as a result of a single recombination event. The virus is produced in the supernatant of the packaging cell line, and can be used at this stage to infect cells. However, the virus is replication defective, hence an access factor of -3.

Host/vector system

Cytochromes P450 are membrane bound chemical metabolising enzymes. These are present endogenously, and have been expressed as transgenes, with no ill effects. AhR, AIP, PPAR and coactivator proteins are signalling molecules which are expressed endogenously, and are extremely unlikely to have any adverse biological effect. Latrophilin receptor is a transmembrane receptor which is expressed endogenously, and it is extremely unlikely to have any adverse effects.

Reporter proteins such as LacZ, GUS, luciferase, GFP and RFP have been expressed as transgenes and are know to be harmless. Fusion of these proteins with...
cytochromes P450, AhR, AIP or PPar are highly likely to be harmless, and there is no basis for proposing a damaging protein arising

**Origin & function**

The intention is to express proteins in mammalian cells and tissues, to achieve high levels of transfection (-100%). The adenovirus system achieves this high transfection efficiency. For transfection of cultured cells, the retroviral system allows efficient selection, and low level constitutive expression of genes using the Tet-off system, thereby enabling much more representative data. The proteins which I will be using are non-toxic and not oncogenic.

**Evaluation of foreseeable effects**

The work to be carried out will use only small scale cultures (11 maximum) and therefore no more than 10^12 organisms will be used at any one time. Normal laboratory containment procedures are sufficient to contain even total spillage of such a culture and since no especial risk of air-borne transmission exists, no special containment within the ACGM2 suite will be required. There are no sensitive populations of either plants or animals or humans in the area surrounding the laboratory and so there is no specific risk associated with accidental release. The research labs are not near a main road or any other building that may be liable to catastrophic explosion, and so a breach in the physical fabric of the laboratory is not seen as a likely event. All organisms are heat sensitive and so in the event of fire they would be destroyed. In the event of a release, gene spread is limited due to the use of non-self mobilisable vectors and the cloned genes are not known to confer any harmful properties and are therefore highly unlikely to cause a problem if released. The viruses are easily destroyed, and there should be minimal chance of environmental contamination. The virus would in any case be unable to replicate. There are no other environmental considerations.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMS - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

The viruses are only infectious immediately after the packaging in specialised mammalian cells, which contain several genes necessary for the infectivity of the virus. The virus particles can only go through one round of infection, and are then unable to produce viable virus. Thus the stage where there is an ability to infect other cells is tightly defined, this stage will normally occur inside a class 2 cabinet (to ensure sterility of the cells and supernatant), and there is little opportunity for aerosol formation. The infectious virus will be clearly labelled. Infection of tissue samples may take place on the open bench; the experiments will be carefully designed to minimise the production of aerosols. HSE guidance confirms that these expression systems are very well characterised, and suitable for class 2 containment. The viruses are also relatively fragile, and are destroyed by ethanol, detergent, or UV. The work will be carried out at ACDP/ACGM Class 2 containment level. Waste will be disinfected using a validated protocol, e.g.

1) Soaking in 1% Stericol for >30 minutes
2) Soaking in 1% Chloros for >30 minutes
3) Autoclaving

### Project Additional Information
### Purposes of the contained use

These proteins are expressed for a variety of structural and functional studies of P450 and other genes involved in chemical carcinogenesis and of molecules involved in the process of neurotransmission.

### Recipient or parental organism

The cloning hosts will be E.coli hosts JM109, HMS 174 and derivatives all RecA-K12 derivatives or BL21 and derivatives. These are disabled and therefore considered non-pathogenic to humans, animals or plants. The strains are all laboratory adapted and so are unlikely to survive outside the laboratory. Induction experiments utilise a host lysogenic for bacteriophage DE3 or else superinfection with the phage CE6. In both instances these phage are disabled cloning strains carrying tetracycline resistance.

### Host/vector system

The plasmid vectors used are pBR derivatives encoding ampicillin or chloramphenicol and are considered non-mobilisable. The typical host used are pT7-7 and pRSET series of plasmids. Expression is by T7 polymerase induced using IPTG.

### Origin & function

These proteins are expressed for a variety of structural and functional studies of P450 and other genes involved in chemical carcinogenesis and of molecules involved in the process of neurotransmission.

The eukaryotic receptor genes are membrane bound, multicellular proteins that are unlikely to be able to functionally express in E.coli which lacks the ability to perform membrane insertion, transport, assembly and other post-translational processing required for functional expression. These proteins are expressed as polypeptide fragments that do not form functional receptors in E.coli. These clones are therefore unlikely to show a biological effect. These proteins all also require the ligand activation.

Functional P450 protein has no known biological effect.

The reporter genes are encoding for products such as beta-galactosidase, luciferase and Green Fluorescent protein that are well characterised and known to be non-toxic. Delta latroinsectotoxin is an insect specific toxin which has no mammalian toxicity. The toxin is degraded when eaten and is only possibly active when injected. It is therefore of no risk to insects in the wild.

### Evaluation of foreseeable effects

The work to be carried out will use only small scale cultures (11 maximum) and therefore no more than 10 12 organisms will be used at any one time. Normal laboratory containment procedures are sufficient to contain even total spillage of such a culture and since no especial risk or air-borne transmission exists, no special containment within the ACGM 2 suite will be required. There are no sensitive populations of either plants or animals or humans in the area surrounding the laboratory and so there is no specific risk associated with accidental release.

In the event of a release, gene spread is limited due to the use of non-self mobilisable vectors and the cloned genes are not known to confer any harmful properties and are therefore highly unlikely to cause a problem if released.

The chance of release of bacterial plasmid hosts into the environment is reduced to negligible levels by employing the above working practices. The recombinant strain is unlikely to survive in the natural environment as growth media supplements are required for growth.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Project notified under transitional arrangements N
**Project Additional Information**

**Purposes of the contained use**

Transfection techniques are used to express receptor and reporter genes in mammalian cells. These transfected cells are then used for functional studies.

**Recipient or parental organism**

Growth and construction of the transfection plasmids in *E. coli* is carried out as for Project I except that pcDNA1 constructs need to be grown in MC1061/P3 which is a RecA+E. coli strain carrying amber stop codon suppressed tetracycline and ampicillin antibiotic resistance genes and a functional chloroamphenicol antibiotic resistance gene.

**Host/vector system**

The cell systems used are both derived from primary tissue (e.g. rat hepatocytes) and also well characterised cell lines (e.g. HEK392). None of the mammalian cell lines could survive outside laboratory culture conditions.

**Origin & function**

The plasmids used for transfection carry either a CMV (cytomegalovirus) promoter (e.g. pcDNA derivatives) or a Rous Sarcoma virus promoter RSV (e.g. pRBK derivatives), together with a combination of selectable markers including tetracycline and ampicillin for bacterial selection and kanamycin resistance for selection in mammalian cells.

The receptors and reporter genes expressed in these experiments are non-toxic.

**Evaluation of foreseeable effects**

The work to be carried out will use only small scale cultures (11 maximum) and therefore no more than 10-12 organisms will be used at any one time. Normal laboratory containment procedures are sufficient to contain even total spillage of such a culture and since no especial risk of air-bourne transmission exists, no special containment within the ACGM 2 suite will be required. Date Ackn'd 18/02/2005

CU2 Project Title PHYSIOLOGY AND PATHOGENICITY OF CAMPYLOBACTER GENE PRODUCTS

Date Project Ceased

Class 2 CultureVolClass2 < 1 Litre Non-GMM Consent Granted Not Applicable
The aim of the project is to evaluate the role of specific Campylobacter genes associated with the physiology and pathogenicity of the bacterium in vivo. To do this gene sequences and their promoters will be reintegrated into the bacterial genome in order to knock-out or alter their function. Campylobacter genes for which we can ascribe a role will be manipulated in an attempt to express them in laboratory strains of E. coli to study the structure and function of the proteins they encode.

**Recipient or parental organism**

- Host: E. coli Top10 cells (Invitrogen) (ACDP 1)
- Host: E. coli BL21(DE3) (Novagen) (ACDP 1)

All the recipient Campylobacter species to be used in this study are wild type ACDP group 2 organisms. No multiply-antibiotic resistant isolates will be used which would preclude therapy with standard antibiotic regimes should infection occur.

- Host: Campylobacter jejuni (ACDP 2)
- Host: Camplylobacter coli (ACDP 2)
- Host: Camplylobacter lari (ACDP 2)
- Host: Campylobacter upsaliensis (ACDP 2)

**Host/vector system**

- Vector: pCR2.1 Topo plasmid (Invitrogen)
- Vector: Approved vectors based on colE1 replicating plasmids (eg pUC18, pBS and pBC)
- Vector: pET series of expression plasmid vectors (Novagen)

All the Campylobacter transforming DNAs will constitute integrative constructions carrying antibiotic selection either to mark a targeted gene knock-out or as second cistron to the functional Campylobacter gene to be reintroduced. These DNA constructions will be assembled in E. coli using the plasmid vectors cited above.

**Origin & function**

Genomic DNAs of the following:

- Campylobacter jejuni (ACDP 2)
- Camplylobacter coli (ACDP 2)
- Campylobacter lari (ACDP 2)
Campylobacter upsaliensis (ACDP 2)  
Campylobacter bacteriophage DNA

The target gene sequences are expected to encode bacterial cell-surface associated proteins or be responsible for the biosynthesis of surface associated components (e.g., lipopolysaccharide, capsular polysaccharide, lipid and glycosylation modifications of proteins). Gene functions may also include products responsible for intracellular DNA modifications.

**Evaluation of foreseeable effects**

Campylobacter enteritis is the most common form of bacterial food poisoning in the world. Campylobacter infection occurs through ingestion (fecal oral route) and results in a self-limiting diarrhoeal disease. A few rare post-infection cases have been associated with the later development of a paralysing autoimmune disease (Gillian Barre syndrome). There is no specific risk of transmission by aerosol known for these organisms. Campylobacter jejuni is known to encode a cytolethal distending toxin. However, the toxin contains multiple sub-units all of which would have to be co-expressed. The host Campylobacter species are initially wild type and have the potential to cause human disease. It is therefore proposed that all experiments will be performed under containment conditions ACDP 2. The resulting GMMs are unlikely to pose any further risk to human health as they will contain DNAs of similar origin and that the ACGM containment level be 2, consistent with the host and donor DNAs.

Birds carry thermophilic Campylobacters in their gut without any known detrimental effect, such that most wild birds and domestic poultry are colonised. It is possible that the modified Campylobacters could survive in avian species if they were to be released into the environment. Therefore it is proposed that all experiments will be performed under containment conditions ACGM 2.

When expressing the Campylobacter genes in E. coli it is possible that some of these genes could increase their fitness and/or human or animal colonisation potential. However, the auxotrophically crippled organisms (E. coli K-12 ACDP 1) will still retain limited survivability in the environment. The majority of genes are not known to be toxic, and when expressed in isolation form the remaining Campylobacter host genes are unlikely to produce any deleterious effects over the parental organism. Owing to the potential for increased expression levels in E. coli the containment level for this work is proposed to be ACGM level 2 consistent with the ACDP level of the donor organisms.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Local Incineration: solid wastes are incinerated at 1000 degrees C for 360 minutes until ash (100% kill). These are discarded as solid waste.

Autoclave: Liquid wastes are autoclaved at 121 degrees C for 30 minutes until to achieve 100% kill (internal temp and pressure monitors) and discarded to the drain once cool. These measures are coupled with condensate thermocouples and thermologue test strips.

Chemical Treatment: 2% Virkon is used to remove contamination from solid surfaces. This concentration will kill the bacterial rapidly as recommended by the supplier. After 15 minutes contact the disinfectant is diluted and the liquid waste discarded to drain.

**Is an emergency plan required according to regulation 20?** N

If yes, tick to confirm that it is attached to this form N
Project approved at Containment level 2 by GM Safety Committee, which includes representatives of all University employees. The project details were assessed by expert members of the committee and the decision was reported to the general safety committee.

**Project Additional Information**

**Purposes of the contained use**

The objectives of the project are to construct stable, disabled strains of N. meningitidis, N. gonorrhoeae and other Neisseria groups, by genetically modifying genes which are essential for growth of the organism in the host. Further manipulations will make the strains unable to repair the mutations. These strains can then be further developed as candidate live attenuated and vesicle vaccine strains for meningococcal infections by upregulating certain protective antigens and removing endotoxin, LOS, and capsule genes.

**Recipient or parental organism**

The modified genetic material will ultimately be reintroduced into wild type Neisseria meningitidis, Neisseria gonorrhoeae or non-pathogenic commensal Neisseria spp.

**Host/vector system**

Genetically manipulated material will be maintained in disabled E.coli strains: XL1-Blue, JM109, DH5aF°, SCS110

All strains are unable to maintain colonisation of the human gut and are disabled.

Examples of cloning vectors to be used include:
(1) pUC19:- colE1 origin, non-mobilisation, non-conjugative
   pCRII  ampicillin resistant, kanamycin resistant
   pGIT-5
   pGEM
   pET
   etc.

(2) pCVD422:- Suicide vector in bacteria not carrying -pir (contains pir dependent origin, of replication). Self mobilisable vector but can only replicate in E.coli -pir strains like SM10. Carries ampicillin resistance and the SacB gene from Bacillus strains which metabolises sucrose to generate a compound lethal to Gram negative organisms. All vectors (except pCVD422) are non-mobilisable. PCVC422 cannot replicate in non lambda pir strains.

**Origin & function**

The genetic material to be modified will be isolated from clinical isolates of Neisseria meningitidis or Neisseria gonorrhoeae - ACDP hazard group2 pathogens and a range of non-pathogenic commensa Neisseria spp. The genetic material will be used to inactivate genes e.g. aromatic amino acid biosynthetic genes essential for prolonged growth or survival of Neisseria meningitidis in the human host.

**Evaluation of foreseeable effects**

**Manipulations in E.coli** - All manipulations are in disabled hosts using non-mobilisable or mobilisation deficient vectors. None of the E.coli strains used will be able to colonise humans. Expression of genes derived from Neisseria meningitidis will be carried out using disabled, non-colonising E.coli hosts and non-mobilisable vectors. All genes expressed with the intention of purifying proteins will be housekeeping genes or genes involved in DNA repair/uptake, global regulation nutritional requirements, or surface LOS/capsule expression, all found in most prokaryotes. Therefore in the unlikely event of ingestion of an over expressing E. coli strain it is unlikely to cause harm.

**Manipulation of Neisseria sp.**

The neisseria strains to be used are wild type and therefore should be handled under containment level 2. However as an additional safety precaution to protect laboratory staff and eliminate the risk of environmental contamination, we intend to handle all Neisseria strains in the Institute category 3 facility (both wild types and mutants). The inactivated gene will be inserted in the exact position of the wild type gene and will have no potential for expression of the target gene above the normal wild type levels at any time during the construction. At no stage will antibiotic markers which could compromise therapy for meningococcal or gonococcal infection be introduced into the wild type organisms.

All cloned DNA will be fragments of well characterised non secreted housekeeping genes involved in bacterial nutrition, regulation of gene expression or structural components of the cell. None of the target genes on their own are known virulence determinants although some may regulate certain virulence genes. These genes will in addition be further deleted to completely abolish expression and normal cellular activity of the gene product in the Neisseria host. All the gene products are highly unlikely to have a deleterious effect on humans and since their expression will be completely abolished in the Neisseria host by the manipulations there is no possibility of any of the products being produced. It should also be noted that homologs of these genes and their protein products are present in most if not all bacteria including those of the human normal flora and therefore could be classed as being present in the environment in high levels.

Taken together, these measures are considered to reduce the likelihood of any potential hazard arising from the proposed genetic manipulation effectively to zero.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable.
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid and liquid waste generated will be autoclaved prior to disposal. No viable counts are expected after the treatment. Laboratory lab coats will be autoclaved prior to laundering.

02/03/2022
The aim of this project is to develop genetic systems to facilitate molecular studies in the clostridia. These will allow basic studies of cell signalling, metabolic processes and virulence gene regulation in the human anaerobic pathogen. Clostridium difficile and expression studies of metabolic genes in Clostridium sporogenes and in the non-pathogenic Clostridium acetobutylicum and Clostridium beijerinkii. These studies will involve 1) mutation of clostridial genes with plasmids or transposons, 2) complementation of mutants with homologous genes from clostridia or those from other bacteria or eukaryotic sources; 3) overexpression in clostridia of specific proteins (excluding known virulence determinants) from clostridia, other bacteria or eukaryotes to investigate effects on clostridial physiology/metabolism and to generate proteins for biochemical studies and antibody generation; 4) introduction of reporter constructs into clostridia for gene expression studies and, 5) expression of clostridial genes (excluding known virulence determinants) or homologues from other bacteria or eukaryotes in E. coli to generate proteins for biochemical studies and antibody production.

Disabled E. coli strains may be used as initial hosts for preparation of constructs but the modified genetic material will ultimately be reintroduced into wild type Clostridium difficile, Clostridium sporogenes, or the non-pathogenic Clostridium acetobutylicum or Clostridium beijerinkii.
The E. coli host strains to be used as cloning hosts are not known to be pathogenic. They have multiple auxotrophic requirements which are unlikely to be met in the environment where they are considered unlikely to survive. These strains can be considered equivalent to ACDP Hazard Group 1 organisms.

Clostridium difficile strains to be used, eg. CD630, CD3, and CD6 are ACDP Hazard Group 2 pathogens capable of causing gastrointestinal infection in humans; infection risk is associated with use of broad spectrum antibiotic therapy and pathogenesis is associated with production of exotoxins. Other strains eg CD37 (non-pathogenic in animal models) are non-toxigenic human clinical isolates likely to have reduced virulence for humans. These organisms may survive under appropriate conditions in the environment.

Clostridium sporogenes is a ACDP Hazard Group 2 clostridial species. Certain strains have been implicated in cases of gas gangrene. Other strains (formerly known as Clostridium oncoclyticum) have been used in the 1960s in human clinical trials for the treatment of brain tumours. The strain to be used here, Clostridium sporogenes NCIMB 10696, is believed to belong to the former category. It was isolated from soil and has previously been used in the testing of sporicidal agents in the quality control of media. It is known to produce toxins.

Clostridium acetobutylicum ATCC, 824, N1-4082 and Clostridium beijerinkii NCIMB 8052 are saccharolytic, non-pathogenic, non-colonising, non-toxigenic bacteria of ACDP Hazard Group 1. Although non-pathogenic these organisms may survive under appropriate conditions in the environment.

**Host/vector system**

**Vectors:** for cloning in E. coli and for use as suicide vectors in clostridia:

- Non mobilisable pUC- and pMTL-derived plasmid vectors, other vectors including Super Cos, Lambda or others which are Bom-/(Nic-), Mob- and Tra-.
- Mobilisation defective: Pinpoint, pBR322, pET30, ptrc99A, pAlterEx2, pJDC9, pMal, pLAFR or other vectors Bom+//(Nic+) but Tra- and Mob- which can efficiently be mobilised if they are co-resident with certain other plasmids.

For cloning/expression in clostridia:

- pMTL500E (based on the pAM 1 replicon) ans pMRL540E (based on the pCB102 replicon), and their derivatives, are non-mobilisable vectors which replicate in both E. coli and clostridia. pMTL9301 and derivatives are mobilisable shuttle vectors which replicate in E. coli and clostridia. Replicons from other plasmids eg pGK12, pCB101, and pBP1, other shuttle vectors eg pMK4 derivatives and plasmids previously used to deliver transposons in other Gram positive bacteria eg Tn917 derivatives may also be used.

Antibiotic resistance markers will include genes encoding resistance to ampicillin, erythromycin, tetracycline, chloramphenicol, kanamycin and spectinomycin.

**Origin & function**

C. difficile.

The genetic material for construction of defined mutants will be isolated from clinical isolates of C. difficile as detailed above. Genes to be mutated or overexpressed will include those involved in cell-cell signalling eg luxS, two component or other gene regulators or metabolic genes. Complementation studies may use gene homologues from clostridia, other bacteria upto ACDP Hazard Group 2 or eukaryotic sources. Reporter constructs may employ reporter genes from bacterial or eukaryotic sources.

C. sporogenes, C. acetobutylicum and C. beijerinkii.

Work with these clostridia will focus on expression studies with known metabolic genes, eg carboxypeptidase, nitroreductase and cytosine deaminase.

E.coli.

Genes for cloning in E. coli will include known metabolic genes or cell signalling genes eg luxS from clostridia, eukaryotic homologues and homologues from other bacteria upto ACDP Hazard Group 2. For construction of reporter fusions, promoters of known virulence determinants eg clostridial toxins may be cloned but no attempt will be made to clone full length genes of these determinants or to express known clostridial virulence determinants in E. coli.
C. difficile and C. sporogenes.

Introduction and/or expression of homologues of known metabolic or cell signalling genes in these clostridia is considered highly unlikely to enhance the virulence of the pathogen or its ability to survive in the environment. Random mutation using transposons or deliberate inactivation or overexpression of gene regulators could potentially reduce or enhance virulence determinant expression. All mutants generated by transposon mutagenesis and those where regulators are deliberately mutated or overexpressed will be fully assessed for production of known virulence determinants eg toxin production and will be handled in a Class 1 microbiological cabinet until fully characterised.

None of the antibiotic markers to be used are routinely used for therapy of clostridial infections so therapy would not be compromised in the unlikely event of accidental infection with a GMO.

C. acetobutylicum and C. beijerincki.

Modification of these organisms is considered extremely unlikely to alter their non-pathogenic status or their ability to survive in the environment.

E. coli

The E. coli strains to be used are disabled and the clostridial genes or homologues to be cloned are not likely to have a detrimental effect on human health. In the unlikely event of infection the consequence of an infection with recombinant E. coli containing these genes is likely to be very low. Modification of the E. coli strain is considered highly unlikely to enhance their survival in the environment.

Evaluation of foreseeable effects

Not applicable.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid and liquid waste generated will be autoclaved to achieve 100% kill. Autoclaved waste will ultimately be disposed to landfill after further heat treatment and processing by approved waste disposal contractors.

Please enter comments on the GM safety committee on the risk assessment

The assessment was passed by the committee with minor modification.

Project Containment
The key aims of this research are:

1. Identification & modulation of genes involved in key physiological processes.

The organism is widely distributed in the environment and as a consequence is commonly found in raw foods. As it is very difficult to prevent, or control, the frequency of C. botulinum, and to apply a defined level of control. In order to more effectively prevent botulism it is imperative to understand those environmental factors that affect the ability of the organism to grow and/or elaborate toxin when present in food. Moreover, as the ability to spores represents one of the, if not the most important, virulence factors. Thus analysis/modulation of the processes that regulate growth, sporulation, toxin production and germination will be a major aspect of this project. The major form of modulation will be seek inactivation of the target gene through either gene disruption, or via antisense RNA. Overexpression of selected gene products may also be pursued, however, in this case the genes studied would not encode a product that could potentially cause harm to human health or the environment, nor result in hyper production of toxin. The effects of modulation will be measured phenotypically, by enzyme assay where appropriate, and using transcriptomics and proteomics.

2. Characterise putative quorum sensing mechanisms.

Preliminary data has shown that the organism contains 35 two-component regulators, in addition to numerous orphan responses regulators and sensor kinases. Such
gene products play a pivotal role in the co-ordination of bacterial gene expression in response to both environmental signals and bacterial derived cell signals, termed autoinducers (Ais). With respect to the latter, homologues of genes involved in bacterial cell signal generation are also evident, including the agr system of staphylococcus aureus that mediates AI-1 synthesis and the ubiquitous LuxS system responsible for bacterial AI-2 production.

3. Develop genetic tools.
The existing genetic system available in C.botulinum are rudimentary in nature. To achieve the above goals more effective tools will be required; in particular vectors that may be employed to bring about gene replacement. These may be used to replace the neurotoxin gene with a useful reporter gene, such as gusA. The use of such a strain in subsequent experiments would further minimise the risks associated with the envisaged studies.

Recipient or parental organism

Category 1 disabled hosts
Escherichia coli (disabled K12 derivatives) and Bacillus subtilis 168. These hosts will be used in experiments aimed at transferring plasmids into C botulinum, (ii) for heterologous expression of proteins of C.botulinum (other than intact BoNT), or (iii) as intermediate hosts to in vivo methylate plasmids before transformation of C. botulinum. Work will also be undertaken using various strains of non-toxinogenic Clostridium sporogenes, and in particular strain 10696 which is classified as Class 1 by the ATCC.

Category 2 The sequenced strain proteolytic C.botulinum type A Hall A (ATCC 3502) will be employed as the primary recipient strain. In addition, we intend to study a number of different strains of proteolytic culture collection, with whom we are collaborating.

Host/vector system

pUC or pMTL-based vectors (based on the ColE1 replicon) will be used for all cloning and expression work in E.coli K12. With the exception of the pET vector series (which is nic+) all vectors to be employed are inc mob minus, and approved in Part 2A Annex II of ACGM Compendium.

The shuttle vectors to be employed in clostridia will carry both Gram-negative and Gram-positive derived components. Thus they will carry the ColE1 replicon (derived from either pUC of pMTL vectors), and in some instances the pBR322-derived bla gene. Neither element functions in clostridial species. Antibiotic resistance genes will include the C.perfringens catP gene, the pAMB1-derived erm gene, the enterococcal Spec gene, and the Tn916-derived tet gene. For those plasmids that need to be introduced by conjugative mobilisation, the plasmids will also possess the oriT region of plasmid RK2. Such plasmids are not self transmissible, but may be mobilised from bacterial donors if the donor carries Tra &Mob functions on a second element.

The use of transposons for generating mutants will also be explored. These will include elements isolated from Gram-positive organisms (eg.Tn552 and Tn916), Gram-negative elements adapted for use in Gram-positives (eg. Tn 10), transposons generated from clostridial IS (Insertion Sequence) elements to which an antibiotic resistance gene (catP) has been added. These would include ISCb1 recently discovered in C. beijerinckii NCIMB 8052, ISCce1 from C. cellulolyticum and group II intron L1. LtrB of Lactococcus lactis.

Inserts
The inserts to be employed will be sequence specific segments of DNA, generated from the C.botulinum genome by PCR. In no instance will a gene be cloned which is perceived to encode a product that has the potential to be harmful to human health or the environment. Under no circumstances will the intact botulinum neurotoxin genes be cloned. In the majority of cases, only non-functional genes will be introduced into Clostridium ie; internal fragments of genes, or genes which have been inactivated by internal deletions/insertions.

In some instances heterologous genes may also be introduced. These could include homologues of regulatory genes or sporulation/germination genes from B.subtilis, but in the main will be genes encoding innocuous reporter enzymes.

Origin & function
Our major focus is to bring about the inactivation of genes as a means of ascribing function and identifying regulatory networks. Therefore, in the main we will be introducing inactive portions of genes consisting of internal fragments (single cross-over knock-out), genes that have been inactivated by insertion or deletion (double cross-over), or fragments encoding the 5'-non-coding region and a portion of complementation studies. These will be expressed either from their native promoter, placed under the inducible (ITPG) control of fac or a similar promoter.

Regulatory Genes:
The genes to be targeted will be transcriptional regulators and sensor kinases. These will form part of two-component regulators (there are estimated to be 35 such systems in the genome sequence), or may be orphan. The only transcriptional regulator that has been characterised in C.botulinum is cntR (clostridial neurotoxin regulator). It is absolutely required for production of toxin. Its inactivation will therefore lead to severe depression of toxin production. It may of course additionally lead to the repression of other genes linked to toxin production.

Genes associated with Spore Formation:
Homologues of B.subtilis involved in both sporulation and germination will be targeted, dependent on the genes seen to be up and down regulated by inactivation of specific response regulators/sensor kinases. These will include homologues of the key spo and ger genes, and other factors implicated in cell differentiation.

Genes involved in cell-cell communication:
All clostridial genomes, including C.botulinum, contain luxS homologues, the gene responsible for production of AI-2, a furanone signalling molecule. AI-2 production has been shown to occur in C.difficile and C. perfringens, and to participate in the regulation of virulence factors. The effect of inactivating luxS, by both knock-out and antisense diffusible signalling molecules that regulate the production of toxins and other virulence factors, but efforts to purify these presumed peptide molecules have been unsuccessful.

Intriguingly, we have identified with C.botulinum two separate unannotated ORFs capable of encoding small proteins (44-54 aa), which share homology with the precursor (AgrD) of the Staphylococcus aureus autoinducer peptide (AIP). AIP regulates the temporal production of virulence factors. In both cases, the identified clostridial agrD genes are preceded by a gene encoding an agrB homologue, the S.aureus transmembrane protein required for synthesis and processing of agrD to AIP. The effect of inactivating these genes, by both knock-out and antisense technology, will be evaluated.

Reporters Genes:
To aid in our analysis of gene regulation, we will also introduce reporter genes encoding innocuous enzymes which have been placed under transcriptional control of C.botulinum gene promoters. These will include lacZ (B-galactosidase), gusA (B-glucuronsidase), xylE (catechol 2,3 monooxygenase) luxAB (luciferase), and other well characterised reporter genes. These will be introduced either into the chromosone, or on autonomously replicating plasmids.

Evaluation of foreseeable effects:
B.subtilis and the proposed E.coli disabled E.coli K12 derivatives strains are all in the biological agents hazard group1. The introduction of C.botulinum genes with known harmless functions will not increase the hazard. C botulinum genes encoding proteins with homologies to known proteins with toxic or harmful properties and genes with unknown functions are to be introduced into the above hosts. These GM stains will be handled at containment level 2 to ensure the overall risk is negligible. A functional BoNT will not be cloned or introduced into these strains.

C.botulinum is not infectious, and therefore classical concerns of virulence, and any enhancement of such properties, are not appropriate. As the principal modifications to be undertaken are the inactivation of genes (regulators and homologues of genes involved in the sporulations process, spore formation and germination) the majority of GMMs will be less hazardous than the recipient itself. It is theoretically possible that certain manipulations could effect the levels of neurotoxin produced, although this in itself may not make the organism anymore virulent/hazardous.

All work with C.botulinum cells (vegetative/spores), supernatants and any media that may contain BoNT will take place in a containment level 2 work suit designated for work with C.botulinum and the above mentioned hosts. This room will have key code access and will only be available for use by members of staff trained in handling C.botulinum. Risk assessments and standard operating procedures will be produced for all aspects of research undertaken. Work is performed in an anaerobic airtight cabinet or in a Class II safety cabinet, thus the risk of exposure to the toxin and to contract botulism is minimized in an appropriate manner. In case of exposure to the toxin, there is a toxin antidote available in Queens Medical Centre which is adjacent to University of Nottingham. In case of exposure of wounds or cuts to C.botulinum,
antibiotic treatment will be available with a penicillin-based antibiotic. The use of the E.coli based ampicillin cassette on shuttle vectors does not confer ampicillin resistance to C.botulinum, and therefore, does not interfere with antibiotic treatment. For the above-mentioned reasons, the risks to staff are considered to be minimized to a very low level.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste C.botulinum liquid cultures (in volumes not exceeding 100ml) will be disinfected overnight in 1% virkon in the anaerobic cabinet before double bagging, autoclaving on sitr then sent for incineration. Contaminated plasticware and solid media will be double bagged, autoclaved on site then incinerated.

Autoclaving at 125°C for 15 mins followed by incineration will give 100% kill of bacteria and inactivation of B0NT (which is inactivated at 100°C for 3 minutes). Both incineration and autoclave procedures are expected to give a 100% kill of all GMMs.

The autoclave has a chart readout which is checked after each discard cycle and is also validated on a six monthly cycle in accordance with HTM 2110.

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Written comments on this Class 2 draft assessment has been received from several members of the committee and these were discussed at the GMSC "C" meeting on 19th November 2004. The general consensus was that there were no major safety issues associated with the genetic modifications proposed. The main issues were operational to ensure safe handling and disposal of the organism and in particular culture supernates containing botulinum toxin. The assessment required modification to address these issues. The committee were informed that the work with this organism would be performed in a dedicated laboratory on B floor CBS and that appropriate containment measures to minimise the risk of exposure to toxin or Clostridial spores would be applied. Issues of vaccination of workers involved in this project against C. botulinum neurotoxins was raised and it was confirmed that the following discussion with the University's Occupational Health Advisor, vaccination could not be made available via Occupational Health though it was subsequently identified that anti-yoxin was readily available in QMC. It was agreed that it was important to limit the number of workers involved in the project to minimise risk and the PI confirmed that the maximum number of workers likely to be involved would be four. In light of the above discussion, an amended assessment was circulated and approved by the committee.

02/03/2022
The scientific aims of this project are to investigate the mechanisms of dimorphic and phenotypic switching in Candida, a fungus that can be pathogenic to humans. Although the project will not address pathogenicity per se, it is possible that switching mechanisms may help to understand the basis of pathogenicity. Candida albicans is a diploid species which makes genetic manipulation more complicated than with a haploid organism. In some cases therefore, Candida glabrata will be used. C. glabrata is a haploid organism that behaves with some similarity to C albicans but is less virulent and undergoes the dimorphic switch to the filamentous form less efficiently.

Strains of Candida will be transformed with vectors containing genes or gene regulons (promoters) derived from Candida with the aim of either deleting genes or producing strains having that gene under a regulatable promoter. Down-regulation of a gene may also be achieved using RNAi approaches. No null mutations in a gene are known to have produced a strain of Candida that has enhanced virulence. In any case, the virulence of Candida is known to by polygenic, ie involves several factors, so alteration in one gene is highly unlikely to lead to a major shift in virulence. The plasmid vectors that are constructed will be amplified in disabled strains of Escherichia coli although the genes are highly unlikely to be expressed in E. coli because only yeast promoters will be used and they are unlikely to function in E. coli. Genes to be regulated by these methods include genes involved in protein secretion and secretion stress (eg HACA) or genes that are putatively involved in control of gene expression due to effects on chromatin (eg DNA methylation or histone modification) or RNA function (eg MTR4).
Candida strains. *C. albicans* is an ACDP category 2 organism. The *C. albicans* strains CA14 (ura3), CA18 (ura3, ade2), RM1000 (his1, ura3) and BWP17 (ura3, his, arg) are the standard hosts for DNA transformations world-wide. BWP17 is the favoured host for the work proposed as it is widely used and is triply auxotrophic. These auxotrophies make *C. albicans* avirulent. Transformation with URA3 plasmids partially restores the virulence of CA14, but this restoration is not complete because the genes neighbouring URA3 remain inactivated. This is enough to partially (but not completely) attenuate virulence. The ura3 marker is recycled for subsequent rounds of transformation and, therefore by necessity, some of the transformants we create are not genetically disabled, although their virulence is slightly lower than the wild type strains of *C. albicans* carried by most individuals. At no time will we need to create *C. albicans* mutants that are free of disabling mutations. The BWP17 strain could be used to generate strains that are up-regulated in gene function. But, the resulting strains would be disabled and, anyway, it is unlikely that production of such strains in non-disabled hosts would have enhanced virulence because virulence is polygenic. Genetically disabled *C. glabrata* strains might be used in some experiments, and it will be entirely appropriate to use similar precautions to those used for our *C. albicans* experiments.

Bacterial strains. The *E. coli* strains to be used are all Rec A- derivatives such as DH5a, XL1-Blue, SURE and TOP10. These strains are disabled and non-colonising and are equivalent of ACDP category 1 organisms (ie non pathogenic to humans or animals). They have limited survivability in the environment as they require specific nutrient supplements not required by wild-type organisms.

Recipient or parental organism

**Host/vector system**

Candida vectors. These are pUC and pBR322-derived plasmids that will be maintained in *E. coli* host before transfer to a fungal host organism. The plasmids contain the Candida URA3 gene to compliment the ura3 auxotrophy in the recipient Candida strain, leaving the other auxotrophies (his and arg in strain BWP17) unaffected. Similarly, other vectors enable the regeneration of the ura marker (to regenerate a triply auxotrophic strain). Due to the nature of the promoters there is unlikely to be any expression of eukaryotic genes in the bacterial strains mentioned. Vectors are integrated into the Candida genome and considered non-mobilisable.

Bacterial vectors. These are pUC derivatives encoding ampicillin, zeomycin or other antibiotic resistance markers. Considered to be non-mobilisable. Hazards arising from mobilisation are unlikely due to poor survivability of *E. coli* strains outside the laboratory.

Origin & function

The Candida strains will only be used in the contained laboratory environment. The aim of the study is to understand the molecular basis of dimorphism in Candida, ie how Candida changes between yeast and filamentous forms.

Candida genes will be isolated and self-cloned back into Candida (having passed through the stage of cloning in disabled strains of *E. coli* using conventional gene cloning approaches. The inserted genes will be used to delete genes from the Candida genome by recombination. So, the strains of Candida that are generated will be deficient (either deleted or down-regulated) in gene function. Up-regulated expression of some genes will only be studied in a multiply disabled strain (above). Genes to be regulated by these methods include genes involved in protein secretion and secretion stress (eg HACA) or genes that are putatively involved in control of gene expression due to nutrient availability (eg GCN4), effects on chromatin (eg DNA methylation or histone modification) or RNA function (eg MTRA).

Evaluation of foreseeable effects

As a scientific level, the studies will reveal the molecular basis of dimorphism and provide possible tools which might be exploited in the future in control of dimorphism (ie design of anti-Candida drugs).

In relation to safety, the most hazardous GMMs to be produced will be derivatives of the ACDM category 2 organism *C. albicans*. There is no indication, however, that any strain produced will be more virulent than the natural commensal strains of *C. albicans*. All strains used are disabled and there is no indication from the literature of any strain, in which a gene has been deleted or down-regulated, having enhanced virulence. The GMM strains will remain disabled due to auxotrophies. None of the target genes are likely, on their won, to have an impact on virulence because of the recognised multigenic nature of virulence in *C. albicans*. Thus, the GMM organisms are considered to be of the same ACDP category 2 as the host strain.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All solid waste and plastics exposed to GM material will be autoclaved prior to disposal. All liquid waste and glassware exposed to GM material will be autoclaved prior to disposal/wash up. Accidental spills will be contained using paper towels and any Candida will be destroyed by Trigene (2%) disinfectant which is effective for killing fungi including C. albicans. The paper towels will be autoclaved.

Class 2 autoclave disposal facility is available in the same laboratory area. The autoclave is subject to a regular programme of annual service and testing for effectiveness and checks are made on completion of cycle (on daily basis).

Please enter comments on the GM safety committee on the risk assessment

The local GM committee (University of Nottingham) GMSCB reviewed the risk assessment on 6th October 2005. They agreed with the assessment of the activity as being Class 2. Questions were raised regarding the related safety issues of a possible need for health screening for workers, potential contraindications to work and the need to provide information to staff who work on the project. Advice was sought from Occupational health on these matters. Minor amendments to the risk assessment were made on the basis of the advice provided.

Purposes of the contained use

The overall goal is to characterise the function of the tumour suppressor gene LIMD1. LIMD1 is involved in suppression of cell growth and thus tumour growth and may constitute a novel targets for cancer therapy. In addition we will also screen primary epithelial cells for novel gene (including LIMD1) which induced immortalisation. Furthermore, in collaboration with 'other named staff' above we will use reagents indicated below to immortalize the primary cell lines, bronchial epithelial cells (HBEC), primary hepatocytes, primary Human Umbilical Vein Endothelial Cells (HUVEC) and airway smooth muscle/myofibroblasts.

Recipient or parental organism

The bacterial host will be DH5 alpha.

Infecitve virus is produced by lipid-mediated transfection of retroviral and lentiviral expression vector into the Bosc23 packaging cell line (to produce ecotropic retrovirus) and the PT67 packaging cell line (to produce amphotropic retrovirus) and the 293gp cell line (to produce amphotropic lentivirus) and collection of culture supernatant. These packaging cell lines express envelope and gag and pol proteins derived from the 10A1 Moloney murine leukemia viral genome and HIV1 viral genome respectively.

The recipient transformed cell lines are HEK293, MCF7, U2OS, SAOS2, A549, MDA-MB435, HeLa, HepG2, ECV304, 293T. The recipient primary human cells to be transduced by retrovirus and lentivirus are bronchial epithelial cells (HBEC), primary hepatocytes, primary Human Umbilical Vein Endothelial Cells (HUVEC) and smooth muscle/myofibroblasts. The work with the immortalised cell lines and primary human cells, which is routinely done in our department, is done at containment level 2.

Host/vector system

Retroviral vectors: gives to <30% transduction efficiency in most cell types, and requires active cell division. In addition, there is integration into the host genome. Unlike adenovirus, recombinant retrovirus is very easy to develop. Retroviral vectors to be used: pBABEpuro, pSuper.retro pWZL and pLXSN (these vectors are retroviral and derived from the Moloney murine leukemia virus (MMLV)).

Lenvitivirus: gives to >80% transduction efficiency, thus lentiviral vectors can mediate the efficient delivery, integration and stable expression of transgenes in dividing as well as nondividing cells in vitro. As such, they open exciting possibilities for both basic research and the genetic treatment of human diseases. As with retrovirus, recombinant lentivirus is very easy to develop. We will also use the Lentiviral based vector pHR.
Both vectors are non-mobilisable and replication defective.

Origin & function

The genetic material ('inserts', see below) have been produced in my lab via molecular biology techniques such as RT-PCR from cellular RNA.

Inserts to be used: LIMD1 (LIM Domain Containing Protein 1), BAF (Barrier-to-autointergration Factor), Grbn7 (Growth Receptor Binding Protein 7), FHOD1 (diaphanous-related formin homology 2 domain containing protein 1).

HIF1alpha (Hypoxia-inducible factor 1alpha), PHD1, 2 and 3; (HIF-pprolyl-hydroxylases, 1, 2 and 3) these genes are not considered proto-oncogenes according to the ACGM classification and will not affect the virulence of the recipient line.

We will also use the Bmi-1 oncogene to induce immortalisation but not transformation of primary human bronchial epithelial cells, primary hepatocytes, primary Human Umbilical Vein Endothelial Cells (HUVEC) and airway smooth muscle/myofibroblasts.

hTERT (catalytic subunits of telomerase), Hras (Harvey rat sarcoma virusl (v-Ha-ras) oncogene homolog, simian virus 40 large T antigen (SV40LT), simian virus 40 small t antigen and Human Papilloma virus E6/E7 will also be used to induce immortalisation.

We will also introduce different combination of the above lenti/retro constructs into the indicated primary cells to induce various levels of transformed phenotype. It is important to state that such transformed lines produced will be no more transformed or pathogenic than HeLa cells which are widely used throughout biomedical research in category 2 facilities.

Evaluation of foreseeable effects

The various inserts will not alter the pathogenicity of the cells. The virus is replication defective and unstable Standard cell culture practice will prevent introduction into humans.

It is important to note that immortalisation of the primary cultures indicated does not cause transformation. As stated above such cells can only survive in very specific in vitro tissue culture conditions. Cell lines created this way will remain none-pathogenic.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We will apply all the measures specified as requirements for containment level 2.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All transfections and manipulations of cells will be performed in a Class II biological safety cabinet (identifiable to other users), preventing release of aerosols. Protective clothing, double gloves to be worn at all times. Because of virus nature of the work, no glassware or sharps will be used, only disposable plastic-ware. All potential infectious waste (solutions and microbiological plates) will be either disinfected [using Trigene] or autoclaved,, prior to disposal via drains or incineration as appropriate. In the event of spillage, the spill will be absorbed onto paper towel, the area will be effectively disinfected with Trigene (1:100 dilution). Towels will be autoclaved prior to disposal.

Disinfectants are used in accordance with manufacturers recommendations and manufacturers data shows that the disinfectants are effective against the organisms in question. Data on the appropriateness and effective degree of kill for these detergents are provided by Brindle Microbiological Consultants (Trigene).
The autoclave is subject to calibration and validation by a service company twice yearly.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The committee approved the assessment as a class 2 activity for lenti and retroviral infection of tissue culture and was satisfied that the location of the work conformed to the required containment level.

Project Additional Information

Purposes of the contained use

Post-graduate research into the pathogenesis of hepatitis C virus (HCV), outlined below:
Hepatitis C virus (HCV) is a major global health problem. The virus was discovered in the early 1990s by molecular techniques and has never been able to be cultured in the laboratory. This seriously hinders progress towards understanding pathogenesis and developing therapeutics.

A new full length HCV replicon (JFH1) has been constructed from wild-type virus and shown to replicate and produce small amounts of infectious HCV when transfected into cell lines. However, studies in cell lines have only limited relevance when compared to primary cells in vivo. We will transfect primary liver cells with the subgenomic replicon of this clone (pSGR-Luc-JFH1) using established methods, to assess:

(a) establish whether replication occurs in the cells and, if so, to what level and;
(b) to establish the effect of the subgenomic replicon on the phenotype and function of infected cells;

We will also transfet cell lines with full-length replicons and aim to infect in vitro cultures of primary liver cells with the virus produced:

c) to establish whether infectious virus is produced from the infected cells and to what extent, and also;
d) to establish the effect of the full-length replicon on the phenotype and function of infected cells;

Depending on the results of this work, further studies on the viral life cycle and effects may be carried out in subsequent studies. In particular, it is anticipated that if viral replication and/or virus particle production is supported in these cultures, we plan also to infect primary human hepatocytes (only) with different genotypes of wild-type (non-GM) HCV. Further studies are likely to involve study of virus binding and entry, through the use of HCV plasmids with modified envelope protein (E1/E2) genes.

If the human hepatocyte cell culture system described above successfully supports replication of and production of HCV, we also plan to introduce hepatitis B virus to the system in similar ways (ie both wild-type and plasmid-encoded virus and viral genes) to use the model to assess differences in HBV genotypes and their natural pathogenesis in liver cells).

Recipient or parental organism

The replicons will be transfected into primary hepatocytes and standard hepatocyte cell lines including Huh7 cells (containment level 1/2 rising to containment level 3 when transfected). Infectious virus produced by Huh7 cells transfected with JFH1 will be introduced to cultures of primary human hepatocytes and primary human stellate cells (all at containment level 3).

Host/vector system

No modification to the HCV replicons will be carried out during our experiments. Transfection of eukaryotic cell lines will be by electroporation (no vector required).

Transfer of genetic material into host mammalian cells will be by transfection of RNA. Multiple RNA copies will be produced from linearised plasmid using an isothermal in vitro RNA polymerase reaction, therefore cloning or use of bacterial hosts will not be carried out.

Origin & function

No modification to any of the genetic material will be carried out during our experiments.
pJFH1
Other than both structural and non-structural wild-type HCV genes, the only addition is that of T7 (an RNA polymerase promoter) and Xbal (a restriction site) in the 5’ and 3’ untranslated regions [see below]

pLuc-JFH1
This full-length bicistronic construct has been engineered with the firefly luciferase gene (see below) at the 5’ end followed by the encephalomyocarditis virus (EMCV) internal ribosome entry site which ensures follow-on translation of the normal HCV 2a wild-type genes. The firefly luciferase gene (luc) has no interaction with the HCV genes or host cell and simply will produce light which can be quantitated in order to permit assessment of the amount of replicon translated in the cells.

pSGR-Luc-JFH1
Other than non-structural wild-type HCV genes, the only additions are that of the luciferase cassette (as above), followed by the EMCV IRES which directs expression of the HCV non-structural genes in the second cistron.

The control plasmids contain various sequences or mutations which prevent replication (or virus production). For example, GND represents a disabling mutation in the active site motif of NS5B polymerase. These are commonly used to ensure that any RNA (or virus) detected is the product of novel replication (or virus particle) production within the transfected (or infected) cells.

Details of the construction of the pSGR-Luc-JFH1 plasmid, JFH1 and Luc-JFH1 replicons are as follows:

Sequence map of JFH1 full-length replicon (Wakita et al. 2005 Nature Medicine). There is a T7 promoter at the 5’ end and an X-Bal restriction site in the 3’ UTR (not shown):

- the Luc-JFH1 replicon (Wakita et al. 2005 Nature Medicine) is as the pSGR-Luc-JFH1 plasmid, but with the addition of the core, E1, E2 and p7 genes between the EMCV IRES and the non-structural genes.

Sequence map of pSGR-Luc-JFH1 (Targett-Adams and McLaughlan, 2005 in press). There is a T7 promoter at the 5’ end and an X-Bal restriction site in the 3’ UTR (not shown):

Luc EMCV NS3 4B 5A 5B

Control plasmids are as follows:

Sequence maps of full-length chimeric control plasmids (Lindenbach et al. Science 2005):

- FL-J6/JFH contains structural genes from the J6 strain (genotype 2a) and FL-H77/JFH contains structural genes from the H77 strain (genotype 1a)

Replication incompetent full-length plasmids with the GND-mutation will also be used as negative controls (see section 5.3).

Sequence map of pSGR-Luc-JFH1/GND [replication-incompetent control plasmid]
(Targett-Adams and McLaughlan, 2005 in press). There is a T7 promoter at the 5’ end and an X-Bal restriction site in the 3’ UTR (not shown):

GND
Luc EMCV NS3 4A 4B 5A 5B

Other JFH1 plasmids, with reporter genes inserted for the purpose of tracking the protein product, may also be used in the future, as they become available. None will be constructed in-house. HCV 1b subgenomic replicons. (replication incompetent) may be used as control plasmids for pSGR-JFH1.

Different genotypes of wild-type (unmodified) HCV, if used, would be recovered from human serum with Ethical consent and will be characterised by the Trent HCV Study Group.

The Genbank accession number for the consensus sequence of JFH1 is ABO47639

**Evaluation of foreseeable effects**

HCV is assigned to category 3 in the ACDP listings, with modifications to BSL 3 requirements possible. HCV is a blood-borne virus spread almost solely by percutaneous exposure (infection may theoretically occur via mucous membrane exposure although only one case of possible transmission via an eyesplash of infected material has every been reported). In approximately 80% of those exposed it causes a chronic infection characterised by liver inflammation and steatosis. This can progress to fibrosis, cirrhosis, liver failure or hepatocellular carcinoma. Non-genotype 1 viruses (from one of which this agent was derived) respond better to antiviral treatment and there is now evidence that antiviral treatment early in the course of infection is more more likely to result in the virus becoming undetectable.

The replicons are constructed from an HCV genotype 2a wild-type virus consensus sequence. They are called pJFH-1 and pLUC-JFH1 (full length) and pSGR-Luc-JFH1 (subgenomic). As the full-length replicon expresses only wild-type HCV genes (with or without the non-toxic luciferase protein) it is anticipated that the hazards associated with the virus it may produce are similar to those of wild-type HCV. Neither the plasmid nor wild-type HCV is known to integrate with the genome of the recipient cell.

The luc gene is not known to have any toxic or harmful effects, even when expressed to high levels in animal models. There is no evidence to show that the EMCV IRES would lead to relative over-expression of the HCV genes in a human host.

All workers with human-derived tissue and cells should be immunised and have a documented response to hepatitis B vaccine. There is no available vaccine for hepatitis C. Pre-employment or routine screening is not required since, due to the long incubation period, baseline status can be determined if an incident occurs. In addition, the virus would be identifiable (by PCR) as having derived from the working environment.

If any percutaneous or mucocutaneous exposure occurs or is suspected to have occurred (including eyesplash), standard first aid should be administered. Eyes should be washed using the available sterile eye-way solution. Cuts, abrasions, penetrating injuries or contaminated mucous membranes should be washed under running water and any bleeding encouraged (without scrubbing).

Occupational Health will be notified of the exposure and baseline blood samples for storage should be taken as soon as possible. Follow-up blood samples for molecular diagnosis and serology will be required at 6, 12 and 24 weeks after the incident, or sooner if illness develops.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

We are applying for a derogation as there is currently no autoclave sited within the CL3 suite or lobby. The room arrangements are detailed in the Code of Practice. We consider it is not reasonably practicable to provide an additional autoclave in D31 [CL3 lobby] for the following reasons.

* D31 is too small to accommodate an autoclave.
* Costs of purchase and installation will be considerable.
* It will not be necessary to transport waste beyond D38 and access to the adjacent corridors is controlled so that only authorised personnel have access.
The following procedural controls will be implemented which we consider will adequately control risk:

* All solid CL3 will be autoclaved at the end of each working session, regardless of the amount of waste produced.
* All waste will be retained in the CL3 laboratory until the autoclave is available.
* Waste will only be handled by the CL3 trained user prior to autoclaving.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Although only the full-length replicon (pJFH1) is capable of producing infectious virus, all waste generated within the CL3 laboratory will be handled in the same way and only by trained personnel, as follows:

According to advice taken from "Guidance for Clinical Health Care Workers: protection against infection with blood-borne viruses" (1998, DoH publication), "HIV and hepatitis viruses are susceptible to heat and wherever possible equipment must be sterilised by conventional procedures employing moist or dry heat. For heat-labile articles and surfaces which cannot be sterilised it will be necessary to employ methods of chemical disinfection. Recommendation of disinfectants for the purpose of inactivation of HIV and hepatitis viruses is restricted by lack of adequate data for many chemical agents. The methodology for evaluating the activity of compounds against HIV and hepatitis viruses is complex, not least because of the need to simulate "real life" conditions where organic contamination is likely to be present".

Manufacturer's validation data for our current disinfectant (Trigene) is available. Testing against Hepatitis B surface antigen (BHsAg) has been carried out by the PHLS (now HPA) to show that addition of a 1% dilution of Trigene (for 5 minutes) neutralised a 5% dilution of serum which was highly reactive for HBsAg.

While there is no available test for the validation of disinfectants or sterilisation against HCV, evidence of action against HBsAg is accepted as a standard substitute and statements to this effect are available. The mode of action of Trigene is not only to disrupt the cell wall and virus envelope, but it will also inactivate and break down nucleic acids on contact, via direct alteration of the secondary structure.

**Solid waste**

Plastic consumables (except pipettes), gloves and contaminated paper towels will be double-bagged into autoclave bags and autoclaved for at least 15 minutes at 121 degrees C.

Currently, there is a well-established procedure for electronic monitoring of the cycle temperatures and for validating that the cycle has run correctly by examining the resultant print-out. A record is kept of each cycle and there is an SOP in the case of suspected autoclave breakdown or failure. All personnel involved will be trained in the handling of CL3 waste. The current systems for autoclave validation will continue to be used (ie printout on every run and when services), however, if a cycle containing CL3 waste is known or suspected to have failed, the procedures for handling the contents will be as for all CL3 waste until successfully autoclaved. Successfully autoclaved material will be sent for incineration. Servicing and external validation is carried out by Lab3. Total Laboratory Service (Lab3 Limited) every 6 months.

**Liquid waste**

Liquid waste containing toxic chemical/materials will be disposed of by existing validated methods for the disposal of the chemicals used. Non-toxic liquid waste will be aspirated into sealed containers containing disinfectant (Trigene). This will be left for at least 12 hours prior to discard into drains. Daily renewal of fresh disinfectant solution to a known level will ensure the final concentration is not less than 5%.

**Spillages**

Spillages that contain, or potentially contain, virus particles, will be subjected to a 5% solution of Trigene (ie final concentration when diluted with the spillage) for 30 minutes as recommended by the manufacturer's guidelines. The decontaminated spill will be mopped up with paper towels and disposed of in a yellow bag for incineration. The worker who deals with the spillage must wear protective clothing ie gloves and a disposable apron and, in the case of extensive floor spillages, protective footwear.

**Other material**
Cells potentially harbouring the full-length (infectious) replicon and/or associated virus particles will not be removed from the CL3 facility unless killed. This will be by fixation, using glacial acetic acid, methanol or paraformaldehyde, or by fatal disruption, using a chaotropic agent such as Trizol, Triton X-100 or guanidine-isothiocyanate extraction. Denatured cell extracts may then be removed for PCR, luciferase activity analysis or for fluorescence microscopy. Once analysed, cell extracts will be disposed of by the most suitable route depending on what has been mixed with the extract during processing but as live virus will not be present in these extracts, CL3 disposal will not be required.

This project was discussed at the meeting of University of Nottingham Genetic Modification Safety Committee “C” on 14th November 2005. The assessment had been circulated to committee members prior to the meeting. This project will use existing full length or subgenomic HCV constructs provided by collaborators and no genetic modification of these constructs will be undertaken. The constructs would be obtained as purified plasmid DNA. No other specific concerns were raised regarding the safety of these constructs and the remainder of the discussion focussed on the procedures to be used in handling transfected cells in which HCV virus was to be replicated.

All work with cell lines containing live virus was to be performed in a Cat 2 laboratory (D38, Boots Building).

It was recognised that it would be necessary to apply for a derogation to allow use of the autoclave in D30 for inactivation of Catr 3 waste. This risk assessment and Code of Practice for the Cat 3 suite was modified to include the necessary procedures to ensure safety.

Once viral RNA had been isolated from transfected cells, further analysis would be done in a designated Cat 2 laboratory in QMC where routine diagnostic HCV work is performed. Given that the RNA extraction kits used for isolation of viral RNA contain chaotropic agents, it was considered unlikely that RNA extracts would contain viable HCV virus, but such extracts would be transported, stored, handled and inactivated according to protocols which took this possibility into account.

The assessment was approved by the committee as a Class 3 activity.

It was agreed that an update on progress of work under this assessment would be presented at each subsequent meeting of GM committee C.

Project Additional Information

Purposes of the contained use

The lab is interested in a number of areas:
Using human embryonic stem cells to model genetic and epigenetic based disease.
Improving differentiation of human embryonic stem cells to therapeutically useful lineages.
Understanding and minimising epigenetic consequences of in vitro manipulation of embryos and embryonic stem cells.

Recipient or parental organism

Non-colonising, non-pathogenic laboratory strains of K-12 derived E.coli: DH5a, HB101, Sbtl3. ACDP Hazard Group 1 will be used for generation of reporter and regulatory gene constructs.

CULTERED MAMMALIAN CELLS ASSIGNED TO ACDP HAZARD GROUP 1

Non-human cell lines and primary cells; or well characterized human cell lines:
Somatic cells (ovine, bovine, murine fibroblasts)
Stem cells (mouse embryonic stem cells)
Immortal cell lines (NTERA and 2103Ep Embryonal Carcinoma cells)

CULTERED MAMMALIAN CELLS ASSIGNED TO ACDP HAZARD GROUP 2

Primary somatic cells (human fibroblasts)
Stem cells (human embryonic stem cells)
Human Embryonic Kidney 293 cells

Some of these cell lines have a theoretical (but not specific) risk of carriage of human pathogens (eg. Primary fibroblasts, embryonic stem cells) and require containment level 2. HepB vaccination is available through the University's Occupation Health department and all staff involved in this work are vaccinated.

Host/vector system

pUC based, non mobilise cloning vectors (eg pBluescript, pGEM and pCR-TOPO vector families) will be used for generation of constructs in disabled E. coli strains.

For manipulation of mammalian cells, a second generation, inducible lentiviral expression system will be used, which requires three separate plasmids. All auxiliary viral genes are deleted i.e. vpr, vif, vpu and nef. Transfection into human embryonic kidney (HEK) 293 cells (from ATCC and produced in this system are replication incompetent. The plasmids are:

1. Transfer plasmid. Includes inserts, psi element, LTR (long terminal repeat) and WPRE (woodchuck hepatitas B regulatory element – this eliminates the need for rev in packaging system and improves the biosafety)
2. Packaging plasmid including gag and pol genes
3. Envelope plasmid including env and vsv-g genes

The complete sequence of all plasmids and inserts to be used is known and can be provided.

The transgenic inserts and shRNA sequences in the transfer plasmid are the only sequences that will be transferred to target cell types described in section 5.1. These sequences are under continual repression from KRAB domain and TET Repressor sequences and repression is only relieved when doxycycline (or tetracycline) is added, thereby increasing the safety of the vector system.

The originating laboratory (see http://tronolab.epfl.ch/) has extensive experience in using this system and supplies researchers worldwide. Their recommendation is that this viral system should be used at biosafety level 2 and therefore assigned to ACDP hazard group 2.

Origin & function

1) Reporters:
GFP (green fluorescent protein)
Luciferase (an enzyme that oxidizes exogenously applied luciferin, releasing photons)
2) Selection markers:
Neomycin and puromycin antibiotic resistance genes.
Thymidine kinase (involved in dTTP synthesis).
3) Gene Modulators and Modifiers:
GATA-4 is a zinc-finger transcription factor which binds a GATA sequence and exerts an effect in embryogenesis and cardiogenesis.
NKX2.5 is a homebox gene involved in heart development.
MEF (myocyte enhancer factor) 2c is a transcription factor involved in muscle development.
TBX-5 is a transcription factor that binds T box sequences and is implicated in heart and upper limb development. Hairpin loops that form double stranded RNA can downregulate the expression of the corresponding gene by inducing the degradation of the gene’s mRNA.
Tet Repressor (TR) bind to tet operator sequences and inhibit transcription KRAB domain from Drosophila is fused to TR sequence. On binding of TR-KRAB to tet operator sequences, repression of the approx 3 kilobases of transgenic/ viral sequences occurs.

Proteins produced (once the above expression system is induced) are believed to be non-toxic and non-virulent.

Evaluation of foreseeable effects

There are no significant perceived hazards to human health or the environment associated with generation of the proposed constructs in disabled E. coli strains.
Following manipulation of mammalian cells, the most dangerous combination of inserted material would be expression of a transcription factor such as DNA methyltransferase 1 may elicit change in phenotype by altering methylation pattern. However, the viral system we will employ is second generation and replication defective. Moreover, the inducible nature means that only when operator intervention occurs (addition of doxycycline) will the transgenes be expressed. The viral system utilises expression of the WPRE (woodchuck hepatitis B regulatory element), which may have oncogenic properties. Accordingly, extra care is needed when handling naked DNA containing such sequences, as prescribed in the Nottingham University's COP for Biological Agents and GMM, part 3.4. Given the properties of the vector system to be used and the inserted material, we believe that mammalian cells containing these sequences will not be any more pathogenic or virulent than prior to transfection. In addition, the lentiviral particles to be generated are replication defective and are unlikely to survive in the environment. The specified gene inserts will have negligible effect on the environment, especially as the constructs are inducible.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid and solid waste containing or exposed to GMO's will be transferred to CBSII prep room A81 for autoclaving to achieve 100% kill, prior to incineration. 121 degrees C for 15 minutes at 2 atmospheres is sufficient to inactivate mammalian cells and E.coli and the human pathogens that present a theoretical risk in our containment level 2 human cell cultures. The autoclave has a chart readout which is checked after each discard cycle and is also validated on a six monthly cycle in accordance with HTM 2110. In the event of spillages, surfaces will be disinfected with 1/100 dilution of Trigene Advance which has been validated by the manufacturer to produce a log5 kill of E.coli and to neutralise human retroviruses.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

This project was circulated for comments to members of University of Nottingham Genetic Modification Safety Committee “C”. The consensus view from comments received was that the risk assessment was comprehensive and adequately described and addressed the risk of the proposed manipulations in E.coli and mammalian cells. The potential hazards associated with use of primary human cell lines were acknowledged. In addition, the potential oncogenic hazard associated with the WPRE (woodchuck hepatitis B regulatory element) was identified and appropriate precautions for handling this element were identified. The investigators indicated that they considered that the proposed project should be undertaken as a class 2 activity. Recent guidelines from HSE which indicated that there is still some uncertainty over stability of the lentiviral vector systems in general, supported this view. The assessment was formally approved by the committee as a class 2 activity at a meeting held on 18/06/07.

Project Containment

Laboratory Activities  Glass Houses  Growth Rooms
Project Ref 470/08.1

Comparative functional genomics of Escherichia coli strains and pathotypes (DO8-01).

Project Additional Information

Purposes of the contained use

The scientific goals and major aims of the project are to compare the whole cell transcriptomics, interactomics, and phenotypic responses of different E. coli strains that have gene knockouts in a range of genes encoding transcription factors and other metabolically important genes, and/or have affinity tagged chromosomally encoded transcription factors which will be used for ChiP-chip (chromatin immunoprecipitation on DNA chip) work. Reporter genes will be engineered in to the chromosome to monitor specific gene expression.

Recipient or parental organism

The major genetic manipulations will be to make gene knockouts in the strains, or to affinity tag, or add in reporter genes that are transcriptionally fused to these genes. These manipulations will be achieved using chromosomai engineering.

Host/vector system

Disabled laboratory K-1 strains (examples: TGI, TG2, XL-Blue), or K-1/B strains (examples: BL21, Origami) will be used as hosts for cloning of genes and/or overexpression of
proteins and in plasmid construction. These are all ACDP HG I
Strains used for chromosome engineering will be E. coli K-12 laboratory strains or strains which have had minimal manipulation made to them: EMG2, MG1655 (genome sequenced), W3110 (genome sequenced), (all ACDPI), and E. coli pathotypes- including the genome sequenced strains: CFT073 (Uropathogenic E. coli), 042 (Enterococcal aggregate E. coli), H10407 (Enterotoxigenic E. coli), E2348/69 (Enteropathogenic E. coli) (ACDP2), APEC01 (Avian pathogenic E. coli) andVT negative 0157: H7 Sakai and EDL933. Both of the 0157:H7 strains have both genes encoding the shigella-like toxin (Stxin and Sbc2) deleted making them ACDP2. Other ACDP2 E. coli pathotypes may be used.

VECTORS
Standard non-mobilisable p15A, pSc101, IncW and ColE1 replicon derived plasmids will be used for cloning and overexpression work which will be carried out in E. coli K-12 laboratory strains only. Plasmids include the pUC plasmids (ampicillin resistance), pACYC184 (chloramphenicol and tetracycline resistance), and GATEWAY vectors (kanamycin resistance- Invitrogen)
Specific gene knockout vectors will include pEXI OOT (Ampicillin resistance and sucrose sensitivity, from sacB, Schweitzer and Huang, 1995, Gene 158: 15-22) or derivatives (Lee et al., submitted) pACBSR (chloramphenicol resistance and lambda red recombinase, Herring et al., 2003, Gene 331: 153-i 63) pKD3 (Kanamycin resistance), pKD4 (Chloramphenicol resistance), pKD2O and pKD4G (both ampicillin resistance and lambda red recombinase) (Datsenko and Wanner 2001, Proc. Natl. Acad. Sci. USA 98: 6640-6645)
The pET series of vectors (ampicillin resistance) will be used to overexpress proteins for raising antibodies if required.

Origin & function
None of the genes that are to be manipulated or overexpressed in order to raise antibodies are known to be toxic, or allergenic. These genes are common to K-12 and pathogenic E. coli strains and can be considered to be core function genes.
The genes that will be inserted will be antibiotic resistance cassettes, which will mark chromosomal alterations; Tag sequences such as FLAG, Protein A, 6x histidine or 12x histidine will be fused to pre-existing genes, and reporter genes, such as green fluorescent protein (gfp) or bioluminescence (lux) genes. Examples of genes which will be tagged or deleted include rpoS (stress/stationary phase regulator), fur (iron uptake regulator), soxR/S (oxidative stress response regulators), fThDC (motility master regulators) and genes involved in metal ion homeostasis.

Evaluation of foreseeable effects
With the exception of the E. coli K-12 laboratory strains, which are recognized as disabled and are ACDP1, and would be used as the host strain in cloning or overexpression work, the parental/recipient organisms are pathogenic E. coli strains classified as ACDP2 and contain no known disabling mutations that could revert. The organisms as such pose the same risk to humans as the original wild-type, but complete deletions of regulator genes or affinity tagging of these genes on the chromosome may attenuate the organisms. Although highly unlikely because the regulators regulate core metabolic function, there is also the possibility that deletion of a gene encoding a regulator may derepress expression of genes in the host that are normally repressed. The organisms are not listed as an animal pathogen controlled by DEFRA.
The E. coli K-12 laboratory strains are defective in environmental survival and capability to establish in the mammalian gut. The pathogenic E. coli strains are human pathogens, and are already present in the environment. The 0157 strains used in this study are defective in verotoxin production because the genes for the toxins have been deleted and therefore the strains are less of a potential hazard than 01 57:H7 already present in the environment.
Identification of further regulators by ChiP-chip and transcriptomics is envisaged in the project. These regulators are likely to be core metabolism regulators, but may include pathogenicity regulators. Deletion of the genes encoding these regulators may lead to expression of pathogenicity factors that are normally switched off until the correct environmental signals are perceived by the bacterium. Any potential expression of a normally repressed pathogenicity gene will not make the strain more hazardous because it already has the capacity to express these genes. It may be disadvantaged compared to the wild-type because regulation of pathogenicity factors has evolved to control their expression, which may have a fitness cost to the bacterium.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
not applicable
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste is routinely inactivated by autoclaving (134°C for 30 minutes). Contaminated plasticware is triple bagged, tagged and taken away by White Rose environmental in locked, leakproof containers for incineration. Contaminated sharps are discarded in Sharpsafe containers before being triple bagged and disposed of as detailed above. These procedures are detailed in the local code of practice. All liquid waste is routinely autoclaved at 134°C for 30 minutes, prior to disposal to drain. Small spills of liquid waste or contamination of equipment is disinfected chemically. These procedures are detailed in the local code of practice. The standard disinfectant used is Virkon (1% WN solution). The disinfectant will only be used to disinfect lightly contaminated areas and not for treatment of substantially contaminated areas or for making safe contaminated organic matter such as paper towels used to absorb spilled cultures- these materials will be autoclaved prior to disposal. Multiple independent tests on pathogenic bacteria including E. coli have shown that 1% solutions of Virkon are effective in achieving at least a b5 reduction in bacterial count under the appropriate conditions. See http://www.antecint.co.uk/main/virkons.htm

Is an emergency plan required according to regulation 20? N

Date Ackn'd 02/03/2022
SVMS_CPW1: Veterinary bacterial pathogens and Zoonoses: virulence genes, pathogenicity, vaccines and immunity.

**Project Additional Information**

**Purposes of the contained use**

This CU2 accompanies the connect programme for working with a range of hazard group organisms groups ACDP1 & 2.

The aim of this connected programme is to gain further insight into mechanisms & pathogenicity and immunity of common bacterial pathogens & livestock species.

**Scope:**
- The study of the role of specific genes by their disruption.
- The function of specific genes by their cloning and transfer to new donors.
- The development of vaccines by employing a combination of both disruption of genes and expression of pathogen antigens in vaccine strains constructs.
- The effect of changes in bacterial gene expression on host immune responses by either disruption, over expressions, or fusion to carrier proteins.
- The over production of specific proteins for the purpose of purification.

Genes will be cloned either into the genome or as episomal clones in plasmid vectors. The specific methods used in any process will be assessed in the individual risk assessments to ensure they fall under or within class 2 activities for genetic modification. The connected programme outlines the restrictions and scope of the work to be carried out. It lists the genera of organisms (section 7 below).

Infection studies will also be carried out under ASPA regulations. Where this is done all work will under class-2 containment. Organisms used in infection are expected to be & equivalent virulence to that of the wild-type parental strains. Full risk assessments and operating procedures for working with animals with these infections will be in force during this work. Waste material from infected animals will be treated as hazard group-2 infectious material and treated accordingly (see below).

The contained use is to reduce the risk of accidental release or spread of GMOs into the environment. Work is to be restricted class 2 activities and below. The work will not generate organisms higher than ACDP2.

**Recipient or parental organism**

The major genetic manipulations will include
- Disruption of genes by insertion of antibiotic markers, tags and fusion proteins.
- The cloning and transfer to new donors within Genera.
- The development of vaccines by a combination of gene disruption of genes and expression of pathogen antigens in vaccine strains constructs. This expression will be across genera and each construct will
Over expressions, of non toxins proteins in Laboratory strains of e coli for the purpose of their purification. These manipulations will be run under the CPW and achieved using a range of standard molecular methodologies. The individual processes will be reviewed independently by GMSCd.

### Host/vector system

Hosts as listed in CPWI: Laboratory E. coli (classi); Salmonella onterica, Campylobacter sp., E. coli (avian serovars), Streptococcus (class I and 2), Lactococcus lactis, Corynebacterium (ulcerans, bovis and pyogenes), Clostridium (perfringens, pyo genes and difflidie), &achyspira sp. & Lawsonia sp. Restrictions on transfer of genes between genera and species are outlined within the CPW.

Vectors: Host vector systems will be detailed in the individual risk assessments held under this CPW. These will be reviewed by the University GM committee prior to work commencing. Vectors will be standard sequencing, expression and gene fusion vectors used in molecular bacteriology studies.

### Origin & function

The origins and restrictions on the transfer of the genetic material are outlined in the CPW in general they cover.

- Transfer of genes from the listed bacterial genera into laboratory strains of E. coli for their manipulation using cloning vectors, expression vectors, over expression and fusion vectors.
- Transfer of antibiotic genes, appropriate for the genera to be studied, to form insertion knockouts in genes to allow study of function.
- Use of low level expression vectors for trans-complementation of genes. None & the genes that are to be manipulated or over-expressed are known to be toxic, or allergenic. These genes are common core function genes. Where genes are involved in virulence they are part of multi-gene systems and individual doning is unlikely to increase virulence of recipient strains.

The details of these will be in the individual risk assessments held under this CPW. These will be reviewed by the University GM committee (GMSCd) prior to work commencing. Vectors will be standard sequencing, expression and gene fusion vectors used in molecular bacteriology studies. Example risk assessments are attached.

### Evaluation of foreseeable effects

With the exception of the E. coli laboratory strains, some Streptococci and Lactococci listed in the CPW and which are recognized as ACDPI. The other parental/recipient organisms are pathogenic and are classified as ACDP2. The GM microorganisms will pose the same risk to humans and animals as the original wild-type. Complete deletions of regulator genes or affinity tagging of these genes on the chromosome may attenuate the organisms. Although highly unlikely because the regulators regulate core metabolic function, there is the possibility that deletion of a gene encoding a regulator may derepress expression of genes in the host that are normally repressed.

The organisms are not listed as an animal pathogen controlled by DEFRA.

The E. coli laboratory strains are defective in environmental survival and capability to establish in the mammalian gut.

The pathogenic strains are veterinary and human pathogens, and are already present in the environment.

The Salmonella Typhi strain listed is defective in the am operon with multiple lesions and has previously been derogated through the HSE to be used in laboratory studies at ACDP2 (see attached letter and section 11).

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

not applicable

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Derogation has already been sought for Salmonella Typhi arc vaccines strains used as controls and in laborai&i1 based vaccine studies. See attached paper work letter from HSE November, 1993. Salmonella Typhi arc strains have been used successfully in human clinical trials without major health risks. This CPW includes there use as vectors for antigens by cloning but places limits work to avoid complementation of the arc lesions.
12. Describe the waste management

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Infectious GM waste will be either autoclaved [121°C 15 minutes] to render non infectious or treated with disinfectant [see below] then sent for incineration at SRCL. The autoclave has a chart readout which is checked after each discard cycle and is also serviced, calibrated & validated [early].

General decontamination will be with either Virkon (1%) or Tn-gene (1%). Bactericidal efficiency of Trigene has been tested for 1 minute contact time for 1% at 1 minute or up to 10 minutes in the presence of high organic load. Validated by the manufacturer to produce a > log5 kill of the organisms to be used. An exception to this is Clostridium difficile where the current literature suggests 2% Trigene solution. Increased concentrations will be used in work with organisms in the presence of blood, serum 10% Tn-gene or Virkon.

In the event of a need arising to send untreated GM waste for off site incineration it will be triple bagged and sent to SRCL [formerly White Rose] who are a GM facility notified under GM CU Regs [GM Centre 779].

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [N]

Tick if you are claiming exemption from disclosure for section of the risk assessment [Y]

Please enter comments on the GM safety committee on the risk assessment

All members of GMSCD were asked to comment on the CPW comments received have been acted on. The committee do not have any outstanding concerns for this CPW or the attached risk assessments as Class 2 activities.

Project Ref 470/08.4

Date Ackn'd CU2 Project Title Class CultureVolClass2 CultureVolumeClass3-4

02/03/2022
Generation of gene knock-out cell lines using the recombinant Adeno-associated virus (rAAV) vector system.

The aim of this project is to develop a variety of permissive human hepatoma cell lines with defined putative HCV cellular receptor(s) knock-outs. The unavailability of an efficient culture system for HCV has restricted the study of the mechanisms of HCV infection and development of effective antiviral agents. Several research groups have applied gene silencing technology by using the short interfering RNA (siRNA) approach in their HCV entry studies (Bartosch, et al. 2003, Zhang, et al., 2004, Lavillette, et al., 2005, Bartosch, et al., 2005, Lavillette, et al., 2005, Evans, et al. 2007). However, the expression of all genes of interest was down-regulated in the range of 60-90%. Although this approach provided some useful information, the interpretation of this method can be difficult because of incomplete inactivation of the studied genes. Therefore, generating HCV receptor gene knockout cell lines will generate a valuable resource which will allow detailed and novel investigation of the exact roles and mechanisms that HCV receptors play in HCV entry.

Recipient or parental organism
Non-colonising and disabled E. coli strains e.g ToplOF' or other K12 derivatives equivalent to ACDP hazard Group 1 will be used for generation of mutant constructs. Mammalian cell lines that will be used in this project are Huh7, Human hepatoma cell line and HEK-293 (Human Embryonic Kidney epithelial-derived cell line) which are only able to survive under specialised laboratory culture conditions. And are considered equivalent to ACDP hazard group 1.

Host/vector system
Non-viral vectors; The vectors pCDNA3.1 Directional TOPO (Invitrogen), pGEMT-Easy (Promega) will be used. These vectors are non-mobilisable. Viral vectors Name: Adeno-associated Virus (MV) serotype 2 recombinant vectors*, pHelper (carrying adenovirus-derived genes) and pAAV-RC (carrying AAV-2 replication and capsid genes) Adeno-associated virus (AAV) is a human parvovirus. It is replication-deficient parvovirus, which have traditionally required co-infection with a helper adenovirus or herpes virus for productive infection. AAV possesses a single stranded DNA genome of 4.7 kb. The wild-type virion possesses two open reading frames (OREs), termed rep and cap, flanked by two inverted terminal repeats (ITRs). The rep ORE encodes proteins involved in viral replication, and the cap ORE encodes proteins necessary for viral
packaging. In most rAAV vectors these OREs are deleted and replaced with a gene expression cassette of interest. The MV helper free system (Strategene) allows the production of infectious recombinant human adeno-associated virus-2 (AAV-2) virions without the use of a helper virus. The system takes advantage of the identification of the specific adenovirus gene products that mediate AAV replication and the demonstration that these gene products can be introduced into the host cell by transfection. In the AAV Helper-Free System, most of the adenovirus gene products required for the production of infective AAV particles are supplied on the plasmid pHelper (i.e. E2A, E4, and VA RNA genes) that is co-transfected into cells with human AAV-2 vector DNA. The manufacturers recommend use of this vector system at Biosafety level 2. The AAV-2 ITR-containing plasmids (pAAV-MCS, pAAV-LacZ and pAAV-hrGFP and pAAV-IRES-hrGFP) do not share any regions of homology with the rep/cap-gene containing plasmid (pAAV-RC), preventing the production of wild-type AAV-2 through recombination.

Origin & function

Antibiotic resistance markers, and reporter genes present in the plasmids to be used for construct generation are from commercial sources and their functions and properties well characterised.

Human DNA will be used as the source of genetic material for generation of gene knockouts in the mammalian cell lines. Genes that will initially be targeted for knockout include:

Scavenger receptor BI (SR-B1), a 509—amino acid polypeptide belonging to the CD36 superfamily, which includes cell surface membrane proteins that bind chemically modified lipoproteins and often many other types of ligand. SRB1 is highly expressed in the liver hepatocytes and steroidogenic tissues (Acton, at at., 1996). It is reported that SRB1 interacts (cellular protein binding) with Hepatitis C virus (HCV) envelope glycoprotein E2 via hypervariable region 1 (HVR1) of E2 (Scarselli, at at, 2002).

CD81, a tetraspanin (membrane protein) which is expressed on hepatocytes and B lymphocytes, was shown to bind to the HCV glycoprotein protein E2 (Pileri, eta!., 1998)

CLDN-1 isa 21 1-amino-acid protein with 4 transmembrane spanning domains that is highly expressed in the liver and is a key component of tight junction strands.

Evaluation of foreseeable effects

None of the proposed manipulations is considered likely to alter the properties of the recipient organisms in a way that will increase their hazard to human health or ability to survive in the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste containing or exposed to GMOs will be autoclaved to achieve 100% kill prior to incineration. The autoclave is validated using thermocouples on a yearly cycle and is tested every three weeks using internal temperature sensors.

All liquid waste will be treated with Trigene (2% vol/vol) as per manufacturer’s recommendation. In the event of spillages, surfaces will be disinfected with 1/100 dilution of Trigene which has been validated by the manufacturersto produce a > log5 kill of E. coli and to neutralise a range of viruses including human Adenovirus type 5 and retroviruses.
This assessment was circulated for comments to members of University Genetic Modification Safety "C". The consensus view was that this was a well focussed assessment which adequately addressed the risks of the proposed modifications in both E. coli and mammalian cells. The AAV vector system has advantages over other systems in terms of safety of use but the recommendation by the manufacturers that this should still be used at Biosafety 2 was recognised by the workers involved who indicated the work involving this vector should be a Class 2 activity. This was endorsed by the committee. The investigators were notified of this decision by the chair of GM committee "C" and this decision will be recorded in the minutes of the next meeting of this committee.

Project Ref 470/08.5

Date Ackn'd 28/08/2008
Date Project Ceased

Development of novel models of glutamatergic central nervous system disorders using in vivo shRNA and transgenic approaches.

Consent Granted Not Applicable

Project notified under transitional arrangements N
Project Additional Information

Purposes of the contained use

Altered glutamatergic neurotransmission is implicated in numerous psychiatric disorders, including schizophrenia and anxiety. The first aim of this project is to use lentiviral delivery of short hairpin RNA (shRNA) to cause selective, partial knockdown of specific components of the brain glutamatergic system (e.g. Excitatory Amino Acid Transporter 2; EAAT2, and Vesicular Glutamate Transporter 1; VGLUT1) in order to create novel models of hypo- and hyper-glutamatergic states. These models could be used to investigate the neurobiological and neurochemical bases of psychiatric illnesses, and assess the efficacy of novel treatment strategies.

The first aim is to perform in vitro studies in immortalised and primary cell lines in order to determine the extent of shRNA-mediated transporter knockdown (at mRNA, protein, and functional levels) and select candidate shRNA sequences for future in vivo use.

The shRNA lentiviral vectors are designed to only target mouse specific gene and will not cross target any other species including rat and human.

The second main aim of the project is to use this same technology to create cre inducible conditional shRNA driven mouse knock-downs for VGLUT1.

Recipient or parental organism

Recipient cell lines are HEK293T, HEK293, HeLa, Neuro-2A (mouse neuroblastoma) and C8-D1A (mouse astrocyte), obtained from ATCC or ECACC. Human cell lines are used for viral production, transduction control and GFP producing unit control determination/viral titre. All work with cell lines that have been transduced with lentivirus will be performed at containment level II. Lentivirus will also be introduced into mouse ES cells. Once transduced these cells are non-productive with respect to viral particles.

Host/vector system

The parental lentiviral plasmid vector to be used for this project is pLKO.1-puro (Sigma MISSION). Recombinant lentiviral particles containing the pLKO.1-puro vector will be generated (by HEK293 cells) using Lentiviral packaging mix. This includes (1) a packaging vector that contains the minimal set of lentiviral genes required to generate the virion structural proteins and packaging functions, and (2) the vesicular stomatitis virus G-protein (pCMV-VSV-G) envelope vector which provides the heterologous envelope for pseudotyping.

Safety features of this system are that (1) no single plasmid contains all the genes necessary to produce packaged lentivirus and resultant particles are replication incompetent, (2) a deletion in the U3 portion of the 3’ LTR eliminates the promoter-enhancer region and further negates the possibility of viral replication, and (3) lentiviral genes not necessary for shRNA packaging have been removed.
This proposal is designed for delivery of mouse-specific short hairpin RNA (shRNA) to cause selective, partial knockdown of specific components of the brain glutamatergic system (Excitatory Amino Acid Transporter 2; EA.AT2, and Vesicular Glutamate Transporter 1; VGLUT1) in order to create novel animal models of hypo- and hyper-glutamatergic states. The expressed shRNA's that will decrease glutamate transporter expression.

**Origin & function**

The shRNA proposed for use are only specific for mouse sequences and will not act against other species. There are no foreseeable effects.

**Evaluation of foreseeable effects**

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Standard containment level 2 procedures to be applied.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Tissue culture plastics & solid waste will be decontaminated by the addition of 2% Trigene solution for a minimum of 1 hour, then placed into yellow clinical waste sacks for incineration.

Liquid waste — 2%Trigene overnight then disposal down sink. For spill wipe down with Trigene and then with 100% ethanol. All tissue can then be disposed in yellow waste bags and sent for incineration.

Use of Trigene as a disinfectant for inactivation of lentivirus is in accordance with manufacture’s protocols and is supported by manufacturer’s independent efficacy testing data.

The overall goal is to reprogram differentiated somatic mammalian cells to a pluripotent state by using molecular components present in amphibian and fish oocytes and eggs. The aim is to transduce primary and immortalised mammalian with specific transcription factors known to regulate pluripotency as well as cDNA libraries derived from axolotl, xenopus, sturgeon and lungfish.

Recipient or parental organism

Somatic cells (ovine, bovine and murine fibroblast)

Insect cell lines: SF9

Amphibian: fish oocytes and eggs.

Host/vector system

Bacteria - Noncolonising, non-pathogenic laboratory strains of E.coli: DH5a, XL1, Blue, Stbl2, Stbl3, DH10bac. ACDP Hazard Group 1.

Vectors: pUC based cloning vectors (pBluecript, pGEM, pCR-TOPO vector families ) (Non mobiliasable) Retrovirus vectors: pMXs, pBASE (all derived from Moloney murine leukeamia virus) ACDP HG 1
Lentivirus vectors: pLenti6/TR, pFUW, pWPXld, pLVTHM, pLVCT (3rd generation HIV-1-based). In addition these vectors require pMD2.G (envelope vector) and psPAX2 (packaging vector) ACDP HG 2

Baculovirus vectors: pFastBac ACDP HG1

Phages: R408 and EX-Assist

1) Reporters: GFP and other colour/stability/localisation variants, dsRED, luciferase, LacZ
3) Gene Modulators and Modifiers: Pluripotency transcription factors and gene modulators (eg Oct4, Nanog, Klf4, Sox2, Rex1), modulators of cell immortalisation (hTERT, SV40LT), epigenetic modifiers (eg DNA methyl transferases, DNA demethyltransferases, histone methyl transferases, histone acetyltransferases, histone deacetylases, histone demethylases, polycomb proteins, histone variants), hairpin loops for RNAi (against transcription factors, modulators and epigenetic modifiers), inducible expression systems (eg tTA, rtTA and TRE sequence for Tet-off/Tet-on systems).
4) Promoters/regulatory elements for expression for reporters, markers or modulators:
   Consitutive promoters (eg PGK, EF1a, CAG, CMV). Tissue specific promoters/ regulatory elements active in haematopoietic development (eg Brachyury, SCL), germ cell development (eg, Vasa, Dazl) and pluripotency (eg, Nanog, Oct4, Rex1)
5) Site specific recombinase genes (eg Cre, Fip) and recognition sequences (eg Lox, FRT)

Origin & function

Many proteins (for the described genes) are reasonably believed to be non-toxic and non virulent. Some cDNA libraries will contain full-length coding sequences. Some encoded proteins may be oncogenic or modulators of growth and differentiation, although overexpression of only one gene is unlikely to result in oncogenic transformation. Some products (eg c-myc) can cause increased cell proliferation and may thus be oncogenic on overexpression, whereas other inserts will cause cell immortalisation (TERT, SV40LT) but not transformation. Others (eg DNA methyltransferases) can modulate gene expression and thus can cause altered cellulose phenotypes upon overexpression.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid Waste. Plasticware, pipettes and small tubes are disinfected by submerging in 5% trigene 12 hours and is then drained and disposed of as clinical waste for incineration. Agar plates and solid bacterial pellets will be sent for autoclaving to the Pathology dept at the QMC Hospital site (this is the general hospital autoclaving facility which routinely tested and calibrated for sterilisation of biohazards) before going for incineration. Validation systems for autoclaves. 121 c for 15 minutes at 2 atmospheres is sufficient to inactivate mammalian cells and E.coli. We will check that the autoclave tape has changed colour at the end of the procedure

LIQUID

Disinfection for 12 hours with 5% trigene prior to disposal to drains. Trigene is Bactericidal, Fungicidal, Virucidal, Mycobacterycidal and sporidical. It has been independantly tested for the manufacturer against a wide range of microorganisms and was found to be effective against them all at a dilution of 1/20 (5%) and most at 1/50 (2%, except <cycobacterium tuberculosis var bovis).

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N
The main area of concern for the GMSC was the use of the lentivirus in mammalian expression systems in association with the use of oncogenes (Specifically c myc) The GMSC felt therefore that Class 2 was appropriate for this project.

Purposes of the contained use

Contained use is used to reduce the risk of accident spread of GMOs into the environment. Work is to be restricted to class 2 activities and below. The work will not generate organisms of higher than class-2 risk (organisms listed in section 7 below). The aim of the programme is to gain insight into the basic virology, epidemiology, diagnosis, pathogenesis, immune evasion and host immune responses of veterinary viruses affecting livestock, wildlife and companion animals.

Several generic approaches will be used. These are described below. Individual combinations of end host, vector and donor virus allowed are outlined in the CPW document. Section numbers refer to the CPW document.

End Host Organisms
Standard mammalian cell lines (e.g. CHO, P815, rabbit kidney cell 13, Cos 7, HEK 293), ACDP 1; Prknery Avian
(chicken and duck) respiratory epithelial cells, ACDP 1; Primary mammalian (pig and human) respiratory epithelial
cells, ACDP 1; Primary ovine and bovine tissue epithelial and fibroblast cells, ACOP 1; Primary Equine Leukocytes,
ACDP 1; Standard insect cell lines (e.g. Sf9), ACDP 1.
BacTera: F. coli K12 Group I, ACDP 1.
Animals to be Infected: Equus caballus, Mus musculus, Oryctolagus cuniculus, Rattus norvegicus, Ovis aries, Mesocricetus auratus, ACDP I
Justification of Hazard group:
ACDP 1, unlikely to cause disease in humans.
ACDP 2, can cause disease in humans but unlikely to spread to the community, effective prophylaxis is available
ACDP3, Can cause severe disease in humans. Either ow risk of community spread or prophylaxis available
DEFRAJSAPSO group 3, exotic to the UK, moderate risk of spread
1DEFRAJSAPSO group 4, exotic to the UK, high risk of spread
Note that viruses masked with an * are not classified under either The SAPO or ACDP systems and have been
assigned a provisional risk category based on their risk to humans and animals -

Host/vector system
Host vector systems Will be detailed in the individual risk assessments held under this CPW. These will be reviews
the University GM committee prior to work commencing. Vectors will be standard sequencing, expression and gene fusion vectors used in molecular virology studies.
Vectors listed below with ACUP hazard group and justification of Hazard Group.
1. Standard bacterial cloning vectors and expression vectors for individual gene products
(ag. E. coli derived plasmids with antibiotic cassettes, transposons and markers), ACDP 1, unlikely to cause disease
in humans.
2. Bacterial Artificial Chromosomes (SAC), ACDP 1, Unlikely to cause disease in humans.
3. Vaccinia virus (NYVAC). ACDP 2, can cause disease in humans but unlikely to spread to the community,
affective prophylaxis is available. Local rules for the use of vaccinia virus will be in force.
4. Saculovirus (AcNPV), ACDP 1, Unlikely to cause disease to humans.
5. Adenovirus (AdS), ACOP 1, can cause disease in humans but unlikely to spread to the community.

Origin & function
The origins and restrictions on the transfer of the genetic material are outlined in the CPW in general they cover.
Transfer of genes and whole viral genomes from the listed viruses into laboratory strains of E. coli for their
manipulation using cloning vectors, expression vectors, over expression, fusion vectors and bacterial artificial Chromosomes
Transfer of genes or whole viral genomos from the listed viruses into mammalian cell lines using3g cloning vectors, expression vectors, overexpression vectors and fusion
vectors
Transfer of genes from the listed viruses into insect cell lines using baculovirus vectors
Infection of animals with constructs derived from genes or whole viruses from the listed viruses.
1. Develop reagents using genetic modification techniques to study the epidemiology of viruses, with the aims of improving or establishing new diagnostic tests and
characterising virus-encoded nucleotide and amino acid
sequences that determine host range and pathogenicity.
2. Use genetic manipulation and subsequent expression of viral genomes, individual genes, gene fragments and control elements to study the V function in vitro and in vivo.
3. Determine the role of manipulated genes in pathogenicity and protective immune responses. Thus the antigenicity of infectious or non-infectious constructs encoding individual viral genes or expressed recombinant protein may be used in vitro or in vivo, including inoculation of animals. The details of these will be detailed in the individual risk assessments held under this CPW. These will be reviewed by the University GM committee prior to work commencing. Vectors will be standard sequencing, expression and gene fusion vectors used in molecular bacteriology studies. Example risk assessments are attached.

**Evaluation of foreseeable effects**

The viruses, vectors and recipient hosts have been assigned to hazard group categories as outlined in section 6. Full details of the justifications are contained in the CPW. Where live virus is to be utilised the corresponding containment level laboratory or animal housing facility will be used. Local rules for viruses that cause disease in humans will be in place and where applicable will outline additional measures that may include vaccination (where available or work within microbiological safety cabinets. These precautions are outlined in the CPW and supporting documents.

**Containment and control measures for GMOs that are not micro-organisms (e.g. GM animals & plants)**

Most of the CMOs that will be created under this CPW are micro-organisms. My cell lines expressing genes or viruses will be held and manipulated under category 2 laboratory containment. It is not anticipated that any hazards greater than appropriate for this level of containment will be created.

GMO animals will not be created. Animals infected with viral GMO’s will be held under category 2 containment facilities or category I faculties (horses) with containment and waste disposal precautions as outlined in the CPW.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

No derogation within this application, not applicable.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Waste management measures include,

(i) Autoclaving and then innerMion at SRCL.
(ii) Contaminated plastic waste triple bagging and then incineration by SRCL (formerly White Rose Environmental)
GM Centre 779 licensed to accept GM waste up to Class 2.
(iii) Sharps disposal in sharp safe containers and disposal through HSE licensed contractors (White Rose HS approved contractors).
(iv) Use of Virkon & Trigeno Advance disinfectants in accordance with manufacturers protocols approved and tested disinfectant sprays to clean surfaces.

**Is an emergency plan required according to regulation 20?**

N

If yes, tick to confirm that it is attached to this form

N

Tick to confirm that you have attached a risk assessment to this form

Y

Tick if you are claiming exemption from disclosure for section of the risk assessment

N
In addition to review by the local GMSC the CPW was sent for external review by individuals with specific experience of using other organisms in the CPW. Amendments were made to the CPW to reflect comments of experts and those of the committee and local rules will be produced where appropriate in accordance with SAGCM guidance before work with the particular organism commences. The GMSC has given initial approval for the CPW at Class 2 but will review all subsequent risk assessments and local rules as they are produced.

The next generation of tissue engineering devices will use growth factors to generate replacement tissues which are of greater similarity to natural tissue. These include growth factors which generate bone and blood supply such as Bone Morphogenic Proteins (BMPs) and Vascular Endothelial Growth Factor (VEGF) as well as a range of other growth factors involved in wound healing or human development.

Growth factors work by stimulating transcription factors inside cells.

Many growth factors are not commercially available. Those which are can be prohibitively expensive costing up to £100,000 for experimentally useful quantities. A reliable in house way to make growth factors will enable the University of Nottingham's Tissue Engineering and Human Development research groups to conduct cutting edge experiments which are not currently financially viable.

Routine molecular cloning will be conducted in non-pathogenic recipient microorganisms such as attenuated E. coli and K. lactis. The genes will be cloned in deemed safe episomal constructs (plasmids from manufacturers with published MSDS).

- DH5α a K-12 E. coli derivative. It is non-colonising and disabled. It is hazard group 1 (SACGM2.3 pp.4) because it is not pathogenic to humans or animal and is rec. Cloning work in these cells will not give expression of any growth factor or oncogenic protein because expression requires DE3 modified strains or helper phage.

- BL21 is a strain derived from B E. coli that has been used in laboratory protein expression for over 30 years. It is rec+ and so has greater risk of transfer of genes into its genome. The HSE commissioned study stated that where BL21 is used to produce proteins which do not give rise to bacterial pathogenicity it may be classed as class-1 (ref: ACGM Newsletter 30, Nov. 2001 and SACGM 2.3 pp4). Commercially available derivatives of this strain include DE3 modified BL21-origami, BL21-rossetta.
BL21-shuffle, Small volume work such as plating and protein expression screening will be classified as level 1. When expressing potential growth factors and oncogenes in large volumes >100mL the potential for significant aspirates and spillage rises and so level 2 procedures will be applied as a precaution.

- Yeasts: Kluyveromyces lactis cells purchased from NEB is the GG799 strain. The FDA classifies K. lactis as "generally recognised as safe" (ref: Panuwatsuk 2003 Biotechnology and Bioengineering 81 (6) 712 -9). Recombiantion events are extremely rare except where intentionally transformed. Selection of modified strains is by ability to use acetamide as a nitrogen source and so does no confer selective advantage outside laboratory settings. K. lactis expressing growth factors will be important for safety. Small volumes and plates for screening can be treated as level 1 (SACGM 2.3 pp3) wheras volumes > 100mL potential for significant aspirates and spillage arises and so level 2 procedures will be applied as precaution.

Mammalian cell expression hosts

- C2C12 cells, human ES, mouse ES cells have minimal ability to colonise humans or survive outside the laboratory so are classified as hazard group 1 (SACGM 2.5). However when treating these cells with growth factors there is a possibility of transformation. When conducting these experiments the cells will be treated as Hazard group 2.

- HEK293T (human embryonic kidney) cells with integrated genes for growth factors or transcription factors pose little risk of colonisation nor are likely to survive outside the laboratory. Their excreted products could be harmful and will be treated with the extra caution advised (SACGM 2.5 pp.10) Therefore these cell lines will be treated as hazard group 2 with additional precautions for workers and disposal protocol.

- MEF (Mouse Embryonic Fibroblast) expressing membrane bound growth factors or receptors. MEFs are derived from disease free and classified mice strains. Modification in a connected program of work to incorporate NOTCH and other membrane bound growth factors and receptors will pose little risk once modified. The cells will act similarly to feeder layers and will be mitomycin C treated to inhibit further replication, they will be classified as Hazard Group 1.

Plasmid vectors to be used in this work are non-mobilisable. No vector includes any mammalian promoters and therefore in the extraordinarily unlikely event of transfer to a human cell the gene would not be expressed. The vectors to be included are:

- E. coli expression vectors such as PDuet are based upon pUC vectors and have a variety of different points of origin including: ColE1, P15A, CloDF13, RSF1030, COLA, mini-F/RK2. Proteins expression is under control of T7lac expression genes and prophylaxis could include a glucose drink. T7 ara an alternative expression system has no background expression.

- E. coli pGEM vectors (of pUC origin) or equivalent will be used to make RNA for in situ hybridisation probes. They use T7 and S6 promoters.

- pKLAC is a plasmid with an E. coli origin for replication and gene manipulation. The plasmid is a pBR322 derivative using the pMB1 origin of replication. When linearised it can recombine with the K. lactis (yeast) genome. Protein expression is under the control of lac promoters and prophylaxis could include a glucose drink.

Growth Factors

- BMP - Bone morphogenic protein family: Growth factors known to enhance differentiation of adult stem cells into bone. They have a pleiotropic role in development reflecting a diverse range of developmental pathways including spinal cord formation and limb bud formation (arms and legs).

- VEGF - Vascular endothelial growth factor family: Cytokines that stimulate new blood vessel formation.

- FGF - Fibroblast growth factor family: Growth factors which stimulate growth and proliferation of cells involved in development and wound repair. Fgf8 is known to play a key role in spinal cord formation and limb bud formation (arms and legs).

- Wnt - Wingless (like Hedgehog) family: Growth factors involved in embryonic development and maintenance of adult stem cell niches.
• Shh - Hedgehog family growth factors involved in embryonic development particularly spinal cord formation and limb bud formation (arms and legs).
• TGFβ - Transforming growth factor beta (TGF-β) family: Growth factors such as NODAL and activin which controls proliferation and cellular differentiation in a number of developmental pathways. TGFβ3 may be significant in limb development.
• IGF - Insulin like growth factor: Growth factors which trigger similar cellular response as insulin and which are involved in a number of developmental pathways.
• BDNF, NGF, NT3 - Brain derived neurotrophic factor, Nerve growth factor and neutrophin-3 respectively are all neurotrophin family of growth factors involved in brain development and neuron survival.
• NOGGIN, CHORDIN - Secreted decoy receptors which compete for BMP proteins so giving an inhibitory effect

**Evaluation of foreseeable effects**

The genes themselves will not provide any selectable advantage for GMOs such as E. coli and K. Lactis, and the strains used are uncompetitive compared to native E. coli and K. lactis. The vectors are not horizontably transmissible.

A remote risk exists of the genes enhancing the growth profile of HEK293T cells but these will be handled using Containment level 2 procedures and need special cell culture medium and so cannot proliferate in the environments.

The genes listed include growth factors that all have a role in differentiation and cell proliferation. The vectors to be used for expression of these genes are not mobilisable and so are generally considered safe but the proteins themselves pose a significant risk for temporary harmful transformation. Because there are no genetic changes the alteration in cell activity should not persist after removal of the growth factor. The proteins will be handled like hazardous chemicals and personal protective equipment will protect the worker.

When the genes are part of naked DNA such as used in gene cloning extra care will be required when handling these sequences and procedures prescribed in University of Nottingham COP for Biological Agents and GMMs part 3.4 will be followed. For example PCR hoods which blow towards the operator to keep the workbench gene free will not be used, a bunsen burner or safety cabinet will be used instead.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste exposed to GMOs such as petri dishes and plasticware will be placed in autoclave bags, sealed and then transferred in sealed containers to A81 for autoclaving prior to transfer off site (SRCL Ltd) for incineration.

Small volumes of liquid waste (<5mL) will be autoclaved and incinerated as for solid waste.

125°C for 15 minutes at 2 atmospheres is sufficient to give 100% kill of E. coli, K. lactis, mammalian cells and human pathogens. The autoclave has a chart readout which is checked after each cycle and is also validated on a six monthly cycle in accordance with HTM 2110.

Larger volumes of liquid waste potentially carrying growth factors or transcription factors will be treated with Trigene for >2hr at recommended concentration before disposal down the drain.
It was felt that the assessment covering use of plasmid expression vectors was very thorough and comprehensive. It was agreed that the GMOs generated were unlikely to have any additional harmful traits which could be disseminated in the environment in the event of accidental release and that the control measures to limit exposure and the proposed waste disposal measures were appropriate. Due consideration was also given to limiting the scale of the work during screening of expression and to the potential hazardous properties of the purified, expressed proteins. Further information was sought concerning proposed use of the second generation lentiviral vectors. Additional details were included in a revised version of the assessment which was recirculated for additional comment. Further discussion on local protocols for containment of the work using designated/dedicated MSCs and standardised disinfection and waste disposal then took place and these were agreed and also included in the final assessment. Due to the nature of the work, and particularly expression of potential oncogenes and specific fusion proteins it was agreed that overall the project is a Class 2 activity.

Project Ref 470/12.1

- Date Ackn’d: 11/01/2012
- CU2 Project Title: Molecular Cell Biology and Genetics of Trypanosome Species B11-06
- Class: Class 3
- Culture Volume: 1-50 Litres
- Consent Granted: Yes
- Project notified under transitional arrangements: N
African trypanosomes are parasite of the blood which cause human 'sleeping sickness' and a major disease of cattle in sub-Sahara Africa. To evade the host immune system, trypanosomes use a system of antigenic variation in which surface coat identity is regularly switched through the expression of 1 of ~2000 alternative coat genes. This requires a specialised genome structure that includes a large number of chromosomes. This project focuses on the mechanisms that ensure the stable inheritance of the unusual genome and control of the system of antigenic variation. In addition to the major disease-causing species, a number of related non-pathogenic trypanosomatid organisms are used for evolutionary comparison.

In addition, because of their position on the tree of life, African trypanosomes are important model systems for understanding the evolution of the eukaryotic cell. The recent sequencing of the trypanosome genome has highlighted features of the trypanosome cytoskeleton that are predicted to be key nodes in their cell biology.

The major aims of the project are:
1) characterisation of the machinery of genome segregation in African trypanosomes (both the proteins and genetic elements involved in chromosome stability)
2) understanding the control of antigenic variation of African trypanosomes and the expression of the major surface proteins
3) analysis of the evolution of the major surface protein families
4) studies of motor proteins involved in cell division, motility and endocytosis

In order to fulfil the aims of the project, the following types of GMOs will be generated:

- knockdown (RNAi) and knockout (gene deletion) of individual endogenous genes for phenotypic analysis
- expression of epitope-tagged endogenous proteins (either by integration of tag to native loci or via ectopic expression of transgenes from inducible promoters)
- creation of modified chromosomes by directed integration of selectable markers
- generation of libraries of RNAi mutants to screen for specific phenotypic defects

Trypanosoma brucei rhodesiense and T.b. gambiense cause potentially serious disease in man, and other Trypanosoma species are potential animal pathogens. However, trypanosomes are not robust outside of culture. They do not form spores, resistant cysts or other dormant stages and are rapidly killed by desiccation, osmotic shock or detergents. The insect vectors required for transmission of Trypanosoma brucei (tsetse flies) are not present in the UK and we do not maintain an insectory. The organisms cannot penetrate unbroken skin. There is effectively zero probability of release by aerosol formation, since the parasites are killed by dehydration and cannot cross mucous membranes. Direct inoculation of a laboratory worker is the only effective hazard of handling, and this will be managed by the measures detailed in the SOPs attached.

Trypanosomes do not perform genetic exchange in culture. As such, it is not foreseeable that any GM made in a trypanosome species could be accessed by other organisms and the potential for release of the GMO itself is negligible.

Other GMOs:
- cloning and manipulation (without expression) of trypanosomal DNA fragments in E. coli in order to generate the genetic modifications above
- production of yeast artificial chromosomes containing large fragments of trypanosome chromosomes and subsequent modification and purification of these YACs (without expression of trypanosomal genes)
- exogenous expression of specific trypanosome proteins in bacterial, yeast or Leishmania tarentolae expression systems for production of purified protein (for biochemical analysis or antibody production)

Escherichia coli (K12/B strain), Saccharomyces cerevisiae, and Leishmania tarentolae are HG1 organisms and all of the GMs to be made are non-mobilisable. There is no foreseeable alteration to the hazard from these organisms as a result of the proposed GM.

**Host/vector system**

The following host systems will be used for GMO:
- Trypanosoma brucei rhodesiense [Hazard Group 3]
- Trypanosoma brucei brucei, T. brucei gambiens [HG2]
- Trypanosoma evansi, T. congolense, T. equiperdum, T. vivax (other African trypanosomes) [not classified by ACDP; treated as HG2]
- Crithidia deanei, C. fasciculata, C. oncopelti, C. bombi (arthropod parasites of the order Trypanosomatida) [HG1]
- Leishmania tarentolae (lizard parasite) [HG1]
- Escherichia coli, laboratory K12 or B strain derivatives [HG1]
- Saccharomyces cerevisiae S288C strain derivatives [HG1]

These hosts will be modified with a variety of non-mobilisable cloning, tagging and expression vectors. Below are examples of vectors currently in use. Similar vectors, antibiotic cassettes or epitope tags may be substituted if required, providing these do not increase the hazards associated with the work (e.g. no antibiotic resistance cassettes against current treatments will be used).

**T. brucei:**
- p2T7-based – plasmid for tetracyclin-inducible RNAi in trypanosomes; integrates stably into genome [hygromycin or phleomycin resistance markers + ampicillin for bacterial growth] [LaCount (2000) Mol Biochem Parasitol 111:67-76]
- pENT-based – integrating plasmid for epitope tagging at endogenous locus. Common epitopes are fluorescent protein (GFP, dsRed or similar) and/or short antigen, such as Myc, HA, FLAG or TV-tags. [hygromycin, puromycin, blasticidin, or neomycin] [Kelly (2007) Mol Biochem Parasitol 154:103-9]

**E. coli:**
- pQE30-based – inducible expression plasmid for [amp] [Qiagen]

**S. cerevisiae:**

**Other:**
- pLEXSY-based – episomal vector for expression and purification of proteins in Leishmania tarentolae [hyg, phleo, neo] [Jena Bioscience]

**Origin & function**

For knockdown of genes by RNA interference (without library production), tagging of endogenous loci, or expression of genes of interest, DNA fragments (or whole CDSs, in the case of expression), will be generated by PCR from genomic DNA isolated by standard methods from the species under study. In the case of RNAi library production, DNA fragments will be again isolated from genomic DNA, but by direct fragmentation and cloning of gDNA.

The vast majority of genes will be inserted into the species from which they are derived (with the exception of expression constructs for protein purification). No genes are anticipated to increase pathogenicity, virulence, host range or transmission.

Most of the genes to be targeted for modification are involved in core cellular activities. Examples include genes encoding for proteins in the mitotic spindle and kinetochore, motors necessary for the beating/assembly of the flagellum, components of the transcriptional machinery and structural proteins of the nucleus. Those involved in the control of antigenic variation are also likely to be homologues of core polymerase or chromatin binding proteins. GM for this project will involve production of
mutant (knockdown/knockout) or epitope-tagged versions of genes, which will be either phenotypically neutral or deficient.

Evaluation of foreseeable effects

In the vast majority of cases, GM for this project will involve only production of mutant (knockdown/knockout) or epitope-tagged versions of genes in their endogenous species. These will at most be phenotypically neutral, and more likely detrimental to cell growth. No modifications proposed are anticipated to increase pathogenicity, virulence, host range or transmission. All modifications to trypanosomatids are likely to result in reduced or unchanged fitness and/or virulence. Moreover, trypanosomes have a complex life cycle with several essential differentiated forms and it is highly unlikely that the transfer of even cryptic genes would result in increased virulence. The reporter genes/epitopes to be used are already widely used and have no intrinsic harmful activity. The parasites themselves do not produce toxic products or immune effectors that are linked to human pathogenicity. Virulence and host-specificity in eukaryotic parasites are complex traits with multiple genetic determinants. It is highly unlikely, in all but one case (detailed here), that any transfer of material from one Trypanosoma strain/species would result in increased pathogenicity or transmissibility. The notable exception is in the development of resistance to normal human serum, which is toxic to T. brucei brucei, T. evansi and T. equiperdum. In T. brucei rhodesiense, a single gene, SRA, confers human serum resistance. In the worst case scenario, transfer of SRA to a non-human infective trypanosome species would confer human serum resistance to this GMO. The resultant GMO would still have no greater host range than T. brucei rhodesiense, for which the containment is already adequate. However, to mitigate this risk, no genes homologous to SRA (or non-specific genetic material such as libraries) will be transferred from human infective parasites to non-infective trypanosomes.

The reporter genes/epitopes to be used are not related to primary therapeutic agents for these parasites. The organisms are not believed to express effectors of the human immune response.

Release of GMOs into the environment forms no part of this programme of work.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

JUSTIFICATION FOR SPECIFIC DEROGATIONS

In accordance with ACDP guidance regarding the use of Trypanosome brucei rhodesiense, the following physical measures, which would normally be associated with full Containment Level 3, are considered unnecessary for safe and contained usage of parasites in C4d.

1) Laboratory not sealable for fumigation
   There is no foreseeable need to fumigate the laboratory. In the event of a major spillage, the bulk of material would be soaked up on absorbent paper towels then autoclaved, killing any parasites. The area would be wiped down with disinfectant. Any aerosols created that were not cleaned in this initial effort would dry out, killing both host cell and parasite. The area of the laboratory would be left isolated for a period to ensure effective drying. Effective parasite transmission is only possible via direct inoculation of viable parasites.

2) No negative pressure, HEPA filtered extract, microbiological safety cabinet or specified measures to control aerosol dissemination
   The organism presents no hazard of infection by the airborne route. Class II microbiological safety cabinets are in use in the dedicated laboratory, they are necessary for sterile culture of the organism; they are not required for operator safety. Activities involve small scale, standard laboratory techniques with no aerosol generating procedures.

3) Autoclave not within the laboratory
   Although room C4d contains the necessary equipment for the proposed work on the parasites, an autoclave cannot be reasonably accommodated within the room. However, a dedicated autoclave facility is in place directly opposite C4 containing regularly serviced and validated autoclaves. Using the procedures outlined in SOP-BW-#03 (attached) all biological waste from C4d can be safely transported to this facility and sterilised. All material for autoclaving is either double-sealed in leak-proof containers or pre-treated with microbiocide and then single-sealed, to manage risk of spills or other contact with material.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All material that has been in contact with live trypanosomes is sterilised by autoclaving prior to disposal. An autoclave for sterilisation of waste is located in C3 directly across the corridor from the C4d. To avoid potential release or exposure of workers prior to autoclaving, material is either sealed in a leak-proof container, or disinfected with a microbiocidal agent proven to kill trypanosomes prior to transport.
All contaminated waste is autoclaved on a standard waste cycle (134°C, 15min) for solid waste or standard sterilisation cycle (121°C, 15min) for disinfected liquid waste. Liquid waste will be treated with 5% Trigene for 2 hours prior to autoclaving. Trigene has been validated as achieving effective 5 log kill at 0.25% in growth medium. Autoclave runs are recorded and checked to ensure effective completion of the cycle. The autoclave is serviced, calibrated and validated every six months by a competent person. More details if required are contained in SOP-BW-#03.

13.

<th>B11-06- Molecular cell Biology and genetics of Trypanosomes PI B W.</th>
</tr>
</thead>
<tbody>
<tr>
<td>It was noted that the general safety and housekeeping arrangements for handling of these SAPO organisms have been approved by DEFRA and are all in place. First use of these organisms has been notified to HSE under COSHH Regs and a derogation has been obtained to not apply all of the measures in CL3 [eg sealability of room, HEPA ON extract]. Subject to approval by the GMSC the project will be notified to HSE as a Class 3 GM activity and similar derogations will be applied for. The PI confirmed that all organisms will be handled to the same standards irrespective of whether they are human or animal pathogen. Members considered that potentially the most risky scenario would be if the SRA gene which allows resistance to human serum and therefore human infectivity were to be transferred to a strain which did not carry this gene. The PI explained that this was highly unlikely to occur by accidental action and that this was not part of the planned experimental work. Genetic exchange is not possible between trypanosome strains except in the fly host (which will not be present) so even if strains were accidentally combined in the lab, no gene transfer would occur. Although sharps will not be used in the procedures, the committee requested that details of prophylactic treatment to be used in case of accidental inoculation should be obtained from Oxford and the UBSA would ensure these were sent to Nottingham Occupational Health so they are aware of the treatment measures required. This information will also be included in SOPs and training given to workers. The PI confirmed that sealed flasks will be used to grow the organisms. The project was approved by the GMSC as a Class 3 activity [with aforementioned derogations].</td>

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N
The aim of this work is to discover and characterize novel effector proteins from bacterial pathogens by high-content screening in mammalian cell lines, followed by detailed biochemical and genetic analysis of putative effectors. We will express individual bacterial proteins in mammalian cells, examining the cells for phenotypes by automated microscopy. Detailed characterisation of proteins of interest will then be performed, including the making of bacterial mutants and marked bacterial strains.

Mammalian cell lines including: HeLa (human, cervical carcinoma), U2OS (human, osteosarcoma), HEK293 (human, embryonic kidney), Caco2 (human, colorectal adenocarcinoma). Mouse embryonic fibroblasts, murine primary cultures and immortalised lines (various knockouts from collaborators). Bacterial pathogens including: Salmonella Typhimurium; non-verotoxigenic E. coli; Shigella flexneri; Listeria monocytogenes; Staphylococcus aureus; Chlamydia trachomatis.

Lentiviral particles: pHR-SIN-CSGW or similar – 2nd generation, non-replicative transduction vectors. Laboratory strains of Saccharomyces cerevisiae. Non-pathogenic. Laboratory strains of E. coli used for routine cloning and construction. Non-pathogenic.

Mammalian expression vectors including pCMV-3xFLAG, pEGFP-C3, pCDNA-derived vectors and similar. Non-mobilisable.

Yeast expression vectors for 2-hybrid screening including pGBT9 and pGAD or similar. Non-mobilisable.

Bacterial expression vectors including pDsRed2, pSA10, pWSK29, pKD46 and pCP20 or similar. Non-mobilisable.

Lentiviral vectors: pHR-SIN-CSGW, pLKO.1 or similar – 2nd generation vector constructs. Non-mobilisable.
The expression of genes from bacterial pathogens in mammalian cells is intended to reveal novel effector functions, via perturbation of normal cell morphology or phenotype. Transient or stable transfection of bacterial effectors is anticipated to yield cells with inhibited growth and altered cellular phenotype. Genes will originate from Salmonella Typhimurium; non-vero toxigenic E. coli; Shigella flexneri; Listeria monocytogenes; Staphylococcus aureus or Chlamydia trachomatis. Gene sets will be enriched for suspected effector proteins and known toxins or oncogenes will not be cloned and expressed. Genetic material to be introduced into bacterial pathogens will be from self, or known markers, fluorescent proteins or epitopes. No virulence factors will be transferred from any pathogen to another pathogenic organism without further notification.

Other proteins and epitope tags that may be introduced into mammalian cells or bacteria include:
- DsRed2 – A bright red fluorescent protein, derived from Discosoma sp. red fluorescent protein.
- EGFP – a brighter, codon-optimised version of green-fluorescent protein
- mKate2 – a monomeric, far-red fluorescent protein, derived from the sea anemone Entacmaea quadricolor
- c-myc, FLAG, HA and poly-histidine epitope tags.

**Evaluation of foreseeable effects**

The majority of genes we plan to study are associated with aspects of bacterial virulence. As such they co-operate with other gene products to co-ordinate virulence processes such as invasion, intracellular survival or extracellular attachment. Individual genes, particularly secreted effectors are unlikely to convey entirely new virulence properties upon organisms lacking the companion proteins (chaperones, secretion apparatus, other effectors).

Expression of tagged effectors in the native pathogen, or effector mutants might alter pathogenicity, but we consider it unlikely that this would result in a more virulent organism. Overexpression of native virulence factors/effectors following complementation of expression in modified bacterial pathogens will be minimized by the use of inducible, low-copy number plasmids. In most circumstances over-expression of effectors results in growth retardation/sickness of the host strain, and to maintain near wild-type protein levels low-copy number vectors are preferred. Therefore it is unlikely that complemented or modified organisms would have increased virulence compared to wild-type bacteria.

Addition of a novel virulence gene from a known bacterial pathogen into a lentiviral vector may represent an additional risk to human health. It is possible that expression of a single gene might yield a toxic effect to cells infected with the virus. However, in general pathogenic effector function is highly dependent upon the action of other effectors. To date only a single oncogenic effector has been observed. It is the nature of effector proteins that they are directly transferred into the host cytoplasm, therefore this would happen only from direct expression in the eukaryotic cells undergoing primary lentiviral infection. It is unlikely that such effectors would be transmitted/transferred to neighbouring cells, so even toxic, lytic effectors would be restricted in their spread throughout tissues.

Expression of a single bacterial effector protein would likely be insufficient to cause overt disease in an infected person and would not rescue viral replication.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

TriGene Advance Disinfectant has been validated by the manufacturer as bactericidal for E. coli, L. monocytogenes, Staphylococcus spp, Shigella spp. and Salmonella spp. Recommended dilutions for high-level contamination are 1:100 (for surfaces) or 1:10 (for highly contaminated liquids and suspensions). Contact times are given by the manufacturer as 30 minutes. These data have been validated under conditions equivalent to or exceeding those of use e.g. in bodily fluids such as blood and vomit, where protein levels are high.

To ensure a robust safety margin we will use TriGene at 1:50 for surface disinfection and 1:10 for decontamination of liquid wastes and glassware. Contact times will be increased to a minimum of 60 minutes. Treated liquids will be disposed of via a laboratory sink.

Contaminated solid waste will be placed into autoclavable bags within a solid-sided plastic container. When full, bags will be loosely sealed (to allow steam entry), a lid placed upon the container and transported on a trolley to the autoclave. Material is autoclaved in the plastic container to avoid further handling. Autoclaves are validated every 6 months. Autoclaved material will then enter the clinical waste stream for incineration.
Following discussion with the GMSC the PI modified his experimental approach from library-based screening to a more targeted genomics and PCR approach. The GMSC requested that vectors with inducible expression should be used wherever possible. The GMSC considered that the project could be covered by two risk assessments, one to cover work with the pathogenic bacteria and the other to cover mammalian cell expression work and use of lentiviral vectors. Other issues discussed for inclusion in local laboratory rules and training were:
- Symptoms to watch out for in case of accidental infection.
- Procedures capable of generating aerosols of pathogens that can infect by this route should be carried out in an MSC as appropriate.
- Dedicated autoclave bins will be used for disposal which will avoid any double handling by autoclave operators.

The GMSC approved the activity as Class 2 with some aspects being class 1.

Project Ref 470/12.3

Date Ackn'd 28/12/2012

CU2 Project Title

- Plant model system for the study of pollen food allergy

Class 2

Consent Granted

Non-GMM

Project notified under transitional arrangements N

Tick if notifying a connected programme of work N
Project Additional Information

Purposes of the contained use
The aim of the project is to define the parameters that characterise the extrinsic allergenicity of plant pollens and assess the mechanisms of immune sensitisation [in-vivo & in-vitro] of Bet v 1 & LTP family of proteins that are both implicated in food allergy.

Recipient or parental organism
Initially these studies will be done in Arabidopsis but may progress to include Tobacco plants in the future.

Host/vector system
The vector system for transfer into the plant system will use plant binary transformation vectors in agrobacterium tumifaciens. Arabidopsis plants will be transformed by floral dip and selected by their ability to grow on kanamycin or hygromycin.

Origin & function
Bet v 1, the major allergen from birch (Fagales), belongs to one of the most well studied families of pollen allergens and is responsible for spring pollinosis in the Northern hemisphere. Therefore large European populations are exposed to this allergen daily. Plant lipid transger proteins (LTPs) comprise a ubiquitous class of plant proteins involved in food allergy mainly triggered by fruits of the Rosacea family. In contrast with the sensitisation via birch pollen, the sensitisier for the LTPs, described mainly in Mediterranean populations has not been identified.

Evaluation of foreseeable effects
The GM plants will be more allergenic than the wild type Arabidopsis plants to individuals that are specifically allergic to Bet v 1 or Art v 3.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
GM plants will be grown in controlled environment rooms where access is restricted. Atopic individuals in general and those allergic to pollen or food allergy of the Rosacea family will be excluded from this room.

- Mesh filters on drains checked and cleaned regularly.
- Sticky mats will be placed the entrance to the room and to the facility.
- Dedicated lab coats.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Plant material will be bagged within growth room and sent for incineration

Is an emergency plan required according to regulation 20?  No

If yes, tick to confirm that it is attached to this form  No

Tick to confirm that you have attached a risk assessment to this form  Yes

Tick if you are claiming exemption from disclosure for section of the risk assessment  No

Please enter comments on the GM safety committee on the risk assessment

The committee acknowledged that whilst this was extremely low risk project the genetically modified plant was potentially more harmful to susceptible individuals that the unmodified Arabidopsis and therefore notification was required. The control measures proposed should reduce risk to low/effectively zero.

CU2 Project Title B 13-01 To test the ability of Proteus mirabilis isolates to swarm across catheter surfaces

Class 2

CultureVol Class 2 1 Litre

Consent Granted

Project notified under transitional arrangements No

Withdrawn No

Tick if notifying a connected programme of work No

Historical Significant Changes
### Project Additional Information

#### Purposes of the contained use

Proteus mirabilis forms part of the normal flora of the gut, but it is also the cause for 40% of catheter-associated urinary tract infections in long term catheter users. Currently the relative contributions of swimming through fluid environment or swarming through the catheter—urethra interface to catheter-associated urinary tract infection (CAUTI) is unknown. In this study, modified Proteus strains deficient in swarming or swimming will be compared for their ability to migrate across catheter material in vitro.

#### Recipient or parental organism

GM strains of Proteus mirabilis are a gift from collaborators at the University of Brighton. Their genetic characteristics are detailed below. No further genetic modification will be carried out.

#### Host/vector system

Recipient or parental organism

- **Swarming-deficient mutants** were generated from *P. mirabilis* strain B4 with a mini-Tn5Km2 transposon and the pUT suicide delivery vector. The delivery vector pUT, carrying mini-Tn5Km2, was transferred to *P. mirabilis* strain B4 from the *Escherichia coli* S17.1Apir donor strain by conjugation.

#### Origin & function

- **f/hA** is the genetic basis for non-swimming, non-swarming mutant NS63.
- **G37** — Non-swarming mutant: WbdN from *E. coli* - putative glycosyl transferase
- **G93** - Non-swarming mutant: SurA from *S. enterica serovar typhimurium* - survival protein precursor; encodes a peptidyl-prolyl-cis-trans isomerase

#### Evaluation of foreseeable effects

- **Origin & function**

  - The identification of f/hA is the genetic basis for non-swimming, non-swarming mutant NS63.
  - G37 — Non-swarming mutant: WbdN from *E. coli* - putative glycosyl transferase
  - G93 - Non-swarming mutant: SurA from *S. enterica serovar typhimurium* - survival protein precursor; encodes a peptidyl-prolyl-cis-trans isomerase

- **Due to the nature of the transposon mutagenesis used to create the mutants, detailed above, *P. mirabilis* mutant strains will have a reduced fitness in respect to the wild type so will not carry any further risk outwith the Hazard category assigned to the wild type [ACDP HG 2]**

- **Mutants generated using the transposon mutagenesis procedure are stable and unlikely to revert to wild type. *P. mirabilis* does not cause infections in normal healthy individuals and is already ubiquitous in environment. Insertion of transposons results in an attenuated phenotype and the vector cannot replicate in the recipient.**

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

- **N/a**
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid cultures will be treated with 1% Distel for 15mins prior to discharge to drains — manufacturer's validation data shows 5log kill. Agar plates/solid media autoclaved — in accordance with NUHT protocols — autoclaves validated in accordance with HTM 2010

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

The committee reviewed the assessment and asked for some clarification on the antibiotics to be used for selection. These were satisfactorily addressed by the PI and the GMSC approved as a class 2 activity

Date Project Ceased:  

Project notified under transitional arrangements
### Project Additional Information

**Purposes of the contained use**

The purpose of the research is to investigate the signalling pathways through which vascular growth factors and their receptors, delivered via non-replicative adenovirus particles, induce vascular remodelling in mesenteric and muscle micro-vessels. Specifically it will investigate the role of the different vascular growth factors on increased permeability and endothelial growth and migration in rodent (rat and mouse) microvessels in vivo. It is expected that mesenteric and muscle cells will express the recombinant protein and the vessels will respond accordingly. This work is part of a program to identify novel therapeutic targets for permeability associated diseases, including cancer, diabetes, psoriasis, etc.

**Recipient or parental organism**

The adenovirus is serotype 5, and has been rendered replication deficient due to deletion of the E1 gene essential for assembly of the infectious virus particles, and deletion of the dispensable E3 gene required for evasion of the host immune system. The appropriate level of containment for replication deficient adenovirus containing harmless genes is Level 1 under SACGM guidelines, but as the inserted genes encode for growth factors that may have a proto-oncogenic effect, the containment should be Level 2. Non-replicative adenoviral particles possessing genes encoding for human and mouse vascular growth factors and their receptors will be produced in a packaging cell line and purified. The recombinant adenovirus will be used to directly infect rodent mesenteric and muscle tissues with the vascular growth factors/receptors by injection of the particles to determine the role of these on vascularisation, angiogenesis, permeability of microvessels, and growth and migration of endothelial cells. There is sufficient homology between the encoded human proteins and the rodent ligands/receptors for functional interactions to occur.

**Host/vector system**

The genes of interest have been cloned into shuttle vectors (constructed at the University of Bristol) and have been incorporated into the AdEasy vector by homologous recombination in E. coli, followed by purification of the DNA. The DNA will be transfected into HEK-293 cells to package the DNA and assemble the virus particles. The E1 gene is provided in trans by the HEK-293 cells.

**Origin & function**

Vascular Endothelial Growth Factors (VEGF) A & C. VEGF-A is a growth factor that induces angiogenesis, vasculogenesis, endothelial cell growth and migration. It also plays a significant role in vascular-related diseases. VEGF-C also promotes angiogenesis and endothelial cell growth, but also has a role in lymphangiogenesis and can affect the permeability of blood vessels.

Soluble VEGF receptor 1 (sVEGFR1) acts as a decoy receptor for soluble VEGF-A.

Endothelial nitric oxide synthase (eNOS) generates nitric oxide in blood vessels that regulates vasodilation by relaxing smooth muscle.

Soluble Delta-like Ligand 4 (sDLL4) and Netrin act as axonal guidance molecules. Netrin has also been shown to play a role in angiogenesis, capillary maturation, and cancer regulation. DLL4 also promotes VEGFR2 expression.

Enhanced Green Fluorescent Protein (eGFP) will be used as a control gene.

Angiopoietin 1 (Ang1) is a growth factor that promotes angiogenesis.

Soluble Tie2 (sTie2) is a soluble receptor for Ang1, and is involved in vascular stabilisation and remodelling. Soluble (sEphrinB2) is a soluble ligand of the EphB4 receptor.

Soluble Ephrin B-type Receptor-4 (sEphB4) is a soluble receptor that binds EphrinB2, and plays a role cell migration, cell-cell interactions, angiogenesis, erythropoiesis, and
in numerous developmental processes, particularly in the nervous system. It also plays a role in axon guidance.

**Evaluation of foreseeable effects**

As all the genes encode for growth factors, or their receptors, they are all equally hazardous as all theoretically have the potential to be proto-oncogenic. A range of animal cells, including human, can be infected by the adenovirus particles. The greatest risk would be associated with accidental infection of someone during handling of the viral particles. Thus, the viral particles will be handled at containment level 2. No sharps will be used during the production and purification of the viral particles, but they will need to be injected into rodent tissues via a syringe. However, in this worst case scenario, no further infectious virus would be produced by the individual's infected cells, the virus would be rapidly inactivated by the host defence systems, and we will be modulating single genes (modulation of multiple genes is generally thought to be involved in transformation of cells), thus reducing the risks involved further. The adenovirus is replication defective due to deletion of the E1 gene. The virus also lacks the E3 gene. There is no possibility of the virus reverting or acquiring either gene via complementation. However, the viral particles produced, although non-pathogenic, are infectious and capable of infecting a variety of animal species, including humans. Adenovirus is capable of surviving within the environment. Infection is unlikely to cause any obvious symptoms, but the encoded genes are potentially harmful. Potential routes of transmission are by aerosols, waste disposal, and by needle-stick injury. No vaccines against adenovirus serotype 5 are available.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid waste will be soaked in 10% Distel before placing into yellow burn bins for incineration. Plasticware will be sluiced thoroughly with 10% Distel and left for 24 hours before disposal in yellow burn bins. Syringes (needles) will be sluiced with 10% Distel before disposal in sharps bins prior to incineration. All solid animal waste, including bedding, will be autoclaved prior to incineration in yellow burn bins. Liquid waste will be treated with 10% Distel for 24 hours prior to disposal via the drainage. Spillages will be contained with paper towelling and soaked in 10% Distel for at least 5 minutes before placing into yellow burn bins where they will be left for at least 24 hours before incineration. The spill site will also be wiped down with 70% ethanol.

GMSC noted that Adenovirus with E1/E3 deletions could be assigned to Class 1 however because the inserts include growth factors Class 2 is appropriate for production, purification and packaging of the modified virus.

**Project Containment**
**Project Additional Information**

**Purposes of the contained use**

To produce recombinant animal/insect/plant/fungal/bacterial proteins for use in allergenicity functional-relationship studies.

**Recipient or parental organism**

E.coli will be transformed with conventional shuttle vectors and after DNA isolation and sequencing the amplified vector will be then transferred to yeast (Pichia pastoris or other), bacteria (mainly E.coli systems), insect cells (drosophila, Spodoptera frugiperda or other using baculovirus system), plants (Arab)

**Host/vector system**

- E.coli to be used JM109, XL1-Blue, BL21, DH10B, MC106 all K12 derivatives and recognised as non-colonising and disabled, ACDP hazard group 1.
- Pichia (pastoris, methanolica), Sacharomyces, Schizosaccharomyces pombe and others are not considered pathogenic to human and animals, ACDP hazard group 1.
- Drosophila melanogaster, Spodoptera frugiperda are common insect cells used in expression and are not considered as pathogenic to human and animals, ACDP hazard group 1.
- Agrobacterium tumefaciens is the most common host to be used in plant transfection is not considered as pathogenic to human and animals, ACDP hazard group 1.
Arabidopsis is innocuous to small mammals and insects when eaten, and is unattractive to large mammals. Arabidopsis is self-compatible, nearly exclusively inbreeding and exhibits cleistogamy (within-flower pollination prior to the flower opening). Outcrossing does not normally occur. The system assessed here is generic plant expression system other than pollen. A pollen specific HSE notified risk assessment "Plant model system for the study of pollen allergy" is already in place (D12-11).

Chlamydomonas reinhardtii and Synechococcus elongates are the most common algae hosts used in photosynthesis studies and are not considered as pathogenic to human and animals, ACDP hazard group 1.

Chinese Hamster Ovary (CHO) cell line derived from DG44 cells and Jurkat cell line (human T lymphocyte) are commonly used in mammalian expression systems and are not considered as pathogenic to human and animals, ACDP hazard group 1. They are well characterised with low risk of endogenous infection with a biological agent presenting no apparent harm to laboratory workers.

Vectors

Plant, bacterial, algal, yeast vector systems — all non-mobilisable. Baculo- virus ACDP HG 1

Origin & function

The product of expression will be in most cases a well characterised allergenic protein. Potentially any protein expressed in a recombinant system will render the system more allergenic. The project will focus on allergenicity of plant proteins in general and in particular in proteins contained in pollen and N/S storage proteins from seeds that are ubiquitous to many organisms. Some major allergens from fungi are also of interest.

Most allergens described at WHO-IUIS are of interest (www.allergen.org). Examples of allergens current being used are: Bet v 1, Ber e 1, Mal d 1, Asp f 1, Asp f 2, Art v 1, Ara h 1, Der p 1, Der p 2, Phi p 1, Phi p 5, Phi p 12.

Evaluation of foreseeable effects

Although the recipient organisms are ACDP HG 1, the insertion of genes that express allergenic proteins is of concern. From point of view of human health it will depend on each allergen and on the susceptibility of the lab worker.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Agar plates /bacterial pellets will be sterilised by autoclaving prior to sending for incineration. Autoclave subject to annual validation.

Liquid waste and cultures will be treated with Distel [10%] overnight prior to disposal to drain, plastic ware will be treated with 2% Distel overnight prior to off site incineration [5log kill as per manufacturers data]

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The GMSC view was that this project was class 2 on the basis that the modified GMMs would produce proteins that were known allergens and could produce allergenic response in susceptible individuals as such an MSC would be required for procedures that involved aerosol generation such as sonication/disruption of bacteria to harvest protein.

#### Project Additional Information

**Purposes of the contained use**

Using parasites lines expressing reporter proteins to allow growth inhibition studies upon administration of antiinfective drugs. This will significantly increase the throughput of the screening experiments and minimize the reagents needed in this sort of experiments and significantly reduce the number of vertebrate animals used in
Recipient or parental organism

The goal of this project is to stably insert and express reporter genes in T. gondii. Commercially available luciferase genes include the secreted Gaussia and nanoluc secreted luciferases and a click-beetle Luc-GFP fusion, all of which we have successfully used in the past. These reporter proteins under the control of their own promoter will be targeted to the UPRT locus using CRISPR/CAS9 (Shen et al., 2014. mBio 5(3):e01114-14). UPRT is a nonessential gene in T. gondii and as such provides a neutral location for insertion of reporters. This project utilizes parasite line T. gondii RH strain as a recipient strain. The inserted DNA codes for widely used reporter proteins which are non-toxic, non-oncogenic and generally regarded as safe. The constructs are thus unlikely to cause any deleterious effect on human health or the wider environment.

- Three strains of Toxoplasma gondii (RH, Me49, NED) will be constructed. The three strains represent different genotypes, but all are of the same species, and belong to the same biological hazard category Level 2.
- Recipient micro-organism (Hazard Group 2); The biological agent is a protozoan parasite called Toxoplasma gondii strain RH, category level 2, will be constructed with reporter bioluminescent gene.
- Recipient micro-organisms (Hazard Group 1);

We will be using 3 E. coli strains listed below to amplify our plasmids in DB3.1 for the ccdB gateway vectors

F- gyrA462 endA1 glnV44 4(ear-recA) mcrB mrr hsdS20(rB-, m8-) ara14 galK2 lacY1 proA2 rpsL20(Smr) xyl5 Bleu mll

TOPO10 (Invitroden)
F- mcrA 4(mrr-hsdRMS-mcr8C) cp8OlacZAM15 4lacX74 nupG recA1 araD139 4(ara-leu)7697 galE15 galK16 rpsL(StrR) endA1 Mach/
- 4recA1398 endA1 tonA 0804lacM15 4lacX74 hsdR(rK- mK+)

Host/vector system

The following vectors will be used:

1-Vector (CRISPR; Toxoplasma expression) with plasmid (pSAG1::CAS9-U6::sgUPRT) and gene/insert (SAG1 5' UTR).
2-Vector (Gateway cloning) with plasmid (pUPRT::DHFR-D) and gene/insert (DHFR cassette).
3-Vector (CRISPR; Toxoplasma gondii) with plasmid (pSAG1::CAS9-U6::sg290860-6) and gene/insert (CRISPR sg290860-6).
4-Vector (Toxoplasma Expression) with plasmid (pCAT-YFP-TetR) and gene/insert (YFP-TetR).

Origin & function

All vectors and plasmids will be bought from addgene (https://www.addgene.org/).
- Inserted genes code for reporter proteins which give a luminescent, fluorescent or chromogenic readout indicating the number of the parasites and/or an indication of the amount of reporter protein.

Evaluation of foreseeable effects

None of the combinations are any more hazardous to others.
- There are no harmful properties associated with the plasmids which we are using as it does not replicate. Moreover the insertion of reporter genes is not toxic and targeted gene (UPRT) is a nonessential gene (no related to virulence) in T. gondii and as such provides a neutral location for insertion of reporters and hence will not be any alteration in the virulence of the agent or in its ability to cause disease. The GMMs that will be generated pose no additional...
risk over and above that of the wild type strains. This genetic modification will not increase the agent's pathogenicity or affect its susceptibility to antiparasitics or other effective treatments. The additional genetic material added to the wild type T. gondii does not in itself constitute an additional risk nor does its enable mobilisation of genetic material to another recipient.

- None of the genes that will be inserted into T. gondii by integration into the chromosome have any intrinsic pathogenic potential. These genes are only tracking genes to enable the fluorescent identification and quantification of the organism in response to the tested drugs in drug screening experiments. Based on scientific evidence no change in the pathogenicity of the organism occurs (Shen et al MBio. 2014 May 13;5(3). pii: e01114-14. doi: 10.1128/mBio.01114-14.)

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

We will inactivate the parasite in the lab by exposure to 5% Distel solution. This is in accordance with the local risk assessment form we follow in the school, university safety guidelines and is also based on scientific literature.

For solid waste:
- Autoclaving and then incineration following the School code and using HSE approved contractors [SRCL] for incineration of Class 2 material. [In accordance with previously obtained Derogation] Contaminated plastic waste disposed of by triple bagging and disposal via HSE licensed contractors.
- Sharps disposal if they are required to be disposed of in sharp safe containers and disposal through HSE licensed contractors

For liquid waste:
- Procedures are detailed in the local code of practice. Autoclaving or disinfectant appropriate to volume and type of material to be disposed of following SVMS local rules.
  Autoclaves will be run at 134°C for 10 minutes

**Please enter comments on the GM safety committee on the risk assessment**

The following points were raised some in independent comments.
- Consensus from several reviewer comments that this is clearly a class 2 activity parental organism is ACDP HG 2, but the final GMO would be no more hazardous than the non-modified.
- This would not be covered under current Class 2 connect programs of work held by the School and so it will require separate notification to the HSE.
Toxoplasma gondii is a single-celled parasite that infects 1/3 of the world population and causes disease in livestock. T. gondii is an obligatory intracellular protozoan parasite belonging to the phylum Apicomplexa similar to malaria parasites Plasmodium. The aim of the research project is to understand the fundamental biology of the parasite development and multiplication in host cells and to use this as a model to understand apicomplexan biology. The main focus will be on the proteins involved in parasite motility, division and invasion into the host cells.

Future work will involve in vivo work with Toxoplasma to test the virulence and growth of transgenic parasites in a rodent model. Relevant risk assessment for this work will be undertaken prior to work commencing.

Recipient or parental organism
Toxoplasma gondii wild type strains e.g T. gondii RH [ACDP Hazard Group 2] and mutant derivatives:
Plasmid vectors used will be non-mobilisable and most are either tagging/conditional vectors or expression vectors. No viral vectors will be used.

T. gondii:
- pCTG vector and derivatives: pCTG contains a chloramphenicol-resistance marker and a GFP expression cassette. Derivatives include vectors containing resistance cassettes such as those for phleomycin, mycophenolic acid and pyrimethamine resistance, as well as fusion proteins such as RFP (DsRed, mCherry and other variants), YFP and other GFP-derived fluorescent protein variants, HA, c-myc, mDHFR, destabilization domain and Ty1 epitope tags. Genes-of-interest may be driven by inducible promotors that include TetR-binding operator sequences (tetO), or by a range of parasite-specific promoter sequences. (See van Dooren et al, PNAS, 105(36): 13574, 2008) for a description of the base vector.
- pTCY vector and derivatives: pTCY contains a chloramphenicol-resistance marker and a YFP expression cassette that is used as a negative selection marker. Derivatives of this vector are used primarily in generating knockouts of genes-of-interest in Toxoplasma or in generating homologous integration events. (See van Dooren et al, PNAS, 105(36): 13574, 2008) for a description of the base vector.
- pPR2-HA3 vector and derivatives: pPR2-HA3 contains a pyrimethamine-resistance cassette and is used for gene replacements. (See Sheiner et al, PLoS Pathog, 7(12): e1002392, 2011) for a description of the pPR base vector that is further modified to include a 3xHA (haemagglutinin) epitope tag and additional restriction endonuclease sites. (See Huynh et al, Eukaryot Cell, 8(4): 530, 2009) for a description of the base vector.
- pLIC-YFP/DHFR vector and derivatives. pLIC-YFP/DHFR contains a pyrimethamine-resistance cassette and is used for 3' gene replacements. Derivatives include vectors containing mycophenolic acid, phleomycin and chloramphenicol resistance cassettes, and HA, destabilization domain, c-myc and Ty1 epitope tags. (See Huynh et al, Eukaryot Cell, 8(4): 530, 2009) for a description of the base vector.
- PSB and TOX cosmids modified by recombineering to introduce resistance cassettes such as those for pyrimethamine, chloramphenicol, phleomycin and mycophenolic acid resistance cassettes and epitope tags. The recombineering procedure and base vectors are described in Brooks et al, Cell Host Microbe, 7(1): 62, 2010.
- loxP flanking sequences is used to induce Cre recombinase excision, and CRISPR/Cas9 sgRNAs will be used to direct Cas9 excision (See Sidik et al, PLoS One, 27:9(6):e100450, 2014).

E. coli:
- pBluescript / pUC based high copy plasmid is used for molecular cloning in bacteria. These plasmids contain a selectable antibiotic resistance marker: ampicillin or kanamycin.
- pGEX4-T-1 / pET series are used for recombinant protein production. These plasmids contain a selectable antibiotic resistance marker: ampicillin or kanamycin.

Origin & function

Examples of the families of T. gondii genes that will be studied include motor proteins like myosin and kinesin gene families involved in motility and cell proliferation and cell division related genes like Centrin, Cyclin and associated kinases. The source and functions of some of the commonly used genes used as selection markers in Toxoplasma gondii are as follows:
- mutant Toxoplasma DHFR gene (pyrimethamine resistance): a drug-resistant form of dihydrofolate reductase/thymidylate synthase, which reduces dihydrofolic acid to tetrahydrofolic acid.
- the Streptomyces BLE gene (phleomycin resistance): binds with high affinity to phleomycin drug to prevent it from interfering with an organism's DNA.
- E. coli-derived chloramphenicol acetyltransferase (chloramphenicol resistance): acetylates chloramphenicol drug which prevents the drug from binding to the prokaryotic ribosome (in the case of Toxoplasma, likely the apicoplast ribosome), its site of action.
- Toxoplasma HXGPRT (mycophenolic acid resistance and 6-thioxanthine sensitivity): adds a phosphoribosyl group to purine bases such as hypoxanthine, xanthine and guanine, providing the parasite with a means of salvaging purines. In the context of Toxoplasma genetic modification, its presence allows the bypass of a second mode of purine salvage that occurs via inosine 5'-monophosphate dehydrogenase, an enzyme sensitive to mycophenolic acid. In the case of negative selection, HXGPRT converts the drug 6-thioxanthine to toxic nucleotides that become incorporated into the parasite's DNA.
- Toxoplasma UPRT (FUDR sensitivity): adds a phosphoribosyl group to the pyrimidine base uracil, thereby functioning in pyrimidine salvage. UPRT catalyses the conversion of FUDR to its toxic nucleotide, which interferes with RNA and DNA synthesis.

Most of the drugs used to select transgenic parasites are not used as a treatment to cure T. gondii, and their use therefore poses little risk for drug sensitive toxoplasma in clinical settings. However pyrimethamine can be used to select transgenic parasites and treat toxoplasmosis.

Tetracycline-controlled expression utilizes modified T. gondii promoters that contain tet operator sequences derived from E. coli, in cell lines expressing variants of the E. coli-derived tet repressor (TetR) protein (see Meissner et al, Science 298(5594): 837, 2002; van Poppel et al, Int. J. Parasitol 36(4): 443, 2006). Other promoters used in transgene expression are derived for T. gondii. Cre Recombinase, and Cas9 (of the CRISPR/Cas9 system) will be expressed in both the parasites, and the host cells with cell penetrating peptides attached (e.g. Penetratin) to allow optimisation of approaches for generating recombination and gene editing in Toxoplasma.

Standard reporter proteins will be used including: fluorescent proteins (GFP and derivatives); epitope tags (e.g. HA, cMyc, Ty); enzyme reporters (e.g. BirA* (mutant biotin ligase), APEX (a modified ascorbate peroxidase)).

Commonly used antibiotic resistance markers e.g ampicillin, kanamycin will be introduced into disabled E.coli hosts.

**Evaluation of foreseeable effects**

T. gondii is a unicellular protozoan parasite that infects all warm-blooded animals and invades all nucleated cells. The infection is either asymptomatic or causes mild flu-like symptoms which are quickly resolved in healthy persons.

In the UK about 30% of the adult population is seropositive for T. gondii and thus immune to further infection. Immunosuppressed persons or pregnant women are at greater risk but these persons are not allowed to work in the facility.

Tagging of T.gondii proteins with fluorescent or epitope tags is considered highly unlikely to affect the virulence or transmissibility of the recipient organism.

Targeted deletion or knockdown of genes involved in motility, proliferation or cell division is considered most likely to decrease the fitness of Toxoplasma strains and would therefore be unlikely to enhance virulence or transmissibility. Where deletion strains are complemented, episomally, there is the possibility that there may be over-expression of a complementing gene but given the complex, multistage life cycle of this organism, it is considered unlikely that this alone would be sufficient to increase virulence or transmissibility.

Given the disabled nature of the host E.coli strains to be used, none of the planned modifications is anticipated to increase their pathogenicity or ability to survive in the environment.

In the unlikely event that any of the proposed modifications resulted in a more hazardous GMM, the proposed containment, avoidance of sharps and disinfection protocols will ensure that any additional risk is effectively zero.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All the solid waste[agar plates/pellets] will be autoclaved using a programmable autoclave with a program of 15 minutes pulsed free steaming and 30 minutes at 132°C. An autoclave [validated in accordance with BS2646] is available directly opposite to laboratory suite C4

Liquid tissue culture waste — 5% Distel for 2hrs — 5 log kill

Surfaces - 5% Distel 10 minutes
This assessment was circulated to all GMSC Central members for comments and also reviewed in detail by one member who currently runs a project involving GM in another human parasite. A biological risk assessment for work with T.gondii was also prepared by the applicants and the laboratory area and equipment where the work would be performed was also inspected by the University Biosafety Adviser and confirmed as meeting the required standard. Additional detail was sought on the classes of genes which were to be investigated in Toxoplasma gondii to define the scope of the work and this information was added to the assessment. Clarification of the use of some anti-parasitic agents e.g pyrimethamine for selection of T.gondii during manipulation was also sought but this drug had previously been used in GM work with T.gondii and overall the risk that its use would compromise therapy was considered to be very small. There was also some discussion over the likely effect of the proposed modifications on virulence and transmissibility of T.gondii and the E.coli hosts to be used for construct generation and recombinant protein expression. Given the complex life cycle of T.gondii, and the targeted approach for gene deletion/regulation it was considered unlikely that any of the planned modifications would enhance virulence or transmissibility of the resulting GMMs above that of the wild type. The modified assessment was approved as a Class 2 activity.

Please enter comments on the GM safety committee on the risk assessment

Project Ref 470/17.1

Date Ackn'd 30/03/2017

CU2 Project Title Reverse genetics of low pathogenicity influenza A viruses

Class 2

CultureVolClass2 < 1 Litre

CultureVolumeClass3-4

Non-GMM Consent Granted Not Applicable

02/03/2022
The scientific goal of the project is to better understand the role of non-structural and 'accessory proteins' in the replication and pathogenesis of influenza A virus. The role of the non-structural protein, NS1, in replication and pathogenesis of influenza A viruses has been established for several years. This highly multifunctional protein continues to be extensively studied. For more than 25 years, it was believed that the eight RNA genome segments of influenza A viruses (PA, PB1, PB2, NP, HA, NA, M and NS) between them encoded only 10 proteins. However, in 2001, the first accessory protein (PB1-F2) was discovered. This small protein (usually up to 90 amino acids long) is translated from an alternative open reading frame of the PB1 gene. Further accessory proteins encoded by the PB1 gene segment (PB1-N40), the M gene segment (M42), the N gene segment (NS3) and the PA gene segment (PA-N155, PA-N183, PA-X) have since been identified. Many of these accessory proteins are not found in all influenza A virus strains suggesting that they are not essential for virus replication but may have an influence on pathogenicity of different strains.

Reverse genetics of influenza A viruses was first established as a technique in 1999. Different methods have been developed, but the principle is that each of the gene segments of influenza A is cloned into a plasmid and these 8 plasmids are co-transfected into a mammalian cell together with 4 plasmids encoding the proteins (PA, PB1, PB2 and NP) required for replication of the virus gene segments. Use of ambisense plasmids means that the expression of the 4 proteins required for replication can be combined with the plasmids encoding the relevant gene segments (an 8-rather than 12-plasmid system). The recombinant viruses generated are then cultured in mammalian cells or embryonated hens' eggs (frequently the more permissive host for influenza viruses).

Swapping of gene segments and/or introducing point mutations or deletions into the gene segment of interest allows the effect on the virus phenotype to be studied. A reverse genetics system is well established for the laboratory-adapted human influenza A virus A/Puerto Rico/8/34 (H1 N1) ('PR8') and this is frequently used to provide a conserved background into which genes from a virus strain of interest can be swapped and the effects on the virus' properties observed (if indeed the virus generated is replication competent). Reverse genetics systems have also been developed to generate a purely equine influenza recombinant virus (e.g. Quinlivan M et al. 2005. Attenuation of equine influenza viruses through truncations of the NS1 protein. J Virol 79:8431-8439).

We propose to use reverse genetics to study the different forms of accessory proteins, with a particular focus on equine and avian influenza A viruses. Comparisons will be made of the ability of viruses with different forms of accessory protein to replicate and induce or inhibit innate immune responses in in vitro cell cultures.

Recipient or parental organism

Plasmids expressing influenza A gene segments will be requested from collaborators including the PR8 system and an A/equine/Kentucky/5/02 (H3N8) system. Additional plasmids expressing equine or avian influenza A gene segments will be generated. Plasmids will be amplified in E. coli and transfected into 293T cells to generate recombinant influenza virus. At no point will viruses be generated that possess a multi-basic cleavage site in the haemagglutinin (HA) molecule, which is the key feature of highly pathogenic avian influenza (HPAI). The sequence of the genes encoded by each plasmid preparation generated will be confirmed before recombinant viruses are generated.

Host/vector system

1) E.coli ACDP 1
All bacterial host strains are disabled or non-colonising and are routinely used for research purposes in many laboratories (e.g. TG1, XL1-blue, Novablue DE3, DH10B,
HB2151).

2) Cell lines

- Well established and characterised continuous cell lines will be used to generate (293T cells) and replicate (Madin-Darby canine kidney cells) recombinant influenza viruses. These will be routinely handled at containment level 2 in accordance with the ACDP guidelines.

3) Embryonated hens’ eggs may be required to replicate recombinant influenza viruses that fail to replicate in MDCK cells. Again, these will be routinely handled at containment level 2.

The vectors are non-mobilisable plasmids.

Origin & function

Each plasmid used in generation of recombinant virus contains an influenza virus gene segment under the control of an RNA or DNA promoter. The eight gene segments encode viral structural proteins, viral proteins involved in replication of the RNA genome and non-structural proteins.

The encoded proteins are not known to be toxic when individually expressed.

Evaluation of foreseeable effects

The recipient E.coli strains that will be produced are attenuated laboratory strains that each only contain plasmids for one gene — there is negligible chance of viral particles being formed from these and the gene products are not themselves toxic. The bacteria are unlikely to survive outside a laboratory.

The cells to be used in this work are established well characterised laboratory cell lines. These cell lines cannot survive outside the laboratory.

Vector —

Inserted material — the individual proteins expressed by the plasmids are not in themselves harmful.

The final GMMs to be generated (recombinant influenza A viruses) could theoretically undergo reassortment with a wild-type influenza A virus. However, the chances of this occurring are extremely unlikely as it requires both the recombinant virus and the wild-type virus to simultaneously infect a host cell.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Please note there is an existing derogation in place for this site as follows;

Part II Table 1 a

8. Autoclave required in the building (for waste that you have identified by risk assessment that is suitable to send off site for inactivation)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste to be sent off site as per derogation; Solid Medium

Cell pellets and tissues infected with GM viruses

Waste that will be inactivated on site;

Concentrated class 2 bacterial cultures by validated autoclave or disinfection Tissue cultures and associated plastics

Note - Our orginal derogation document stated we would use trigene. As this is no longer availabale we have moved to Distel and we have validation documentation for this product.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]
8 Comments
1. This looks OK to me, the only comment is of the routine use of Distel at 10%, this should not be required for surface disinfection, 1% would be better.
2. A few minor points - I checked the Viral Connected programme of work and influenza virus reverse genetics is specifically mentioned as not being covered under that CPW. The ACDP flu guidelines referred to also specifically mention that some HA subtypes should be handled at higher containment than class II and it needs to be made clearer under this assessment that the parent viruses and viruses being produced don't fall into those categories (ie exactly which HA subtypes are present on what virus as quite a few are mentioned).
3. From AB email:
   Sent: 30 August 2016 08:49
   Subject: RE: D16-04 Reverse genetics influenza.
   Yes — happy with this. And I just checked with J that I understood it.
4. This looks like it would be HG2 work. Check this with author. If not covered by CPW would require notification.

5. Comments sent back to PI
   HI J
   Can you respond to the following comments regarding the assessment submission D16-04 Reverse Genetics Influenza. Sorry this got a bit delayed due to changes in
   • A few minor points - I checked the Viral Connected programme of work and influenza virus reverse genetics is specifically mentioned as not being covered under that CPW.
   • The ACDP flu guidelines referred to also specifically mention that some HA subtypes should be handled at higher containment than class II and it needs to be made clearer under this assessment that the parent viruses and viruses being produced don't fall into those categories (i.e. exactly which HA subtypes are present on what virus as quite a few are mentioned).
   • comment is of the routine use of Distel at 10%, this should not be required for surface disinfection, 1% would be better.
   • If the points above can be answered as clarified as required in the assessment this can be signed off. However would be a HG-2 recombinant pathogen and as the work
is not directly covered by the CPW it would need to be notified to the HSE and that will incur a fee to the HSE to notify this or to alter the CPW which would require review (ca. £900 last time one was put in).

6.

Delayed posting fault on workspace meant no posted when sent in. response from JD

From:

To:
Subject: RE: D16-04 Reverse Genetics Influenza.
Hi M

Apologies for the long time to respond to this — it got a bit buried as a result of various other things taking priority unfortunately, but I do really need to progress this for S PhD.

Please see responses below. Do I have to pay the fee to HSE, in which case I would use Sanjeev's cost centre = A138Q8.

I attach the revised version here.

Subject: D16-04 Reverse Genetics Influenza.

Hi J

Can you respond to the following comments regarding the assessment submission D16-04 Reverse Genetics Influenza.

• A few minor points - I checked the Viral Connected programme of work and influenza virus reverse genetics is specifically mentioned as not being covered under that CPW. Yes, hence the dash

• The ACDP flu guidelines referred to also specifically mention that some HA subtypes should be handled at higher containment than class II and it needs to be made clearer under this assessment that the parent viruses and viruses being produced don't fall into those categories (i.e. exactly which HA subtypes are present on what virus as quite a few are mentioned). The ACDP guidance refers to wild-type viruses. I have added the following to section 5. 'Only established reverse genetics systems will be used and where these are based on virus subtypes for which the wild-type virus falls into the category of 'Viruses that should NOT be handled at containment level 2' in the ACDP guidance, these will have been manipulated so that they may be handled at CL2 (see 'mitigating circumstances' in the ACDP guidance). To ensure that the latest advice is followed, before any novel construct is generated, the ACDP advice and WHO guidelines will be referred to.'

• comment is of the routine use of Distel at 10%, this should not be required for surface disinfection, 1% would be better. I know I got this from somewhere, but cannot remember where — have changed to 1%.

• If the points above can be answered as clarified as required in the assessment this can be signed off. However would be a HG-2 recombinant pathogen and as the work is
not directly covered by the CPW it would need to be notified to the HSE and that will incur a fee to the HSE to notify this or to alter the CPW which would require review (ca. £900 last time one was put in).

7.

requested further clarification
And actually reading it, I would want more info! I am not really happy with this statement; 'Viruses that should NOT be handled at containment level 2' in the ACDP guidance, these will have been manipulated so that they may be handled at CL2 (see 'mitigating circumstances' in the ACDP guidance).
It still doesn't tell me what they are doing to ensure that virus that require a higher containment level are not used. Thanks

8.

Discussed with PI response and addition here new version uploaded above under any edits.
Had a quick chat and we have added new text see added in yellow. The construct is made externally such has relevant changes. And there are also ways, although expensive, where you don't need to go anywhere near a wild-type virus, you can just get all the genes synthesised and manipulate them at the plasmid level.

Addition to section 5:
at The Pirbright Institute has established a reverse genetics system in which recombinant virus is generated with the internal genes of avian influenza but the HA and NA from PR8. These constructs have already been generated under relevant HSE approved containment and ACGM management systems and Dr S will supply the plasmids.
In addition, it is possible to synthesise gene segments so that manipulations such as removing the multi-basic cleavage site can be undertaken at the plasmid level.
Therefore, only ACGM class 2 virus will be handled at SVMS in this project.

Project Additional Information

**Purposes of the contained use**

The aim of this project is to develop viral culture models to study the consequences of infection of permissive cells with Zika virus, Sindbis Virus and Semliki Forest Virus. These viruses, belong to the Flaviviridae and Togaviridae families are categorised as HG2 organisms. Semliki Forest Virus and Sindbis Virus are selected as model organisms or similar pathogens such as Chikungunya virus (CHIKV), which are categorised as HG3. Infection will be performed in transformed cell lines and primary neuronal cells, including ex vivo rat primary neuronal cells, to investigate the epiphenomenon and pathogenesis of these neurotropic virus infections. Nociception will be assessed using ion flux assays. The site of virus replication will be assessed using fluorescent reporter assays.

Virus particles will be generated from molecular clones provided by external collaborators (Andres Merits, University of Tartu; Andrew Tuplin, University of Leeds). These molecular clones will be transcribed into viral RNA, then transfected into permissive cells to generate virus particles. These viruses will be used to infect appropriate target cells (infected cells will be assessed for gene expression, localisation of virus replication complexes. Genetic modification will be required to produce attenuated variants of SFV, SIN and ZIKV as control preparations. Additionally, viral genes will be sub-cloned into mammalian expression vectors for investigation of protein function.

**Recipient or parental organism**

Escherichia coli cells for propagation of plasmid containing cloned alphavirus/flavivirus genomes (Class 1): TOP10 (Invitrogen) E.coli Genotype F- mcrA A(mrr-hsdRMS-mcrBC) cp8OlacZAM15 AlacX74 recA1 araD139 A(araleu)7697 galU galK rpsL (StrR) endA1 nupG NEB10 (NEB) E.coli DH10OBtm derivative; A(araleu)7697 araD139 fhuA AlacX74 galK16 galE15 e14- cp80dIacZAM15 recA1 relA1 endA1 nupG rpsL (StrR) rph spoT1 A(mrr-hsdRMS-mcrBC)

Mammalian cells used to propagate human viruses (Class 2):

Zika virus, Sindbis Virus and Semliki Forest Virus will be propagated from molecular clones in mammalian cell culture. The following cultured cell lines may be used for propagation:

COS-7 (BSL2 - contains SV-40 viral DNA sequences) - an African Green Monkey fibroblast immortal cell line, derived from CV-1 simian cells transformed by an origin-defective mutant of SV40 (Simian Vacuolating virus 40).

HEK 293T (BSL-2 contains Adeno and SV-40 viral DNA sequences) - a Human Embryo Kidney epithelial-derived cell line.

Both cell lines produce the SV40 T antigen that allows replication of SV40 origin-containing plasmid during transient expression experiments. The cell-lines are only able to survive under specialised laboratory culture conditions.

HuH7 and (BSL1) hepatocyte derived cellular carcinoma.

HeLa (BSL2 - contains human papilloma virus) — derived from a cervical epithelial adenocarcinoma of a 31 year old black female.

SK-HEP-1 (BSL1) - of human liver endothelial adenocarcinoma origin from a 52 year old Caucasian male.

BHK-21 [C-13] (ATCCO CCL-10Tm) (BSL1) - derived from Syrian golden hamster kidney.

CHO (BSL1) — derived from a biopsy of an ovary of an adult Chinese hamster.

I HepG2 (BSL1) - derived from a liver hepatocellular carcinoma of a 15 year old Caucasian male.
A549 (BSL1) - derived from explant culture of lung carcinomatous tissue from a 58 year old Caucasian male.

Host/vector system

Vectors containing virus genomes: The BSL2 viral genomes, or fragments thereof, are directly cloned into non-mobilisable vectors, including pGEMT, pcDNA3, pCAGG and phCMV and their derivatives. pcDNA3.1 contains the CMV immediate early promoter to facilitate protein expression and the T7 promoter to enable viral RNA transcription.

Origin & function

The inserted genomes facilitate completion of the entire replication cycle of the Zika virus, Sindbis Virus and Semliki Forest Viruses. The genomes include the structural proteins required for virus assembly (viral capsid, envelope glycoproteins), and the non-structural gene products including virus-encoded polymerases, proteases and helicases. No directly toxic gene products, e.g. toxins, cytokines, growth factors, allergens, hormones or oncogenes, are encoded by these viral genomes.

Evaluation of foreseeable effects

The mutations introduced into these genomes will be used to attenuate virus replication. As such none of the GMM created during this project are anticipated to be more hazardous than the wild-type cloned virus genome of Zika virus, Sindbis Virus or Semliki Forest Virus (all BSL2).

Genetic modification of the target viruses using reverse genetics approaches are unlikely to introduce new hazards associated with the pathogenicity, host range, tropism or transmission of these viruses. All attenuation mutations are anticipated to maintain these traits while reducing replication and pathogenicity. However, no individual gene is over-expressed in these experiments over and above that required for virus replication. None of the gene products are identified as direct oncogenes or toxins.

Viral particles generated in mammalian cells will carry recombinant RNA genome and are capable of infecting human (and animal) cells. The Zika virus, Sindbis Virus and Semliki forest Virus are all categorised on the ACDP Approved List as HG2. The viruses can infect cells expressing appropriate receptor molecules and could therefore infect human cells (including neuronal cells) if accidentally injected into humans. Although they can cause human disease and may present a hazard to laboratory staff working with these pathogens, there is little risk of spread to the community, and the consequences of infection are low. Upon cell entry and uncoating the genome will be transcribed and proteins synthesized. Infection can result in arthralgia, which is treatable with analgesics.

In the event of a release of these blood borne viruses on-going transmission is highly unlikely. These viruses are vector-borne, transmitted by mosquitoes of the Culex/Culiesta genera (Sindbis virus) and Aedes genus (Zika virus and Semliki Forest Virus), which would be required to transmit the viruses between human hosts.

Propagation of the Vectors in E- coli: The vectors are non-mobilisable. The E coli K-12 derived laboratory strains are non-colonising and disabled. Transfer of plasmids containing viral genomes to other plasmids or bacterial strains would not create a pathogen of concern.

Transfer of viral sequences to environmental viruses. Species belonging to the viral families Flaviviridae and Togaviridae are documented to undergo recombination. Recombination of these viral cloned virus genomes with other viruses of these families could result in novel virus variants with altered pathogenic properties. However, this would require contact with wild-type Zika virus, Sindbis virus or Semliki Forest virus. None of these pathogens are present in the UK and as such the likelihood of these recombination events is low. The consequences to pathogenicity would also be low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Plastic consumables (except pipettes), gloves and contaminated paper towels will be placed into autoclave bags and autoclaved for at least 10 mins at 134oC. Autoclaves are validated annually.

Plastic pipettes or other hollow instruments will be discarded into dilute, working concentration disinfectant solution for manufacturer's recommended contact time to discarding for incineration/liquid waste containing toxic chemical / materials will be disposed of by existing validated methods for the disposal of the chemicals used.

Non-toxic liquid waste will be aspirated into sealed containers containing disinfectant (Distel). This will be left for at least 12 hours the manufacturer's recommended contact...
time prior to discard into drains. Daily renewal of fresh disinfectant solution to a known level will ensure the final concentration is not less than 5% Waste will then be disposed of as clinical waste.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
While the proposed work will produce viable recombinant viral particles it is unlikely that the recombinant viruses will be any more virulent than their wild-type counterparts. The containment procedures and waste disposal procedures in place make exposure of personnel or the environment with recombinant viruses highly unlikely. I see no reason why this work should not be approved.

This is not my area of expertise but I agree with Karl that exposure to the virus would be mitigated by the systems in place. The work has been previously carried out with cloned viruses and the point mutations are likely to disable/attenuate the particles over enhance virulence.

I agree, this looks OK to approve.

K earlier comments cover the main point - i.e. modified virus almost certainly less hazardous than WT virus. Containment plans for handling wild-type virus seem appropriate.
Looks ok by me (it is my area of expertise).

I agree that the planned modification of the wild type viruses is unlikely to generate viruses that are any more pathogenic than the original strains, and can be handled safely using the proposed containment and disposal procedures. It seems unlikely that recombination with wild type viruses in the environment is an issue given the fact that these viruses are not naturally present in the UK. Transmission by insect vectors is also highly unlikely given the specific vectors involved do not exist in the UK. I am happy that this assessment can be approved.

</tr>
</tbody>
</table>

Project notified under transitional arrangements: No
Genome sequencing of fungal species has revealed the presence of thousands of yet uncharacterised gene clusters required for the biosynthesis of secondary metabolites. In order to identify metabolites produced from these gene clusters, heterologous gene expression with subsequent metabolite extraction is required. Respective biosynthesis genes will be amplified by PCR from genomic DNA of the originating organism or produced by gene synthesis. After a cloning of genes into Aspergillus expression plasmids, the plasmids will be amplified in Escherichia coli, purified and used for transformation of Aspergillus expression platform strains. Transformants will be analysed for the genomic integration of expression vectors and selected strains will be cultivated for induction of gene expression. Metabolites will be purified by extraction with organic solvents from culture supernatants and mycelium and subjected to HPLC analytics. In addition, the mycelium will also be used for purification of the proteins produced from recombinant gene expression.

**Bacterial strains.** The E. coli strains to be used are all Rec A- derivatives such as DH5α, 10-p, XL1-Blue, SURE and TOP10. These strains are disabled and non-colonising and are equivalent of ACDP category 1 organisms (i.e. non-pathogenic to humans or animals). They have limited survivability in the environment as they require specific nutrient supplements not required by wild-type organisms. For protein expression using a pET vector system E. coli BL21(DE3) Rosetta2 cells will be used as these strain contain an endogenous phage T7 polymerase (DE3) and a plasmid that codes for rare E. coli tRNA sequences (Rosetta2).

**Fungals strain.** All Aspergillus strains have now been classified as category 2. Therefore, all work will be carried out under safety category 2. Parental wild type strains such as A. oryzae RIB-40, A. terreus SBUG844, A. niger A1144 and A. fumigatus CBS144.89 will be used as recipient strains.

**Host/vector system**

Bacterial vectors. These are generally pUC and pBR322 derivatives encoding ampicillin, zeomycin, kanamycin or other antibiotic resistance markers. Vectors include pUC19, pJET1.2, pET43 or pBluescript. They are considered to be non-mobilisable. Hazards arising from mobilisation are...
unlikely due to poor survivability of the E. coli derivatives outside the laboratory.

Fungal vectors: Plasmids re-isolated from E. coli will be used for fungal transformation. These vectors cannot replicate in Aspergillus species and require integration into the genome. As this happens either by homologous recombination or by non-homologous end-joining repair mechanisms, plasmids become part of a chromosome and have no self-mobilisation ability.

Origin & function

Genes of fungal origin will be used for cloning and expression that produce enzymes with metabolic activity and substrate conversion. The genes will derive from fungal gene clusters assumed from in silico prediction to be responsible for the production of secondary metabolites. A priority will be given to genes that code for enzymes belonging to the classes of polyketide synthases, non-ribosomal peptide synthetases (NRPS), NRPS-like enzymes and terpene synthases. Depending on gene cluster composition, additional genes such as monoxygenases, methyltransferases or reductases will be cloned for recombinant expression in Aspergillus species.

Evaluation of foreseeable effects

It is unlikely that the risk classification of E. coli strains used in this study will increase as no specific virulence determinants will be cloned and/or expressed. The promoter sequence used in generation of expression constructs for fungal transformation are of eukaryotic origin and not recognised by E. coli. In addition, most genes will derive from fungal genomic DNA and open reading frames are interrupted by intron sequences that cannot be spliced by E. coli. In pET gene expression and protein production only genes will be cloned of which the function is known and which are not increasing the risk potential of E. coli.

Resulting strains from fungal transformations with secondary metabolite biosynthesis gene will most likely not increase the pathogenic potential of the transformants. However, as this project aims in the identification and characterisation on novel secondary metabolites, biological activity of the resulting substances is unknown and needs to be tested. However, gene expression will be regulated by the composition of the growth medium and initial culture volumes will not exceed 100 ml to keep the maximum amount of metabolites produced at low level. In conclusion, as Aspergillus species are already classified as category 2, this classification will not be exceeded in recombinant strains.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Surface disinfection with 2% Distel before and after work. Validated by manufacturers data.

Autoclaved Waste

Solid Waste — waste pipette tips/swaps/spreaders within CLII cabinets which may be contaminated with spores will first be collected in jars containing 2% Distel and soaked overnight before autoclaving.

All Liquid waste will be autoclaved

Autoclave waste loads validated annually.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment N
This would appear to be a pretty standard Class II assessment, based solely dependent on the HG2 classification of the Aspergillus species in use. E. coli GM work is not designed to express any heterologous proteins in the main, although if required, any proteins expressed in E. coli are unlikely to affect its pathogenicity. Aspergillus work is not designed to express any known factors that would be expected to increase host pathogenicity and will not provide the host strains with increased resistance to any antibiotic agents that might be used to treat any infection. Sufficient precautions appear to be suggested in the advent of any significantly toxic metabolite being produced as a result of the proposed GM work. All work will be carried out in designated CL2 laboratory spaces.

Reply Edit Delete Like 09 Feb, 2018
User icon: plzah
A H
I agree, this is a CL2 activity with the appropriate safeguards in place. The main risk still remains infection / allergens from Aspergillus, and this is unlikely to be increased by the work proposed.

Reply Edit Delete Like 09 Feb, 2018
User icon: plzww
B W
Agree with comments above. E. coli work is straight-forward and v. low risk. Aspergillus work contains an (identified) risk due to necessary uncertainty regarding toxicity, but in my opinion this is well managed in proposed work.

Reply Edit Delete Like 12 Feb, 2018
User icon: Add a picture of yourself
L C
Comment from A C
There does not seem to be any expected increased risk from the modifications and I think this is well described. Biggest issue for me is preventing exposure to spores (possible allergen risk is the main concern), but also containment of the GM spores so they don’t escape into the environment – They consider breech of containment would not cause problems because of the nature of the modifications and because the genes they are looking at are widely distributed in the environment anyway -which again I happy with.
So I think hazard/containment has been considered appropriately but there is just a bit of inconsistency in different sections of the form.

In Part 1 section 9 – they say they will use CL2 containment to limit contact of GMMs (primarily spores) with humans and the environment.

Are you confident that the final GMMs will not be hazardous to humans or the environment, even in the event of a total breach of containment?

If YES you must justify your answer

If the answer is ‘No’ or you are in any way unsure, Part 2 of this form must be completed.

Yes – Specific cultivation conditions are required to induce the expression of recombinant genes. These conditions (high starch content, doxycycline) are unlikely to be present in the environment. In addition, gene clusters derive from fungal species ubiquitous in the environment. Therefore, the resulting metabolites from heterologous gene expression, though yet not characterised, are already produced in the environment by the originating fungal species. However, an allergenic potential of spores produced by fungal GMMs will remain, but not increase in comparison to the parental strains.

A containment level 2 facility and use of good microbiological practice will be sufficient to limit contact of arising GMMs with humans and the environment. All exposed glassware, solutions and plasticware will be autoclaved following use, prior to disposal or wash up. Lab areas in which manipulations occur will be disinfected with 2% Distel on a regular basis.

In Part 2 section 2/3 they also mention use of an MSC to limit human exposure to GM spores (and presumably dispersal).

Should the MSC also be mentioned in Section 1 Part 9? Also given the risk of allergy to spores is considered the same if they are GM or non-GM, do they routinely work with non GM spores in the MSC?

Assignment of a provisional containment level that is adequate to protect against hazards to human health.

This step will involve considering the containment level necessary to control the risk of the recipient microorganism (i.e. the ACDP Hazard Group of the recipient micro-organism) and making a judgement about whether the modification will result in a GMM, which is more hazardous, less hazardous, or about the same. Sometimes it may help to compare the GMM with the relative hazard presented by other organisms that would fall within the same ACDP Hazard Group as the GMM.

The highest risk for distribution of the GMMs from this project occurs from airborne spores. To keep exposure risk at a minimum, all work with spores will be performed under a class II safety cabinet.

Fungi growing in liquid cultures are forming mycelium with a very low potential for infection. Due to the general classification of Aspergillus species in risk category II, all work will be performed in category II lab space.

02/03/2022
The major aims of this project are: (A) modifying the genome of producing Actinomadura strains in order to prevent or enhance the production of metabolites of interest, (B) cloning the relevant genes within suitable vectors for their characterisation, modification, and expression, (C) transiently or stably transforming selected E. coli, Streptomyces, or Actinomadura hosts with the appropriate recombinant constructs containing Actinomadura genes, and (D) obtaining the expression of the recombinant biosynthetic enzymes and the production of the respective natural or synthetic products.

The work to be carried out on Actinomadura will include the mutation, deletion or insertion of appropriate DNA sequences within the host's genome in order to obtain genetically-modified strains with depleted or enhanced production of the target metabolites, or the production of novel ones. Due to the well-known difficulty in the growth and manipulation of some Actinomadura species and to their poor productivity, standard microorganisms such as E. coli and Streptomyces lividans will be initially employed in order to easily obtain and engineer the constructs to be later introduced in Actinomadura, or as final hosts for the efficient expression of the desired biosynthetic enzymes and/or their products.

The molecular biology techniques to be used for the purposes above include, but are not limited to: molecular cloning, DNA mutagenesis (both random and site-directed), gene knock-out and knock-in, DNA deletion and insertion, chromosomal integration, overexpression, insertion of reporter and selection genes.

The Actinomadura strain in our possession is an unidentified specimen previously isolated by an external group. Its genome has been fully-sequenced and a database search followed by phylogenetic analysis placed the organism evolutionarily close to Actinomadura macra.
Three strains belonging to the genus Actinomadura are classified ACDP Hazard Group 2 pathogens for humans, as they are known to be responsible for some cases of actinomycetoma, a chronic subcutaneous infection of the skin and connective tissue, generally acquired by inoculation of fungal or bacterial spores through a breach in the skin. The initial symptoms of an actinomycetoma lesion appear as a small, painless, subcutaneous nodule which softens to form a sinus releasing seropurulent or purulent discharge, often containing characteristic large, white to yellow granules. Multiple nodules are formed gradually and later ulcerate and drain through sinus tracts, while the surrounding tissue becomes swollen and deformed. A few antibiotics are successfully used in the treatment of the infection. The strain used for the purposes of this project will be treated as Class 2 pathogens.

The Streptomyces strains to be used will be derivatives of S. lividans 1326 (e.g. TK24), one of the two model organisms for streptomycetes and the best genetically-characterised Streptomyces strain. Its lack of methylated-specific restriction systems and its low endogenous protease activity make this organism ideal for cloning and expressing heterologous proteins, including complete natural product biosynthetic pathways. Streptomycetes are infrequently pathogen and do not have an ACDP hazard group classification although, in rare cases, some species have been associated with mycetoma in humans. The strain used for the purposes of this project will be treated as Class 2 pathogens.

The E. coli strains to be used will be laboratory derivatives of B or K12 (e.g. DH5α, BL21, BAP1, G1724) which are considered to be disabled, non-colonising and non-pathogenic for humans, animals, and plants. All of these strains have multiple auxotrophic requirements which are unlikely to be met in the environment, where their survival is considered unlikely. All of these strains are considered ACDP Hazard Group 1, and introduction of replicative plasmids and vectors containing DNA from other organisms into these laboratory strains is not considered to raise this classification.

### Host/vector system

Plasmid vectors suitable for cloning, expression, and/or chromosomal integration in Actinomadura, Streptomyces, or E. coli will be employed, as well as shuttle vectors for two or more of the strain used.

The starting vectors will be routinely-used, engineered versions of natural plasmids (e.g. ColE1 derivatives such as pUC family, pBluescript family, pJ702) or further derivatives thereof (e.g. pJ773, pSE101, pSET152, pUWLKS, pUZ8002) which, with the exception of pSET152 and pUZ8002, are non-mobilisable. pUZ8002 is a conjugative vector providing transfer functions for pSET152 in Streptomyces, but possesses only very low levels of self-transfer.

Derivatives of the plasmids above featuring Actinomadura and/or Streptomyces DNA will also be used, which will be obtained as a result of this project.

### Origin & function

The genes involved in this project will be antibiotic resistance genes to allow for the selection of the desired recombinant strains, reporter genes to monitor gene expression or visually tag the bacteria, and Actinomadura genes (or parts thereof) coding for putative or known biosynthetic enzymes involved in the production of secondary metabolites.

None of the genes above or the products they encode for has been shown or predicted to be harmful for humans, also when over-expressed.

Selectable markers will include resistance genes against (3-lactams (e.g. ampicillin, carbenicillin), aminoglycosides (e.g. kanamycin, gentamicin), tetracyclines and natural cyclic oligopeptides (e.g. thioestrepton, an antibiotic for Streptomyces).

Reporters genes will be those routinely used in research, encoding for example 3-3-galactosidase, fluorescent proteins, luciferase, and tyrosinase (converting the amino acid tyrosine into the dark pigment melanin). The genes to be inserted into the aforementioned hosts will originate from Actinomadura or Streptomyces and will encode for one or more modules of the mega-enzymatic complexes involved in the recognition, activation and polymerisation of the amino acid units forming the desired secondary metabolites.

None of the inserted genes has been shown or suspected to alter any pre-existing traits of the host organism.

None of the antibiotics to be used in this project (e.g. ampicillin, kanamycin, tetracycline and thioestrepton) is routinely used for the treatment of actinomycetoma.

Genes that will be expressed as part of this project are the resistance markers mentioned above (e.g. ampicillin, kanamycin, tetracycline and thioestrepton), reporter genes such as those coding for 3-3-galactosidase, fluorescent proteins, luciferase, as well as genes for the mega-enzymatic complexes involved in the production of secondary metabolites.

One or more genes involved in the production of secondary metabolites in Actinomadura and/or Streptomyces may be overexpressed to increase the production yields of desired metabolites.

The genes to be (over)expressed will be controlled by inducible systems (e.g. lac, PBAD) and their expression activated upon addition of suitable inducers (e.g. IPTG, arabinose).
None of the inserted genes or the products they encode for has been shown or predicted to be harmful for humans when (over)expressed or alter any pre-existing traits of the host organism in a harmful way.

The Actinomadura and Streptomyces strain used in the course of this project are wild type organisms, and therefore able to survive in their natural environment. The genetically-modified versions of these organisms will generally make them less fit in the environment, either by loss of function (such as losing the capacity to produce antimicrobial metabolites, etc.) or by metabolic overburden (overproduction of desired metabolites at the expense of other biological functions).

The E. coli strains to be used have multiple auxotrophic requirements which are unlikely to be met in the environment, where their survival is considered unlikely. The genetically-modified versions of Actinomadura and Streptomyces strain used in the course of this project will not differ significantly from their wild type parents, as they will be likely producing a natural product or engineered version of it. However, these modifications are likely to be at the cost of their ecological fitness, which is not important in the laboratory. Such GGMOs are therefore very unlikely to have direct consequences on the environment.

The E. coli strains to be used will be laboratory derivatives of B or K12 (e.g. DH5a, BL21, BAP1, GI724) which are considered to be disabled, non-colonising and non-pathogenic for humans, animals, and plants, and introduction of replicative plasmids and vectors containing DNA from other Actinomadura or Streptomyces into these laboratory strains is not considered to increase the hazard they pose.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste (liquid culture, agar plates, other in vitro cultures and consumables contaminated with bacterial culture) will be autoclaved at 126 °C for 15 min.
The disinfection procedure for Actinomadura was validated with 5% Chemgene (Medi-Mark Scientific) for less than 10 minutes

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

A number of minor issues were requested to be addressed by the committee, this included the proposed use of RPE, information on spills and as below:
Section 7. The genetically-modified versions of these organisms will feature the appropriate selection markers to ensure their dependency on laboratory conditions' Needs further clarification as per WS comments Approved in principle as a Class 2 activity, when changes made
Note — The committee agreed that the use of RPE was not required.

Project Containment

Laboratory Activities

Glass Houses

Growth Rooms

02/03/2022
The aims of the project are to delete surface protein genes from S. marcescens to test the theory that their induction reduces the effect of Bdellovibrio predation. Initially we used wild type S. marcescens and Bdellovibrio in serum to detect gene expression changes in S. marcescens during a period of "growback" after predation. This study identified pilus, outer membrane and capsule genes to be critical for avoiding predation. We also have an interest in deleting Type VI secretion machinery. We now want to make direct deletions of these genes in S. marcescens and then test the resulting deletion mutants in a) (commercial) human serum and b) in our zebrafish larval infection model for sensitivity or resistance to predation by Bdellovibrio.

We will also have to construct and test complemented strains of the deletion mutants with the genes returned.

Recipient bacterium into which the gene deletions will be finally delivered is wild type Serratia marcescens which is a clinical isolate with carbapenem resistance. We are removing surface virulence genes in our deletion experiments to...
make the strain less virulent.

Host/vector system

The plasmids being used are Steptomycin and Apramycin (separate) versions of the broad host range conjugable but non-self mobilizable plasmid pKNG1 01. The plasmid is mobilisable by the S17-1 E. coli host. The reference for this plasmid is as follows:

Origin & function

We are deleting individual gene systems for the production of fimbriae which are surface pilus like fibres.
We are deleting individual genes for the production of capsule on the surface of the Serratia.
We are deleting individual genes for outer membrane modification.
We are receiving strains with the Type VI genes (an injection system of Serratia) deleted - produced by Dr Coulthurst.
We will be adding mCherry, mNeon, mCerulean genes to produce coloured bacteria by expression at the deletion site.

Evaluation of foreseeable effects

There will be a reduction in virulence as we are deleting surface gene products that are known to be pathogenicity determinants. They are also surface factors which may ameliorate the interaction with Bdellovibrio bacteria. None of the genes we are inserting have toxic properties. The mNeon, mCherry and mCerulean are non-toxic fluorescent proteins engineered from an original fluorescent protein of jellyfish and routinely used to colour bacteria. The antibiotics on the plasmids Apramycin (is a Kanamycin like antibiotic) and Streptomycin are conventional antibiotics. They are on plasmids that replicate in the S17-1 il-pir donor strains of E. coli but the design of the experiment is that they are on a suicide plasmid in Serratia so when the experiment to construct the strains in complete, the plasmids will be lost and the Serratia will be non-resistant. During the screen for plasmid loss, there will be some antibiotic expression but the hazard is not increased as these are not clinical treatments for Serratia infections.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste run, 3 mins at 134 °C (1.52 Bar) in C floor Med School Sapphire autoclave
Distel is used at 10%

If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
* I get the point that the zebra fish are not "animals" for home office licencing purposes but really that section of the RA does need filling in (this is about risk not where they fit in the legislation) and actually a quick google search for this pathogen in fish does indicate it is a pathogen (hence what happens to the water etc they are incubated in does matter and it shouldn't just go down the sink) *

"If autoclaving waste water - a fluid cycle on the autoclave and appropriate additional safety precautions will of course be required. I am sure it is in hand but autoclaving larger volumes of fluids has the potential to go horribly wrong, hence my comment."

### Project Additional Information

#### Purposes of the contained use

Influenza D virus (IDV) was first isolated from pigs with respiratory disease in 2011. However, it was subsequently determined that cattle are likely to be the reservoir host as there is higher prevalence of IDV among cattle in all countries where studies have been conducted. Little is known about the pathobiology of IDV. The virus is potentially involved in respiratory disease complex in cattle; experimental infection of cows causes limited disease. Like influenza A virus (IAV), IDV appears to be capable of infecting a broad range of mammalian species but unlike IAV, there is no evidence that birds are infected. Although antibodies against IDV have been detected in horses and people, virus has only been isolated in nature from pigs and ruminant species. The virus is genetically similar to influenza C virus (ICV). In ICV and IDV; there are 7 rather than 8 gene segments with segment 4 encoding a single surface glycoprotein, the hemagglutinin-esterase-fusion (HEF) glycoprotein, rather than the two surface glycoproteins separately encoded by segments 4 and 6 in IAV. Influenza C virus (ICV), which occurs in people and pigs, is relatively under-studied as it is rarely isolated and usually only associated with mild disease.

The nine known viral proteins expressed by the seven IDV genome segments include the polymerase proteins (P3, PB1 and PB2), which form the RNA-dependent RNA polymerase complex and are expressed by the three largest gene segments (1-3) and the nucleoprotein (NP) expressed by segment 5 (Figure 1). These four proteins are associated with the RNA gene segments in the mature virus particle and are required for virus replication. As previously mentioned, a single surface glycoprotein (HEF) is encoded by segment 4. The HEF glycoprotein possesses receptor binding, receptor destroying and membrane fusion activities. Segment 6 encodes two matrix proteins (M1 and CM2). The M1 protein forms a stabilising layer inside the lipid envelope, which is acquired from the host cell membrane, while the CM2 protein forms ion channels in the envelope. Finally, segment 7 encodes two proteins, the non-structural protein NS1, and NS2. By analogy with the other influenza viruses, it is likely that both proteins play various roles in virus replication. The NS1 protein has been most extensively studied in IAV; it interacts with the host's innate immune system, either up- or down-regulating the production of pro-inflammatory cytokines depending on the virus strain and the host cell type.

Reverse genetics systems to generate infectious virus particles in which a specific gene is modified in order to determine its function were first published for IAV in 1999. The earliest approaches involved transfecting mammalian cells with 12 plasmids — 8 expressing template RNA for each gene segment and 4 expressing the 4 viral proteins required for virus replication (Figure 2). If isolation of effects on the 4 polymerase complex proteins is not required, use of 8 ambisense plasmids to produce viral RNA and protein from the same plasmid is more efficient. Typically, a co-culture of 293T and MDCK cells is transfected as 293T cells have higher transfection efficacy and MDCK cells are more permissive to virus growth. The virus produced is then amplified by culture in either MDCK cells or embryonated hens' eggs. Although ICV is little studied, a reverse genetics system using a similar approach to the IAV system was reported around 10 years ago.

The aim of this project is to take a comparative approach to study the role of the IDV NS1 protein in modulating the innate immune response in cell cultures from different host species.

#### Recipient or parental organism

Plasmids expressing each of the seven gene segments of IDV will be generated by amplifying cDNA from virus isolates held at SVMS or provided by collaborators using primers including a Sapl restriction endonuclease site. The cDNA will be cloned into a plasmid designed for generating recombinant IAV, e.g. pDZ. Plasmids will be amplified in E. coli and transfected into 293T cells (or co-cultured 293T and MDCK cells) to generate recombinant influenza virus (as described above). To amplify recombinant viruses generated, the supernatant from transfected cells will be inoculated onto MDCK cell monolayers or into embryonated hens' eggs. After generating the wild-type virus, segment 7, encoding the NS1 protein will be modified and the effects on virus replication and induction of innate immune responses in cells determined. The importance of the NS1 protein will be tested by introducing a stop codon so that NS1 is not produced (1'NS1). If variation in NS1 proteins is observed in nature, these changes will be introduced to determine whether there is an effect on virus replication of innate immune responses.

#### Host/vector system

E.coli ACDP 1

All bacterial host strains are disabled or non-colonising and are routinely used for research purposes in many laboratories (e.g. TG1, XL1-blue, Novablue DE3, DH10B, HB2151).

Cell lines
- Well established and characterised continuous cell lines will be transiently transfected to generate (293T cells) and replicate (Madin-Darby canine kidney cells) recombinant influenza viruses. These will be routinely handled at containment level 2 in accordance with the ACDP guidelines.

Embryonated hens’ eggs
- Inoculation into embryonated hens’ eggs may be required to generate larger or higher titre stocks of recombinant influenza viruses. Again, these will be routinely handled at containment level 2.

The vectors are non-mobilisable resistance plasmids e.g. pDZ. The pDZ plasmid was derived from the protein expression plasmid pCAGGs. It has a human RNA polymerase I promoter and a mouse terminator sequence that encodes the negative sense genomic RNA. In ambisense, it has a polymerase II transcription cassette consisting of a chicken 3-actin promoter and polyA signal to encode the viral proteins from the same viral gene. The sequence of the genes encoded by each plasmid preparation will be confirmed before recombinant viruses are generated.

Origin & function
- Each plasmid used in generation of recombinant virus contains an influenza virus gene segment under the control of either an RNA or DNA promoter or, in the case of the ambisense system both. The seven gene segments encode viral structural proteins, viral proteins involved in replication of the RNA genome and non-structural proteins as described in section 4. The encoded proteins are not known to be toxic.

Genes;
- Influenza D virus segments 1 to 7
- Ampicillin or kanamycin resistance markers

Evaluation of foreseeable effects
- The inserted genes do not alter any existing traits of the bacterial host. The plasmids used encode resistance to standard antibiotics (ampicillin and kanamycin).
- Influenza D virus segments 1 to 7 will be expressed in transiently transfected mammalian cells. Genes will be expressed from mammalian promoters after transient transfection. None of the genes have any known known properties.
- The recipient micro-organism is not capable of infecting any plant, animal or insect species (see part 1).
- The final GMM (recombinant influenza D virus) is an enveloped RNA virus and therefore unlikely to survive long in the environment, similarly to other influenza viruses, for example influenza A viruses only survive for around 5 minutes on the hands and 24-48 hours on stainless steel or plastic (Weber & Stilianakis, 2008). Therefore, the risk of exposure of susceptible animals to infectious virus in the event of unexpected environmental contamination would be very low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Derogation from Schedule 8, Table 1a, containment measure 8, Autoclave required in building.
In line with previously issued derogation against the above containment measure we would like to derogate this work against the requirement to have an autoclave in the building.
All solid medium containing GMM's will be placed in a burn bin and sent for validated incineration as infectious GM waste. These waste procedures are reflected in our local codes of practice and induction training.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All CL2 liquid waste will be autoclaved before final disposal.
Solid medium containing GMMS [1 &2], [e.g. agar plates, bacterial slopes/stabs], cell pellets [in eppendorf tubes] and tissues infected with GM Viruses and other solid waste which cannot be effectively disinfected will be placed in a burn bin and sent for validated incineration as infectious GM waste. This is in accordance with our existing derogation and SVMS local rules.
Contaminated recycleable materials (e.g. glassware) will be autoclaved prior to cleaning and recycling

Please enter comments on the GM safety committee on the risk assessment
Looks fine to me. 12 plasmid system?! Rather you than me...

No major comments.
One comment though on submission. I wondered if this was effectively an amendment for current reverse genetic work with Al.
I discussed with the school BSO RT and it was felt that it a full document assessment aided clarity for review. Can we discuss in meeting?

The existing connected programme of work specifically excludes influenza reverse genetics as there are and have been significant concerns about "gain of function" experiments in Influenza A viruses. There is an existing Influenza A GM risk assessment but these D viruses are very different in terms of genetics, risk and epidemiology and very much lower concern. We felt it would be a lot simpler keeping these separate than tangling it up with the endless discussion of human and avian pandemic influenza's.
Rachel clarified my immediate concern. I agree with the 12 constructs... insane

5.
Nothing more to add.

6.
No further comments.

7.
Again, no major concerns, but like others I can't understand the 12 plasmid approach (and 4 genes seems to be repeated...). How do you troubleshoot this?! If 'only' 11 plasmids get transfected, how do you work out which is missing?! Is there any reason why the genes all have to be encoded on separate plasmids?

8.
I'm not going to comment on whether this will work or not, especially as I won't be doing it. Though apparently at least one group have got it to work. Safety wise it seems ok.
I've transfected 15 plasmids previously in a screen, would have to be a pretty effective transfection! RA wise is fine.

**Project Ref** 470/19.3

- **Date Ackn'd**: 30/05/2019
- **CU2 Project Title**: The characterisation of regulatory networks, and identification of genes involved in virulence and biofilm formation, in Acinetobacter spp., Proteus spp. and Klebsiella spp.
- **Class**: 2
- **Culture Vol**: Class 2, ≤ 1 litre
- **Class Culture Vol**: 2
- **Culture Volume**: Class 2, ≤ 1 litre
- **Non-GMM**: Consent Granted
- **Project notified under transitional arrangements**: No
- **Withdrawn**: No
- **Tick if notifying a connected programme of work**: Yes
Bacteria adhere to almost every surface and in the context of healthcare, medical-device biofilm-centred infections pose an enormous threat, particularly from multi-antibiotic resistant super-bugs. Following an initial reversible surface-attachment step, bacteria become irreversibly surface-attached leading to the formation of antibiotic tolerant/resistant biofilms that are almost impossible to eradicate. Consequently, a better understanding of bacterial-surface interactions will aid the discovery and development of novel anti-attachment materials that can be used as coatings on implanted medical devices.

The aim of the project is to understand how Proteus spp., Acinetobacter spp., and Klebsiella spp. sense polymer surfaces, and more generally how biofilm formation, and pathogenesis, is regulated by answering the following questions:

1. How do bacteria regulate their behaviour in response to the polymer surface?

We will study the expression of key master regulators using lux/gfp reporter fusions in combination to DIC and fluorescence video microscopy techniques.

2. What is the role of flagellar rotation, type IV pilus, quorum sensing, two-component systems and cell wall stress in surface sensing?

Strains with mutations in different components of the flagellar apparatus will be created by homologous recombination and biofilm formation and assessed using video microscopy. In addition, we will construct gene fusions and fluorescent fusions.

3. Which other genes/pathways are involved in surface recognition, biofilm formation, and pathogenesis? Screen Tn5 transposon mutant libraries on the biofilm RPs for increased/decrease swarming motility and/or increased/decreased biofilm formation to identify genes involved in surface detection using swarming assays and biofilm formation assays.

Acinetobacter spp. GMM:

Acinetobacter baumanii deletion mutations in targeted genes will be generated by allelic exchange using plasmid vectors which will result in unmarked deletion strains. This will involve conjugation of parental Acinetobacter strains with a conjugation-efficient E. coli strain (32163, that is also a diaminopimelate auxotroph) containing a suicide plasmid that is unable to replicate in Acinetobacter. The plasmid integrates into the chromosome, resulting in Trimethoprim resistant Acinetobacter (occasionally we will use a variant of the plasmid that contains Apramycin resistance). A second plasmid is then conjugated into these Acinetobacter, this confers Tetracycline (or Hygromycin) resistance, and expresses a restriction enzyme that causes a double strand break only in the presence of the suicide plasmid. The resulting deletion mutants will have the second plasmid cured by plating on sucrose, resulting in strains that have no additional resistance cassettes, no replicating plasmids, and that vary from the parental Acinetobacter only by the removal of one gene.

Initial construction will be in E. coli and antibiotic resistance cassettes will be introduced into Acinetobacter mutant strains whilst being constructed. Where possible antibiotic selection used will be for antibiotics not used clinically and will not result in an increase in the hazard classification group, and, where possible, resistance markers
will be removed by use of recombinases or sensitivity enrichment protocols. Mutants will be complemented by introduction of intact copies of genes on plasmids or by insertion into the chromosome. It may be necessary or advantageous to regulate expression of the complementing gene using an inducible or constitutive promoter, and these may be incorporated into the complementation construct. The isogenic mutants and their complemented counterparts will be used in a wide range of phenotypic testing. The impact of gene mutations will also be tested in bioassays such as those to monitor biofilm formation in vitro under Containment Level 2 within the designated laboratory areas in the Centre for Biomolecular Sciences and the Food Sciences building.

Transposon libraries using the mini-Tn5 construct will be used to screen for the genes that are important in virulence factor production (mainly genes involved in biofilm formation, quorum sensing molecules production and phase-variation). This will involve the use of the plasmid pRL27 which contains a Tn5. The plasmid requires the pir gene, and as Acinetobacter do not have this gene the Tn5 is transposed into the chromosome where it is stable due to loss of the tnp gene. The Tn5 is known to randomly insert throughout the genome and confers kanamycin resistance to the Acinetobacter. The resulting strains will be screened for phenotypes of interest (e.g. biofilm, phase variation or quorum sensing inhibition) and the sites of Tn5 insertion sequenced. The resulting mutants of interest will likely have the Tn5 inserted within a gene of interest, thereby disabling the gene.

An A. baumannii strain AB5075-UW transposon mutant library which belong to the three-allele transposon mutant library generated by Gallagher et al. (2015) will also be utilised. The transposon used to disrupt the genes is T26, which contains a TcR gene. Details about the transposon used can be found at: http://www.gs.washington.edu/labs/manoil/transposons/transposons.pdf.

In addition, to study the effect of mutations in target genes in Acinetobacter spp. including A. baumannii we will make gene reporter fusions in both plasmids and in the chromosome, using reporter genes such as luxABCDE, gfp, yfp, mNeonGreen, mRuby3, DsRed, lacZ, phoA etc. The expression of these genes will be monitored in laboratory cultures (A. baumannii only). These experiments will all be performed under controlled conditions in CL2 laboratories. In the worst case scenario, the mutations, fusions, or antibiotic resistance genes are unlikely to increase the level of risk of the resulting strains beyond what is acceptable for hazard group 2.

Considering that A. baumannii is an opportunistic human pathogen and that the isogenic mutants are unlikely to be more virulent than the parent strains, the consequence of human infection by any of these mutants is low, and in the unlikely event that human infection were to occur, the antibiotic therapies currently available would be sufficient treatment. Antibiotics used to treat A. baumannii infections that will not be used for this work include colistin, imipenem, meropenem and tigecycline.

Proteus spp. GMM:
Proteus mirabilis deletion mutants in targeted genes will be generated by allelic exchange using plasmid vectors. Initial construction will be in E. coli and antibiotic resistance cassettes will be introduced into mutant strains while being constructed. Where possible antibiotic selection used will be for antibiotics not used clinically and will not result in an increase in the hazard classification group, and, where possible, resistance markers will be removed by use of recombinases or sensitivity enrichment protocols. Mutants will be complemented by introduction of intact copies of genes on plasmids or by insertion into the chromosome. It may be necessary or advantageous to regulate expression of the complementing gene using an inducible or constitutive promoter, and these may be incorporated into the complementation construct. Transposon libraries using the mini-Tn5 construct will be constructed to screen for the genes that are important in virulence factor production (mainly urease activity and swarming motility). The nature of these transposon mutations are obviously unknown but will include incorporation of a kanamycin resistance cassette.

The isogenic mutants and their complemented counterparts will be used in a wide range of phenotypic testing and also in C. elegans, G. mellonella and eukaryotic cell lines.

The impact of the mutations will also be tested in bioassays such as those to monitor biofilm formation in vitro under Containment Level 2 within the designated laboratory areas in the Centre for Biomolecular Sciences.

In addition, to monitor the expression of target genes in Proteus spp. including Proteus mirabilis we will make gene reporter fusions in both plasmids and in the chromosome, using reporter genes such as luxABCDE, gfp, yfp, mNeonGreen, mRuby3, DsRed, lacZ, phoA etc. The expression of these genes will be monitored in laboratory cultures (P. mirabilis only). These experiments will all be performed under controlled conditions in CL2 laboratories.

Klebsiella spp. GMM: This work will require the production of a range of plasmids that will then be transferred into Klebsiella. The plasmids will be produced and maintained in attenuated (HG1) strains of E. coli.

Klebsiella deletion mutants will be generated by allelic-exchange resulting in unmarked deletion strains. This will involve conjugation of parental Klebsiella strains with a conjugation-efficient E. coli strain ((32163) containing a suicide plasmid that is unable to replicate in Klebsiella. The plasmid integrates onto the chromosome, resulting in Trimethoprim-resistant Klebsiella (occasionally a variant of the plasmid that contains Apramycin resistance will be used). A second plasmid will be conjugated into these Klebsiella, conferring Tetracycline (or Hygromycin) resistance, which expresses a restriction enzyme that causes a double strand break only in the presence of the suicide plasmid. The resulting deletion mutants will have the second plasmid cured by plating on sucrose, resulting in strains that have no additional resistance cassettes.
replicating plasmids, and that vary from the parental Klebsiella only by the removal of one gene. These gene deletion mutants will then be genetically complemented by having a copy of the deleted gene introduced into the chromosome at a non-native site, using a variant of the same plasmid system used for the deletion mutagenesis. The resulting strains will not contain any additional resistance cassettes or replicating plasmids. The inserted genes will be present at single-copy level on the chromosome, and will be under the control of a copy of their native promoter so should be expressed at wild-type levels.

A range of Klebsiella strains that will include fluorescent and luminescent markers (luxABCDE, gfp, yfp, mNeonGreen, mRuby3, DSRed, lacZ, phoA etc.) will be constructed. Some of them will have the fluorescent/luminescent marker genes under the control of a constitutive promoter, while others will have the reporter gene under the control of a promoter from Klebsiella. These will be introduced via the same suicide vector system described above, resulting in strains that contain no additional resistance cassettes or replicating plasmids.

In addition, a transposon system to generate libraries of randomly mutated Klebsiella will be utilised. This will involve the use of the plasmid pRL27 which contains a Tn5. The plasmid requires the piri gene, and as Klebsiella do not have this gene then the Tn5 is transposed into the chromosome where it is stable due to loss of the tnp gene. This Tn5 is known to randomly insert throughout the Klebsiella genome. The Tn5 confers kanamycin resistance to the Klebsiella. The resulting strains will be screened for phenotypes of interest include reduction of biofilm formation and the sites of Tn5 insertion sequenced. The resulting mutants will likely have the Tn5 inserted within a gene of interest, thereby disabling the gene.

For all three genera (Proteus spp., Acinetobacter spp. and Klebsiella spp.) GMM:

It may also be necessary to express some proteins in E. coli (e.g. BL21/DH5a) for purification and biochemical analysis and/or for complementation of in-frame deletion mutants. Wherever possible these will be done with the incorporation of a regulatory system so that the protein is only expressed in the presence of either IPTG or arabinose, two compounds unlikely to be found outside the laboratory. This work will also largely be done in E.coli, but it may be necessary to shuttle these constructs into A. baumannii or K. pneumoniae to examine protein expression. Due to the need for a precise set of environmental requirements (such as the need for IPTG or arabinose induction) and the low chance that these vectors could accidentally shuttle between strains in the laboratory, it is unlikely that protein-expressing strains will increase the virulence of the organism.

It is also proposed that some gene products will be altered, usually by truncation or amino acid substitution, in order to further elucidate the function of the unknown gene product, such as protein binding domains. These alterations are unlikely to result in a gene product that is more hazardous than the original wild-type strain and will most likely result in attenuated function.

Host/vector system

All of the E. coli strains we propose to use (e.g. DH5a, BL21, JM109, (32163 and S17-1) are K12 derivatives which are considered to be non-colonising and non-pathogenic for humans and animals. All of these strains have multiple auxotrophic requirements which are unlikely to be met in the environment where their survival is considered unlikely. All of these strains are considered equivalent to ACDP Hazard Group 1.

A. baumannii, P. mirabilis and K. pneumoniae are ACDP Hazard Group 2 organisms and are recognised as human and animal pathogens and are capable of causing human infections. While infectious, these organisms are opportunistic pathogens and requires a compromised immunity in order to establish an infection.

A. baumannii, P. mirabilis and K. pneumoniae host strains to be used include (but are not limited to) the common laboratory strains A. baumannii AB5075-UW, P. mirabilis Hauser 1885 and K. pneumoniae NCIMB10104.

A range of A. baumannii, P. mirabilis and K. pneumoniae clinical strains that have been isolated from patients will also be used in experiments. As such, they have not been disabled and can cause a variety of diseases including UTIs, lung infections and sepsis. They typically infect the elderly, and patients in intensive care units, rarely causing infection in healthy individuals. Acinetobacter spp. clinical isolates include (but are not limited to) A. baumannii 17978 and 19606, clinical/environmental isolates of Acinetobacter iwoffii, and clinical/environmental isolates of Acinetobacter baylyi. Klebsiella spp. clinical isolates include K. pneumoniae 52.145 (Seq type ST66, Capsule type K2), 43816 (Seq type ST493, Capsule type K2), MGH78578 (Seq type ST38, Capsule type K52), NJST258-1 (Seq type ST258, Capsule type cps-2), clinical/environmental isolates of A. baumannii, K. pneumoniae, K. oxytoca and K. variicola.

The antibiotic sensitivity profiles of these strains will already be known or will be determined before they are used. Specific note for Klebsiella spp.:

Klebsiella isolates are exhibiting rising levels of antibiotic resistance in the clinic, which is why they are of immense importance. However, the primary strain we will focus on, K. pneumoniae 52.145, is sensitive to beta-lactams (including ampicillin and penicillin), carbapenems, tetracyclines, and aminoglycosides. It has been relatively well-studied in the literature for its interactions with host immune cells, and a complete genome sequence is available. It is considered to be highly virulent, as it contains gene for all the known major virulence factors found in Klebsiella species, but it is unlikely to cause disease in healthy individuals.

A variety of vectors may be used in E. coli, Acinetobacter spp., P. mirabilis and/or Klebsiella spp. for the manipulation and creation of novel strains are detailed in section
5.2.2.

The genome insertion plasmids insert into the chromosome of a range of bacteria but the conditions for this to occur are very stringent and unlikely to be met outside of the laboratory or by accident, for example the Tn7 derived plasmids require an accessory plasmid to be co-conjugated in order for insertion to occur. The self-mobilizable vectors require a stringent set of conditions that are unlikely to occur outside of the laboratory. Vectors which are required for the expression of a protein will have a regulatory component (wherever possible) so that protein expression is linked to the presence of either IPTG or arabinose, which are unlikely to be found outside the laboratory.

Transposon libraries have been or will be created using the Gram-negative specific transposon mini-Tn5, which requires unique conditions for transposition and subsequent mutation to occur. These conditions are likely only to be met in laboratory environments and are unlikely to occur in the environment, and spread to environmental bacteria is considered highly unlikely.

All the plasmids carry at least one resistance marker against the following antibiotics: aminoglycosides (kanamycin, gentamicin, streptomycin, spectinomycin, apramycin, hygromycin B), 13-lactams (ampicillin, carbenicillin), chloramphenicol, trimethoprim, tetracycline, and mercuric ions.

Example of plasmid vectors to be used for:

a) Complementation of mutations and biosensors in A. baumannii:

- pMO557M: This is an Acinetobacter shuttle vector, which contains colE1 origin of replication (E.coli), pWH1266 origin of replication (A. baumannii), araC, pBAD promoter and has hygromycin B resistance gene. This vector is low-copy and is non-mobilisable (contains oriT and no tra genes). This vector will be used for fluorescence tagging, for genetic complementation and for promoter fusions. Genes which will be cloned under their native promoter in this vector include the quorum sensing gene abal and csuR (tip of the csu pili, involved in surface attachment), fluorescent proteins for bacterial in vivo tagging (mNeonGreen, mRuby3 or E2-Crimson), and csu promoter in frame with the bioluminescent reporter genes (luxCDABE).

- pUC18-miniTn7-hygromycin B: miniTn7 is contained in a delivery plasmid, pUC18T with CoLE1 origin of replication, OriT, ampicillin resistance cassette and hygromycin-B 4-0-kinase (hph) gene for antibiotic resistance selection. Used for mutant complementation in the chromosome. This plasmid in non-mobilisable and can't transfer without a helper plasmid either as it does not contain the transposable gene. This vector will be used for fluorescence tagging and for the construction of two promoter fusions: briefly the abar gene (quorum sensing transcriptional regulator) will be cloned together with the promoter of the neighbour gene abam (a quorum sensing transcriptional regulator) and the bioluminescent reporter operon (luxCDABE). Alternatively, the abar and abam genes (both quorum sensing transcriptional regulators) will be cloned together with the promoter of the neighbour gene abal (a quorum sensing synthetase) and the bioluminescent reporter operon (luxCDABE) to measure the transcriptional activity of abal. In addition, dslRed express and gfp genes will be cloned in this vector for in vivo tagging.

b) Mutations (Tn5 or in frame deletion), complementation of mutations and biosensors in P. mirabilis:

- pGEMTeasy (Promega): multipurpose cloning vector (Ampr, on, f1 on, lacZ). This vector will be used to express biosynthetic genes involved urease production (ureC) and in flagellation synthesis (fhaA) for complementation of in frame deletion mutants.

- pCVD442 and pDM4: these are a suicide vectors (containing oriR6K, sacB and Ampr for pCVD442 and Cmr for pDM4). These vectors do not replicate in Proteus mirabilis and will be used to generate in frame deletion mutants of the ureC and fhaA biosynthetic genes, resulting in a strain incapable of producing urease or a non-flagellated strain (for pCVD442: see Zunino et al., 2007 https://doi.org/10.1111/j.1574-695X.2007.00285.x).

- pUT-miniTn5: oriT tnp Tn5 [oriR6K, KanR], which results in the insertion of the Tn5 into the genome of Proteus. The vector does not replicate in Proteus and the resulting strain will contain a tnp5 insertion stably maintained in a fixed chromosomal location as the tnp gene will be lost after Tn insertion.

- Plasmids vectors used to generate mutants and complementation of mutants in Klebsiella and Acinetobacter spp.:

- pGP1-Scel: oriR6K TpR mob+ carries I-Scel cut site, which cannot replicate in Klebsiella or Acinetobacter (due to oriR6K).

- pDA1-Scel-SacB: oripBBR1, TetR mob+ carries I-Scel gene, which replicate in Klebsiella and Acinetobacter, but the final mutant strains will not contain the plasmid as they will have been cured via growth on sucrose-containing plates.

- pRL27: oriT TetR tnp Tn5[oriR6K, KanR], which is temperature sensitive and results in the insertion of the Tn5 into the genome of Klebsiella and Acinetobacter. The resulting strains will not contain a replicating plasmid, and the Tn5 insertion is stable in a fixed chromosomal location as the tnp gene (required for movement of the Tn5) is lost after Tn insertion.

d) E.coli molecular cloning vectors for the creation of genetic constructs (e.g. pBlueScript II, pGEM series, pUC series) which are or non-mobilisable plasmid vectors.

All the plasmids carry at least one resistance marker against the following antibiotics: aminoglycosides (kanamycin, gentamicin, streptomycin, spectinomycin), (3-lactams (ampicillin, carbenicillin), chloramphenicol, trimethoprim for Acinetobacter spp. and Proteus spp., or hygromycin, apramycin and trimethoprim for Klebsiella spp.

Origin & function
The nature of this project is to identify novel genes which affect the surface adherence, biofilm formation, pathogenicity and motility of Proteus spp., Acinetobacter spp. and Klebsiella spp. There are likely to be genes which are unknown and in-frame deletion mutants of these genes will need to be complemented with intact copies of the gene. This gene will in most cases be under the control of the native promoter but it may be necessary to put under the control of a constitutive or inducible promoter. The expression vectors used in Proteus spp. will contain chloramphenicol, ampicillin, kanamycin or gentamicin resistance markers, hygromycin-B 4-0-kinase (hph) or ampicillin resistance markers in Acinetobacter spp., and trimethoprim, tetracycline, apramycin or hygromycin in Klebsiella spp.

Non-native genes to be inserted into A. baumannii, P. mirabilis or Klebsiella spp. will include reporter genes that may be used singly or in combination:

- Luciferases (e.g. lux, luc, gluc) which encode bioluminescent proteins.
- Fluorescent proteins (e.g. gfp, mNeonGreen, mRuby3, DSRed, cfp, mTurquoise2, tdTomato, mSapphire or mCerulean).
- lacZ which encodes beta-galactosidase.

These genes do not encode for any toxins, and will not result in increased bacterial growth. These are typically energy-intensive proteins to produce, and if they result in an effect on cell replication/survival rates, they are usually detrimental. All of these marker genes have been well-studied in a variety of organisms including the above-mentioned species.

These genes have a role in virulence and the complementation of mutants of these genes (even if under the control of an inducible or constitutive promoter) is not expected to increase the virulence beyond that of the wild-type. This list is not exhaustive and it is expected that other potential candidates will be included, but again, none of them when complemented should result in a strain with greater virulence than the wild-type.

For Acinetobacter spp., Proteus spp. and Klebsiella spp., genes which will be investigated will code for regulatory proteins involved in cell-to-cell communication (Quorum Sensing) or will code for sensory proteins controlling bacterial cell surface behaviour (swarming and swimming motility, and biofilm formation).

Examples of genes which would be targeted for deletion in Acinetobacter spp. are:

- Abal/Abar/AbAM (Quorum sensing system)
- Two component regulatory systems (OmpR/EnvZ, GacA/GacS, BfmR/BfmS, PilR/PilS, PhoR/PhoQ, AdeR/AdeS)
- Other sensory proteins (KdpD, PilH, PUG, QseB BaR, CopR)
- CsuA-E (chaperone husher protein)
- Diguanylate cyclases and phosphodiesterases
- Structural proteins involved in the formation of fimbriae, exopolysaccharides or polyamines (e.g. 1,3 diaminopropane).

Genes which will be investigated in Proteus spp. will code for cell division proteins, involved in flagella synthesis, virulence factors synthesis (e.g. urease) or will code for sensory proteins controlling bacterial cell surface behaviour (swarming and swimming motility, and biofilm formation).

Examples of genes which we would like to target for deletion in Proteus spp. are:

1. Flagellar genes:
   - fliDC (master regulator switch of flagella motility).
   - motAB (flagellar stator).
2. Che (Chemotaxis) system:
   - MCPs (Methyl Accepting sensory Proteins) (PMI2808; PMI2809).
3. Virulence genes:
   - zapAB (IgA degrading protease).
   - hpmAB (hemolysin). uraABC (urease).
4. Self-identity genes:
   - idsA, idrAB (cell-to-cell communication).
5. Cell division genes: minCDE, ftsZA.
6. Fimbrial genes:
MRP: mrpA PMF: pmfA UCA: ucaA
In Klebsiella spp. a range of genes that we predict to have a role in either biofilm formation or other virulence traits will be investigated. Examples include: polyamine synthesis enzymes; cyclic-di-GMP related proteins: diguanylate cyclases and phosphodiesterases; structural proteins involved in the formation of structures such as fimbriae; and genes for proteins involved in the synthesis and/or transport of exopolysaccharides such as cellulose and poly-glutamic acid. We will also look at the roles of the synthesis of polyamines (such as putrescine and spermidine) by Klebsiella by deletion of the genes encoding enzymes needed for polyamine synthesis.

Evaluation of foreseeable effects

It is anticipated that mutation of the majority of the genes to be studied will reduce rather than enhance the virulence of the host strains. However, mutation of the regulatory genes which may co-ordinately control expression of a number of virulence factors, as it may happen by Tn mutagenesis, has the potential to generate strains which may express elevated levels of some gene products. However, Acinetobacter spp., Proteus spp. and Klebsiella spp. all have several gene regulators which interact to control gene expression and in a number of cases more than one regulator appears to control gene expression of a single gene. Consequently, mutation of a single or even multiple regulators is considered highly unlikely to result in a strain which will have significantly enhanced virulence given the multifactorial nature of the infection process and importance of predisposing factors in most cases of an infection. Introduction of additional antibiotic resistance markers is considered unlikely to affect the therapeutic potential in the unlikely event of laboratory acquired infection or breach in CL2 physical containment.

The reporter genes to be introduced are not considered likely to enhance the virulence of the recipient strains or to affect the therapeutic potential.

The E. coli strains to be used for construct generation and protein expression are considered disabled and are unlikely to survive for significant periods of time outside the laboratory. None of the complementation constructs to be generated is considered likely to enhance the virulence of the E. coli hosts.

Any gene in section 5.3.1 which has been mutated could be deliberately cloned in a broad-range cloning vector (e.g pUC18, section 5.2.2.) and over-expressed in E. coli (DH5a, TOP10 or BL21) for protein function analysis. The resulting strain is expected to be non-virulent and non-pathogenic. It may also be necessary to overexpress some of these genes in Acinetobacter spp, Proteus mirabilis or Klebsiella spp.

The genes to be inserted into A. baumannii, P. mirabilis or K. pneumoniae are largely to complement the deleted gene of interest. They will be, where possible, under the regulation of the native promoter and it is therefore unlikely that such complementation would increase the virulence and pathogenicity of the organism beyond that of the wild-type. Sometimes it may be necessary to have the Gene Of Interest (GOD under the control of an inducible or constitutive promoter of appropriate strength. This may increase the production of a single GOI but in these cases this is considered unlikely to increase the virulence or pathogenicity of the organism beyond the wild-type.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

SOLID WASTE:
Centre for Biomolecular Studies
Solid media used for the culture of microorganisms will be autoclaved before incineration. All contaminated plastic ware will be autoclaved and incinerated in the same manner. All contaminated glassware will be autoclaved and then washed before reuse. Contaminated insect and/or nematode work will be sealed in autoclave bags and then autoclaved. All reusable sealed containment equipment will be decontaminated by autoclaving before being reused. The autoclaves have chart recorders for monitoring load and drain temperatures.
Food Sciences
All solid infectious waste (culture plates, contaminated tissues, gloves etc) will be sterilised by autoclaving (126°C for 15min on a validated cycle) before off-site incineration (via SRCL).
LIQUID WASTE:
Liquid waste will be autoclaved before disposal via the drains.
ANIMAL STUDY WASTE:
Cages will be autoclaved and washed before re-use. Bedding and animal carcasses will be inactivated by autoclaving prior to disposal. Water bottles will be soaked overnight in 1% Virkon solution.

Is an emergency plan required according to regulation 20? \(N\)

If yes, tick to confirm that it is attached to this form \(N\)

Tick to confirm that you have attached a risk assessment to this form \(Y\)

Tick if you are claiming exemption from disclosure for section of the risk assessment \(N\)

Please enter comments on the GM safety committee on the risk assessment
Person A
Can the PI confirm how control of susceptible groups will be managed?
I think the autoclave cycle is 162°C for 10 mins, can this be checked?

Person A
The GM assessment notes that A. baumannii has been designated a red alert human pathogen due to its extensive antibiotics resistance spectrum. Can this information be entered into the BARA.
GMRA Section 5. Can the antibiotics used clinically that will not be used for this work be listed.
GMRA 5.1 The host has been entered as HG3 rather than 2
GMRA assessment refers to the infection of animals but the associated paperwork has not been provided
GMRA autoclave run time needs checking

Person B
The discard autoclave cycle is 126°C for 10 min.
The disabled E. coli hosts should be ACDP HG 1 and the wild type A. baumannii is ACDP HG 2. These need changing on the form.
4. **Person B**

Correction:
The discard autoclave cycle is 126oc for 15 min.

---

5. **Person C**

Based on comments and clarifications above I am happy with this.

I see no reason why this is any different in risk form wild type so controls suitable for wit should suitable for the GM.

With additional waste management caveats.

---

6. **Person D**

The Antibiotic resistance profile on the GM RA is indeed a bit confused - which antibiotic resistance genes/plasmids are you putting into these? This information would be needed if someone did manage to infect themselves with it. Its also not clear if you are working with well characterised strains (ie ones in which you know their antibiotic resistance profiles) or field isolates (where you won't know).

Minor point c elegans is not an insect - it is a nematode. I also personally prefer people to give common and latin names for things like your Galleria melona (wax wing moth larvae) as it took me a while to remember what these are.
Person E
It says in part 5 It may also be necessary to express some proteins to further characterise the function of the molecule*. What proteins are they, and what is the consequence of them being expressed if there was an exposure.

Person D
new version generally looks ok to me (it is making more sense combined)

Person F
The RA specifies the containment that will be used to control spread of infection from and between the experimental animals. However I would like clarification as to if the procedures involve imaging. If this is the case the control measures involving the individually Ventilated Cage and Class 1 MSC may not be able to provide the required containment. This is because the optical imaging in the IVIS requires animals to be moved from the MSC to the imaging kit and imaged in the open room outside any filtration controls.
No major issues with this. The GM proposed is either routine TN based random mutagenesis or directed mutagenesis of genes for the species listed. However the actual use of specific vectors is unclear. If there are references for the methods then these could be cited. I am finding hard to define what's being used for what out of the vector list. i.e. pBBR1 is self-mobilisable therefore poses greater risk for transfer but what is it used for?

I am less worried regrading which specific genes are being knocked out as in effect all genes (except essential) are potential KO targets. In section 5.3.2 if anything it overplays the uniqueness of risk from GM inserts in regulators. While this potential exits via simple point mutation which is happening as a natural process in all bacteria. If these KOs were beneficial they would be expected to develop naturally. They are correct in their view that the risk form this is low.

Overall, this looks reasonable and I see no reason why it shouldn't be a class 2 assessment.

Main GMRA
Agree w/ Michael re. clarity over what some of the listed vectors are to be used for.
I'm unclear on the animal usage in the main GMRA. Unless I'm missing it, it's not mentioned until we get to section 8 (control measures) - perhaps some descriptive overview of what's to happen with this earlier in the RA?
Section 8.6 - C. elegans is not an insect and what developmental stage is G. mellonella to be used at? Presumably not as adult moths? Are these actualit required for this work?
Section 11 - mentions mammalian cell lines. Maybe it's me, but haven't seen this mentioned before this. Needs more explanation surrounding this - actually required for this work?
Supplementary GM animal RA
No mention of C. elegans or G. mellonella here. Inconsistent with main GMRA?

Sorry, just noticed that the version uploaded isn't the most up to date version of the GMRA - section 8.6 should state that the G. mellonella is the larvae only. The waxmoth...
and nematode work won't be done in the BSU, but in the lab. In terms of plasmids, Laura is using:
pGP1-Scel (suicide vector) and pDA1-Scel-SacB (used for curing the strains of the integrated pGP1-Scel plasmid) and the transposon carrying plasmid pRL27.

Person C
I have just seen the changes. They help make combinations clearer but now pose the following query.
While the listed insert genes appear low risk...
However I am surprised by the use of self-mobilisable vectors for complementing of genes under native promoters. pBBR1 seem particularly broad host range. Is these and the other self mobile vector routine for the complementation process.
Could this not be in a less mobile vector system for complementation?
The general approach for GM is to reduce risk options in any constructs and one of the min risks here is mobilisation of previously non mobile genes. When I first read the assessment it was unclear what the role of these vectors was?
Is there a non mobile vector that can be substituted.
If not we need to define the genes cloned for complementation more clearly.
As said the TCRs listed probably pose limited risk but the paper work suggest other inserts.

Project Ref  470/21.1

Date Ackn'd  | CU2 Project Title  | Class  | CultureVolClass2  | CultureVolumeClass3-4

02/03/2022  |  |  |  |  |
The overriding scientific goal of this project is to determine the role(s) of individual MERS-CoV proteins in the context of a viral infection in vitro.

Therefore, the major aims of this project are to:
1) Establish the reverse genetic system to create recombinant MERS-CoV
2) Create a library of MERS-CoV mutants for use in experiments to determine the role(s) of individual MERS-CoV proteins in various aspects of MERS-CoV biology
3) Create reporter viruses expressing markers to assay MERS-CoV replication rapidly
4) Use recombinant MERS-CoV in assays (based on preliminary data).

Recipient or parental organism
Recipient organisms are:
1. Disabled commercially available laboratory strains of Escherichia coli (E. coli), such as DH5a, will be chemically transformed to express the plasmids.
2. Common continuous human cell lines, such as Vero E6, HEK293T, HeLa or Huh7 cells.
3. In the final step, Vero E6 cells will be transfected with the full-length MERS-CoV genome and N mRNAs to create virus. There is no evidence that any of these cell lines poses a danger to human health. However, full Class 3 precautions (including use of a Class I MSC) will be used.
4. Cell lines will be infected with MERS-CoV mutants and full Class 3 precautions (including use of a Class I MSC) will be used.

Host/vector system
The segments of the MERS-CoV genome will be cloned into plasmids in order to propagate them in E.coli. Commercially available plasmids, such as pUC19, that contain Ampicillin or Kanamycin resistance along with appropriate restriction sites will be used for this purpose.

Origin & function
The inserted genes will all be wild-type or mutated versions of coronavirus genes.

Coronaviruses have three groups of gene products that will be expressed:
1) Non-structural proteins, named nsp1 – nsp16, synthesised initially as 2 large polyproteins (1a and 1b). These proteins carry out biochemical functions critical for virus replication – such as components of the RNA-dependent-RNA-polymerase that transcribes and copies the viral genome. They also include proteins that induce subcellular rearrangements necessary for virus replication. Some have unknown/unclear functions.

2) Structural proteins. These proteins make up the physical structure of the virion.

3) Accessory proteins. These proteins usually have functions that allow viral survival, such as inhibition of immune signalling pathways. Some have unknown/unclear functions.

These genes have important functions in coronavirus replication, but only when expressed all together in the context of a virus infection.

**Evaluation of foreseeable effects**

Because the MERS-CoV genes all have functions that are required for some (in some cases unknown) aspect of MERS-CoV biology, deleting or modifying a gene is most likely to make the virus less ‘fit’ biologically. Whether that be replication, pathogenicity, host range, tropism, transmission and/or changing the host immune response. Indeed, in some cases, it may be that no infectious virus is recoverable as the gene in wild-type configuration is absolutely essential for virus replication. Under the ‘ideal’ replication conditions of tissue culture, it may be that deletion or modification of some genes has no significant effect on MERS-CoV biology. But, this means the virus is only as dangerous as the wild-type. Also, to reemphasise, I do not intend to mutate MERS-CoV in any way that may be considered ‘gain of function’ – such as swapping MERS-CoV genes for those of any other virus.

The only genes that may be inserted for reporter assays will be GFP, RFP, luciferase or similar. None of these have any known biological effects.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste will be autoclaved prior to removal from the CL3 suite and disposed of using normal approved disposal routes. E.g. liquid waste will be disposed of in the sink.

Waste container(s) of at least 1:100 Distel (final dilution) will be used for liquid waste, tips and other small items prior to autoclaving.

All containers will be sprayed with 2% Distel for 30 mins prior to removal from the MSC, therefore, the contents will also have at least 30 minutes contact time.

Distel is validated by the manufacturer at a 1:100 dilution for 30 mins against feline coronaviruses and a validation experiment will be conducted to confirm Distell activity against MERS before work begins.

Project Additional Information

Purposes of the contained use

The aim of this activity is to quantitatively assess the early stages of the coronavirus replication cycle. This technique was previously used in my postdoctoral laboratory (Coleman CM & Sisk JM et al, 2016. Journal of Virology).

Specifically, the project will utilise a lentivirus reporter pseudotyped with viral entry proteins to quantify entry and virion fusion. The core of these pseudoviruses is a lentivirus lacking the entry protein (Env) and most of the accessory proteins. The pseudoviruses are then pseudotyped with a virus entry protein to create single-cycle...
virions. In this case, the pseudoviruses also carry a reporter protein (HIV-1 Vpr fused to β-lactamase, which is packaged into the virion) to allow for quantification of virus fusion.

Ultimately, the aim is to use this system to quantify virus entry and fusion under various experimental conditions, including:

a) In normal cells – both immortalised cell lines and primary human cells
b) In cells with a knockdown of cellular proteins
c) In the presence of drug treatments predicted to block virus entry/ fusion

The main advantage to this approach is that it does not require high containment virus handling, as would be required for working with wild-type viruses, while also allowing for specific quantification of the steps of the virus replication cycle.

Recipient or parental organism

Recipient organisms are:

1. Disabled strains of Escherichia coli (E. coli), such as DH5α, will be chemically transformed to propagate the plasmids. These E. coli are commonly used for this purpose and have all pathogenicity genes removed and so pose no risk to human health.
2. Immortalised eukaryotic cell lines, such as HEK293T, HeLa or Huh7 cells. No cell lines with confirmed productive chronic infections will be used. There is no evidence that any of these cell lines poses a danger to human health. However, as they are derived from human cells, Class II precautions will be taken out of an abundance of caution.
3. Primary human cells. These will be obtained from commercial sources, certified free of any human pathogen. There is no evidence that any of these cell lines poses a danger to human health. However, as they are derived from human cells, Class II precautions will be taken out of an abundance of caution.
4. Immortalised or primary human cells (from 2 and 3 above) that have been knocked-down specific cellular proteins. This will be achieved by transfection of siRNA. If a stable line is required, separate approval will be obtained.

Host/vector system

The viral vector contains:

1. The lentiviral structural proteins and replication incompetent genome
2. A reporter protein that is incorporated into the lentivirus virion
3. An entry protein from another virus that is expressed on the surface of the lentivirus

I will deal with each in turn to describe how the lentivirus is attenuated:

1. The second generation lentiviral packaging vector is based on HIV-1. This plasmid will produce a lentiviral genome and some structural proteins. However, the HIV-1 Env (HIV-1 entry protein) and most of the accessory proteins (that confer pathogenic qualities upon the virus) have been removed and, therefore, is replication incompetent. The plasmid, and resultant genome, contain only the bare minimum to form a virion: HIV-1 Gag/Pol, Tat and Rev only.
2. The reporter protein has no effect, positive or negative, on the safety of the viral vector.
3. The entry proteins from other viruses confer the ability to infect specific cell types upon the viral vector. However, this ability is not genetically inheritable by the vector for 2 reasons: a) this is not provided as part of the lentivirus packaging vector and b) the entry protein plasmids are NOT incorporated into the viral vector in themselves (they lack a lentivirus packaging sequence).

Origin & function

The inserted genes have the following functions:

1. The pCMV-R8.2 has multiple genes that code for proteins involved in HIV-1 virion assembly, integration and expression. These will be expressed in the transfected HEK293T cells and transduced cells (thought the time limitations of the experiment should exclude this).
2. HIV-Vpr-Lactamase is a HIV-1 accessory protein that serves as the reporter for the virion fusion assay. This gene includes a Myc tag. This gene will be expressed only in transfected HEK293T cells.
3. Virus entry protein genes. These genes encode proteins that allow entry of various viruses. This gene will be expressed only in the transfected HEK293T cells.

All of these plasmids also contain an ampicillin resistance gene that confers resistance upon transformed bacteria.

Finally, the pMM310-Myc contains a gene for eukaryotic cell selection – resistance to the antibiotic zeocin.

All genes will be overexpressed in the transfected 293T cells and, indeed, are designed to be overexpressed to ensure efficient vector production.

The plasmids contain the following genes.

pCMV-R8.2, a second generation lentiviral vector (these are also the genes that, theoretically, will be expressed upon transduction by the lentiviral vector):

- HIV-1 Gag/Pol
- HIV-1 Tat
- HIV-1 Rev
- Ampicillin resistance gene

pMM310-Myc:

- HIV-1-Vpr-Blam-Myc
- Ampicillin resistance gene
- Zeocin resistance gene

Viral entry protein plasmids:

- A coronavirus entry protein – either SARS-CoV or MERS-CoV spike. Or another virus entry protein – currently have VSV-G and Ebolavirus GP as controls for different entry pathways
- Ampicillin resistance gene

**Evaluation of foreseeable effects**

The sources of hazard related to alteration of existing traits in this protocol are as follows:

1) Expression of Amp/Kan resistance in E. coli strains during plasmid propagation, making the E. coli resistant to one of these antibiotics.

2) (In some cases) Expression of antibiotic resistance genes in eukaryotic cell lines, making them resistant to said antibiotic.

3) Expression of lentivirus, coronavirus and/or host surface proteins by eukaryotic cells that may alter the structure/function/appearance (in the immunological sense) of the cytoplasmic membrane of the cells.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

3. Generally pretty thorough (and a fairly routine method for this type of work). Only section that really needs tidying up is the disinfectant - Distel is fine (bleach is unnecessary). Probably simpler to just autoclave all GM waste (rather than disinfect chemically and then autoclave - not necessary at CL2)

5. Proposed work has been designed to be inherently safe (compared to working with wild type viruses). Measures to attenuate the lentiviruses appear to be thorough. The remaining risks appear to have been thoroughly considered and appropriate measures put in place to minimise them. As with most RAs the waste management procedures will need to be revisited regarding a replacement Distel.

6. The building is not completed, where will this work take place?
   Disposal route needs to be clear that waste will be autoclaved rather than disinfected
   I'd prefer Bleach removed unless there is a good reason for it
   This assessment will require notification to the HSE.

7. no further comments

8. I think this is logically presented and argued, and beyond some of the questions above, I'm happy with it.

9. Have asked PI to address minor comments and return via me for signoff.

Project Additional Information

Purposes of the contained use

We are interested in studying the role of individual bacterial genes in (a) the pathogenesis of bacterial infection (b) the host immune response to products of these genes, and (c) killing by colicins. The studies are designed to increase our understanding of host-pathogen interaction and develop new preventative and therapeutic methods against invasive bacterial disease. We attempt to detect proteins of interest (usually vaccine candidates or antimicrobials) from sequence data or genomic expression libraries (eg in the phage based x-ZapII) and identify their encoding genes. We then amplify the genes by PCR, clone them in plasmid vectors and express them under the influence of IPTG. These will be used to carry out studies on the characterisation of the molecular, immunochemical and functional properties of the antigens of interest.

Recipient or parental organism

Neisseria: including Neisseria meningitidis, N. gonorrhoea and commensal Neisseria (eg N. lactamica)
Campylobacter: Campylobacter jejuni and C. coli.
Klebsiella: K. pneumoniae ssp and K. oxytoca.

Host/vector system

Hosts:

All are E. coli, derivatives of strain K12: Examples:
JM109 (recA1, endA1, gyrA96, thi, hsdR17 (rK-,mK+), relA1, supE44, (lac-proAB), [F’, traD36, proAB, lacIqZM15].
XL10-Gold (Tetr, (mcrA) 183, (mcrCB-hsdSMR-mrr) 173, endA1, SupE44, thi-1, recA1, gyrA96, relA1, lac hte, [F’proAB lacIqZ M15 Tn10 (Tetr) Amy Camr].
XL-1 Blue (endA1, hsdR17 (rK-, mK+) relA1, supE44, thi-1, gyrA96, (lac-) [F’ proAB lacIqZ M15 Tn1].

Vectors (examples)

1. Plasmid vectors that will be used for studies of protein over-expression from native and inducible promoters (native constructs - pGEM-T, pBr4, pBR322, pUC18/19; inducible vectors - pBAD, pET etc) are considered non-Mobil sable or mobilisation defective. These plasmids will remain in the transformed host and will confer antibiotic resistance genes to the host. Examples of antibiotics to be used are tetracycline, kanamycin, chloramphenicol or ampicillin.

pBluescript: pUC19 derivative, which is non-mobilisable. It contains a colE1 origin of replication, T3 and T7 promoters, and an ampicillin resistance gene. It has an F1
origin that contains an initiator and terminator for M13 DNA replication and the lacZx peptide for blue/white selection.

pGEM: pUC19 derivative, which is non-mobilisable. It contains the coIE1 origin of replicatio, SP6 and T7 promoters, ampicillin resistance marker and the lacZx peptide for blue/white selection.

pREP4: pACYC-184 derivative, which is non-mobilisable. It contains a kanamycin resistance gene and lacIq for constitutive expression of the lac repressor.

pQE30: pDS-56 derivative, which is non-mobilisable. It contains an ampicillin resistance gene and a 6x Histidine tag for Ni/NTA purification of expressed proteins.

PET and pBAD: non-mobilisable expression vectors that contain; ampicillin or kanamycin resistance genes and a 6x Histidine tag for Ni/NTA purification of expressed proteins (pET); or an arabinose inducible promoter for regulated, inducible expression (pBAD).

PCRT7/NT-TOPO and its related plasmids: pUC derivative, which is non-mobilisable. It contains an ampicillin resistance gene and a 6x Histidine tag for Ni/NTA purification of expressed proteins.

2. Phages:

zapII: a based expressed phagemid useful for cloning genomic DNA in the range of 2-10 kb. zapII contains the pBluescript replicon. At the junction between n and the pBluescript DNA sequences there is an initiator and terminator for M13 replication.

Transposons: Tn5 derivatives (eg EZ::TN transposomes from Cambio) which have been constructed to transpose once. Plasmid vectors that will be used for studies of protein over-expression from native and inducible promoters (native constructs - pGEM-T, pBR322, pUC18/19; inducible vectors- pBAD, pET etc) are considered non-Mobilisable or mobilisation defective. These plasmids will remain in the transformed host and will confer antibiotic resistance genes to the host. Examples of antibiotics to be used are tetracycline, kanamycin, chloramphenicol or ampicillin.

Origin & function

Origins of the geneic material are the above mentioned bacterial pathogens. They include:

Neisseria: including Neisseria meningitidis, N. gonorrhoea and commensal Neisseria (eg N. lactamica)
Campylobacter: Campylobacter jejuni and C. coli. Helicobacter pylori
Klebsiella: K. oxytoca and K. pneumoniae ssp.

Evaluation of foreseeable effects

All of the E.coli host strains that we propose to use are K12 derivatives, which are recognised to be non-colonising and are considered to be non-pathogenic to humans or animals. In addition, they have multiple auxotrophic requirements which are unlikely to be met in the environment and so they are assumed to have very limited survivability in the environment.

The pathogens are mostly human commensal and/or opportunistic bacteria. They are common colonisers of skin and mucosal surfaces. Normal healthy individuals, when exposed, usually become transiently colonised with no consequences. However, in susceptible individuals, the pathogenic bacteria can cause invasive disease and in some cases (particularly N. meningitidis) they are capable of causing life threatening diseases.

The plasmid vectors used are all non-mobilisable and are, therefore, unlikely to be transferred to other environmental bacteria. The genes cloned from these bacteria will initially be of unknown function. It is unlikely, however, that any DNA sequence will confer on the host a significant increase in fitness or pathogenicity to the host due to the multiple disablements present in the host and the multifactorial nature of pathogenicity.

The antibiotic cassettes that we propose to use as selectable markers to facilitate inactivation of genes in the bacteria will confer resistance to antibiotics that are not in use.
in either the treatment or prophylaxis of disease. Furthermore, the mutants can be constructed in such a way that the selectable marker can be subsequently removed where appropriate.

The proposed E. coli host strains are all disabled E. coli K12 derivatives are are in the biological agents hazard group 1. Although the introduction of cloned genes might conceivably increase the fitness or survivability of these organisms it is assumed to be very unlikely. However, because of the small potential increase in perceived hazard the recombinant organisms will be treated as biological agents hazard group 2 and, therefore, containment level 2 precautions will be applied. The organisms will, therefore, be provisionally classified as hazard group 2.

All the bacteria included in the study are in the biological agents hazard group 2. After inactivation of the genes of interest, it is highly unlikely (although theoretically possible) that there will be an increase in the virulence or fitness of the organism.

All manipulations of live bacteria (including host E. coli in which genes of interest are overexpressed) will be contained using containment level 2. Genetically modified bacteria and, where appropriate, host E. coli in which genes of interest are overexpressed will be handled in a class 1 cabinet.

The containment precautions to be used are considered sufficient to reduce the risk of accidental infection, or release to the environment, to negligible or zero.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**N/A**

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**N/A**

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All bacteria will be handled and disposed of using rigorous procedures, including autoclave of all cultures and contaminated materials. All genetically modified E. coli will be cultured in volumes of less than 100 ml (except for large scale production in an E. coli expression host) in the Microbiology laboratory. Genetically modified bacteria will always be contained and handled in a class 1 microbiological safety cabinet within a category 2 laboratory. Genetically modified pathogenic bacteria will be cultured in volumes of less than 100 ml in sealed containers that can be autoclaved. All liquid cultures will be transferred in sealed containers to be autoclaved before disposal via the sink. Solid media on which modified bacteria have been cultured will also be transferred in sealed containers to be autoclaved before disposal. All liquid non-recombinant E. coli cultures will be sterilised in a 2% (v/v) phenolic disinfectant (Hycolin) for 24 hours before disposal down the sink waste. Solid media on which genetically modified E. coli have been grown will be autoclaved before disposal. If, in the unlikely event the genetically modified E. coli should escape the risk will still be negligible, as the host E. coli are disabled and unable to colonise a human host or persist in the environment. The risk of escape of genetically modified test pathogens will be negligible because of the level of containment that we propose to use. In the unlikely event of an escape of these bacteria the genetically modified organism is unlikely to survive for more than a very short time in the environment. The risk of transfer of vectors from genetically modified E. coli to environmental organisms is also low due to the non-mobilisable nature of the vectors to be used.

To reduce the likelihood of transmission of GMMs to people in the laboratory, in addition to the precautions detailed above (recombinant test bacteria and, where appropriate, recombinant E. coli to be contained and handled in class 1 cabinet) laboratory personnel will wear gloves to reduce the likelihood of contamination of hands. All waste produced while handling genetically modified test bacteria will be transferred immediately by the person handling the organism to be autoclaved. Contaminated laboratory coats will also be autoclaved.

These measures are considered to reduce the likelihood of any potential hazard effectively to zero.
The risk assessment were discussed thoroughly, and passed, at the appropriate committee.

Project Ref 594/02.1

Date Ackn'd: 18/02/2005

CU2 Project Title: THE REGULATION OF CD95 (FAS) EXPRESSION BY MEMBRANE TRAFFICKING

Class: Class 2

Consent Granted: Not Applicable

Class Culture Vol Class 2 Culture Volume Class 3-4

< 1 Litre

Non-GMM

Project notified under transitional arrangements: N

Historical Significant Changes: GM94/02.1 TRANSFERRED TO GM470 ON 18/02/2005
### Project Additional Information

#### Purposes of the contained use

CD95 is a cell surface protein that transduces apoptotic signals critical to B cell development. Loss of CD95 function may also be important in the genesis of B cell lymphoma. We have made the novel observation that expression of CD95 in certain B cell lymphomas appears to be regulated by membrane trafficking (1). This project will investigate the mechanisms controlling trafficking of the CD95 molecule. The project is based on the creation of cell lines expressing tagged recombinant wild type or mutated CD95. Retroviral vectors are the most efficient tools for creating such cell lines.

#### Recipient or parental organism

The commercially available retroviral packaging cell line PT67 (expressing viral proteins gag, pol and env in trans) will initially be used to facilitate the production of replication incompetent retrovirus that can be used to introduce CD95 into other mammalian cells lines which will be used for trafficking studies.

Recombinant virus will be used to transduce the Burkitt's lymphoma - like cell lines Mutu I and Mutu III will also be transferred into immortalised (virus-negative) human breast cancer cell lines MCF-7.

Future studies may require introduction of constructs into additional, known virus-negative human cell lines.

All cell lines to be used are considered to be equivalent to ACDP hazard Group I and are routinely handled using Class I containment precautions.

#### Host/vector system

pRevTet off and pRevTreat are commercially available retroviral vectors derived from moloney murine leukaemia virus and moloney murine sarcoma viruses respectively. The expression of cloned inserts within pRevTet off is tightly controlled using tetracycline. Both retroviruses are defective, that is they lack the genes necessary (gag, pol and env) to undergo a full found of replication outside their packaging cell line PT67N.

The cell line PT67N provides the genes in trans that are missing in the retroviral vector. This is a commercially available standard packaging cell line.

Virus containing the cloned insert is produced transiently in the packaging cell line and used to transduce the target cell lines Mutu I, Mutu III or MCF-7.

#### Origin & function

Human CD95 is readily available as a cloned reagent from investigators. A CD95/CFP (cyan fluorescent protein) fusion protein will be generated as well as fusion proteins containing mutations within CD95 itself. These constructs will be cloned into the pRevTet off vector under the tight control of the tetracycline operator and used to transduce the target cell lines. Trafficking of the wild type fusion protein and the effect of mutations on trafficking will then be observed.

#### Evaluation of foreseeable effects

Modification of the retroviral packaging cell line PT67 or the Burkitt's lymphoma - like cell lines Mutu I and Mutu III by introduction of recombinant CD95 is considered highly unlikely to affect the ability of these cell lines to establish themselves in a mammalian host. These GMOs are therefore considered to pose no significant risk to human or animal health or the environment.

The effects of expressing mutant forms of CD95 in cells already expressing wild type protein are unknown, however, the possibility of generating a trans-dominant mutant within an amphotropic retrovirus must not be discounted. CD95 is not an oncogene but deletion of CD95 has been linked to development of lymphoma. This situation could potentially arise if workers were accidentally exposed to packaged recombinant retrovirus and the virus became integrated into mammalian cells. This likelihood will be minimised by use of a Class 1 Microbiological safety cabinet for all manipulations involving packaged recombinant retrovirus and derivation of stable cell lines. The risk from accidental exposure of workers to recombinant retrovirus is also likely to be further reduced by the nature of the defective retrovirus which dictates that replication is only possible within the packaging cell. Once integrated into mammalian cells the retrovirus is unable to replicate and produce further virus.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Once the cell lines have been established they are considered to pose no threat to human or animal health or the environment as the defective retrovirus can not undergo replication and viral particles are not produced. It is therefore requested that to make effective use of these reagents, once the cell lines have been established they are classified as equivalent to ACDP hazard Group 1 organisms allowing their use under containment procedures, appropriate for Class 1 activities.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid and liquid waste will be autoclaved to achieve a 100% kill. Autoclave waste will then be removed from the site by licensed disposal contractors prior to disposal to landfill.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The initial assessment was modified to recognise the potential risk to human health of packaged retrovirus to be used for transfection into cell lines for trafficking studies and this part of the work was considered to require the additional containment precautions of a Class 2 activity plus the use of a Class 1 microbiological safety cabinet.

02/03/2022
The aim of this project is to develop a single cycle infection system to study the role of hepatitis C virus (HCV) and human immunodeficiency virus (HIV) glycoproteins in cell attachment and entry. The unavailability of an efficient culture system for HCV has restricted the study of the mechanisms of HCV infection and development of effective antiviral agents. Several research groups have developed systems to generate infectious pseudoparticles displaying heterologous viral glycoproteins in their functional form onto retroviral core particles. Recently, Bartosch et al. (2003) described such a system for producing pseudotype particles carrying functional HCV glycoproteins on their surface.

The pseudotype retrovirus systems utilise replication-defective packaging and transfer vectors. The transfer vectors containing the transgene are rendered replication-defective by inactivating critical genes involved in viral replication (e.g., the env, nef and vpr genes), which still retain the viral cis-acting sequences such as LTRs, packaging sequences and regions involved in reverse transcription. The transfer vectors are propagated by trans-complementing constructs (packaging vectors) which supply in trans the packaging proteins whose genes have been deleted in the transfer vector. The packaging vectors are also replication defective as they lack cis-acting sequences such as LTRs, packaging sequences, some structural genes (e.g., gag and pol) and regions involved in reverse transcription. The trans-complementing factors on the packaging vectors can be segregated and supplied as two separate complementing genomes, the first one for the Gag-pol proteins and the second one for the viral glycoproteins. For the generation of pseudotype particles, the glycoproteins derived from the virus of interest are used.

The project will utilise existing retroviral transfer/packaging vectors and vectors encoding HCV or HIV glycoproteins supplied in trans to produce infectious replication-competent pseudotype viruses. Three packaging/backbone vectors will be used: two derived from HIV and the other from murine leukaemia virus (MLV). Three systems will be used because they have been shown to have different efficiencies in different cell types.

Recipient or parental organism

HCV pseudotype particles generated in mammalian cells will carry recombinant RNA genome and are capable of infecting human (and possible animal) cells. The particles are likely to be hepatotropic due to the presence of HCV glycoproteins on their surface and could infect the target cells if accidentally injected into humans. Alternative routes of transmission are unlikely to be successful since the HCV envelope proteins will determine the tropism, and route of entry. Upon cell entry and uncoating the genome will be transcribed and proteins synthesized. However, the packaged RNA genome is incapable of replication and therefore no virus progeny will be produced.

HIV pseudotype particles generated in mammalian cells will carry recombinant RNA genome and are capable of infecting human (and possible animal) cells. The HIV envelope proteins will therefore confer the ability to infect cells expressing CD4 plus one of the known co-receptor molecules (e.g., CCR5 and CXCR4), which are
predominantly, but not exclusively, expressed on cells of the immune system. The particles could therefore infect the target cells if accidentally injected into humans. Upon cell entry and uncoating the genome will be transcribed and proteins synthesized. However, the packaged RNA genome is incapable of replication and therefore no virus progeny will be produced.

Host/vector system

1st generation HIV vector (pNL4-3.Luc.R-.E-): HIV is a category 3 human pathogen that is predominantly transmitted via sexual contact, vertical transmission (from infected mother to infant) and also via contaminated blood and blood products (eg needlestick injury). The transfer vector, pNL4-3.Luc.R-.E, is a disabled (ie replication-incompetent) retroviral vector carrying the provirus sequences derived from HIV isolate NL4-3. The construct has been rendered replication defective by introducing two frameshift mutations into the vpr and env genes. In addition, a reporter gene has been introduced into the nef gene, rendering the vector nef. Two versions of the vector will be used. One has the reporter gene firefly luciferase (lux), whilst the other contains green fluorescent protein (GFP). This vector retains all the cis-acting elements (such as LTRs, packaging sequences and regions involved in reverse transcription) and encodes functional Gag-pol proteins necessary for particle assembly and secretion. In addition, it also encodes all the remaining viral proteins.

The pseudotype virus particles will be recovered from the vector backbone by co-transfecting mammalian cell lines with vector expressing CMV promoter-driven HCV envelope proteins E1 and E2 or HIV gp120/41 (see below). These pseudotype particles will package the original defective backbone pNL4-3-derived RNA.

2nd Generation HIV packaging/reporter vectors (Packaging vector pCMV D R8.91, lentiviral reporter vector pWPT-GFP: pCMV D R8.91 is a disabled (ie replication-incompetent) HIV-1 retroviral vector that has been rendered replication defective by removing the accessory genes vpr, vif, vpu and nef as well as the env gene. This acts as a source of reverse transcriptase and gag proteins, which assemble and package transcripts produced from the pWPT-GFP vector. This vector is the only genetic material transferred to the target cells. It comprises the transgene cassette (GFP) flanked by cis-acting elements necessary for its encapsidation, reverse transcription and integration. The vector is a self-inactivating (SIN) HIV-1-derived vector, which loses the transcriptional capacity of the viral long terminal repeat (LTR) once transferred to target cells. This minimises the risk of emergence of replication competent recombinants (RCR) and avoids problems linked to promoter interference. The post-transcriptional regulatory element of woodchuck hepatitis virus has been inserted to enhance transgene expression.

MLV (MLV-CMC pr-gag-pol and MLV-CMVpr-GFP): MLV is an amphotropic virus but is non-pathogenic to humans. Vectors derived from MLV are frequently used in gene transfer/therapy experiments. Here we propose to use a three vectors systems for generating HCV pseudotype particles. The three vectors are: the MLV-CMV/pr-gag-pol packaging vector (which serves as a source of retroviral packaging proteins and is transcribed via a CMV promoter), a transfer vector, pMLV-CMVpr-GFP (carrying CMV promoter-driven GFP transcriptional unit flanked by MLV LTRs and a packaging signal), and a plasmid expressing HCV glycoproteins (see below). Complete pseudotype particles will be produced from mammalian cells co-transfected with the three plasmids.

Vectors containing the HCV glycoprotein (envelope) genes: The HCV envelope genes E1 and E2 derived from various genotypes have been amplified via PCR and directly cloned into pcDNA3 based vectors that contain the CMV early promoter to facilitate mammalian protein expression.

E.coli host. The vectors will be maintain in the TOP10F strain of E. coli (F mcrA [mrr-hsdRMS-mcrBC], 80lacZ M15, lacX74, deoR, recA1, araD139 [ara-leu]7697, galU, galK, rpsL, endA1, nupG) or other K-12 derived laboratory strains that are non-colonising and disabled. The survival of these bacteria in the environment is expected to be low as they have multiple auxotrophic requirements that are unlikely to be met outside of laboratory culture: the recA1 disablement of TOP10F means that it is unable to repair DNA by homologous recombination and is UV sensitive, and the [ara-leu] 7697 mutation shows that it is auxotrophic for leucine, and unable to grow in the presence of arabinose.

Origin & function

pNL4-3.Luc.R-.E-: The transfer vector, pNL4-3.Luc.R-.E, is a disabled (ie replication-incompetent) retroviral vector carrying the provirus sequences derived from HIV isolate NL4-3. The construct has been rendered replication defective by introducing two frameshift mutations into the vpr and env genes. In addition, a reporter gene has been introduced into the nef gene, rendering the vector nef. The original pNL4-3 clone was derived from NY5 (5’) and LAV (3’) cloned directly from genomic DNA into pUC18.
This vector retains all the cis-acting elements (such as LTRs, packaging sequences and regions involved in reverse transcription) and encodes functional Gag-pol proteins necessary for particle assembly and secretion. In addition, it also encodes all the remaining viral proteins, apart from vpr, as well as a reporter gene. Production of pseudotype viruses occurs when this plasmid is co-transfected with the viral glycoprotein-carrying pcDNA3 vectors.

MLV-CMVpr-gag-pol: The MLV-CMVpr-gag-pol packaging vector serves as a source of retroviral packaging proteins and is transcribed via a CMV promoter. Production of pseudotype viruses occurs when this plasmid is co-transfected with the viral glycoprotein-carrying pcDNA3 and the MLV-CMVpr-GFP vectors.

MLV-CMVpr-GFP: The MLV-CMVpr-GFP vector (carrying CMV promoter-driven GFP transcriptional unit flanked by MLV LTRs and a packaging signal), acts as a transfer vector. Production of pseudotype viruses occurs when this plasmid is co-transfected with the viral glycoprotein-carrying pcDNA3 and the MLV-CMVpr-gag-pol packaging vector.

Vectors containing the HCV glycoprotein (envelope) genes: The HCV envelope genes E1 and E2 derived from various genotypes have been amplified via PCR and directly cloned into pcDNA3 based vectors that contain the CMV early promoter to facilitate mammalian protein expression. This vector acts as a source of viral glycoproteins for pseudotype formation.

Evaluation of foreseeable effects

The vectors may be able to undergo recombination with endogenous retroviruses present in the culture cells (or accidentally infected host), or package transcripts from endogenous retroviral sequences. Also, the vectors could undergo recombination with wild-type virus. However, the resulting recombinant would not be more pathogenic than the wild-type virus.

Pseudotype viruses could in principle cause infection, but would not replicate. The potential target cell would be dictated by the envelope proteins incorporated into the pseudotype virus (ie HCV envelope proteins). Infection by pseudotype virus would result in reverse transcription then possible integration of the packaged genome. This in turn might lead to the production of viral/reporter proteins, but as the genome is defective, new infectious virus would not be produced. The effect of GFP or luciferase expression on the host cell is unknown, whilst some of the HIV gene products have been shown to have some detrimental effects (eg apoptosis, toxicity etc), at least in vitro. Whilst, cells producing viral proteins would be targeted by the host immune response (eg cytotoxic T-cells), it cannot be assumed that exposure to the GMM will not cause harm.

Containment and control measures for GMOs that are not microorganisms (eg GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

HCV E1E2 pseudotypes produced using the pNL4-3 system: The parental virus for the pNL4-3 vector is a category III organism. Infection by the pseudotype virus would lead to the production of viral proteins and reporter proteins. The pathogenic potential of these proteins is largely unknown, although some effects have been reported in in vitro studies. Whilst the resulting pseudotype virus produced is infectious, it is not able to replicate. Infection could lead to insertion of the packaged genome into the host chromosome. However, it lacks known transforming sequences. The risk of recombination between the HCV E1E2 containing vector and the pNL4-3 is low. As the inactivating mutations within the pNL4 backbone are small deletions there is a small risk of reversion and subsequent production of wild type virus. However, the cell lines used to produce the pseudoviruses are incapable of supporting HIV replication. Even so, the viruses are infectious and are capable of integration and subsequent protein production. There is a small but real risk of the mobilisation of endogenous retroviral sequences and the formation of replicative competent retroviruses. Therefore we propose that the containment level for this aspect of work is Level 2, with the following additional precautions.

All work involving the pseudotype viruses to be carried out within a Class 1 or Class II safety cabinet located in a room where access is restricted at times when manipulations involving these viruses are taking place. The work will involve standard laboratory procedures, however, considering the routes of infection of the viruses (parenteral), no sharps or glassware will be used when handling the pseudotype viruses. All solid waste materials will be autoclaved and liquid waste disinfected with gluteraldehyde. Training records for all new staff using these methods will be kept.

HCV and HIV pseudotypes produced using the 2nd Generation HIV packaging/reporter vectors (Packaging vector pCMV DR8.91, lentiviral reporter vector pWPT-GFP):
pCMV D R8.91 is a disabled (i.e. replication-incompetent) HIV-1 retroviral vector that has been rendered replication defective by removing the accessory genes vpr, vif, vpu and nef as well as the env gene. This acts as a source of reverse transcriptase and gag proteins, which assemble and package transcripts produced from the pWPT-GFP vector. This vector is the only genetic material transferred to the target cells. It comprises the transgene cassette (GFP) flanked by cis-acting elements necessary for its encapsidation, reverse transcription and integration. The vector is a self-inactivating (SIN) HIV-1-derived vector, which lose the transcriptional capacity of the viral long terminal repeat (LTR) once transferred to target cells. This minimises the risk of emergence of replication competent recombinants (RCR) and avoids problems linked to promoter interference. The post-transcriptional regulatory element of woodchuck hepatitis virus has been inserted to enhance transgene expression. Complete retroviral particles are produced in the presence of a third vector containing the viral glycoproteins under study. Infection of actively replicating cells allows reverse transcription of the RNA genome and subsequent integration of the GFP marker protein. Upon accidental transmission, the transcribed GFP cDNA may become integrated into recipient cells. The transfected cells will contain viral genes on split plasmids. Details of the constructs and the demonstration that they do not give rise to replication competent viruses are available in Zufferey et al Nat Biotechnol. 15: 871-875. There is evidence that such replication defective retroviruses are not pathogenic when tested in mice. Therefore we propose that the containment level for this aspect of work is Level 2, with the following additional precautions:

All work involving the pseudotype viruses to be carried out within a Class 1 or Class II safety cabinet located in a room where access is restricted at times when manipulations involving these viruses are taking place. The work will involve standard laboratory procedures, however, considering the routes of infection of the viruses (parenteral), no sharps or glassware will be used when handling the pseudotype viruses. All solid waste materials will be autoclaved and liquid waste disinfected with gluteraldehyde. Training records for all new staff using these methods will be kept.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 2: All work involving the pseudotype viruses to be carried out within a Class 1 or safety cabinet located in a room where access is restricted at times when manipulations involving these viruses are taking place. All solid waste materials will be autoclaved at 134-137 degrees C, 21.-2.2 bar pressure with a holding time of 5 minutes. A chart record is maintained for each run. Autoclaves are also subject to quarterly thermocouple testing. All liquid waste known to be, or potentially infected with category 2 viruses will be discarded into a 500 ml polyethylene discard pot containing 50 ml of 100% Gigasept, so that when full with liquid waste the final concentration of Gigasept will be 10%. An expiry date for the gigasept, which should be two weeks from the date of first use, will be written on the surface of the discard pot. If the discard pot is not full before this expiry date then the discard pot will be filled to 500 ml with water and left for 24 hours to inactivate virus. Preparation of working dilutions of Gigasept will be carried out within the class 1 cabinet.

Containment level 3: All liquid waste known to be, or potentially infected with category 3 viruses will be discarded into a 500 ml polyethylene discard pot containing 50 ml of Gigasept, so that when full with liquid waste the final concentration of Gigasept will be 10%. An expiry date for the gigasept, which should be two weeks from the date of first use, will be written on the surface of the discard pot. If the discard pot is not full before this expiry date then the discard pot will be filled to 500 ml with water and left for 24 hours to inactivate virus. Preparation work working dilutions of Gigasept will be carried out within the class 1 cabinet. All solid waste will be autoclaved prior to disposal. Autoclaving of waste will take place using a destructive cycle of 126 degrees C for 45 minutes. The maximum load will be one autoclave bag (containing a maximum of 2 laboratory gowns) together with 4 discard pots. The autoclave is checked on a 6 monthly basis by independent thermocouple testing using typical loads. Cabinet generated solid waste will be accumulated in paper bags placed within the cabinet. At the end of each working period the waste will be placed into an autoclave bag and transferred to the autoclave. Solid waste bags will be left open and screw-capped lids loosened prior to autoclaving to allow steam penetration. Discard of all Gigasept solutions will take place using the designated sink within the main virology laboratory.

**Project Additional Information**

**Purposes of the contained use**

The project aims to investigate whether the filamentous fungus *Aspergillus fumigatus* has the potential to undergo sexual reproduction. Recent genome analysis has revealed the presence of a series of genes involved with sexual reproduction, some of which are known to be expressed. However, the fungus is only known to reproduce by asexual means. Resolving this question is of major significance to understanding the population biology of this species in the wild and related management of the fungus. Insights into the sexual potential of the species might also allow exploitation of the sexual cycle in classical genetic studies to study inheritance of traits such as fungicide sensitivity/resistance or pathogenicity determinants.

There are two broad areas in which recombinant gene technologies will be used.

A) Cloning of putative genes involved in sexual development from *A. fumigatus* into E. coli hosts and vectors. This comprises genes regulating sexual compatibility, genes involved in sexual pathway signalling and genes involved with fruit body development.

B) Transformation of fungal genes involved in sexual development into fungal hosts. This encompasses:

- Transformation of putative sexual genes from *A. fumigatus* into class 1 ADCP host strains which lack the ability to undergo sexual reproduction as a result of previous gene disruption. This will allow complementation studies to assay the functionality of the *A. fumigatus* genes.
- Transformation of known functional sexual genes from class 1 ADCP host strains into *A. fumigatus*. These genes will be either under the control of native, constitutive or inducible promoters. Such studies may result in enhancement/restoration of sexual development in *A. fumigatus*, allowing possible exploitation of the sexual cycle.

Such studies have already been performed with sexual and asexual relatives of the plant pathogens *Cochliobolus* and *Bipolaris* species in the USA.

**Recipient or parental organism**

**Fungal strains.** *Aspergillus fumigatus* is a common environmental species, widespread in soil and in decomposing vegetation. It is not normally a risk to healthy persons. However, it occasionally causes aspergillosis, an invasive disease of the lungs and other organs, upon opportunistic infection of immunocompromised patients. It may also cause opportunistic infections of patients with existing medical disorders. The spores may in addition cause allergic reactions in certain patients. Thus the fungus is classified as ADCP class 2 (a potentially pathogenic microbe). More detail available in risk assessment.

**Bacterial strains.** The E.coli strains to be used are all Rec A-derivatives such as DH5a, XL1-Blue, SURE and TOP10. These strains are disabled and non-colonising and are equivalent of ADCP category 1 organisms (ie non pathogenic to humans or animals). They have limited survivability in the environment as they require specific nutrients supplements not required by wild-type organisms.

**Host/vector system**

**Fungal vectors.** These are pUC and pBR322-derived plasmids that will be maintained in E. coli host before transfer to a fungal host organism. Some plasmids will have fungal promoters that are either constitutive or induced under certain environmental conditions. Vectors are integrated into the fungal genome and considered non-mobilisable or mobilisation defective.

**Bacterial vectors.** These are pUC derivatives encoding ampicillin, zeomycin or other antibiotic resistance markers. Considered to be non-mobilisable.

**Origin & function**

Inserts are genes involved with sexual development in filamentous fungi. These may be categorised into three main areas:

a) Genes involved with determination of sexual compatibility. Examples include mating-type (MAT) genes determining sexual identity, pheromone precursor genes involved...
with production of short chain amino-acid pheromones; pheromone processing genes involved with enzymatic modification of pheromone precursor molecules.

B) Genes involved with sexual signalling pathways. Examples include pheromone receptor genes encoding transmembrane surface receptors, a series of MAP kinase elements involved with signal transduction, and final transcription factors activating sexual development.

C) Genes involved with fruit body development. These include genes encoding hormonal factors regulating hyphal morphogenesis, and transcriptional factors altering developmental pathways.

These genes are not virulence determinants so unlikely to alter the pathogenicity of the host organism. The antigenicity of these proteins is not known. Previous work with similar genes involved with sexual development in fungi has not revealed any risk, so the protein products are considered unlikely to pose a toxic hazard.

**Evaluation of foreseeable effects**

A fumigatus is classified as an ACDP class 2 organism (a microbe potentially capable of causing human disease). It is a common environmental fungus associated with decomposition of organic matter in soil and vegetation. It is not normally a risk to healthy persons. However, it occasionally causes aspergillosis, an invasive disease of the lungs and other organs, upon opportunistic infection of immunocompromised patients. It may also cause opportunistic infections of patients with existing medical disorders. The spores may in addition cause allergic reactions in certain patients.

The potentially most hazardous GMMs to be constructed in this work are the transformed strains of the ACDP class 2 fungus Aspergillus fumigatus. However, it should be stressed that these will be transformed with genes involved in sexual reproduction, which themselves have no known link to virulence or pathogenicity. They are not involved with toxin production, so unlikely to alter the pathogenicity of the host organism. Also the strains to be transformed will be pre-screened to ensure that they are sensitive to the main antifungals (Amphotericin B anditraconazole) used in clinical treatments.

The genes under study, those involved with sexual reproduction in ascomycete fungi, are widespread in numerous ascomycete fungi in the wild with the same functional gene families present in many harmless fungi. Thus potential transfer of such genes is not considered a risk, as it is stressed again that the genes under study do not related directly to the pathogenic potential of A. fumigatus.

There is the potential hazard that resultant GMM strains of A. fumigatus may have enhanced sexual fertility, which may be spread into wild-type strains of A. fumigatus through sexual recombination, promoting gene flow within the species. This might conceivably include flow of genes linked to virulence. However, there is no known occurrence of a sexual cycle of A. fumigatus in the wild and it is thought that A. fumigatus reproceses only by asexual means. Thus, if sex does occur in the wild it is at likely to be of very low occurrence if at all. Therefore there is low risk of spread of genes promoting sexual fertility. The hazard of spread of antibiotic resistance genes, used as selective markers, is thus also considered low risk.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste and plasticware exposed to GM material will be autoclaved prior to disposal.
Liquid waste and glassware exposed to GM material will be autoclaved prior to disposal/wash up.
Class 2 autoclave disposal facility available in same lab suite.

2% trigene will be used to swab benches and disinfect as required. It has been shown by the manufacturer to be effective for control of filamentous fungus and is used in accordance with their instructions.
Standard procedure for spillage/breach of containment involves absorbing onto paper towels followed by cleaning of area with disinfectant (2% Trigene). Paper towels then sent for autoclave.
The local GM committee approved the assessment of Class 2, subject to inclusion of some minor additions to the assessment which have been made. There were concerns raised about health of workers in respect of anyone who may be immuno-compromised or have other allergy/lung disorders. The UoN Occupational health physician was consulted and has advised that staff who are working on the projects will complete a health screening questionnaire and be approved as fit for the work by OH Department.

In addition the assessment was submitted to 4 other scientists for review:
Dr Alastair Chambers, School of Biology, University of Nottingham
Dr Marcos Alcocer, School of Biosciences, University of Nottingham, Loughborough, Leicestershire
Dr M Dickinson, School of Biosciences, University of Nottingham, Loughborough, Leicestershire
Dr S Avery, School of Biology, University of Nottingham, University Park, Nottingham

All supported assignment to Class 2 and any comments made were incorporated into the assessment.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Maximum volumes used are 150 ml per time. The waste is autoclaved. All autoclaves are on a full service contract. Each run is monitored and there is a cut out if the run falls below the set times and temperatures. Each week the monitoring is checked by an engineer.

For activities involving GMMs, describe the waste management measures which will apply to the activity

No bacterial culture will be greater than 20 ml in volume. After processing, all bacterial pellets and plasticware used for processing will be sealed and added to a "Sinbin" (normally used for "sharps" disposal). This will be sealed on the same day and then transported to the hospital incinerator. All surfaces will be decontaminated with Virkon immediately after use.

Contaminated materials are sterilised either by autoclaving (solids, small liquid volumes) or by treatment with hypochlorite solution (liquid cultures).

Operations involving animals (fish) are conducted in contained laboratories and all effluent is treated with a hypochlorite drip prior to release. The sterility of the effluent is monitored at regular intervals. Transgenic animals are destroyed by incineration at the end of each experiment.

Genetically modified plants are autoclaved prior to disposal.

Both buildings have autoclaves on site that are tested annually. Chemical disinfection of materials is carried out with a standardised hypochlorite solution according to local rules.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Project Ref 479/13.1

Date Ackn'd 29/07/2013

Date Project Ceased

CU2 Project Title The use of lux-marked non-toxigenic strain of Escherichia coli O157:H7 and a lux marked strain of Salmonella enterica serovar typhimurium to study the effect of environmental parameters on the survival and activity of possible pathogens

Class 2

CultureVol

Class 2 < 1 Litre

Non-GMM Consent Granted

Project notified under transitional arrangements

Historical Significant Changes

Tick if notifying a connected programme of work
E. coli O157:H7 is a toxigenic strain of E. coli and ingestion of the organism may occasionally lead to severe illness including life threatening hemolytic-uremic syndrome. E. coli O157:H7 is a class 3 organism according to the ACDP classification and as such requires level 3 containment for safe use, a requirement that can limit studies on this organism due to the expense of constructing and maintaining such facilities. A naturally occurring strain of E. coli O157:H7, retaining the O157 and H7 phenotypes but which is non-toxigenic, since it lacked the toxin genes stx1 and stx2, was previously chromosomally marked with the lux CDABE cassette using transposon mutagenesis to provide a low-risk substitute to verocytotoxin producing E. coli O157:H7 in environmental survival studies (Ritchie et al 2003). A strain of S. enterica serovar typhimurium containing a plasmid borne lux gene fusion is also available enabling safer and more accurate detection and quantification of this organism (Lewis et al. 2006). The purpose of this project is to use a luminescence assay to determine how a range of environmental parameters effect the survival and activity of the bacteria. This project will not involve the creation of any new GMOs.

Recipient or parental organism

The recipient E. coli strain was a naturally occurring isolate of E. coli O157:H7 which was shown via PCR to lack the genes stx1 and stx2 which encode cytotoxins. The recipient Salmonella strain was S. enterica serovar typhimurium DT104 which is a well characterised and common pathogen in humans.

Host/vector system

The recipient E. coli strain was mated with E. coli s17 lamda pir which contained a suicide plasmid harbouring a transposon Tn5 derivative with a luxCDABE cassette. The absence of the suicide plasmid in the transposon mutated E. coli O157:H7 strain was confirmed by an inability to grow on ampicillin (the plasmid conferred ampicillin resistance) and via small scale plasmid DNA preparations. The recipient S. enterica strain was transformed, via electroporation, with the broad host range plasmid pBBR1MCS-5 in which the lux CDABE genes from Photorhabdus luminescens had been cloned. Gentamycin selection was used to confirm transformation since the plasmid encodes gentamycin resistance.

Origin & function

The genetic material transferred to the E. coli O157:H7 strain included a gene for kanamycin resistance enabling antibiotic selection for successful transposon mutagenesis together with the lux CDABE cassette from Photorhabdus luminescens encoding the ability to produce bioluminescence. The genetic material transferred to the S. enterica strain strain included a gene for gentamycin resistance enabling antibiotic selection for successful transformation.
together with the lux CDABE cassette from Photorhabdus luminescens encoding the ability to produce bioluminescence.

Gentamycin is not generally used by General Practitioners to treat cases of Salmonella infection. Gentamycin is not systemically active when given orally, as it is not taken up to any great extent from the small intestine. The therapeutic use of this antibiotic for Salmonella is thus largely limited to intravenous or intramuscular injection in a hospital setting. In addition, gentamycin has ototoxic and nephrotoxic properties (Gronroos et al., 2008; Kusunoki et al., 2004) and is not likely to be a drug of first choice for Salmonella infections. A number of other antibiotics are available for the treatment of Salmonella infections, for example cefotaxime and ciprofloxacin (The British National Formulary). The potential impact of the introduction of gentamycin resistance into S. Typhimurium is very limited. Many Salmonella infections do not require antibiotic treatment and due to the toxic side effects of gentamycin and a lack of efficacy when administered orally it is not widely used for treating Salmonella infections. Alternative antibiotics are available and the genetically modified strain of Salmonella remains a hazard group 2 microorganism.

Evaluation of foreseeable effects

There are no hazards arising directly from the inserted DNA since the genes do not encode the production of any toxins or other virulence factors or extend the host range of the bacteria. In the case of the genetically modified strain of E.coli, the likelihood of the inserted DNA being transferred to related organisms is small and in any case they would not increase the pathogenicity of the recipient organisms. The naturally occurring non-toxigenic strain of E.coli O157:H7 does not pose a risk to the environment and the genetic modification performed has not resulted in any increased potential for environmental damage. The likelihood of the inserted material in the modified strain of S.enterica being transferred to other organisms is greater since the plasmid containing the cloned DNA has a broad host range and is mobilisable if the RK2 transfer function is provided in trans (Kovach et al 1995). However, even if transfer did occur it would not increase the pathogenicity of the recipient organisms or their ability to cause environmental damage.

It is well-established that the toxin genes stx1 and stx2 play a key role in virulence of entero-hemorrhagic strains of E.coli O157:H7. The lack of stx genes in the naturally occurring non-toxigenic strain of E.coli O157:H7 means that it is a low risk to human health. However, if this bacteria were to acquire the ability to produce toxins via plasmid transfer from another organism it has the potential to cause disease since it retains the intimin phenotype and can colonise human guts (Ritchie et al. 2003). In such circumstances the genetic modification of the strain increases the risk to humans marginally since kanamycin would no longer be an effective antibiotic with which to treat any disease. It should be noted, however, that kanamycin is actually very rarely used as a treatment for E. coli O157:H7 infections in any case.

S.enterica serovar Typhimurium DT104 is recognised as a major cause of food poisoning worldwide and is assigned to Hazard Group 2. The wild type strain is characterised by multiple drug resistance and hence the genetic modification does increase marginally the risk to human health since gentamycin would no longer be an effective treatment in case of infection.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not Applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not Applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

This work will produce a variety of wastes including contaminated pipette tips, agar plates and liquid cultures. Contaminated pipette tips are immediately placed in a solution
of sodium hypochlorite (12-14% v/v aqueous solution) and subsequently autoclaved using a cycle including an initial steam purge and kill step of 121 °C, 15 psi for 20 minutes. All petri dishes and liquid wastes are killed via autoclaving as described above. Autoclave tape is routinely used and the efficacy of the kill cycle regularly checked by autoclaving a thick culture (approx 1 E9 colony forming units per ml) and subsequently plating on non selective agar and checking for growth at 37 °C over a 4 day period. All autoclave use is documented and autoclaves are subject to regular inspections and maintenance.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

All small volumes produced will be autoclaved and then disposed of in yellow bags for incineration, as per UWCM/Trust policy. Cell remnants and solid waste will be treated in the same manner. Autoclaves operated in accordance with the departmental SOP and serviced and tested by the Trust Works Dept.

Larger volumes of liquid waste - no greater than 1 litre - will be disinfected by the addition of bleach (hypochlorus acid) to a final concentration of 10% before disposal.

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

02/03/2022
### Purposes of the contained use

- Preparation of microorganisms
- Evaluation of virulence and protection in mice evaluation of immune responses in mice

### Recipient or parental organism

- Strain B16B6, Neisseria meningitidis. It is possible some mutants will be based on strains of other stereotypes, for instance H44/76, but all will be Neisseria meningitidis group B.

### Host/vector system

- E coli

### Origin & function

The objectives of the project are to construct stable, disabled strains of N. meningitidis by genetically modifying genes that are essential for growth of the organism in the host. These strains can then be used safely for experiments that at present involve virulent, clinical isolates. Furthermore by modifying the expression of global regulators of virulence (such as fur and lux homologues), surface expressed determinants such as LOS and Opc, and recombination or DNA uptake systems (such as recA and comA respectively) construct an enhanced live attenuated vaccine.

The initial E.coli and Neisseria recombination work will be performed in the Institute of Infections and Immunity at the University of Nottingham. Certain reagents, including transformation stocks of Neisseria containing mixtures of parental, single recombination event-generated recombinants, and cells carrying the desired deletions, will be stored at Cantab as a back-up source of materials. Neisseria cultures grown at Cantab will consist of auxotrophic mutant strains, strains that are rendered more biosafe or have disrupted cell division and strains that are altered for the expression of the fur. The cultures grown at Cantab will then be transported to Churchill to be tested in a mouse model for safety, efficacy and immunogenicity.

The strains to be used in the in vivo evaluation experiments will either be deletion mutants in one of the genes specified in the list below, or combinations of deletions of two or more of these genes. The design of the final vaccine strain will be based on the experimental findings using the single and multiple deleted constructs. The strains may still have resistance genes to kanamycin, erythromycin or tetracyclin in the deleted portion of the organism. This is a transient stage, as the final vaccine will not contain antibiotic resistance genes. None of the antibiotic resistance genes present in the constructs is used to treat Neisseria meningitidis clinically.

### Evaluation of foreseeable effects

<table>
<thead>
<tr>
<th>Origin &amp; function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>asd</td>
<td>Genes involved in the synthesis of the essential nutrient diaminopelic acid (DAP). A lesion in the gene asdA, encoding the enzyme aspartate B-semialdehyde dehydrogenase would render the organism auxotrophic for DAP. Since this compound is an essential constituent of the cell wall for Gram-(ve) and some Gram +(ve) organisms and is absent from mammalian tissues, mutants would undergo lysis after about 3 rounds of division in mammalian tissues.</td>
</tr>
<tr>
<td>aro</td>
<td>Mutations in any of the genes in the aro pathway would render the organism auxotrophic for aromatic amino acids. In addition any such mutation would refer a requirement for two other compounds, (1)p-aminobenzoic (pAB) and (2) 2,3-dihydroxybenzoate (DHB) neither of which are found in mammalian tissue. Any such mutant would be unable to proliferate in mammalian tissue.</td>
</tr>
<tr>
<td>pur</td>
<td>Mutations in any of the genes in the pur pathway would render the organism auxotrophic for purines essential constituents of nucleic acids. Many of the intermediates of the pathway are unavailable in mammalian tissues.</td>
</tr>
<tr>
<td>pyr</td>
<td>Mutations in any of the genes in the pyr pathway would render the organism auxotrophic for pyrimidines essential constituents of nucleic acids. Many of the intermediates of the pathway are unavailable in mammalian tissues.</td>
</tr>
<tr>
<td>fur</td>
<td>The product of the fur (ferric uptake regulation) gene controls the expression of numerous genes. Among these genes are those involved in iron uptake via high</td>
</tr>
</tbody>
</table>
affinity siderophore systems and many genes involved in virulence, such as toxins. Mutations in the fur locus may cause loss of viability of the resulting strain. Although fur is a negative regulator of gene expression it is thought that this loss of viability may be explained by the fact that in some organisms certain essential genes are positively regulated by fur. To overcome this potential problem we intend to place fur under different control. This would give low basal level of expression (required for some essential genes) and full control of fur expression by turning on or off the promoter fused to fur. Likely promoters to use are lactose, chloramphenical and tryptophan.

Cap: Gene needed to give the organism its final capsule, containing polysaccharides. Non-capsuled strains are more serum-sensitive and may lead to better immune responses. Non-capsuled stains which occur naturally are not known to cause disease.

rec: There are many genes involved in recombination but the central gene is recA. RecA is essential for all homologous recombination pathways. Mutations in recA would render the strain UV sensitive as well as unable to carry out homologous recombination to repair constructed deletions.

galE - The galE gene is essential for normal LOS/PLS in N.meningitidis and N.gonorrhoea. Without the essential galactose residue in the LOS the side chains cannot be synthesised. The result of this is a LOS with a greatly reduced size. Such mutants would no longer be resistant to the effects of human serum.

com - Mutations in this locus would render the organism unable to take up exogenously added DNA. This mutation would (along with the recA mutation) make the biosafe strain genetically isolated and therefore more stable.

min - Mutations in either of the minC, minD or minE will cause aberrant cell division and the production of DNA-less minicells or membrane vesicles.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid cultures will be chemically inactivated using Lifeguard at a ration of 1:1. This was shown to kill all measurable organisms after 5 minutes (sensitivity 99.99%). All solid waste, including mouse bodies, will be double bagged and autoclaved. Mouse bodies will then be incinerated. All sharps will be put in sharp bins and autoclaved.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The committee considered that although the risk to the health of the operator from infection with the recombinant Neisseria was negligible, the wearing of gloves and safety glasses, the use of a Class 2 safety cabinet and the avoidance of sharps where possible, would reduce the risk to essentially zero. The use of sharps cannot be avoided when working with animals, but extra care should be taken.

### Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

02/03/2022
Liquid waste is treated via one of the following routes:

**Domestos**
Contains 1000,000 ppm available chlorine on manufacture. For discharging spent medium final dilution will be 10% (if the indicator, present in the medium fails to decolorise then there is insufficient active chlorine present and additional bleach should be added).
For spillage - 10000 ppm ie 10% v/v
For contaminated glassware - 25000 ppm ie 2.5% v/v
Dilute in tap water.

**Virkon**
Use at a 1% solution and is effective in discard jars with 10 mins soaking time (solution is active when pink, inactive if colourless).
For fluid spillages Virkon powder can be applied direct.
Presept
(Bacterial, Yeast)
Dichloroisocyanurate Na salt  1,000 ppm  General lab use
2,500 ppm  Pipette jars, spent media
10,000 ppm  Blood spillages

Other Waste
All other waste including agar is autoclaved, then disposed of by incineration. The autoclave is validated annually and a certificate of calibration is issued after calibrated thermocouple test. Manual recording of the autoclave process is documented where a chart recorder is not available.

**Project Additional Information**
**Purposes of the contained use**

The aim of the project is to evaluate in malignant human glioma cell lines cytotoxicity, dose response effect, and IL12 secretion of a recombinant Semliki Forest Virus vector (SFV) expressing transgene human IL12.

**Recipient or parental organism**

The recipient micro-organism are immortalised human malignant brain tumour cells (cell lines U87MG, LNZ308, T98).

**Host/vector system**

The vector is based on SFV, an insect alphavirus naturally infecting and replicating in subtropical mosquito species only. The human IL-12 gene has been inserted downstream from non-structural genes of SFV, whose structural genes encoding essential capsid and membrane proteins have been deleted and are provided by a helper vector. Recombinant SFV vectors are produced by recombination in the packaging cell line HEK293.

**Origin & function**

The inserted cDNA encodes human IL-12, an immunostimulatory cytokine identified as an activator of the cytolytic function of NK cells, antigenspecified cytotoxic T cells, and a potent inducer of IFNγ production.

**Evaluation of foreseeable effects**

Natural SFV infection only occurs when infected mosquitoes take a blood meal from viraemic vertebrate hosts. There is virtually no risk of natural spread of SFV from one human to another or from an animal to a human in the absence of the competent mosquito vector. There are no known mosquito species susceptible to SFV in the UK and therefore the risk of virus transmission to wildlife is considered negligible. Humans infected with SFV by mosquitoes may develop mild symptoms with uncomplicated and complete recovery. The present SFV virus is not mobilisable because it is replication incompetent. Replication disabled SFV mutants have been produced by deleting structural virus genes, which are provided in trans by a helper vector for recombination in a suitable cell line. This ensures that the r recombinant SFV undergoes only one cycle of infection without further replication. In theory, replication competent virus (RCV) may be produced by recombination in the packaging cell line, but the real chance of such recombination is virtually nil because of the multiple deletions in the virus genome. In addition, the SFV vector does not encode resistance to any drug or antibiotic. The human IL-12 gene cannot be incorporated into the virus envelope, and thus the possibility of alteration of tissue tropism or host range of SFV is considered negligible. Furthermore, liposomal encapsulation further reduces natural SFV tropism. All virus preparations will be produced at the facilities of Regulon, Inc., in Palo Alto, CA, USA. Sterile recombinant SFV in suspension is delivered ready to use. The inserted human IL12 gene does not encode a pathogenic protein as proven by prior in vitro and in vivo data. No harmful biological activity of hIL12 is known.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste which may contain viable SFV vectors, such as used medium, SFV infected cells, and plastic disposable objects (flasks, pipettes, etc.) will be collected and autoclaved. The autoclaved waste will be then subjected to the normal waste management cycle in the laboratory. The autoclave is managed by a contractor company (Priorclave Tactrol). Autoclave testing and quality assurance are performed and recorded yearly. The autoclave is located in the laboratory tract immediately across the GM rooms and run by lab staff.

**Project Additional Information**

**Purposes of the contained use**

PKC has been shown to be a key signalling molecule in pathophysiology of the pancreas. The aim of this study is to examine Ca (2+) dependent/independent translocation of GFP tagged PKC isoforms in living mouse pancreatic acinar cells. A variety of PKC isoforms will be expressed in pancreatic acinar cells using replication deficient adenoviruses.

**Recipient or parental organism**

During production of replication deficient adenoviruses following Host organisms will be used: E.coli derivatives: XL1 BLUE, DH10B and a cells line QB1-HEK-293 (supplied by Obliogen, Nottingham, UK). All hosts are well characterised, non-pathogenic and are included by Obliogen (Nottingham, UK) in a standard kit for production of replication deficient adenoviruses. Finally replication deficient adenoviruses will be used to transfect freshly isolated pancreatic acinar cells maintained in primary culture. These cells are short lived, and therefore will not be able to survive outside tissue culture conditions and do not present any danger to environment.

**Host/vector system**

Vestors to be used in this project pEGFP (Clontech, Oxford, UK), pCDNA 3 (Invitrogen, Paisley, UK), pCR259 and pCR276 (Qbiogene, Nottingham, UK) pGEM, pSHUTTLE (Promega, Southampton, UK).

Recombinant PKC - GFP constructs will by produced and incorporated into virus transfer vectors. The production of replication deficient adenoviruses will require standard E. coli derivatives (XL1 Blue, DH10B) and HEK-293 cell lines.

All viral vectors contain necessary components for Tn7 transposition events. Viral vectors: pCR259, a 4488bp adenoviral transfer vector containing coding sequences for Ampicillin resistance, Tn7 transposition CMV promoter, origin of replication and a multiple cloning site. Transpose-Ad 294 vector is a 38275 bp vector containing the adenoviral genome (minus regions E1-3 needed for replication) and coding sequences for Tn7 transposition.

**Origin & function**

E. coli derivatives (XL1 Blue (Stratagene California, USA), DH10B (Qbiogene, Nottingham, UK) and QB1-HEK-293 cell lines will be purchased from Obliogen (Nottingham, UK) other vectors (see above) will be purchased from Clontech (Oxford UK), Invitrogen (Paisley, UK) and Promega (Southampton, UK). PKC encoding vectors, PKC-GFP encoding vectors and/or virus transfer vectors of these constructs and/or E1-E3 deficient recombinant viral plasmids will be received from collaborating laboratories. There are a few laboratories that developed PKC-GFP constructs (eg laboratory of Professor Saito in Tohoku University in Japan, Laboratory of Professor R. Rizzulto in University of Ferrara in Italy, Laboratory of Professor T Mayer in Stanford University, USA). We will receive constructs from one or more of these highly reputable laboratories. The overall aim of the project is to elucidate the role of PKC activation in pathophysiology of acute pancreatitis. A variety of PKC isoforms from different sources will be expressed in pancreatic acinar cells using replication deficient adenoviruses.

The cells will be stimulated by substances that could potentially be responsible for triggering acute pancreatitis (bite acids, ethanol and high doses of calcium releasing secretagogues). The activation/translocation of PKC isoforms will be monitored using fluorescence microscopy.

**Evaluation of foreseeable effects**

The PKC constructs encode functional regulatory proteins. This necessitates containment level 2. The constructs are linked to non-hazardous reporter proteins (eg GFP). Viruses containing constructs of interest could potentially be able to infect human cells. However these viruses would not be able to replicate in human cells. The recombinant adenoviruses made with Transpose-Ad expression system kits are replication deficient viruses that have deletions in the E1 and E3 regions; they will not replicate in cells other than complementing cells (QB1-HEK-293).

The E.coli derivatives to be used are disabled, non-pathogenic in man and considered ACDP group 1. The DNA inserted plasmid is eukaryotic in origin, contains a promoter which does not encode for a protein and hence is not hazardous, the marker proteins (eg green fluorescent protein) have no known hazardous effects. Eukaryotic genes delivered are unlikely to give a selective advantage to the E. coli host and it is unlikely that they would be processed in bacteria correctly as they contain eukaryotic signals eg for mRNA processing.
Established mammalian cell lines require defined media and conditions for growth, and therefore are unable to survive outside these conditions.

Isolated pancreatic acinar cells are short living cells, and unable to survive more than 24 hours after isolation.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Both liquid and solid GM waste produced during the stages of virus production including and following transfection of QB1-HEK293 cells will be autoclaved to achieve 100% kill prior to disposal. Autoclaving will be done at the end of each working day when contained work has been carried out. The autoclave is managed by laboratory staff and maintained by Priorclave engineers. The autoclave is services and calibrated every half year by Priorclave engineers. The autoclave is located in the laboratory suite (room 1.05a in Henry Wellcome Gastro Laboratories). Both liquid and solid waste will then be sent for incineration.

Solid waste produced at earlier stages of the virus production (including bacterial culture plates, disposable plastic pipettes, pipette tips and microfuge tubes) will be disposed of into autoclave bags in dedicated bins for regular autoclaving. Autoclaved waste will be later incinerated. Disposable culture vessels and other contaminated glass and plastic ware will be soaked in disinfectant overnight, then sent for incineration. Waste media produced before stages of virus production (before transfection of QB1-HEK 293 cells) will be chemically disinfected (1% Vircon overnight) prior to disposal in dedicated sinks. Re-useable glass and plasticware will be disinfected overnight or autoclaved. Benches will be disinfected routinely before and after procedures and at the end of each day.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment

On its meeting held on 27 January 2003 the Genetic Manipulation Committee of Departments of Physiology and Human Anatomy and Cell Biology of The University of Liverpool considered application for contained use of PKC constructs and replication deficient adenoviruses containing PKC constructs. The Committee considered that containment level 2 is appropriate for stages of laboratory work involving transfection of HEK 293 cells, maintenance of these cells in culture, isolation of viruses and transfection of pancreatic acinar cells. These procedures will be conducted in Henry Wellcome Gastro Laboratories facilities shared by Department of Medicine and Department of Physiology, located on the premises of Department of Medicine. Other stages of experimentation will require containment level 1. The Genetic Manipulation Committee considered and approved Risk Assessment and waste disposal procedures for this project.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

UBS Health and Safety Committee. This is chaired by the Director of Facilities, meets three times per year.
Biological/GM safety is a standing agenda item.
UBS has a Bio/GM Safety Committee. It meets virtually or face-to-face, as required. It reports into the UBS H&S Committee.
UBS has a Biological Safety Officer (BSO).
The UBS Bio/GMSC is comprised of representatives from management, academics, technicians and other experts as required. Additional expertise is sought from the BSOs and GMSCs from those departments that make use of and extend their GM activities to these facilities. These departments assess their GM activities through their own GMSC/BSO and then in collaboration with UBS as the provider of these biomedical facilities.

Project Additional Information

Purposes of the contained use

The purpose of the contained use is to determine the potential of stem cells that are present, in low abundance, in a variety of tissues to transdifferentiate to pancreatic endocrine cells. This will be done by using adenoviruses to introduce into mammalian cells in culture transcription factors that are known to regulate the development of insulin secreting cells of the endocrine pancreas.

Recipient or parental organism

The recipient or parental organism is primary rat or human liver cells in culture.

Host/vector system

The vector system is recombinant replication deficient adenovirus. These are deleted in the E1A and E3 region so preventing any possibility of infection. The gene of interest is inserted in the E1A region so recombination in this region will remove the inserted gene.

Origin & function

The genetic material involved includes the gene sequences encoding the transcription factors PDX1, Ngn3, NeuroD, Pax4, Pax6, and Nkx6.1 and the marker protein EGFP and its derivatives.

Evaluation of foreseeable effects

The work will involve the use of recombinant replication defective adenoviruses. Wild type adenoviruses are common causes of infections resulting in diarrhoea in infants, and upper respiratory tract infections and conjunctivitis in children and adults. Such infections are self-limiting. Around 70% of the population have evidence of previous infections with adenovirus and immunity is lifelong. Its natural tropism is for the respiratory tract. There are no reports of formation of wild type virus from recombinant adenovirus in vivo. There is no evidence that adenoviruses of the serotypes used in the proposed work cause infections in animals apart from minor infection in cotton rats, which are not indigenous to the UK or Europe.

The genes will be inserted under control of the CMV promoter and will give moderate levels of expression. The gene can not be mobilised.

The transcription factors used in this work would be active if expressed in human cells. If the lung (the most likely route of entry into humans) took up the adenoviruses and the transcription factors were expressed, it is possible that isolated stem cells within the lung could be converted to a pancreatic endocrine like phenotype.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The liquid waste will be disposed by adding presept (to a resulting concentration of 5%) to waste for 1 hour (effectively 100% kill). Presept tablets are used routinely to inactivate biological material in liquid cultures. To confirm the efficacy of this procedure, Min6 cells (a cell line derived from the endocrine pancreas of the mouse) were resuspended in 10 ml of culture medium and presept was added to give a final concentration of >2500 ppm as recommended by the suppliers. The cell suspension was then added to a tissue culture flask and incubated overnight at 37 degrees C in a humidified tissue culture incubator. No cell growth was observed.

Plasticware will be collected in a marked bag and autoclaved (effectively 100% kill).

**Project Additional Information**

**Purposes of the contained use**

We have identified a novel MAL-related protein which we hypothesise plays a role in targeting proteins into secretory granules. In order to determine the function of this protein we need to express it in mammalian cells. The most efficient method of expressing proteins in mammalian cell lines is using adenoviral vectors. This will allow expression of our novel protein in a high percentage of cells allowing functional analysis to be carried out.

**Recipient or parental organism**

The recipient cells are mammalian cell lines, primarily B-cells but may also include other endocrine cells as well as fibroblast and epithelial cell types.

**Host/vector system**

The vector system is recombinant, replication deficient adenovirus. The vector DNA is deleted in E1A and E3 regions preventing production of infectious viral particles in any cell except for those that can supply the missing E1A genes.

**Origin & function**

The genetic material encodes a novel protein, H09290, which is related to MAL, a protein that may function in regulating secretion from the apical surface of epithelial cells. In addition we have identified an isoform of H09290 which is identical except for the N-terminal region. Both these MAL-related proteins will be inserted into the adenoviral vector to allow expression in a variety of mammalian cell lines in order to determine their functional relevance.

**Evaluation of foreseeable effects**

The recipient microorganism is replication deficient and can only produce infective virus if propagated in early passage HEK293 cells that supply the missing E1 gene. Once these viruses are used to infect other mammalian cells which do not contain E1-encoded trans-complementing factors, the virus is unable to replicate and produces only a transient non-cytopathic infection. There are no reports of formation of wild-type virus from recombinant virus in vivo. Wild-type adenovirus causes upper respiratory tract infections and approximately 70% of the population shows evidence of previous infections with immunity being lifelong following primary infection. Replication deficient Ad vectors have no mechanism for long term maintenance in cells and expression in the lining of the epithelium declines with time and is limited to ~2 months. In the absence of episomal replication of E1-deleted Ad5 in normal human cells long term maintenance would require integration into the genome which only occurs at a frequency of 1 per 10 (to the power of 5) pfu in exponentially growing cultures of primary human cells. In addition, deletion of the E3 gene makes the virus less able to establish and maintain an infection within cells. E3 normally inhibits translocation of MHC molecules to the cell surface so deletion of E3 may be expected to enhance presentation of viral antigens to the immune system. While there is evidence that infection of cells with E3-deleted virus results in a greater, localised inflammatory
response, this could have the beneficial effect of accelerating the clearance of infected cells. Hazards associated with the recipient organism are therefore minimal.

The inserted gene is not anticipated to be harmful. It is a membrane protein that shuttles between the Golgi and the plasma membrane. It is not thought to enter the nucleus or act as a transcription factor and is therefore not likely to affect gene expression or act as an oncogene. In vitro experiments with the MAL homologue have shown that prolonged over-expression is toxic to cells and results in cell death. Short-term over-expression of MAL (which would be the likely result following accidental exposure) increases the level of secretion to the apical cell membrane, causing membrane ruffling. It is not known whether H09290 will perform a similar role in lung epithelia but if it did the outcomes would be to either increase the normal secretory process or cause cell death which would result in clearance of infected cells. In addition the gene of interest is inserted in the E1A region so if recombination were to occur with wild-type adenovirus this gene would be lost. The inserted gene should not alter the tropism of the adenovirus or give it harmful properties.

There is no evidence that human Ad serotypes can naturally infect animals and replication is very limited in, for example, mouse cells. Replication has been shown to occur in the lungs of experimentally infected cotton tail rats when administered a high dose of virus. Such doses are not likely to occur outside the laboratory.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste from viral preparations and cell infections will be put into bottles for subsequent autoclaving at 121 degrees C for 15 min. Small tips, centrifuge tubes will be immersed in Klorsept 87 for a period of 24 h. Larger plastics will be double bagged and autoclaved at 121 degrees C for 15 minutes. Autoclaving will produce effectively 100% kill. After autoclaving the material will be placed into an orange bag, sealed and designated for continuous feed auger (CFA) prior to landfill.

Autoclaves are tested daily by insertion of indicator strips that only change colour when exposed to the correct temperature for the appropriate period of time. These are inserted into a full load into the autoclave at the beginning of each day to ensure the autoclave is performing adequately.

### Project Additional Information

**Purposes of the contained use**

To define the mechanisms by which mutations in the sequestosome 1 gene cause Paget's disease of bone.

**Recipient or parental organism**

The GMOs used will include the E. coli strains NM522 or JM109 (both Promega), DH5a (Gibco), XL1-blue, SOLR or XL10-Gold (all Stratagene), INVaF or TOP10 (both inVitrogen). The natural environment of E. coli is the gut but these experimental strains are laboratory adapted E. coli K-12, being classified as disabled hosts in the ACGM guidelines, and are unlikely to survive in the human gut or elsewhere.

**Host/vector system**

The organisms listed above will be transfected with plasmid vectors which have had the cDNA's for human and murine sequestosome 1 introduced into the multiple cloning site. The plasmids used for sequestosome 1 expression will include pBluescript II SK- (Stratagene), pcDNA3.1/V5-His TOPO or pcDNA3.1-CT-GFP-TOPO (inVitrogen), pTRE2 (Clontech), pTet-Off (Clontech), pUBI (Nucleic Acids Res 1996; 24:1787-1788) and pUC-H2-LTR (J Cell Biol 1993; 122:685-701), pGEM, pGEX, pCMV-script, pCVM-tag, pUC derived cloning and expression vectors.
Origin & function

The wild type sequestosome 1 gene is normally expressed in many cell types. Neither the wild type nor the mutant sequestosome 1 is thought to cause cell transformation. Inoculation or ingestion of plasmids or cell lines expressing sequestosome 1 is not thought to represent a significant hazard to human health for several reasons. First, it is extremely unlikely that inoculated plasmids or cell lines would survive attack by the immune system. Even if the cell lines and plasmids were able to evade immune destruction, it is very unlikely that sustained expression of the recombinant protein would occur in relevant target cells such as osteoclast precursors. Even if expression did occur in target cells, we know that humans who normally express the mutant sequestosome 1 in all cells do not develop appreciable pathology (i.e. Paget's disease of bone) until at least the age of 55 years. In order to minimise the risk of accidental inoculation, through skin abrasions or needlestick injuries, gloves will be used by laboratory workers and the use of sharps (e.g. needles and scalpels) will be prohibited when handling cultures of cells.

Evaluation of foreseeable effects

The expression constructs will be used to generate transgenic mice which express wild type sequestosome 1 and mutant sequestosome 1. These studies are the subject of a separate application which has been classed as non-notifiable by the University of Aberdeen Foresterhill GM safety committee.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The expression constructs will be used to generate transgenic mice which express wild type sequestosome 1 and mutant sequestosome 1. These studies are the subject of a separate application which has been classed as non-notifiable by the University of Aberdeen Foresterhill GM safety committee.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste (from bacterial and mammalian cell cultures will be autoclaved at 121 degrees C for at least 15 minutes before disposal. Plastics and other solid disposable waste will be autoclaved at 121 degrees C for at least 15 minutes before disposal. Glass bottles and other non-disposable vessels will be soaked in the appropriate concentration of Haztabs (10,000 ppm free chlorine) and extensively rinsed before being autoclaved at 121 degrees C for at least 15 minutes before re-use. Haztabs at a concentration of 10,000 ppm free chlorine is the recommended concentration of chlorine to disinfect liquid waste according to manufacturer's guidelines (Guest Medical). Prestige Medical TST Control Integrators will be placed inside the autoclave with each load of GMM waste. The Prestige Medical TST Control changes colour from yellow to purplish blue when the correct sterilisation parameters have been met (>121 degrees C for 15 minutes). The expected killing of micro-organisms and mammalian cells exposed to these conditions is 100%.

Is an emergency plan required according to regulation 20? N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The goal is to examine the chitin structure of the cell walls of Aspergillus fumigatus chitin synthase mutants created elsewhere. We are studying specific genes with negligible roles in virulence of A. fumigatus. The chitin synthase mutants are either unaffected in virulence or have decreased virulence relative to the parent wild type strain.
The wild type strain (parental strain) of Aspergillus fumigatus that will be used is 237. No genes will be modified within this study, but the genes already modified are chsA, chsB, chsC, chsD, chsE, chsF, chsG (chs = chitin synthase). Various chitin synthase mutants will be analysed that have originated from this wild type strain, the strain numbers of which are H-452, H-458, H-460, H-466, H-473, H-480, H-484, and P-1. No vectors will be used in this study. The mutants have been created by gene inactivation by the insertion of a positive selectable antibiotic marker (encoding the hygromycin resistance gene HPT) or auxotrophic markers that are not used clinically and which has no effect on cell virulence. The mutants have been created by integrative transformation with selectable markers and are known to be either attenuated or unaffected in virulence.

### Host/vector system

No genes will be modified within this study, but the genes already modified are chsA, chsB, chsC, chsD, chsE, chsF, chsG (chs = chitin synthase). Various chitin synthase mutants will be analysed that have originated from this wild type strain, the strain numbers of which are H-452, H-458, H-460, H-466, H-473, H-480, H-484, and P-1. No vectors will be used in this study. The mutants have been created by gene inactivation by the insertion of a positive selectable antibiotic marker (encoding the hygromycin resistance gene HPT) or auxotrophic markers that are not used clinically and which has no effect on cell virulence. The mutants have been created by integrative transformation with selectable markers and are known to be either attenuated or unaffected in virulence.

### Origin & function

The strains will be provided from other academic groups in the UK and in France. No genetic manipulations will be carried out at Aberdeen. The goal is to examine the chitin structure of the cell walls of Aspergillus fumigatus chitin synthase mutants. These mutants have been created elsewhere and would be grown in enclosed, sealed bottles in relatively small volumes and then immediately killed with alkali and acids to extract the acid and alkali-resistant chitin. The wild type and mutant strains will be grown and analysed (mainly by transmission electron microscopy).

### Evaluation of foreseeable effects

The strains to be used are attenuated by either (1) auxotrophy or (ii) due to disruption in chitin synthase genes. Wild type strains that have not been subjected to genetic manipulation may be used as controls. This is essentially no risk to the environment. Aspergillus fumigatus spores are very common in all environments since it is a part of the normal microflora of all plants and decaying vegetation. It is not a primary pathogen and is asexual and cannot cross with other A. fumigantus or Aspergillus strains. Because the fungus is sporogenic additional precautions will be taken to prevent the release of spores. All cultures will be grown in bottles with screw-top seals and will be killed immediately for harvesting for chitin preparations. There is no requirement to use heavily sporulating cultures and this will be minimised. Procedures will be used to minimise possible exposure to air-borne spores. Heavily sporing cultures will not be opened, but rendered safe by autoclaving. Therefore there is minimal opportunity for the spores to be released. Our experiments are of minimal risk because we do not have to make DNA or enztme preparations or carry out any treatments that require the fungus to be viable. Once biomass has been generated boiling in strong alkali or acid treatments is used in the first steps of the chitin extraction procedures. This is an extremely harsh, lethal treatment that completely sterilises the cultures. Again it is stressed that the practical concern for release of spores is the possible contamination of other work in the lab rather than a health hazard. Many labs manipulate the fungus in the open. Accidental breakages will follow the same guidelines as those used to deal with other category 2 microorganisms in the laboratory. The fungus is sensitive to all decontaminating agents and disinfectants currently used. Cultures will be killed by autoclaving or chemical extraction.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

None

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Because even acute exposure to high numbers of spores does not lead to disease it will not be necessary to confine work to safety containment cabinets. All cultures are in sealed dishes or bottles and are killed by autoclaving prior to cleaning. No agar plate (Petri-dish) cultures will be used. Cultures that are heavily sporing will not be opened and used for sub-cultures. Because even acute exposure to high numbers of spores does not lead to disease it will not be necessary to confine work to safety containment cabinets. Accidental breakages will follow the same guidelines as those used to deal with other category 2 microorganisms in the laboratory. The fungus is sensitive to all decontaminating agents and disinfectants currently used. Cultures will be killed by autoclaving or chemical extraction.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Our standard procedures for use of Presept have been validated experimentally to kill > 99.99% of cells and spores. Viability tests were performed on killed cultures. Autoclaves on level 1 of the Institute of Medical Sciences are validated at least annually by means of biological indicators. In addition we have validated killing at 99.99% by plating samples harvested from the centre of autoclaved samples. In daily use, monitoring is by thermocouple temperature recordings and autoclave strips included in the loads. Bench-top autoclaves in our laboratory are also tested regularly. Our laboratory manager tests these autoclaves annually. We have validated killing at >99.99% by plating.
samples harvested from the centre of autoclaved samples. Presept (1 tablet per 500 ml). During experiments cultures will be killed in 0.1 M Na OH or 0.1 M HC1. The samples are also autoclaved in hydrogen peroxide and glacial acetic acid during the chitin extraction - the chitin residue being the only biochemical known that can stand these harsh treatments. The experimental procedure itself can therefore be considered an extreme form of disinfectant.

Historical Significant Changes

Tick if notifying a connected programme of work Y

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

To date most of our studies in this area have focussed on Streptomyces phages. Thanks to bacterial genomic sequencing we have hypothesised a more general nature to some of our discoveries and we now wish to test some of these theories. We now propose to use several known human pathogens in our research.

**Recipient or parental organism**

Several organisms will be manipulated; Salmonella typhimurium SL 1344 and LT2, Thermobifida fusca, Streptomyces sp. Mycobacterium smegmatis (mc2155), M. avium, M. marinum, M bovis BCG, E. coli K12.

**Host/vector system**

Chromosomal genes in S. typhimurium and in E. coli will be mutated using the lambda red pcr targeting gene replacement system; the red genes will be introduced via pKD20 or pKD46 or similar. Gene replacement in T. fusca and S. coelicolor will reply on homologous recombination via DNA introduced by mating on suicide vectors derived from E. coli CoIE1 derived plasmids (eg pSET151). We also intend to use site-specific integrating vectors (eg pSET152). Mutations in the mycobacterial chromosomes will also be generated by homologous recombination with DNA cloned on suicide plasmid vectors or on phasmids. E. coli vectors used will be derived from CoIE1, p15A, or defective lambda phage.

**Origin & function**

All the genes we will be studying were discovered through research on host-phage interactions. All the genes when mutated in S. coelicolor give an altered response to phage infection. Some of the genes (the pgl genes) are involved in a phage resistance phenotype in S. coelicolor whilst others (such as pmt1 and ppm1) are required to synthesise the phage receptor. In S coelicolor the pgl genes involve proteins with the following predicted functions; a protein kinase (pglW), DNA methyltransferase (pglX), an ATPase (pglY) and a protein of unknown function (pglZ). Homologues of these genes will be knocked out in S. typhimurium, T. fusca and in the genetic elements SXT and CTnR391 (derived from V. cholera and P. rettgeri respectively and transferred by conjugation into E. coli). In each case an antibiotic resistance marker (usually kanamycin, chloramphenicol, apramycin, hygromycin or spectinomycin resistance genes) will replace the pgl gene. The pgl homologues from these organisms will also be cloned into E. coli and Streptomyces. The pmt1 and ppm1 genes appear to be involved in a protein glycosylation pathway, which is common to all the actinomycetes. Pmt1 and ppm1 homologues (and other genes involved in the glycosylation pathway) in mycobacteria will be replaced by antibiotic markers, kanamycin or hygromycin. The pmt1 and ppm1 genes from mycobacteria will also be inserted in E. coli and streptomyces.

**Evaluation of foreseeable effects**

It is unlikely that any of these manipulations described here will result in any increase in the hazardous nature of these organisms. If anything their fitness will be reduced either due to sensitivity to phage infection or due to defects in synthesising key cell wall proteins. Indeed other people's attempts to knockout the pmt1 gene in M. tuberculosis so far have failed. The knockout mutants will contain antibiotic resistance genes but these will no confer resistance to any known therapy for any disease caused by the organisms in question. Cloning of the heterologous glycosylation genes in E. coli K12 strains or in Streptomyces is not likely to confer any degree of pathogenicity on these bacteria. We intend to use E. coli K12 containing the mobilisable SXT and CTnR391 elements which originate from V. cholera and P. rettgeri. These elements are known to encode several antibiotic resistance genes and several genes of unknown function. Given these known properties E. coli containing these elements will be used under class 2 containment to eliminate any possibility of spread.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

To date most of our studies in this area have focussed on Streptomyces phages. Thanks to bacterial genomic sequencing we have hypothesised a more general nature to some of our discoveries and we now wish to test some of these theories. We now propose to use several known human pathogens in our research.
The class II safety cabinet will be used for manipulating Mycobacterium avium, M. bovis BCG and Thermobifida fusca at all times. This is because they are known to cause pulmonary disease and there is a clear danger of infection via an airborne route. For S. typhimurium, E. coli, M. smegmatis and M. marinum there is little danger from the airborne route and these organisms will normally be manipulated on the bench with protective clothing and gloves.

The class II safety cabinet will always be used whenever aerosols are expected, such as vigorous mixing or resuspending cells after centrifugation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1% Trigene kills E. coli, S. typhimurium, Streptomyces sp. T. fusca, M. smegmatis and 5% kills M avium and M Bovis BCG. We expect to get 100% inactivation and validation will be routinely tested. Information on testing of most of these organisms is described at http://www.medichem.co.uk/medical_products.html. Streptomyces sp and Thermobifida fusca are not mentioned in this information but we have performed our own tests on Streptomyces and found 1% Trigene to be sufficient for 100% killing. The concentration of Trigene for killing of T. fusca will be thoroughly tested before GM work begins.

In practice the lab will routinely use 5% Trigene for killing of liquid cultures and for disinfection of contaminated glassware and spills. Disinfection will take place in containers with lids for no less than 24 hours before disposal. Disinfected cultures and glassware will be disposed of down the sink with plenty of water.

Plates will be taped together, placed in a double autoclave bags, sealed and sent for autoclaving on the premises for sterilising.

Is an emergency plan required according to regulation 20? N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The genetic modification safety committee accepted the scientific procedures and hazard assessments as reasonable. They requested that only one type of disinfection should be used throughout the laboratories for simplicity sake, which we have implemented by converting to the use of Trigene. The committee also requested a clear statement of when the safety cabinet should be used and when it is safe to work at the bench.

The risk assessment was passed pending these changes. It was decided that the labs where the work will take place would be inspected for compliance with level 2 containment prior to receipt of microbes classified as ACDP hazard group 2.

Project Additional Information

Purposes of the contained use

Beta secretase (BACE) is the enzyme involved in the generation of the toxic beta amyloid peptide, leading to neurodegeneration in Alzheimer's disease. The aim of the project is to generate an approach that allows BACE1 inhibitors to be tested in vitro and in vivo. Proteins relevant to beta amyloid formation will be expressed both in vitro and in vivo. Recombinant adenoviruses will be used as a gene expression system to express the proteins, APPswe/lon (with V717I/K670N/M671L mutations), Tau (with mutations P301L and R406W) and BACE1.

Recipient or parental organism

The recipient micro-organism is recombinant replication-deficient adenovirus. These are deleted in the Early Regions 1 (E1) and 3 (E3) of wild-type Ad5 adenovirus and form a kit Stratagene (AdEasy XL Adenoviral Vector System). The target organisms will be SH-SY5Y neuroblastoma cells, primary mouse neuronal cultures and live recipients (mice).

Host/vector system

pShuttleCMV vectors containing the transgenes of interest will be used for recombinant into pAdEasy constructs which will allow for the production of virus in HEK293 cells (contain the necessary machinery for the replication of virus).
The recombinant adenoviruses to be used will express the transgenes APPswe/lon, Tau and BACE1. These will be fused to different fluorescent proteins, EGFP, ECFP and dsRed (Clontech). The APPswe/lon transcript contains two mutations (London mutation V717I and Swedish mutations K670N and M671L) which make it more susceptible to cleavage by BACE1 (Beta secretase 1). APPswe/lon when expressed in eukaryotic cells gives rise to Beta amyloid plaques in brain tissue which is a pathological indication in Alzheimer's disease. BACE1 is to be used in the human wild-type form. BACE1 is known to cleave APPlon/swe to form Beta amyloid plaques. The Tau protein is known to be associated with the formation neurofibrillary tangles in the brain. The form used in this study contains two mutations (P301L and R406W).

BACE1 inhibitors will be tested both in vitro and in vivo on neuronally derived cells, expressing the three above transgenes, to assess whether the production of APP-derived toxic peptides and subsequent cell death is reduced.

Evaluation of foreseeable effects

Recombinant adenoviruses developed in this way cannot in human tissue (all Ad5 vectors E1a and E1b deficient). No stable disabling mutation is likely to result due to the lack of propagation in human cells.

Expression of the inserted genes is transient and the risk genomic integration is negligible (1 per 105 pfu in exponentially growing cultures). Wild-type adenoviruses are common causes of infections resulting in diarrhoea in infants, and upper respiratory tract infections and conjunctivitis in children and adults are self limiting. Around 70% of the population have evidence of previous infections with adenovirus and immunity is lifelong. It's natural tropism is for the respiratory tract. There is no evidence to suggest that inhaled adenoviral particles can spread to brain tissue. There are no known reports of wild type virus from recombinant adenovirus in vivo. Adenoviruses are sensitive to heat and can be inactivated in 1 hour at 56°C. There is no evidence that human Ad serotypes can naturally infect animals and replication is minimal in mouse cells for example.

In the unlikely event that viral particles are accidentally inhaled, it has been shown that endogenous BACE1 in human lung tissue is almost absent (Rossner et al, 2001) and therefore cleavage of mutant APP into the known neurotoxin Beta Amyloid is negligible. Even should cleavage occur, there are no symptoms in AD patients relating to cardiovascular or respiratory problems despite considerable Beta Amyloid expression in blood. High titer viruses expressing BACE1 and APP in this study will be handled separately to insure exposure to both viruses simultaneously is kept to a minimum.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

SH-SY5Y neuroblastoma cells and primary mouse neuronal cultures will be kept in sealed flasks in designated incubators. These flasks will only be opened within Class II tissue culture hood at containment level 2.

Recombinant adenoviruses will be used to infect mice for short term studies. Since expression of the transgenes is transient, we do not consider the animals to be genetically modified. However, animals following adenoviral injection will be kept in separate designated rooms. No adenoviral particles will be present in mice when they are euthanised due to the short life expectancy of the adenovirus. Because the virus cannot replicate in cells that do not contain the E1- encoded trans-complementing factors, the virus will not propagate in vivo mice. Please see attached GMM form for additional measures.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste (from bacterial and mammalian cell cultures) will be autoclaved (Institute of Medical Sciences prep room) before disposal down the sink. Plastics and other solid waste will be autoclaved before disposal. Glass bottles and other non-disposable vessels will be soaked in the appropriate concentration of Trigene (according to manufacturers recommendations).

Validation of the autoclaving process involves the use of independent thermocouples placed at the centre of the load, to determine whether the correct time and pressure have been reached for the required time. To verify inactivation of the adenovirus, neat autoclaved cell culture waste will be added to HEK293 cells to determine a cytopathic effect.
Trigene will be used to clean bench tops. Glass bottles and culture vessels will be soaked in trigene and extensively rinsed before being autoclaved in the IMS autoclave facility for re-use.

The proposal has been assessed and approved as Class II activity by the genetic modification safety committee (see attached risk assessment).

Historical Significant Changes

Historical Date of Additional Info

02/03/2022
Flow cytometry can be used to analyse and sort fluorescently labelled genetically modified cells or micro-organisms on the basis of differential fluorescence or other parameters such as cell size and granularity. Additional fluorescent can be used to identify and quantify expressed specific molecules and to define the phenotype and function of the modified cells. This notification is for generic approval for work undertaken by FACS facility involving unspecified GMO's requiring level 2 containment measures where confidentiality may be an issue (eg IP on gene modified).

1. Well characterised fish, rodent or mammalian cell lines such as HL60, COS, CHO J774 etc,
2. Primary cells such as leukocyte subsets, epithelial or endothelial cells.
3. Micro-organisms such as E.coli, candida, or saccharomyetes (attenuated or wild type) in hazard groups C1 or C2 according to ACDP.

1. Commercially available or well characterised transient or stable transfection systems or regulated expression systems.
2. Commercially available or experimental fluorescent reporter genes such as GFP, YFP or other fluorescent proteins.
3. C1 or C2 hazard group adenoviral or lentivrus vectors

The genetic materials involved will be for research applications in biology or medicine. Intended function of the research will be studies on the function of intracellular or secreted proteins and the effects of mutations, overexpression, deletion or functional inactivation of genes on biological processes.

The client will be required to provide a risk assessment containing specific information on GMM and potential risks both to human health and the environment, consistent with assignment of work to containment level 2, plus evidence of CU2 notification before work is started. If client is from out-with UK, equivalent risk assessments and written evidence that UK containment level 2 measures are appropriate for GMO will be required from the client.

The following issues will be confirmed with client prior to work being started.

i) Hazards specific to recipient organisms.
ii) Hazards specific to inserted/disabled/deleted gene.
iii) Likelihood of gene transfer to other organisms.
iv) Likelihood of inserted/disabled/deleted gene increasing pathogenicity of the recipient organism.

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None
Waste management measures sufficiently stringent to contain and inactivate (100%) any organism covered by level 2/3 containment will be standard. Protocols will be confirmed as appropriate with client before work commences.

Fluid waste will be collected into 1:200 Chloros which is standard procedure for fluid waste from FACS equipment. Chlorine levels in waste will be increased to provide 100,000 ppm available chlorine (10% chloros 1 hour minimum). Where 10% chloros cannot be used for fluid waste (corrosion risks), 1% Virkon (1 hour minimum) will be used before flushing waste to drain.

Solid waste will be biohazard double bagged for autoclaving or yellow bag incineration. Autoclave situated within laboratory suite (4.07) is fitted with internal probes that allow external monitoring of temperature, humidity, time and pressure. The efficacy of the sterilisation cycle is tested with Prestige indicator strips. Solid waste that cannot be autoclaved or decontaminated will be incinerated.

Spills
70% ethanol, 10% chloros or 1% Virkon as appropriate for size of spill and surface/material affected. Absorbent swabs will be double bagged and incinerated.

Cleaning protocols
All cytometers are routinely cleaned internally using 1:200 Chloros and are sterilised using 70% ethanol. External surfaces, pipettes and work surfaces around instruments are cleaned with 70% alcohol.

Risk assessment has been discussed and approved by Foresterhill Genetic Modification Committee.

Studies of growth, cell wall synthesis and tropic responses of the fungus, Cryptococcus neoformans. The genes have been deleted in C. neoformans Serotype A strains of opposite mating types, H99 (alpha) and KN99 (a). H99 (alpha) is a clinical isolate that has become the reference strain for this Serotype. KN99 was created through a series of back-crosses between an a-type clinical isolate and H99 to create a congenic a-strain that is estimated to be 96.9% similar to H99. In murine and rabbit models of Cryptococcal meningitis, KN 99 was no more virulent than the clinical isolate, H99.

Recipient or parental organism
The genes have been deleted in H99 and KN99 by the stable insertion of linear, PCR-generated constructs, carrying genes for hygromycin, neomycin of nourseothricin (antibiotic) resistance, into the target genes. No plasmid vectors were used and the use of antibiotics is not required for the maintenance of mutant strains.

Origin & function
The origins of antibiotic resistance genes used as genetic markers are bacterial and are stably integrated into the C. neoformans genome. They were used to disrupt fungal genes that function within the calcium-signalling and response pathway and include calcium channel genes (CCH1, MID1, PMR1/ECA1), calcineurin and its regulators (CNA1, CNB1, CBP1) and genes involved in the biosynthesis of chitin and chitosan (CHS1-8, CSR1-3), which may function downstream of calcium-signalling.
Previous work using the filamentous fungus, Candida albicans, with mutations that impaired calcium-signalling suggested that perturbation of this pathway results in the inability of the micro-organism to sense and respond to its environment (Brand et al, 2007). We now seek to test whether this process is conserved in another filamentous fungus, C. neoformans, by growing hyphal filaments for short periods (<24H) and observing any changes in cell composition, enzyme phosphorylation status and growth behaviour using standard biochemical tests and microscopy.

**Evaluation of foreseeable effects**

In studies carried out in animal models, mutants with impaired calcium-signalling in C. neoformans and other fungi were severely reduced in virulence (Odom et al, 1997, Bates et al, 2005, Steinbach et al, 2006). Perturbation of calcium-signalling also affects survival of C. neoformans at human body temperature (Odom et al, 1997). The inactivation of calcineurin has been identified as a target in the development of anti-fungal drugs (Sanglard et al, 2003). In previous work using the human opportunistic pathogen, C. albicans, it has been shown that disruption of calcineurin (CNA1) results in the failure of the organism to survive in serum (Blankenship et al, 2005). We have shown that disruption of CCH1, MID1, FIG1 (calcium channels), CNA1, CNB1, CRZ 1 (signalling) in C. albicans reduce the ability of the micro-organism to sense and respond to the environment (Brand et al, 2007). It is therefore likely that C. neoformans strains with mutations in this pathway are similarly disabled and that the observed reduction in virulence in C. neoformans is a human pathogen in ACDP Hazard Group 2. It is ubiquitous in the environment and is commonly isolated from soil and decaying wood. The infectious particles are desiccated spores and yeast cells that become airborne when decaying material is disturbed. Particles enter the respiratory tract through inhalation and are carried and cleared asymptomatically by immunocompetent hosts. If the host immune system is severely impaired, for example, due to AIDS, colonisation by C. neoformans Serotype A can lead to the development of Cryptococcal meningitis. No transmission of Cryptococcosis between animals or humans has been recorded. C. neoformans is a micro-organism of low pathogenic potential in healthy individuals.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid spills will be inactivated using 1% Trigene. The contaminated area is flooded with Trigene (to a final concentration of 1%, mopped with paper towels and reswabbed with 1% Trigene. Contaminated material is autoclaved. Liquid and solid waste, glassware and plasticware will be autoclaved. Our standard procedures for the use of Trigene have been validated experimentally to kill >99.99% of C. neoformans vegetative cells. Viability tests have been performed on Trigene-exposed cultures. Central autoclaves are validated at least annually by means of biological indicators. In addition we have validated killing at >99.99% by plating samples harvested from the centre of autoclaved samples. In daily use, monitoring is by thermocouple temperature recordings and autoclave-indicator tape included in the loads. Bench-top autoclaves are monitored on a daily basis using autoclave-indicator tape and by checking external temperature and pressure gauges. Our Laboratory Manager tests bench-top autoclaves on a monthly basis using Brownes tubes, which are included in the load and change colour on exposure to correct autoclave conditions. Killing by these autoclaves has been validated at 99.99% by plating from solid and liquid samples taken from the centre of the autoclave. After inactivation normal routes for disposal are used for liquid and solid waste. Killed liquid waste is discarded down the sink. Disposal of inactivated solid waste is by continuous feed auger processing (heat treatment and maceration followed by landfill). Contaminated sharps are placed in Cin-bins, bagged and incinerated.

### Project Additional Information

**Purposes of the contained use**

To safely and efficiently transduce RANK (wildtype and mutant - see attached risk assessment for details) genes into osteoclasts and osteoclast precursors, using replication-deficient lentiviral vectors. In related experiments, we will also use commercially available adenoviral Cre Recombinase to knockout the RANK gene in osteoclasts generated from mice in which the RANK gene is flanked by two loxP sites.
Recombinant adenoviruses are considered unlikely to cause disease. They will only propagate in cells that contain and express the E1-encoded trans-complementing
lentiviral vector stocks using derivatives specific for protoviral components such as VSV-G.

Stock supernatant into mitotically active indicator cells (eg 293FT cells) and monitoring for syncitia formation or by DOR analysis of cells that have been transduced with
after infection of a cell they are incapable of further replication. It will be possible to demonstrate that the lentiviral vectors are replication deficient by plating 5% of the vector
Lentiviruses require close contact for their transmission and their survival in the general environment is poor. Replication deficient lentivirus cannot propagate so therefore,
transmission. Individuals known to be HIV-positive or to be immunocompromised will not be allowed to work on this project, these risks will be made clear to all personnel in
wildtype virus. Thus, there would be the potential risk of mobilisation and transmission of the recombinant lentivirus to other individuals via the normal route of HIV 1
human health due to the reasons described in section 6 above. In carriers of wildtype HIV there may be a theoretical risk of recombination of the lentiviral vector with

We would not expect any specific symptoms as the result of an accidental infection with the genetically modified micro-organisms described in this application since the
lentiviral vectors and recombinant adenoviruses cannot replicate. There is a very small theoretical risk that, if the lentiviral expression plasmid was accidentally injected into an
individual carrying wildtype HIV, the vector could recombine, via the truncated LTR’s, with the wildtype virus to produce replication competent virus, carrying the RANK
genes. The likelihood of this occurring is extremely low since a) the use of sharps will be prohibited, b) plasmid DNA does not enter cells readily and c) the plasmid would
have to be internalised by a CD4+, HIV infected T cell. The lentiviral vectors themselves are capable of transducing a broad range of cell types, (as a result of the VSV-G
gene) and therefore the RANK genes will be stably integrated into any cell type that the vectors are exposed to. However, this is not thought to pose a significant risk to
human health due to the reasons described in section 6 above. In carriers of wildtype HIV there may be a theoretical risk of recombination of the lentiviral vector with
wildtype virus. Thus, there would be the potential risk of mobilisation and transmission of the recombinant lentivirus to other individuals via the normal route of HIV 1
transmission. Individuals known to be HIV-positive or to be immunocompromised will not be allowed to work on this project, these risks will be made clear to all personnel in
the laboratory.

Lentiviruses require close contact for their transmission and their survival in the general environment is poor. Replication deficient lentivirus cannot propagate so therefore,
after infection of a cell they are incapable of further replication. It will be possible to demonstrate that the lentiviral vectors are replication deficient by plating 5% of the vector
stock supernatant into mitotically active indicator cells (eg 293FT cells) and monitoring for syncitia formation or by DOR analysis of cells that have been transduced with
lentiviral vector stocks using derivatives specific for protoviral components such as a VSV-G.

Recombinant adenoviruses are considered unlikely to cause disease. They will only propagate in cells that contain and express the E1-encoded trans-complementing
factors. For all other somatic cell types that are susceptible to adenoviruses leads to a transient non-cytopathic infection.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste (from mammalian cell cultures) will be autoclaved before disposal down the sink. Plastics and other solid disposable waste will be collected in autoclavable bag within the biological safety cabinet, sealed and then sprayed with virkon (1% as per manufacturer’s instructions). The bag will then be removed from the safety cabinet into a clean autoclave bag, sealed and taken to the autoclave in a sealed container. The degree of kill following autoclaving will be 100% since there is a high expectation of kill of GM microorganisms exposed to 121 degrees for 15 minutes. The autoclaved waste will then be disposed of by continuous feed auger.

Glass bottles and other non-disposable vessels will be soaked in the appropriate concentration of Virkon (1%, according to the manufacturers recommendation) in a bucket with a sealed lid, rinsed and then autoclaved for future use.

Validation will involve regular testing of the autoclave to demonstrate, using independent thermocouples placed at the centre of the load, that the correct time and pressure have been reached for the required time. At the start of the project we will validate the inactivation of lentiviral vectors following autoclaving HT1080 cells will be grown in the presence of increasing (10 fold) amounts of inactivated waste. The cells will then be selected for using the antibiotic blasticidin and incubated for 10 days before being stained with Crystal violet. The identification of any blasticidin-resistant colonies demonstrates the presence of active lentiviral vector within the ‘inactivated’ waste.

The virucidal disinfectant, Virkon, has been validated for inactivation of lentivirus at a concentration of 1%. Details of Virkon testing from independent studies can be found at http://www.antecint.co.uk/main/virkonvi.htm

02/03/2022
Survival and pathogenicity of Escherichia coli O157:H7

This strain of E. coli O157:H7 is a naturally occurring, non-toxigenic isolate. The isolate was originally obtained as an environmental isolate and is likely to exist naturally in the human gut of a proportion of the population. The genetic modification subsequently carried out was to introduce marker/reporter genes (stably into the chromosome) which allow us to detect and monitor them in environmental matrices safely in a contained, laboratory environment.

Recipient or parental organism

Escherichia coli O157:H7 strain 3704.

This strain of E. coli O157:H7 is a naturally occurring, non-toxigenic isolate. The isolate was originally obtained as an environmental isolate and is likely to exist naturally in the human gut of a proportion of the population.

Host/vector system

E. coli O157:H7 strain 3704 Tn5 luxCDABE was constructed by biparental mating of a spontaneous rifampin-resistant mutant of E. coli O157:H7 strain 3704 with a donor strain, followed by suicide plasmid delivery and transposon mutagenesis. The donor strain, E. coli S17 aprt luxCDABE Km2 contains the luxCDABE cassette from Photobacterium luminescens and the antibiotic resistance genes for ampicillin and kanamycin. The rifampin-resistant mutant of E. coli O157:H7 strain 3704 was made by plating serial dilutions of an overnight culture onto Luria-Bertani (LB) plates containing rifampin (100 μg ml-1). Transconjugants in which Tn5 luxCDABE had inserted into the chromosome were initially selected on the basis of growth on LB containing rifampin (100 μg ml-1) and kanamycin (50 μg ml-1) and then by visible bioluminescence in the
The absence of the plasmid (which conferred ampicillin resistance) was confirmed by small-scale plasmid DNA preparations and by the lack of growth of the transconjugant LB plates containing ampicillin (50 μg ml-1). The stability of the lux phenotype was examined by successive subculturing of the selected E.coli O157:H7 strain 3704 Tn5 luxCDABE in LB broth without addition of kanamycin and subsequent confirmation of colony growth on LB agar with versus without kanamycin (50 μg ml-1). To confirm that mutagenesis had not disrupted the O157, 57 or intimin phenotype of the strain, multiplex PCR was performed.

E.coli O157:H7 strain 3704 was kindly provided by Fiona Thompson-cartier (E.coli reference laboratory, University of Aberdeen, United Kingdom). The strain was originally isolated from a farm drain and has been proven to be nontoxigenic due to the absence of toxin activity (by Verocell assay) and toxin genes (by PCR) (F. Thomson-Carter, unpublished observation).

Introduced genes are luxCDABE genes (from Photorhabdus luminescens) and natural antibiotic resistance genes, which do not confer harmful properties to the micro-organism or human health.

In the event of a culture being split, the liquid must be absorbed into paper towels which must then be autoclaved. The contaminated area must then be thoroughly cleaned using Hibicet.

All contaminated equipment must be cleaned thoroughly using 10% Hibicel solution.

Contaminated clothing must be autoclaved before being washed.

All waste must be autoclaved at 121º for 60 mins. Liquid waste can be autoclaved in sealed containers. Solid waste should be placed into a double autoclave bag. Once autoclaved, the waste can be incinerated.

As the autoclaves are out with the lab, all waste must be transferred by the person who generated it in sealed boxes. The same operative must also empty the autoclave once finished as well as noting the disposal number for the waste.

Astell autoclaves have a temperature probe and digital readout to show autoclave has reached the required temperature and pressure.
TST control indicator strips may also be used. Cultivation techniques will confirm inactivation of GMM before waste is collected for incineration by disposal company contracted to University of Aberdeen.

Project Additional Information

Purposes of the contained use

To safely and efficiently knockdown proteins involved in both cell division and migration induced by electric field application in mammalian cell lines. Genes will be silenced using replication-deficient lentiviral vectors which are created from the commercially available MISSION TRC shRNA constructs and the lentiviral packaging mix, both by Sigma Aldrich. Please see: http://sigmaaldrich.com/life-science/functional-genomics-and-rnai/shrna/learning-center/getting-started.html

Recipient or parental organism

HEK293T cells will be used as the packaging cell line for the lentiviral vectors.
Cell lines where gene knockdowns will be performed are HEK293, HELA and possibly chronic wound human fibroblasts, SHSY5Y and PC12 cells.

Host/vector system

Pseudo-typed lentiviral particles will be produced in HEK293T cells using a third-generation packaging system, which has many features that lead to enhanced biosafety. Recombinant lentiviruses produced with the MISSION lentiviral Packaging Mix (Sigma Aldrich catalog number SHP001) have not been shown to produce replication competent viral particles because of designed safety features. It is a three plasmid system consisting of:
1. The packaging vector, which contains the minimal set of lentiviral genes required to generate the virion structural proteins and packaging functions.
2. The vesicular stomatitis virus G-protein (pCMV-VSV-G) envelope vector, which provides the heterologous envelope for pseudotyping.
3. The shRNA transfer vector (pLKO.1-Puro), which contains the sequence of interest as well as the cis acting sequences necessary for RNA production and packaging.
This vector contains a sequence encoding a puromycin resistance gene.
The multi-plasmid approach results in no single plasmid containing all the genes necessary to produce packaged lentivirus.
The Lentiviral Packaging Mix contains the first two components, it is designed to be co-transfected along with a compatible lentiviral transfer vector in order to create high titer pseudo-typed lentiviral particles used. Resulting particles are replication-incompetent and deletion in the U3 portion of the 3' LTR eliminates the promoter-enhancer region, further negating the possibility of viral replication. The system has also removed virulence genes which are not necessary for shRNA packaging. In addition, the lentiviral vector contains a self-inactivating 3' LTR that renders it unable to produce the infectious virus once it integrates into the host chromosome. These features combined have improved biosafety and handling. This information appears on-line in: http://www.sigmaaldrich.com/life-science/functional-genomics-and-rnai/shrna/learning-center/mission-faqs/biosafety.html
HEK293, HELA, human fibroblasts, SHSY5Y and PC12 cells will be transduced with the pseudo-viral particles. In most cases and in order to rule out compensatory effects of the protein knockdowns, the resulting cell ines will be phenotyped and then disposed at the end of the experiment. In the remaining cases, stable cell lines will be generated. In these cases, no additional hazards compared with any other transformed cell line are present as the lentiviral vector contains a self-inactivating 3' LTR that in all cases renders it unable to produce infectious virus once integrated into the host chromosome.

Origin & function

Mammalian targeted genes will be the serine threonine phosphatases PPP4, PP2A and PP1 catalytic (c) and regulatory subunits; the Na+/H+ antiporter (SLC9A1); METTL10; kinases YLK4 and STK28A; ZNF365 and PDE4DIP.
- PP4c and its regulatory subunits are involved in microtubule organization at centrosomes, maturation of spliceosomal snRNPs, apoptosis, DNA damage and cell migration.
- PP2Ac and its regulatory subunits are implicated in the negative control of cell growth and division.
- PP1 is essential for cell division, and participates in the regulation of glycogen metabolism, muscle contractility and protein synthesis.
- The Na+/H+ antiporter (SLC9A1) is involved in pH regulation to eliminate acids generated by active metabolism or to counter adverse environmental conditions. Plays an important role in signal transduction.
- Q5JPI9 (encoded by METTL10) is a predicted protein of unknown function. It may be involved in vesicle transport processes.
- ULK4, STK28L ZFP465 and PDE4DIP genes are involved in neurite outgrowth and cell migration.

Cells resulting from the phosphatase protein knockdown experiments may have disrupted progression of mitosis and may present altered migration competence. Cells resulting from SCL9A1 gene silencing may present compromised pH regulation and electrotactic competence. And METTL10 knockdown may affect vesicle transport.

Cells resulting from ULK4, STK28L, ZFP465 and PDE4DIP gene silencing may show neurite outgrowth and cell migration.

**Evaluation of foreseeable effects**

We would not expect any specific symptoms as the result of an infection with the genetically modified microorganisms described in this application since the lentiviral vectors cannot replicate.
No sharps will be used in any of these experiments.
The vectors have been designed so that they are incapable of recombining with the wild-type virus in any way that would produce viable virus. Because viral structural genes have been placed on different genetic units, multiple recombination events must occur before a replication competent helper virus is generated. Furthermore, areas of homology among the units expressing the helper virus proteins have been minimized. Also, heterologous promoters for the helper virus proteins are used. Resulting particles are replication-incompetent and deletion in the U3 portion of the 3’ LTR eliminates the promoter-enhancer region, further negating the possibility of viral replication (http://www.sigmaaldrich.com/life-science/functional-genomics-and-rnai/shrna/learning-center/mission-faqs/biosafety.html)

However, highly improbable viral replication-competence will be checked by subjecting cell cultures to puromycin resistance after treating these cells with media collected from cells that have been treated with viral supernatant which would lead to puromycin resistance. Additionally, cell media will be immunoblotted in order to rule out the presence of the viral protein p24.
The transfected cultured cell lines will not survive outside the culture medium and all liquid and solid waste will be autoclaved on site. This rules out the possibility of escape into external environment and survival, establishment or dissemination therein.

Factors such as congenital immunodeficiency caused by serious illness or chemotherapy would increase the susceptibility to infection by micro-organisms, including the genetically modified micro-organisms described in this application. In carriers of wild type HIV there may be a theoretical risk of recombination of the lentiviral vector with wildtype virus. Thus, there would be the potential risk of mobilisation and transmission of the recombinant lentivirus to other individuals via the normal routes of HIV-1 transmission. Individuals known to be HIV-positive or to be immunocompromised will not be allowed to work on this project, these risks will be made clear to all personnel in the laboratory.

Date of Significant Change
Project Additional Information

**Purposes of the contained use**

To safely and efficiently deliver shRNA targeted against YAP gene into myogenic cells using replication-deficient lentiviral vectors.

**Recipient or parental organism**

For transformation of the lentiviral cloning vector, disabled k12-derived E.coli (XL-1 Blue, Stratagene) will be used. The 293T cell line (a fast-growing cell line derived from human embryonic kidney cells, containing the large T-cell antigen) will be used as the packaging cell line for the lentiviral vectors.

The target cells that will be transduced with the lentiviruses encoding shRNA against Yap are:
1) Primary mouse skeletal muscle myofibres (this preparation will include the associated muscle stem cells).
2) The well characterised myogenic mouse cell lines C2C12 and the mouse embryonic fibroblast C3H/10T1/2.
3) Mouse and human mesenchymal stem cells, derived from bone marrow, synovium, periosteum and adipose sources.

**Host/vector system**

VSV-G pseudotyped lentiviral vectors will be produced virus by co-transferring the 293 T cell line with the expression construct and 2 lentiviral packaging plasmids each individually carrying genes encoding the necessary viral structural and replicatory proteins (2nd generation packaging system).

**Origin & function**

YAP is ubiquitously expressed transcriptional coactivator that regulates the expression of genes involved in cell proliferation (cyclins, growth (Akt) and apoptosis (caspase 3, BIRC5, Survivin). Members of the TEAD family of DNA binding proteins are known to drive the expression of at least some of the genes that YAP regulates. Overexpression of constitutively active YAP (YAP S127A and YAP SS) promotes cell proliferation and tumour formation in Drosophila and a variety of mammalian cells/tissues, leading to the consideration of YAP as an oncogene. Knock-down of Yap can protect against cancer formation in certain cells types (Zhou et al., 2011 Moi Med Report). In stem cells, YAP influences pluripotency and cell fate decisions, with over expression of wt YAP enhancing pluripotent induction of mouse fibroblasts and forced expression of YAP S127A leading to an expansion and delayed differentiation of several progenitor cell populations in vivo. Knock-down of Yap in embryonic stem cells leads to enhanced differentiation and loss of pluripotency. Whole body knock-out of Yap is embryonic lethal in mice. YAP activity is negatively regulated by the 'Hippo pathway', consisting of the core kinases; mammalian ste20-like kinase (MST1/2) and large tumour suppressor (LATS1/2). LATS1/2 inhibits the transcriptional activity of YAP via phosphorylation at serine residue 127, which promotes the binding of YAP to 14-3-3 proteins and translocation out of the nucleus.

The insertion of these genes is not expected to alter the tropism of the lentiviral vector or give it harmful properties. Accidental uptake of the lentiviral vectors into human cells could result in expression of the YAP shRNA. However, this is not likely to cause any pathogenic effect since:
1) DNA integration is unlikely to cause tumorigenesis as silencing of Yap is a well established mechanism for tumour suppression in a variety of cancer cell lines and in vivo models.
2) Knock-down of Yap has been shown to induce apoptosis in vivo in a variety of cell types. Apoptosis of infected cells is likely to be beneficial as it will limit the number of progeny containing the integrated DNA.

**Evaluation of foreseeable effects**

We would not expect any specific symptoms as the result of an accidental infection with the genetically modified micro-organisms described in this application since the lentiviral vectors cannot replicate. There is a very small theoretical risk that, if the lentiviral expression plasmid was accidentally injected into an individual carrying wildtype HIV, the vector could recombine, via the truncated LTR’s, with the wildtype virus to produce replication competent virus, carrying the YAP shRNA. The likelihood of this occurring is extremely low since a) the use of sharps will be prohibited, b) plasmid DNA does not enter cells readily and c) the plasmid would have to be internalised by a CD4+, HIV infected T cell. The lentiviral vectors themselves are capable of transducing a broad range of cell types (as a result of the VSV-G gene) and therefore the YAP shRNA will be stably integrated into any cell type that the vectors are exposed to. However, this is not thought to pose a significant risk to human health due to the reasons...
described in section 6 above. In carriers of wildtype HIV there may be a theoretical risk of recombination of the lentiviral vector with wildtype virus. Thus, there would be the potential risk of mobilisation and transmission of the recombinant lentivirus to other individuals via the normal routes of HIV-1 transmission. Individuals known to be HIV-positive or to be immunocompromised will not be allowed to work on this project; these risks will be made clear to all personnel in the laboratory. Lentiviruses require close contact for their transmission and their survival in the general environment is poor. Replication deficient lentivirus cannot propagate so therefore, after infection of a cell they are incapable of further replication. It will be possible to demonstrate that the lentiviral vectors are replication deficient by plating 5% of the vector stock supernatant into mitotically active indicator cells (eg293T cells) and monitoring for syncitia formation or by PCR analysis of cells that have been transduced with lentiviral vector stocks using primers specific for pro-viral components, such as VSV-G.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste (from mammalian cell cultures) will be autoclaved before disposal down the sink. Plastics and other solid disposable waste will be collected in autoclavable bag within the biological safety cabinet, sealed and then sprayed with Virkon (15, as per manufacturer's instructions). The bag will then be removed from the safety cabinet into a clean autoclave bag, sealed, and taken to the autoclave in a sealed container. The degree of kill following autoclaving will be 100% since there is a high expectation of kill of GM microorganisms exposed to 121°C for 15 minutes. The autoclaved waste will then be disposed of by continuous feed auger. Glass bottles and other non-disposable vessels will be soaked in the appropriate concentration of Virkon (1%, according to the manufacturer's recommendation) in a bucket with a sealed lid, rinsed and then autoclaved for future use. Validation will involve regular testing of the autoclave to demonstrate, using independent thermocouples placed at the centre of the load, that the correct time and pressure have been reached for the required time. At the start of the project we will validate the inactivation of lentiviral vectors following autoclaving. HT1080 cells will be grown in the presence of increasing (10 fold) amounts of inactivated waste. The cells will then be selected for using the antibiotic blasticidin and incubated for 10 days before being stained with Crystal Violet. The identification of any blasticidin-resistant colonies demonstrates the presence of active lentiviral vector within the 'inactivated waste'. The virucidal disinfectant, Virkon, has been validated for inactivation of lentivirus at a concentration of 1%. Details of Virkon testing from independent studies can be found at http://www.antecint.co.uk/MAIN/virkonvi.htm

Project Ref 490/11.3

Lentivirus-mediated genetic modification of mammalian cells for the study of mesenchymal stromal cells

Class 2 < 1 Litre

Non-GMM Consent Granted

Project notified under transitional arrangements

Tick if notifying a connected programme of work

Recipient or parental organism

For cloning of the different genes into the lentiviral cloning vectors, disabled K12-derived E. coli (One Shot Stbl3, Invitrogen or XL-1 Blue, Stratagene) will be used. The HEK293FT cell line (Invitrogen) and the HEK 293 LTV cell line (Cell Biolabs) (fast-growing cell lines derived from human embryonic kidney cells, containing the large T-cell antigen) will be used as the packaging cell lines for the lentiviral vectors.
VSV-G pseudotyped lentiviral vectors will be produced using the Cell Biolabs Virasafe Lentiviral Expression System and/or the ViraPower lentiviral expression kit (Invitrogen) by co-transfecting the 293FT and the HEK293 LTV cell lines with the expression construct and a lentiviral packaging mix containing 3 plasmids, each carrying genes encoding the necessary viral structural and replicatory proteins (to improve safety).

The live lentivirus and the lentivirus-infected cells will be cultured in a CL-2 biocabinet, and housed in a CL-2 CO2 incubator used solely for virus-infected cells.

**Origin & function**

<table>
<thead>
<tr>
<th>GFP</th>
<th>mCherry</th>
<th>LacZ</th>
</tr>
</thead>
<tbody>
<tr>
<td>is a 27kDa protein that exhibits bright green fluorescence when exposed to blue light.</td>
<td>is a protein emitting bright red fluorescence when excited by orange light.</td>
<td>encodes the bacterial protein beta-galactosidase, which catalyses the metabolism of lactose to glucose and galactose.</td>
</tr>
</tbody>
</table>

GFP, mCherry and LacZ are commonly used reporter genes whose expression can be deleted by fluorescence (GFP, mCherry), by using a substrate such as X-gal that is cleaved by beta-galactosidase to yield an insoluble blue product (LacZ), or by immunohistochemistry using antibodies against GFP, mCherry and beta-galactosidase. The insertion of these genes should not alter the tropism of the lentiviral vectors or give them harmful properties. Uptake of the lentiviral vectors into human cells could result in expression of the inserted genes.

Inoculation or ingestion of lentiviral vectors expressing reporter genes such as GFP, mCherry or LacZ is not thought to represent a significant hazard to human health nor to cause any pathogenic effect for the following reasons:

1. GFP, mCherry or LacZ activation does not lead to cell transformation.
2. It is highly unlikely there will be system-wide effects since these are genes encoding for proteins not present normally in the mammalian organisms, and therefore no biochemical or metabolic pathway should be affected by them.

**Evaluation of foreseeable effects**

We would not expect any specific symptoms as the result of an accidental infection with the genetically modified micro-organisms described in this application since the lentiviral vectors cannot replicate. The lentiviral vectors themselves are capable of transducing a broad range of cell types (as a result of the VSV-G gene) and therefore the reporter and expression genes will be stably integrated into any cell type that the vectors are exposed to. However, this is not thought to pose a significant risk to human health due to the reasons described in section 6 above; also, since lentiviral vectors will only be handled in a class II safety cabinet and sharps will be used in extremely controlled conditions, the risk of accidental injection, inhalation or ingestion of the lentiviral vectors is extremely low. The likelihood of this occurring is therefore extremely low also since plasmid DNA does not enter cells readily.

There is a very small theoretical risk that, if the lentiviral expression plasmid was accidentally injected into an individual carrying wildtype HIV, the vector could recombine, via the truncatedLTRs, with the wildtype virus to produce replication competent virus, carrying the expression or reporter genes. Thus, there would be the potential risk of mobilisation and transmission of the recombinant lentivirus to other individuals via the normal routes of HIV-1 transmission. Individuals known to be HIV-positive or to be immunocompromised will not be allowed to work on this project; these risks will be made clear to all personnel in the laboratory.

Lentiviruses require close contact for their transmission and their survival in the general environment is poor. Replication deficient lentiviruses cannot propagate so therefore, after infection of a cell they are incapable of further replication. It will be possible to demonstrate that the lentiviral vectors are replication deficient by plating 5% of the vector stock supernatant into mitotically active indicator cells (eg 293FT cells) and monitoring for syncitia formation or by PCR analysis of cells that have been transduced with lentiviral vector stocks using primers specific for pro-viral components, such as VSV-G. The insertion of the genes discussed in section 6 above is not expected to alter the tropism of the lentiviral vector or give it harmful properties.

The bacterial organisms are E. coli K12 derivatives; they have a proven safe history of use in routine cloning work and are unlikely to survive in the human gut or elsewhere. None of the genes expressed here would be expressed in these bacterial cells since the genes lack a bacterial promoter. Even if expression did occur, it would not be anticipated to confer any pathological advantage to the bacterial host. There is unlikely to be any hazard to the environment from these bacterial organisms.

The use of sharps will be generally prohibited, and allowed only in particularly planned and controlled circumstances.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be autoclaved before disposal down the sink. Plastics and other solid disposable waste will be collected in autoclavable bag within the biological safety cabinet, sealed and then sprayed with Virkon, (1:100, following manufacturer's recommendations). The bag will then be removed from the safety cabinet into a clean autoclave bag, sealed and taken to the autoclave in a sealed container, where they will be autoclaved at 121°C for 15 minutes. The degree of kill following autoclaving will be 100%. The autoclaved waste will then be disposed of by continuous feed auger.

Glass bottles and other non-disposable vessels will be soaked in the appropriate concentration of Virkon (1:100 dilution, according to the manufacturer's recommendations) in a bucket with a sealed lid, rinsed well and then autoclaved at 121°C for 15 minutes.

Validation will involve regular testing of the autoclave to demonstrate, using independent thermocouples placed at the centre of the load, that the correct time and pressure have been reached for the required time.

To validate the inactivation of lentiviral vectors following autoclaving. HT1080 cells will be grown in the presence of increasing (10-fold) amounts of inactivated waste. The cells will then be selected for, using the antibiotic blasticidin and incubated for 10 days before being stained with Crystal Violet. The identification of any blasticidin-resistant colonies demonstrates the presence of active lentiviral vector within the 'inactivated waste'.

Regarding waste coming from in vivo experiments, harvested biological materials (tissues and body fluids) will be either fixed in 4% paraformaldehyde or preserved in PBS for further analysis or culture expansion of the freshly isolated samples. In the latter case, tissues will be transported back to our lab in appropriate CL-2 safety containers.

At the end of all experiments, any remaining lentiviruses, unfixed tissues or cells will be disinfected in 1% Virkon and then autoclaved at 121°C for 15 minutes prior to disposal.

The virucidal disinfectant, Virkon, has been validated for inactivation of lentivirus at a concentration of 1%. Details of Virkon testing from independent studies can found at http://www.antecint.co.uk/MAIN/virkonvi.htm

Salmonella enteritidis and S. typhimurium continue to be a major worldwide cause of disease. Their pathogenicity has been linked to virulence factors, of which flagella and fimbriae are considered to be important in early association of the bacteria with the gut epithelium and immune system. However, the exact roles of these virulence factors remain unclear.

To evaluate the roles of these bacterial factors in pathogenic interactions with the host gut and immune system, genetically altered (GA) salmonella strains unable to express virulence factors, including flagella [FliC], fimbriae [sef21 (type 1), sef17, sef14, lpf or pef] or combination thereof were prepared at the Veterinary Laboratories Agency (Weybridge, Addlestone, Surrey KT15 3NB). Strains with disabled flagella (che- or mot-) or containing in addition Green Fluorescence Protein (GFP) as a marker have also been developed. These GA strains will be applied to epithelial or immune cells in culture to monitor their effects on key molecular signalling systems and gene activation, in particular production of pro-inflammatory or survival factors. Alternatively, they will be used to orally infect mice (normal or genetically altered [deletions in key bacteria response pathways, such as Toll-like Receptors] mice). The ability of the strains to colonise the gut, interact with and modulate cross-talk between epithelial and immune cells, interfere with the local immune system, invade and spread systemically and cause acute and long-term illness will be evaluated.

The overall aims of the studies are to establish the roles of flagellin and fimbriae in short- and long-term host responses to infection and identify possible new therapeutic strategies to prevent or ameliorate infection by salmonella.
### Host/vector system

Deletion mutants: DNA fragments, which encoded relevant regions for flagella or fimbriae were amplified by PCR. These fragments were sub-cloned separately into pCRSCRIPT. Antibiotic resistance gene cassettes were cloned separately into these fragments, either by direct sub-cloning or by splice overlap extension PCR. The insertionally inactivated genes were sub-cloned on to appropriate PERFORM vectors and electroporated into Escherichia coli. The PERFORM vectors were transferred by conjugation from host E. coli (Allen-Vercoe et al, 1999). The deletion mutants carry no recombinant vector sequence (confirmed using Southern Blot Analysis). The nature of the recombination event led to complete loss of vector sequence from the strains.

Insertion mutants: Green Fluorescence Protein (GFP): GFP plasmid DNA, purified from E. coli XL1-blue, was electroporated into Salmonella (Wild-type or GA) strains.

### Origin & function

The GA salmonella strains are unable to express flagella [FliC] or individual fimbriae [sef21 (type 1), sef17, sef14, lpf or pef] or combinations thereof. Alternatively, they have disabled flagella (che- or mot-) or strains (wild-type and GA) in addition contain Green Fluorescence Protein (GFP) as a marker.

GA strains will be applied to cells in culture or given orally to mice (wild-type or GA [for example mice with deletions of key bacterial-response pathways]) to monitor and compare their effects on host cell metabolism and pathogenicity.

The studies will establish the requirements and roles of flagellin and fimbriae for effective and appropriate in short- and long-term host gut and immune responses to infection. This should facilitate development of new therapeutic strategies to combat or ameliorate infection by salmonella.

### Evaluation of foreseeable effects

Deletion of fimbriae will either have little or no effect on the pathogenicity of salmonella or will reduce its ability to infect. Experimental studies in vitro and in vivo with GA strains unable to express selected fimbriae support this (Allen-Vercoe et al. 1999; Robertson et al. 2000).

Results from studies with aflagellate salmonella are equivocal. The infection caused by aflagellate salmonella in salmonella-resistant mice is slightly more severe than that triggered by the parent strain (Vijay-Kumar et al, 2006). This appears to be due to failure of the host immune system to properly recognise or respond to aflagellate salmonella [lack of signalling via flagellin / TLR5 axis]. In contrast, the differences in pathogenicity of flagellate or aflagellate salmonella are much less marked in salmonella-susceptible mice, which are often used to model of severe systemic salmonellosis in humans. Furthermore, aflagellate salmonella is much less infective than wild-type salmonella for rats and chicks (Allen-Vercoe et al. 1999; Robertson et al. 2003).

The GA salmonella have specific antibiotic resistance cassettes within the targeted genes and thus have resistance to ampicillin, chloramphenicol, zeocin, kanamycin, tetracycline, trimethoprim or combinations thereof. They remain susceptible to the action of other antibiotics. In humans, treatment of salmonellosis with antibiotics is done only if the infection spreads from the intestines or otherwise persists. The antibiotics used would be ampicillin, gentamicin, trimethoprim/sulfamethoxazole, ceftriaxone, amoxicillin, or ciprofloxacin.

Human health could possibly be at slightly greater risk if exposed to aflagellate S. enteritidis or S. typhimurium as compared to its wild-type counterpart. However, the effects of the aflagellate salmonella strains we hold still remain far less severe than those caused by the most pathogenic of wild-type salmonella strains.

Recent studies have revealed that a proportion of the human population have polymorphisms in TLR5. If this prevents activation of TLR5 by flagellin, the susceptibility and reactivity of these individuals to wild-type salmonella is likely to be increased in a manner similar to that which we have observed with aflagellate salmonella.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Culture waste, tissue homogenates, containers and vessels, dilutions, agar plates and extracts derived during the study and associated laboratory waste will be autoclaved as will be caging, tissue, carcass, faeces and urine, bedding material, culture and food waste collected during animal experiments. Isolators are sterilised by being sprayed down with 1% Virkon or are sprayed down with Alcide, prepared in accordance with the manufacturer’s instructions. A kill efficacy of 100% is expected and all facilities are regularly monitored to ensure effective operation / killing

Please enter comments on the GM safety committee on the risk assessment

Original notification
GM227/95.1 Prevention of salmonellosis in humans and farm animals by natural dietary compounds [15 Feb 95].

Notification under the transitional provisions of the GMO Contained Use Regulations 2000
GM227 Role of fimbriae and flagella in pathogenicity of Salmonella enteritidis in the rat or mouse [14 Feb 01].

Present Application (CPU2): Movement of project from the GM Centre at the Rowett (Centre GM227) to GM Centre at Foresterhill (GM490).

The Committee discussed with Drt how he felt the aflagellate mutants of S. enteritidis and S. typhimurium may increase the severity of infection compared to wildtype strains. The Committee were satisfied, following Dr ’s explanation, that the overall risk to human health from these aflagellate strains was much less severe than that posed by most wildtype strains of salmonella and thus remained within the limit of acceptable risk for activity class 2 organisms.

This project was approved at Activity Class 2, Containment Level 2 by the Local Genetic Modification Safety Committee.
Project Additional Information

Purposes of the contained use

The goal of the work is to examine the virulence of Fusarium oxysporum urease mutants. These mutants have been created elsewhere and would be grown in enclosed, sealed bottles in small volumes (<200ml). Conidia of the different strains will be used for virulence assays on mice, as well as for microscopy analysis.

Recipient or parental organism

Fusarium oxysporum is a soil-borne fungus that is a common part of the plant decomposing microflora and can act as a plant pathogen. It can occasionally cause opportunistic infections in severely immunocompromised humans. Every one of us is likely to be exposed to spores of this fungus every day from environmental sources.
Host/vector system

Fusarium oxysporum targeted mutants lacking the genes ureG (urease accessory protein), ure1 (structural urease) or dur3 (urea transporter), as well as complemented strains of these mutants have been created elsewhere. The mutants have been generated by gene inactivation via the insertion of a positive selectable antibiotic marker (encoding the hygromycin or phleomycin resistance gene, hph or phleo, respectively). GFP- and cherryFP-labelled transformants were also created and will be used for microscopy analysis.

Origin & function

DNA fragments for construction of the GMMs, containing the sequences flanking the genes ureG (urease accessory protein), ure1 (structural urease) or dur3 (urea transporter), the complete sequences of these genes, the positive selectable antibiotic markers encoding the hygromycin or phleomycin resistance genes, and the GFP- and cherryFP genes were all generated elsewhere by PCR amplification. No transfer of these DNA sequences will be performed in this study.

Evaluation of foreseeable effects

The urease mutants under investigation attenuate the fungus, preventing infection of plants. It is anticipated that the mutants will also be attenuated in humans compared to the wildtype strain but these data are yet to be confirmed and published. Sporulating cultures will not be used in this project, thus preventing the risk of aerosol generation in these experiments. In any event, individuals who are severely immunocompromised will not be permitted to work on the project.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All cultures are in bottles (liquid cultures) and are killed by autoclaving prior to cleaning. Chemical activation of spills and cleaning bench surfaces and equipment will be performed using 2% Trigene, as recommended by the manufacturer. Validation will involve regular testing of the autoclave to demonstrate, using independent thermocouples placed at the centre of the load, that the correct time and pressure have been reached for the required time. At the start of the project we will validate the inactivation of the GM F. oxysporum by plating samples on solid YPD laboratory medium. This process will be repeated monthly and records kept of test results. Trigene inactivation will again be validated by plating samples on solid YDP agar. This process will be repeated monthly and records kept of the test results.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

This application was approved at Containment Level 2 by the local Genetic Modification Safety Committee. They were satisfied that since there is no intention to generate spores in cultures of GM F. oxysporum there was no requirement for the use of a safety cabinet to handle the cultures.

**Project Additional Information**

**Purposes of the contained use**

To safely generate induced pluripotent stem cells (iPSC) from human peripheral blood mononuclear cells (PBMCs) using Sendai viral vectors.

**Recipient or parental organism**

Sendai virus (SeV): No modification/production of the viral vectors will be performed on site. We will purchase the viral vectors as part of a ready to use kit. Sendai virus is ACPD class 1 organism and is a murine parainfluenza virus that is non-pathogenic to humans, yet these genetically modified sendai viral vectors can transduce human and animal cells. The Sendai virus in the CytoTune kit is a non-transmissible virus, with the Fusion protein deleted. Therefore they are no longer capable of producing infectious particles from infected cells. (ref: Li, H.O. et al. A cytoplasmic RNA vector derived from nontransmissible Sendai virus with efficient gene transfer and expression. J. Virol.)
Peripheral blood mononuclear cells: human peripheral blood mononuclear cells purchased from commercially available sources (Frozen PBMC, STEMCELL, cat# PB003F). This would help us to optimise and standardise protocols for iPSC generation.

Host/vector system

CytoTune™-iPS Reprogramming System uses vectors based on replication incompetent Sendai virus (SeV) to safely and effectively deliver and express key genetic factors necessary for reprogramming somatic cells into iPSCs. The CytoTune™-iPS Reprogramming Kit contains four SeV-based reprogramming vectors, each capable of expressing one of the four Yamanaka factors (i.e., Oct4, Sox2, Klf4, and c-Myc) and are optimized for generating iPSCs from human somatic cells.

Origin & function

Unlike other viral transduction methods, SeV (belonging to the paramyxoviridae family) does not integrate in the host genome and remains in the cytoplasm (ref: Fusaki, N. et al., Efficient induction of transgene-free human pluripotent stem cells using a vector based on Sendai virus, an RNA virus that does not integrate into the host genome. Proc Jpn Acad Ser B Phys Biol Sci 85, 348-362, 2009). The SeV vectors replicate in the form of negative-sense single-stranded non-segmented RNA in cytoplasm of infected cells and does not go through a DNA phase. Reprogramming would be achieved by transfecting PBMCs with the four Yamanaka factors (Oct4, Sox2, Klf4, and c-Myc, ref: Takahashi, K. & Yamanaka, S. Induction of pluripotent stem cells from mouse embryonic and adult fibroblast cultures by defined factors. Cell 126, 663–676, 2006).

Oct4, Sox2, Klf4, and c-Myc will each be delivered in separate SeV vectors. Oct4 regulates the pluripotency of embryonic stem cells and under and overexpression has been associated with cell differentiation. Sox2 acts cooperatively with Oct4 to regulate pluripotency. Klf-4 is a transcription factor that regulates transcription factor expression during development. C-Myc, with roles in regulating cell proliferation and apoptosis, is a proto-oncogene and is overexpressed in many cancers. Together, they are a recognised cocktail of genes required for reprogramming somatic cells to a stem cell phenotype. The expression of these genes results in cells adopting a phenotype whereby they have self-renewal capacity and the ability, under managed conditions to proliferate indefinitely.

Evaluation of foreseeable effects

Although human is not the natural host for the SeV, and the virus is non-pathogenic to humans, appropriate care must be taken to prevent the potential mucosal exposure to the virus, since the vectors are capable of transducing human cells.

Given that the deletion of the fusion protein within the CytoTune sendai virus results in a non-transmissible virus, the hazards associated with these vectors are as a result of the nature of the inserted genes. Overexpression of any of these genes can result in dysregulation of cell proliferation, differentiation and survival and therefore potentially transform the cells. Therefore, following centrifugation and for all handling, the tubes containing CytoTune sendai viral particles will be opened in the Class 2 safety cabinet to avoid exposure to aerosolised particles.

Serologically positive rodents (the natural host for sendai virus), animals that have already been infected with wild type SeV, may be able to make infectious CytoTune™-Sendai virus. Sendai virus affects the respiratory tract and causes severe respiratory disease in rodents. It can be spread by contact and airborne transmission including through air circulation systems. We will not be performing any experimental work with animals, however, as a rule it is recommended that after handling sendai viral vectors or infected animals, a period of at least 3 hours should elapse before contact with other animals.

Once reprogrammed to iPSCs, there will be no additional hazard of handling the human cells (above that of handling the untransduced cells) given that the sendai virus is non-transmissible.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be autoclaved before disposal down the sink. Plastics and other solid disposable waste will be collected in autoclavable bag and autoclaved, collected in "orange waste bag stream" for maceration to make it unrecognisable and further heat treated before being placed in landfill. All waste will be transferred to the autoclave facilities in a sealed container. The degree of kill following autoclaving will be 100% since there is a high expectation of kill of sendai viral particles exposed to 121ºC for 15 minutes. Trigene disinfectant (2%, to be validated prior to start of the project) will be used to deal with spills.

Validation will involve regular testing of the autoclave to demonstrate, using independent thermocouples placed at the centre of the load, that the correct time and pressure have been reached for the required time. Sendai viruses are inactivated at temperatures above 37ºC. At the start of the project and at monthly intervals, we will validate the inactivation of sendai viral vectors following autoclaving by incubating cultures of Hela cells with autoclaved liquid waste. We will then perform reverse transcription on RNA isolated from the Hela cells, followed by PCR using primers to specifically amplify the viral genome to determine whether any virus had been incorporated into the cells.

Records will be kept of the results from each test.

Date Project 02/03/2022  Page 7842 of 15326
The main aim of the work is to examine interaction of host neuronal cells and fluorescently labelled HSV-1 in in vivo and in vitro experiments and their response to stress (surgery). These GM HSV-1 mutants were created elsewhere, would be used predominantly for confocal microscopy analysis.

Herpes simple virus-1 - linear double DNA stranded virus - is well spread pathogen in normal population. In some populations almost 90% of healthy adults are serologically positive and as such they have been previously exposed to HSV-1 without any local or systemic symptoms or sequela. It can occasionally cause opportunistic infections in severely immunocompromised individuals. As GM modification of WT virus is adding fluorescent tags to the normal WT genes, it is unlikely that GM virus would have different virulence characteristics than WT virus.

The GM HSV-1 were generated elsewhere by insertion of final constructed plasmid [fluorescent tags - gene for green fluorescent protein (GFP), red fluorescent protein (RFP) and Cherry red] together with HSV-1 RE infectious DNA into Vero cells, using Lipofectamine 2000 (Invitrogen, Carlsbad,CA) as per the manufacturer's instructions. These GFP-, RFP- and Cherry red-labelled transformants will be used for microscopy analysis.

Origin & function

Published in vitro replication kinetics and in vivo infectivity of fluorescent HSV-1 mutants seems to mimic and certainly it is not more severe the infection with wild type virus (in Srividya Ramachandran, Jared E. Knickelbein, Christina Ferko, Robert L. Hendricks, Paul R. Kinchington: Development and pathogenic evaluation of recombinant herpes simplex virus type 1 expressing two fluorescent reporter genes from different lytic promoters. Virology 378 (2008) 254–264.).

In any event, individuals who are severely immunocompromised and pregnant woman will not be permitted to work on the project. Any exposure of laboratory personell with WT or GM HSV-1 will be treated effective prophylaxis, which is available (Acyclovir tablets).
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

LIQUID WASTE - All liquid will be drained with a pastette to waste beaker and will be treated with 1% Virkon solution, left 12 hours or overnight before flushing to drains with copious amounts of water. Beaker will be placed on white biohazard tray so that any spillage can be easily identified and dealt with. All waste will be clearly labelled.

SOLID WASTE - HSV-1 contaminated plastics will be placed in autoclave bag along with any other associated solid waste. Contaminated surfaces will be sprayed with 1% Virkon solution and wiped clean with paper towel. Autoclavable waste will be removed from lab as soon as work is completed double bagged and blue tagged and autoclaved at 121 degree C for 15 minutes.

Autoclave is fitted with internal probes that allow external monitoring of temperature, humidity, time and pressure. The efficiency of the sterilisation cycle is tested with Prestige indicator strips.

Degree of kill is 100% when using autoclave for decontamination of solid waste, 1% Virkon for a minimum of 1 hour will be used for liquid waste. This is standard method for inactivation of a wide spectrum of micro-organisms including viruses.

Project Ref 490/12.5
Characterisation of a C-type lectin receptor

This application covers a range of specific projects with the overall aim to define the ligand and range of mycobacterial species that are recognised by a C-type lectin receptor, and to determine the physiological role of this receptor in vitro and in vivo. In particular, this project will utilise a range of non-pathogenic mycobacterial species including both wild-type and GM Mycobacterium smegmatis and M. bovis BCG.

Recipient organisms include M. bovis BCG strains Tokyo and Pasteur and M. smegmatis mc2155. All mycobacterial strains used in this project are either listed as hazard group 2 (M. bovis BCG) or are not listed (M. smegmatis). M. smegmatis is a non-pathogenic soil organism, but due to its taxonomic grouping it is being treated as a group 2 organism. M. bovis BCG is routinely used as a vaccine against M. tuberculosis in humans.

The risk of life-threatening infections with M. smegmatis and M. bovis BCG is negligible in healthy individuals. However, M. smegmatis has been reported to cause localized skin and soft tissue infections following traumatic injury or cardiac surgery. Immunocompromised and elderly individuals are more susceptible to M. bovis BCG, which can cause pulmonary infections.

In some of the experiments, tissues which may contain small amounts of live GM bacteria are removed from infected animals and transported back to the IMS in sealed containers for various experiments including the determination of bacterial burden and histology (IMS 4.08 and 4.27). Frozen, unfixed sections may be analysed by fluorescence microscopy (IMS 4.28). These sections would contain very small amounts of bacteria therefore present minimal risk. Local GM regulations will be posted in all locations.
In other experiments small amounts of fixed GM mycobacterial cells will be analysed by FACS (<106 cells per sample, IMS 4.08A). Local GM safety procedures have been established for the decontamination of samples and equipment. Fixed samples are expelled directly into 5% Tri-gene. Local GM regulations will be posted in all locations.

Origin & function

The nature of the mycobacterial ligand is currently unknown but possible candidates include genes encoding pathways responsible for the production of cell wall components such as lipids, PIM1,2, PIM6, MAME, LAM, man-LAM, TDM, which could be involved in host cell recognition. More commonly, we will be utilising mycobacterial strains expressing fluorescent markers, such as GFP or commonly used markers for studying immunological processes, such as ovalbumin.

Evaluation of foreseeable effects

It is extremely unlikely that gene deletion and complementation with heterologous genes will alter the virulence of the GMM compared to that of the parent organism. In fact, deletion of cell wall components is most likely to reduce virulence, as has been demonstrated in the literature (Mahon RN et al, 2012, Smith I, 2003).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- Liquid waste: 5% Trigene (as per the manufacturer’s instructions)
- Glassware: Soaked with 5% Trigene or autoclaved.
- Plasticware: autoclaved
- Sharps: Contaminated sharps are placed in CinBins, bagged and incinerated.
- Slides from microscope facilities: Slides are transported to/from microscope rooms in plastic petri dishes with their tops sealed with tape or parafilm, and then disposed of as per Sharps.
- Animals and Tissues: All carcases are autoclaved within the MRF, and remaining tissues are autoclaved prior to disposal.
- FACS facility: Fixed samples are expelled directly into 5% Trigene and equipment will be decontaminated with 5% Trigene.

The degree of kill achieved will be >99.99% This is based on previous disinfection validation procedures and information from the equipment and chemical suppliers. Validation will involve sampling inactivated cultures and culturing the samples in rich media plates. Survival of mycobacteria will be assayed by growth at 37°C (M. smegmatis, and M. bovis BCG).

Once GMMs have been inactivated, killed liquid waste is discarded down the sink. Inactivated solid waste is discarded by CFA processing.

**Project Ref** 490/13.1

- **Date Ackn'd**: 04/02/2013
- **CU2 Project Title**: Interspecies interactions and mechanisms of killing of the fungus, Candida albicans, by the bacterium, Pseudomonas aeruginosa
- **Date Project Ceased**: 23/02/2021
- **Date of Significant Change**: N
- **Historical Significant Changes**: Yes
- **Historical Date of Additional Info**: Yes
- **Significant Change ID**: N
- **Project notified under transitional arrangements**: N
- **Consent Granted**: Non-GMM

**Project Additional Information**

Candida albicans and Pseudomonas aeruginosa are opportunistic pathogens that can be co-isolated from the cystic fibrosis lung. They have also been used as a model system by several labs for the study of interspecies communication. Previous work by Dr. B has shown that killing of C. albicans hyphae, but not yeast, by the bacterium can occur through the activity of bacterial secreted factors but is more efficient in the presence of the bacterium. The rate of killing is also affected by alterations in the glycosylation state of the fungal cell-wall (Brand et al, 2008).
a. GOALS OF THE PROJECT:
1. To determine the role of P. aeruginosa quorum-sensing (QS) signalling in the killing of C. albicans;
2. To elucidate the mode-of-action in the killing of C. albicans by P. aeruginosa;
3. To characterise inter-species interactions in the context of mixed-species biofilms.

Recipient or parental organism
The P. aeruginosa GM strains used in these experiments are generated in the well-described wild-type backgrounds PAO1 (Stover et al. 2000) and PA14 (Rahme et al. 1995), two fully sequenced strains (www.pseudomonas.com). The strains will be sent to the University of Aberdeen by Dr. S D, using triple-layer packaging and UN3373 labelling, according to Packaging Instruction P1650 for the transport of a Biological Substance Category B.

Host/vector system
Although vectors will be used to deliver DNA elements into the P. aeruginosa genome in order to generate mutant strains, this work will be carried out at the University of Nottingham. The strains used in Aberdeen will not contain vectors and no vectors or plasmids will be used or held in Aberdeen.

Origin & function
We will be using strains which have been genetically modified by gene deletion, gene mutation or gene reporter fusions. The deleted or modified genes will be those associated with quorum sensing in P. aeruginosa. Specifically these are genes regulating, and regulated by, the las operon, the rhl operon and the pqs operon. These include lasI, lasR, rhlI, rhlR, pqsA, pqsB, pqsC, pqsD, pqsH, pqsE, pqsR, pqsL, chic (chitinase), cbpD (chitin binding protein), pvdA, pvdD, pvdH, mexA, mexB, mexH, mexI, opmD, rhiA, phzB1, phzB2, phzA1, phzA2, phnA, phnB, phoB, phoR, lecA, lecB, rsaL, pchA, pchE, catA, catB, hcnA, hcnB, hcnC, rpoS, qscR.

Evaluation of foreseeable effects
a. P. aeruginosa is an environmental bacterium that lives naturally in water, moist soil and swamp conditions. It can become an opportunistic human pathogen in patients with compromised epithelial and immune defences, such as sufferers of cystic fibrosis or those with wounds or burns. P. aeruginosa falls within the ACDP Hazard Group 2. Transmission to people within the laboratory could occur via ingestion, wounds and the eye mucosa, particularly in wearers of extended-use soft contact-lenses. Gloves should be worn to minimise the likelihood of mouth/eye/wound transmission from the hand. Soft contact-lens wearers will use safety goggles when handling the organism. The pathogenic P. aeruginosa can be transmitted via the respiratory tract to people who are severely immunocompromised or are suffering from cystic fibrosis. Such people will not be permitted to work with the organism. P. aeruginosa work is routinely carried out on open-top benches in Class 2 laboratories but risk of exposure to aerosols will be avoided. P. aeruginosa cultures will be centrifuged in sealed-bucket centrifuges and the tubes allowed to sit for 10 minutes prior to opening to allow the aerosols to settle. In the event of equipment failure, such as a burst tube, the centrifuge bucket and the tubes it contains will be removed to a microbiology safety cabinet for decontamination. Safety goggles will be worn during the vortexing of cultures. Lab workers are made aware of these risk factors and are asked specifically in the Local Regulations to make their supervisors (or Occupational Health) aware if they are exposed or susceptible to any such risk factors.

b. The genes inserted as selectable markers will confer resistance to the antibiotics gentamicin or tetracycline, which are not commonly used to treat infection by P. aeruginosa. The compounds, gentamicin and tetracycline, will not be used routinely in Aberdeen, since the insertions are stably in the genome and plasmid maintenance is not required. The genes inserted as fluorescence markers will be standard fluorescent proteins (eg, GFP) used for localisation studies by microscopy. Genes inserted as promoter reporters will be commonly used constructs such as the lacZ gene, which produces a colour change in the cells. The genes inserted for investigation of protein function will be P. aeruginosa genes that have been modified by point mutation with the aim of disabling QS signalling (see c below). The risks arising from the insertion of these genes are low.

c. The virulence factors produced by P. aeruginosa are regulated through the QS pathways, which will be disabled by mutation or deletion of the regulators and effectors of these pathways. The mutation or deletion of QS genes results in an overall reduction of potentially harmful production of toxins (Williams and Camara, 2009). The QS mutants to be used have been shown, in many animal experiments, to be significantly less virulent than wild-type organisms (Rumbaugh et al. 1999; Rumbaugh et al. 2009). The isogenic mutants are extremely unlikely to be more virulent than the parent strains, even in susceptible patients. In addition, a human infection by any of these mutants can be eradicated by antibiotic therapy.
d. The mutants used will have QS genes chromosomally disrupted, so there is little chance of the natural transfer of the mutated gene to other organisms.

In summary, the “Likelihood of Hazard” is medium, since we are handling a potential pathogen and it is not possible to exclude accidents entirely, although there have been no accidents involving P. aeruginosa since the start of work on wild-type cells in the AFG in 2003. The “Consequence of Hazard” is low, since serious infections only occur in individuals with pre-disposing conditions (cystic fibrosis, open wounds/burns or severely compromised immune systems. Therefore the “Estimation of Risk to Humans” is low.

Quorum-sensing mutants have been shown to be significantly less virulent than their wild type counterparts. If these mutants were to enter the environment they would provide no extra risk than those posed by natural populations of P. aeruginosa found in the environment. In addition, natural QS mutants can be isolated from both the environment and human cystic fibrosis infections so quorum sensing mutation is natural within P. aeruginosa populations.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- Liquid waste: 2 % Trigene/Distel (active ingredient = TM307).
- Glassware: Soaked with 2 % Trigene/Distel (TM307) or autoclaved.
- Plasticware: autoclaved.
- Sharps: Contaminated sharps are placed in CinBins, bagged and incinerated.
- Slides from microscope facilities: Slides are transported to/from microscope rooms in plastic petri dishes with their tops sealed with tape or parafilm, and then disposed of as per Sharps as they carry minimal volumes of cultured cells (<20μl) and present minimal risk.
- Samples used for analysis by scanning electron microscope will be fixed in 2.5 % glutaraldehyde and 3 washes with ethanol, which has been established experimentally to kill 99.99 % P. aeruginosa cells.
- Liquid waste, after inactivation, will be disposed of to drain. Solid waste, after inactivation will be sent off site as part of the “orange bag” waste stream. The waste will be macerated to make it unrecognisable and further heat treated before being placed in landfill.
- In the event of spillage, the contaminated area is flooded with concentrated Trigene/Distel (to 2 % final conc.), mopped up with paper towels, and reswabbed with 2 %. Killing at >99.99% has been validated experimentally. Contaminated material is autoclaved.
- The use of Trigene/Distel has been validated experimentally to kill >99.99% of cells. Viability tests were performed on Trigene/Distel-exposed cultures. Central autoclaves are validated at least annually by means of biological indicators. In addition we have validated killing at >99.99% by plating samples harvested from the centre of autoclaved samples. In daily use, monitoring is by thermocouple temperature recordings and autoclave strips included in the loads. Bench-top autoclaves in our laboratory are also tested regularly. We test these autoclaves monthly, and in addition they are examined by external experts twice a year. We have validated killing at >99.99% by plating samples harvested from the centre of autoclaved samples.
- No viable cells have been recovered after fixation in 2.5 % glutaraldehyde and 3 ethanol washes, as used for scanning electron microscopy.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
This application was approved at Containment Level 2 by the local Genetic Modification Safety Committee. They were satisfied that generally the work could be carried out on the open bench. Following experiments to determine the risk posed by aerosols after centrifugation, it was agreed that tubes containing more than 10 ml culture should be allowed to sit for 10 minutes following centrifugation prior to opening the tube. In the event of a split tube, the centrifuge bucket would be opened in a Class 2 microbiology safety cabinet for decontamination.

Project notified under transitional arrangements: N
Project Additional Information

Purposes of the contained use

The objective is to understand how zygomycete fungal pathogen interacts with innate immune systems and how calcineurin is involved in this interaction. The two calcineurin mutants have been created at Duke University, Durham, NC, USA. Wild-type and mutants will be grown on agar plates for spore or yeast production. The spores or yeast then will be co-cultured with macrophages in vitro to examine the interactions.

This experiment is to elucidate 1) how spore size affect the host-pathogen interactions and 2) how calcineurin is involved in the host-pathogen interactions.

Recipient or parental organism

Mucor circinelloides is a soil-borne fungus that is common part of microflora. Mucor is also known as bread mould and a common lab contaminant. Therefore exposure to these organisms with high spore counts in immunocompetent individuals does not normally cause problems. Zygomycete fungi are potential human pathogens in immunocompromised individuals and are therefore ACDP Hazard Group 2. Under certain circumstances such as neutropenia due to solid organ or bone marrow transplant, and in poorly controlled diabetic patients this fungus is a potential life-threatening pathogen of high morbidity. Rare cases have been reported in individuals with no apparent underlying predisposition but systemic infection does not occur in healthy individuals so is readily treated with anti-fungal agents. The strains (CBS277.49 and NRRL3631) used in this study are not virulent in the heterologous murine host.

Two wild-type strains will be used: CBS277.49, a larger spore producer and NRRL3631, a small spore producer

Host/vector system

Mucor circinelloides has one calcineurin B regulatory subunit (CnbR) and three calcineurin A catalytic subunit (CnaA, CnaB, and CnaC). MSL9 and MSL10 are cnaA mutants and MSL7 and MSL8 are cnbR mutants

Origin & function

We will be using strains of Mucor circinelloides which have been genetically modified by gene replacement. The cnbR and cnaA genes were replaced with the auxotrophic marker gene, pyrG, that is originated from its own genome and has no effect on virulence.

Evaluation of foreseeable effects

The strains to be used are attenuated by either (i) auxotrophy or (ii) due to disruption in calcineurin genes. Wild type strains that have not been subjected to genetic manipulation may be used as controls.

Mucor circinelloides spores are very common in all environments since it is a part of the normal microflora of all plants and decaying vegetation. The main hazard is from the inhalation of large numbers of spores leading to sensitisation over many years (e.g. "farmers lung") or invasive mucormycosis in a few severely immunocompromised patients who would normally already be in intensive care. These patients include organ and bone-marrow transplant patients and cancer patients. In terms of diabetics, it is usually associated with poorly controlled diabetes involving ketocidosis. Individuals will be made aware of the risks of the project and will be asked to inform their supervisor or Occupational Health if they have any concerns. Although extremely rare, mucormycosis generally affects the skin, sinuses or lungs. It is anticipated that the calcineurin mutants used in this study will be less pathogenic than their wildtype counterparts.

We will therefore prevent the release of spores. All cultures are in sealed dishes or bottles and are killed by autoclaving prior to cleaning. Cultures that are heavily sporylating will only be opened in a microbiology safety cabinet and used for sub-cultures although even acute exposure to high numbers of spores does not lead to disease. It is noted that mucoraceous fungi do not produce large numbers of aerially dispersed spores, such as with Aspergillus species.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste: 1% Trigene
Glassware: soaked with 1% Trigene or autoclaved.
Plasticware: autoclaved
Sharps: Contaminated sharps are placed in CinBins, bagged and incinerated.

Our standard procedures for use of Trigene have been validated experimentally to kill >99.99% of cells. Viability tests were performed on Trigene-exposed cultures. Autoclaves on level 1 are validated at least annually by means of biological indicators. In addition we have validated killing at >99.99% by plating samples harvested from the centre of autoclaved samples. In daily use, monitoring is by thermocouple temperature recordings and autoclave strips included in the loads. Bench-top autoclaves in our laboratory are also tested regularly. Our laboratory Manager tests these autoclaves annually. We have validated killing at >99.99% by plating samples harvested from he centre of autoclaved samples.

Project Ref 490/13.3

Date Ackn'd 19/08/2013  Project Title Protein expression in mammalian cells using lentiviral constructs

Class 2  CultureVolClass2 < 1 Litre  CultureVolumeClass3-4

02/03/2022  Page 7852 of 15326
Project Additional Information

Purposes of the contained use

To examine how overexpression of factors regulating translation affect neuron function.

Recipient or parental organism

- E. coli K12 derivatives DH5-alpha, XL-1 blue, JM-109 will be used for amplification of the pLKO.1 and perceiver plasmids containing expression cassettes for shRNA and protein expression, respectively.
- HEK293TN cells, primary rodent neurons, neuronal cell lines including SH-SY5Y, HCN-A94 and PC12 cells, transformed mammalian cell lines including HeLa and U2OS cells.

Host/vector system

- System Biosciences’ (SBI) lentivectors are a set of third generation lentivectors developed for gene therapy. The multi-plasmid system consists of three plasmids that make up the packaging mix, and one plasmid, the lentivector, containing the expression cassette and elements for the synthesis of the production of viral RNA. The packaging mix is composed of pPACKH1-GAG, pPACKH1-REV and pVSV-G, and these are transfected together with a lentivector into HEK293TN cells to produce infective particles. The viral RNA expressed from the lentivector is then packaged by the proteins produced by the packaging mix into viral particles.

Origin & function

We have discovered mutations in the promoter of the translation initiation factor eIF4E that increase eIF4E expression in patients with autism and schizophrenia (Neves-Pereira et al., J. Med. Genet. 46;759-765) and there is evidence from others that overexpression of eIF4E predisposes to autism. eIF4E is central to the control of translation, and localized post-synaptic translation is involved in long-term potentiation and instrumental in memory and learning. We will examine how overexpression of eIF4E affects neuron function. We have already tested the effects of eIF4E overexpression using plasmid-based overexpression. Although findings are promising we were hampered by low transfection efficiency in achieving our aim, the analysis of the effects of candidate protein expression on neuronal differentiation, RNA and protein expression. This problem can be solved by using lentivirus-based constructs for protein overexpression. We will express eIF4E, an essential translation initiation factor conserved in humans and rodents in neuronal and other cells.

Evaluation of foreseeable effects

- Lentivectors have several biosafety features that prevent replication or recombination with wild-type virus in any way that would produce viable virus. They have a deletion in the enhancer of the U3 region of 3'LTR that ensures self-inactivation of the lentiviral construct after transduction and integration into genomic DNA of the target.
cells. The RSV promoter (in HIV-based vectors) and the CMV promoter (in FIV-based vectors) upstream of 5’LTR in the lentivector allow efficient Tat-independent production of viral RNA, reducing the number of genes from HIV-1 that are used in this system.

- The number of lentiviral genes necessary for packaging, replication and transduction is reduced to three (gag, pol, rev). The corresponding proteins are expressed from different plasmids that lack packaging signals. The packaging plasmids share no significant homology to any of the expression lentivectors, the pVSV-G expression vector, or any other vector, to prevent generation of recombinant replication-competent virus. None of the HIV-1 genes (gag, pol, rev) are present in the packaged viral genome, as they are expressed from separate plasmids lacking packaging signal. Therefore, the lentiviral particles generated are replication-incompetent.
- Produced pseudoviral particles will carry only a copy of your expression construct.
- This multi-plasmid approach results in no single plasmid containing all the genes necessary to produce packaged lentivirus.

The eIF4E protein is not toxic. Elevated expression of eIF4E has been found in cancer tissues and eIF4E overexpression promotes tumor formation (De Benedetti, A. and Graff, J.R.. eIF-4E expression and its role in malignancies and metastases. Oncogene 23: 3189-3199). Recently it was also described that mice overexpressing eIF4E develop autistic traits (Santini et al., Nature 493, 411-415).

As cells used are not able to colonise humans, and no sharps will be used to avoid accidental injection the eIF4E sequence does not present any additional risk.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

n/a

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Adding 1% Virkon to biological wet waste and plastics and leaving overnight prior to rinsing and disposal in double hazardous waste bags. Then all bags will be tagged with blue tags and labelled with the lab number prior to autoclaving and disposal. Inactivated liquid waste will then be disposed with normal liquid waste. Solid waste will be macerated and further heat treated before being placed in landfill.

Autoclaving is by validated (internal temperature probe linked to printout) autoclave, in the IMS building, reserved only for inactivation of waste (effective 100% kill). The autoclave undergoes annual testing to ensure correct operation.

The virucidal disinfectant, Virkon, has been validated for inactivation of lentivirus at a concentration of 1%. Details of Virkon testing from independent studies can be found at [http://www2.dupont.com/RelyOn/en_US/products/virkon.html](http://www2.dupont.com/RelyOn/en_US/products/virkon.html) or requested through [http://www2.dupont.com/RelyOn/en_US/sales_support/contact.html](http://www2.dupont.com/RelyOn/en_US/sales_support/contact.html).

Monitoring measures: HT1080 cells will be grown in the presence of increasing (10 fold) amounts of inactivated waste. The cells will then be selected for using the antibiotic blasticidin and incubated for 10 days before being stained with Crystal Violet. The identification of any blasticidin-resistant colonies demonstrates the presence of active lentiviral vector within the ‘inactivated’ waste.

### Additional Information

#### Purpose of the contained use
To investigate the effect of the Salmonella Typhimurium effector GtgE on the Rab32/BLOC-3 pathway

#### Recipient or parental organism
1) S. Typhimurium wild type strains SL1344, LT2 and 14028S.
2) Standard laboratory strains of disabled E. coli, such as DH5 and XL-1 blue, will be used for standard molecular biology procedures. The E. coli strain CC118 lambda-pir will be used for cloning pSB890-derived plasmids and the E. coli strain beta-2163 Δnic35 (described in Babic et al. doi:10.1016/j.resmic.2008.06.004) for conjugative transfer of pSB890-derived plasmids.

3) Human cell lines such as Hela or THP-1 and mouse cell lines such as RAW 264.7.

4) VSV-G pseudotyped replication-defective retroviral vectors based on Moloney murine leukemia virus.

**Host/vector system**

Non-mobilisable low copy plasmids (such as pWSK129 and pACYC184) and high copy plasmid, such as pUC, pcDNA3 or pEGFP, will be used in standard molecular biology procedures to transform disabled E. coli strains. The conjugative plasmid pSB890, which carries an R6K origin of replication only functional in strains expressing the pir gene, will be used for homologous recombination and allelic exchange. pLZRS retroviral vector, which contains contains long terminal repeat and packaging sequences from the Moloney murine leukemia virus, will be used to clone host transport factors (such as Rab32), will be used to generate VSV-G pseudotyped virus, and transduce mouse RAW 246.7 macrophages.

**Origin & function**

Fluorescent proteins (e.g., GFP and mCherry) will be cloned in low copy plasmids such as pWSK129 and pACYC184. The resulting plasmid will be transformed into and S. Typhimurium strains to be able to visualize the bacteria by live imaging microscopy.

We have previously shown that the S. Typhimurium effector GtgE is a cysteine protease that targets Rab32 and antagonize the Rab32/BLOC-3 pathway. Introduction of gtgE into S. Typhi allows S. Typhi to survive in mouse macrophages as a consequence of antagonizing the Rab32/BLOC-3 pathway (Spanò and Galán, Science, 338, 960). The anti-microbial mechanism associated to this transport pathway remains completely unknown. It is intended to to delete Salmonella type III secretion effector genes from S. Typhimurium. To this purpose the flanking regions (~800 bp) of specific Salmonella type III secretion effector genes will be cloned into the pSB890 plasmid and the plasmid transformed into the E. coli strain CC118 lambda-pir. The plasmid will be then transformed in the E. coli strain beta-2163 Δnic35 and conjugation with S. Typhimurium strains will be performed. Homologous recombination and allelic exchange will be performed as described in “Genetic Analysis of Pathogenic Bacteria”, Cold Spring Harbor Laboratory Press.

**Evaluation of foreseeable effects**

E. coli: The bacteria to be used in the protocol are disabled through the use of multiple stable disabling mutations that make them highly unlikely to survive in the environment and unable to colonize the intestine. Salmonella type III secretion effector genes tagged with specific epitopes, such as 3xFlag, or flanking regions of Salmonella type III secretion effector genes are unlikely to alter existing pathogenic traits in E.coli disabled strains.

S. Typhimurium: The manipulations of the bacterial genes to be carried out will introduce loss of function mutations and will not increase the pathogenesis of the bacteria. Fluorescent proteins are not been reported to alter any existing pathogenic traits. Salmonella type III secretion effector genes tagged with specific epitopes, such as 3xFlag, or flanking regions of Salmonella type III secretion effector genes are unlikely to alter existing pathogenic traits in S. Typhimurium as they include only homologous DNA and commonly used epitope tags. They are unlikely to alter stability or pathogenicity of the recipient strains.

Mammalian cells: Host transport factor genes, such as the small GTPase Rab32 gene, do not alter any existing pathogenic traits in cell cultures.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Contaminated waste (solid and liquid) will be inactivated by autoclaving at +121°C for 15 min which is expected to result in 100% kill. The autoclaves are serviced and calibrated twice per year to confirm that the necessary levels of temperature and pressure are maintained for the required time. Further validation will be on a monthly basis using an autoclave indicator stick will be included in the waste.

Inactivated solid wastes will be sent off site as part of the "orange bag" waste stream. The waste will be macerated to make it unrecognizable and further heat treated before being placed in landfill.

Spills will be treated with Haz-Tab solutions containing 10,000ppm chlorine

Date Project Ceased: 02/03/2022
To derive testicular somatic cells and germ cells from pluripotent stem cells. We will transduce genes specifying these cells into ES/iPS cells and tissues dissected from mice, using replication-deficient lentiviral vectors. Moreover, for generation of iPS cells from mouse skin fibroblasts, pMX replication-deficient retroviral vector will be used.

For cloning of genes specifying somatic or germ cells into viral vectors, E. coli K-12 based strains, such as DH5α, XL-1 Blue, α-Select, Stable2, will be used. Platinum-E (Plat-E) and HEK293 cell lines will be used for packaging retroviruses and lentiviruses, respectively. Using these viral vectors, we will transduce primary cells isolated from mouse gonads. We will also transduce mouse ES and iPS cells to differentiate into a specific gonadal cell-type, such as Sertoli cells, Leydig cells and germ cells.

Recipient or parental organism

For cloning of genes specifying somatic or germ cells into viral vectors, E. coli K-12 based strains, such as DH5α, XL-1 Blue, α-Select, Stable2, will be used. Platinum-E (Plat-E) and HEK293 cell lines will be used for packaging retroviruses and lentiviruses, respectively. Using these viral vectors, we will transduce primary cells isolated from mouse gonads. We will also transduce mouse ES and iPS cells to differentiate into a specific gonadal cell-type, such as Sertoli cells, Leydig cells and germ cells.

Host/vector system

pMX retroviral vector (Kitamura et al., Exp Hematol.11, 1007-1014. 2003) that carries 5’ and 3’ LTR, but lacks gag, pol and env will be used for generating mouse iPS cells. Platinum-E (Plat-E) cells will be used as an ecotropic retrovirus packaging cell line. We also use commercially available 3rd generation lentiviral vectors that contain SIN (self-inactivating) mutation in the LTR and lack gag, pol, env and rev. For packaging, the lentiviral vectors will be co-transfected with additional plasmids, pRRE, pVSV-G, and pRev into HEK293 cells (human embryonic kidney cells transformed with sheared adenovirus 5 DNA).

Origin & function

To derive testicular somatic cells and germ cells from pluripotent stem cells, ES/iPS cells are transduced with lentiviral vectors carrying genes required for differentiation of Sertoli cells, Leydig cells and germ cells. The precise identity of these genes cannot be specified at the moment because they will be identified by future high-throughput gene expression profiling experiments.

A number of genes are expressed in the testis as shown by other groups. Some of them are originally thought to be oncogenes and therefore unregulated expression in mammalian cells may cause transformation when transduced. The eukaryotic systems have been designed that functional protein would be expressed only when lentiviral vectors were introduced to mammalian cells.

Genes required to generate iPS cells are Klf4, Sox2, Oct4 and Myc. These genes encode transcription factors involved in many aspects of cell differentiation, e.g. neurogenesis, epithelial cell differentiation, and most notably formation of pluripotent stem cells in the inner cell mass (ICM) of early embryos. Myc is a well-known oncogene, but the retrovirus carrying the myc cDNA protein will not infect humans because the virus is ecotropic.

Evaluation of foreseeable effects

Although the viruses primarily produced are infectious; the retrovirus are ecotropic (infects only rodents) and the lentivirus is amphotropic (infects mammals including...
humans), secondary viruses will not be produced from infected cells because gag, pol, env and rev genes are absent. We would not therefore expect any specific symptoms as the result of an accidental infection with the genetically modified micro-organisms described in this application.

However, if the lentiviral vector were accidentally injected into carriers of wildtype HIV, there may be a theoretical risk of recombination of the vector with wildtype virus to produce replication competent virus. Thus, there would be the potential risk of mobilisation and transmission of the recombinant lentivirus to other individuals via the normal routes of HIV-1 transmission. Individuals known to be HIV-positive or to be immunocompromised will not be allowed to work on this project, these risks will be made clear to all personnel in the laboratory.

Genetically modified micro-organisms could not survive outside laboratory conditions and thus there is no hazard to the environment. Therefore, the chances of any of the retroviral vectors (ectropic retroviruses or VSV-G pseudotyped lentiviruses) coming into contact with rodents is extremely low. All waste will be inactivated prior to leaving the premises and cultures containing retroviruses will not be removed from the laboratory.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste from mammalian cell cultures will be autoclaved before disposal down the sink. Plastics and other solid disposable waste will be collected in autoclavable bag within the biological safety cabinet, sealed and then sprayed with 1% Virkon (according to manufacturer’s instructions). The bag will then be removed from the safety cabinet into a clean autoclave bag, sealed, and taken to the autoclave in a sealed container. The degree of kill following autoclaving will be 100% since there is a high expectation of kill of GM microorganisms exposed to 121°C for 15 minutes. The autoclaved waste will then be disposed of by continuous feed auger.

Glass bottles and other non-disposable vessels will be soaked in the appropriate concentration of 1% Virkon in a bucket with a sealed lid, rinsed and then autoclaved for future use.

Validation will involve regular testing of the autoclave to demonstrate, using independent thermocouples placed at the centre of the load, that the correct time and pressure have been reached for the required time. At the start of the project, we will produce retrovial and lentiviral vectors carrying the EGFP gene, and then validate the inactivation of these viral vectors following autoclaving. Proliferative mouse embryonic fibroblasts will be grown in the presence of increasing (10 fold) amounts of inactivated waste. The cells will be incubated for 10 days. The identification of any green fluorescent colonies demonstrates the presence of active viral vectors within the ‘inactivated’ waste.

The virucidal disinfectant, Virkon, has been validated for inactivation of lentivirus at a concentration of 1%. Details of Virkon testing from independent studies can be found at http://www.antecint.co.uk/MAIN/virkonvi.htm.

#### Project Additional Information

**Purposes of the contained use**

At present, very little is known about how dermatophytes cause disease, due to poor infection models (having to use zoophilic species rather than anthropophilic species) and poor genetic tools. Dermatophyte infections are the most common fungal infections in the World, affecting up to 20% of the population at any one given moment. Some individuals have recurrent infections, but it is not yet known whether these infections represent new infections or reactivation of a latent infection. At present there are few research groups working on these pathogens; however, the recent public release of the genome sequences of seven dermatophytes by the Broad Institute and the Hans Knoll Institute, Jena, will change this, stimulating research in this field.
The scientific goals of this study are to investigate the pathogenesis of dermatophyte infections, including regulation and mechanisms of cell wall biosynthesis, and response to nutrients and stresses, by using targeted gene disruption to create null mutants or to over express specific genes. Mutants expressing an iRFP (infra-red fluorescent protein) reporter will also be created to allow in vivo imaging in experimental models. The study also intends to study the host immune response to dermatophytes using mutants which lack or over express specific genes, to determine which fungal cell wall components are important in the host-pathogen interactions.

Dermatophyte fungi cause superficial skin, hair, and nail infections (e.g. tinea, ringworm, jock itch and athlete's foot). Dermatophyte infections can affect the skin on almost any area of the body, such as the scalp, legs, arms, feet, groin, and nails. These infections are usually itchy. Redness, scaling, cracking of the skin, or a ring-shaped rash may occur. Dermatophyte infections are usually spread through direct contact with an infected person or animal. Clothing, bedding and towels can also become contaminated and spread the infection. Symptoms typically appear between 4 and 14 days following exposure (www.cdc.gov). The most common causes of these infections are Trichophyton species, Microsporum species and Epidermophyton floccosum. All dermatophyte fungi are classified as ACDP Hazard Group 2.

**Recipient or parental organism**

| Trichophyton rubrum, Trichophyton mentagrophytes, Microsporum canis and Epidermophyton floccosum (dermatophytes) isolates. |

**Host/vector system**

Vectors to carry out transformation will have either the Hygromycin B phosphotransferase (hbp) gene, the neomycin phosphotransferase (nptII) gene (Yamada et al., 2008 J. Dermatol Sci), or the nourseothricin acetyltransferase (NAT) dominant selectable marker (Alshahani et al. 2010 Med Mycol).

**Origin & function**

The genetic material involved will represent plasmid DNA obtained from collaborators and/or created by the Aberdeen Fungal Group, University of Aberdeen or will be polymerase chain reaction (PCR) amplified DNA fragments, neither of which can be autonomously replicated in fungal cells.

The plasmid DNA or PCR fragments will contain DNA regions identical to sections Genes in the fungal genome allowing integration of the DNA into the fungal genome through homologous recombination. In addition the plasmid DNA or PCR product will also contain a selectable marker allowing cells which have taken up the new genetic DNA to be selected in culture.

**Evaluation of foreseeable effects**

To date, any stable gene disruptions made in dermatophyte fungi have either led to reduced growth rates or have had no effect on growth. Similarly, virulence of the strains has either been reduced or unaffected.

The dominant selectable markers to be used in this study have not been shown to affect the virulence of dermatophytes.

There do not appear to be any hazards associated with altering potential pathogenic traits of these fungi. With gene disruption, we are aiming to create strains which have reduced virulence, and with overexpressing strains we are aiming to produce strains which stimulate the host immune response to clear the fungus (again reducing virulence). To date, all genetically modified dermatophytes have either shown reduced or unaffected virulence.

There is no evidence for any ability of dermatophytes to be capable of transferring genetic material with other organisms. Where strain typing has been attempted, there is little evidence for huge strain differences, suggesting relatively stable genomes and a lack of evidence for exchange of genetic material.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste management:
Liquid waste: add 1% Distel (previous name: Trigene) as per the manufacturer’s instructions. In the event of spillage, the contaminated area is flooded with concentrated Distel (to 1% final conc.), mopped up with paper towels, and reswabbed with 1% Distel. Contaminated materials are autoclaved.

Glassware: Soaked with 1% Distel or autoclaved.

Plasticware: autoclaved

Animals and Tissues: All carcases will be autoclaved within the MRF, and remaining tissues are autoclaved prior to disposal.

Contaminated waste, with the exception of carcases in the MRF, will be autoclaved either in the research laboratories or in the IMS level 1 wash-up facilities.

Once GMMs have been inactivated, normal routes of disposal are used for liquid and solid waste. Killed liquid waste is discarded down the sink. Inactivated solid waste is discarded by CFA processing.

Distel:
Our standard procedures for use of Distel have been validated experimentally to kill >99.99% (degree of kill) of all dermatophyte species relating to this application (Trichophyton species, Microsporum species and Epidermophyton floccosum) (www.tristel.com).

Autoclaves:
Autoclaves on in the central autoclave facility are validated at least annually by means of biological indicators. In daily use, monitoring is by thermocouple temperature recordings and autoclave strips included in the loads.

Bench-top autoclaves in our laboratory used for inactivation of waste are tested regularly (using Browne tubes for assessing whether time and temperature within autoclave has been reached) and serviced.

Samples from autoclaved or Distel-treated, inactivated waste will be regularly (once a month) plated and assessed for fungal viability. A written record will be kept of all test results.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  Y

Please enter comments on the GM safety committee on the risk assessment

02/03/2022
Genetic modification safety committee did not make additional recommendations on the risk assessment, but emphasised the need to enforce wearing of protective garments (gloves and lab coats) when handling dermatophyte fungi.

**Project Ref** 490/14.3

**Date Ackn’ed** 27/05/2014

**CU2 Project Title** Insight into filamins from filamin pathological mutations

**Class** Class 2

**CultureVol** < 1 Litre

**Class CultureVol** Class 2 < 1 Litre

**Consent Granted**

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

a) The scientific goal of the project is to understand how cells sense the mechanical cues in the extracellular space and how they are transmitted to the cytoskeleton and, in turn control the re-arrangement of extracellular matrix. The role of the cytoskeletal proteins filamins will be analysed in detail. Initially overexpression or knocking down of filamins family members will be performed and the resulting modifications induced in the cells will be studied using biochemical and microscopical techniques. Then this kind of analysis will be expanded and applied to the filamins interactors with the final aim to characterise the complete signalling pathway involved in the mechanosensitive.
mechanism.

**Recipient or parental organism**

Human cells lines such as Hek293T, Hela and HT1080 will be used as final recipient of the plasmids. In case there is a need for a non human cell type, NIH 3T3, mouse MEF or CHO will be used.

**Host/vector system**

Pseudo-typed lentiviral particles will be produced in HEK293T cells using a third-generation packaging system, which has many features that lead to enhanced biosafety. Recombinant lentiviruses produced with the MISSION Lentiviral Packaging Mix (Sigma Aldrich catalog number SHP001) have not been shown to produce replication competent viral particles because of designed safety features. It is a plasmid system consisting of:

1. The packaging vector, which contains the minimal set of lentiviral genes required to generate the virion structural proteins and packaging functions.
2. The vesicular stomatitis virus G-protein (pCMV-VSV-G) envelope vector, which provides the heterologous envelope for pseudotyping.
3. The shRNA transfer vector (pLKO.1-Puro), which contains the sequence of interest as well as the cis acting sequences necessary for RNA production and packaging. This vector contains a sequence encoding a puromycin resistance gene.

The multi-plasmid approach results in no single plasmid containing all the genes necessary to produce packaged lentivirus. The lentiviral vector contains the first two components; it is designed to be co-transfected along with a compatible lentiviral transfer vector in order to create high-titer pseudo-typed lentiviral particles used. Resulting particles are replication-incompetent and deletion in the U3 portion of the 3’ LTR eliminates the promoter-enhancer region, further negating the possibility of viral replication. The system has also removed virulence genes which are not necessary for shRNA packaging.

In addition, the lentiviral vector contains a self-inactivating 3’ LTR that renders it unable to produce infectious virus once it integrates into the host chromosome. These features combined have improved biosafety and handling. This information appears on-line in: http://www.sigmaaldrich.com/life-science/functional-genomics-and-mi/shrnawww/learning-center/mission-faqs/biosafety.html

HEK293, HELA, HT1080, NIH-3T3, mouse MEF or CHO cells will be transduced with the pseudo-viral particles. In most cases and in order to rule out compensatory effects of the protein knockdowns, the resulting cell lines will be phenotyped and then disposed at the end of the experiment. In the remaining cases, stable cell lines will be generated. In these cases, no additional hazards compared with any other transformed cell line are present as the lentiviral vector contains a self-inactivating 3’ LTR that in all cases renders it unable to produce infectious virus once integrated into the host chromosome.

**Origin & function**

In the overexpression experiments all filamin family members will be investigated. A large range of proteins will be tested in the suppression experiments (i.e. using the shRNA to suppress their expression in cultured cells). In this case proteins that are known to interact with filamins will be examined. So far there are around 90 proteins described as Filamin interactors. Among them there are cytoskeletal proteins (FILIP, ILK, TRIO) transmembrane receptors (ITGB1, ITGB3, ITGB7, CFTR, CASR) protein kinases (SRC, MAPK14), E3 ligases (ASB2) and deubiquitinases (OTUD1).

The majority of the genes used in this project do not have a known oncogenic potential. The effect on cell differentiation/proliferation of the overexpression or suppression of filamins is not well characterized, however the available data indicate that both the overexpression and the removal of filamins proteins have adverse effect on cell growth. Some of the filamin interacting proteins to be used in the suppression experiments have been involved in cell proliferation in some specific conditions (SRC, Integrins) but the only one shown to be a tumour suppressor is BRCA2. This is the only protein among the filamin interactors that could promote cell proliferation if silenced and will not be studied in this project.

**Evaluation of foreseeable effects**

The GMM and transfected cells will be of very low hazard to the environment as they cannot survive outside of laboratory. The use of the heterologous envelop protein such VSVg in place of the native HIV-1 decreases the risk for human health, however it may broaden the host and tissue tropism and it could be a concern for the environment. The frequency of recombinant competent lentivirus generation using lentivirus vectors is very low, however to minimize the risk only relative small volume will be used.

We would not expect any specific symptoms as the result of an infection with the genetically modified micro-organisms described in this application since the lentiviral vectors cannot replicate.

No sharps will be used in any of these experiments.
The vectors have been designed so that they are incapable of recombining with wild-type virus in any way that would produce viable virus. Because viral structural genes have been placed on different genetic units, multiple recombination events must occur before a replication competent helper virus is generated. Furthermore, areas of homology among the units expressing the helper virus proteins have been minimized. Also, heterologous promoters for the helper virus proteins are used. Resulting particles are replication-incompetent and deletion in the U3 portion of the 3' LTR eliminates the promoter-enhancer region, further negating the possibility of viral replication (http://www.sigmaaldrich.com/life-science/functional-genomics-and-rna/shrna/learning-center/mission-faqs/biosafety.html)

However, highly improbable viral replication-competence will be checked by subjecting cell cultures to puromycin resistance after treating these cells with media collected from cells that have been treated with viral supernatant which would lead to puromycin resistance. Additionally, cell media will be immunoblotted in order to rule out the presence of the viral protein p24.

The transfected cultured cell lines will not survive outwith the culture medium and all liquid and solid waste will be autoclaved on site. This rules out the possibility of escape into external environment and survival, establishment or dissemination therein.

Factors such as congenital immunodeficiency and secondary immunodeficiency caused by serious illness or chemotherapy would increase the susceptibility to infection by micro-organisms, including the genetically modified micro-organisms described in this application. In carriers of wildtype HIV there may be a theoretical risk of recombination of the lentiviral vector with wildtype virus. Thus, there would be the potential risk of mobilisation and transmission of the recombinant lentivirus to other individuals via the normal routes of HIV-1 transmission. Individuals known to be HIV-positive or to be immunocompromised will not be allowed to work on this project, these risks will be made clear to all personnel in the laboratory.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1% Virkon will be added to biological wet waste and plastics and this waste will be left over night prior to rinsing and disposal in double hazardous waste bags. Virkon is a unique, synergised oxidising system based on potassium monopersulphate which is proven effective against all major pathogens known to man such as viruses HIV/AIDS, hepatitis B, polio, lassa and rift valley fevers. Proven against a wide range of antibiotic-resistant strains. For more info, please see: http://www.rmsupply.co.uk/Virkon_lab_products.htm.

All bags with the material previously inactivated as described above will be then be taken to the central autocalving facility. Autoclaving is by validated (internal temperature probe linked to printout) autoclave, reserved only for inactivation of waste (effective 100% kill). The autoclave undergoes annual testing to ensure correct operation. Waste will be transferred to the autoclave in covered containers.

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

The aim of the project is to determine if nuclear factor kappa-light-chain-enhancer of activated B cells (NFkB) is involved in the development of inflammation in the brain that occurs as seasonal animals adapt to the lighting of their environment. This inflammation is thought to cause hypothalamic remodelling, involved in the regulation of seasonal body weight changes and the timing of reproduction. Similar inflammation has been reported to occur in conditions of chronic over nutrition. The aim of the project is to generate replication incompetent lentiviral vectors that will cause modified NFkB signalling; specifically, vectors will be produced that will (1) express the dominantly negative nuclear factor of kappa light polypeptide gene enhancer in B-cells inhibitor, alpha (IkBa) that is a potent inhibitor of NFkB expression or (2) facilitate...
constitutive expression of IKKβ that will stimulate NFκB overexpression.

Recipient or parental organism

Lentiviral vectors will be delivered to rats intracerebrally using a stereotaxic frame to allow reproducible site directed delivery to the hypothalamus using coordinates according to the Bregma line and brain maps. The virus will be delivered through a Hamilton syringe with blunt needle which will be placed into the frame whilst empty. The syringe will be loaded from stock tubes held in clamps keeping fingers clear of the needle and lowered slowly to a precise depth using a screw mechanism which is part of the frame set up, and done whilst the rats are under general anaesthetic. At the end of a surgery day, the syringe and needle will be removed from the frame and discarded as a single unit into a sharps bin. These measures should reduce needle stick injury risk.

Barriers to prevent escape of rats will be present at exits, drains and vents or other ducts or possible escape routes. Unauthorised or untrained personnel will not have access to the lentiviruses. These lentiviruses will be clearly labelled and stored in screw-capped tubes within a sealed container in an appropriate fridge or freezer with biohazard warning labels.

The rats will be monitored for food intake and body weight for a period of at least 4 weeks following inoculation with the lentiviruses, with the objective being to see differential responses compared to control rats. The rats may be kept for up to 16 weeks before killing. Brains will be removed and immediately frozen on dry ice. The carcasses will be disposed of to waste as described below. The brains will be transported to the RI NH and stored at -80°C. Brains will be cryosectioned at the RI NH and processed for gene expression analysis.

Although extremely unlikely, the potential exists for the transfer of genetic material from the infected animal to other animals, with increased tropism conferring the capability to infect a wide range of mammalian cells due to the incorporated VSV-G envelope protein, in the first 48-72 hours post-infection through transfer of virus from body fluids. After this time risk of active virus transfer reduces to negligible levels as does the potential for transfer of genetic material between the GM rat and other organisms due to the viral incompetence to replicate, short half-life and inefficient transduction rates, thus the risk of transmission outside the laboratory is effectively zero. The viruses will not infect microbial organisms.

Host/vector system

Lentivirus will have been generated off site (e.g. Vector Biolabs) using Invitrogen’s ViraPower™ Lentiviral Expression System that allows creation of a replication incompetent, HIV-1-based lentivirus. The ViraPower™ Lentiviral Expression System is a third-generation system based on lentiviral vectors developed by Dull et al., 1998*. This third-generation lentiviral system includes a significant number of safety features designed to enhance its biosafety and to minimize its relation to the wild-type, human HIV-1 virus. These safety features are as described by Invitrogen are copied below:

The pLenti expression vector contains a deletion in the 3′ LTR (ΔU3) that does not affect generation of the viral genome in the producer cell line, but results in “self-inactivation” of the lentivirus after transduction of the target cell. Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing packageable viral genome.

• The number of genes from HIV-1 that are used in the system has been reduced to three (i.e. gag, pol, and rev).
• The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 envelope.
• Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids. All four plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus (Dull et al., 1998).
• Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293FT producer cell line, none of them contain LTRs or the Ψ packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced.
• The lentiviral particles produced in this system are replication-incompetent and only carry the gene of interest. No other viral species are produced.
• Expression of the gag and pol genes from pLP1 has been rendered Rev dependent by virtue of the HIV-1 RRE in the gag/pol mRNA transcript. Addition of the RRE prevents gag and pol expression in the absence of Rev (Dull et al., 1998).
• A constitutive promoter (RSV promoter) has been placed upstream of the 5′ LTR in the pLenti expression vector to offset the requirement for Tat in the efficient production of viral RNA (Dull et al., 1998).

Origin & function

The inserted genes IKKβ (CA) and IκBα (DN) impact directly on the expression of NF-κB which is widely used by eukaryotic cells as a regulator of genes that control cell proliferation and cell survival. As such, many different types of human tumours have misregulated NF-κB. Active NF-κB turns on the expression of genes that keep the cell proliferating and protect the cell from conditions that would otherwise cause it to die via apoptosis. Defects in NF-κB results in increased susceptibility to apoptosis leading to increased cell death. In tumor cells, NF-κB is active either due to mutations in genes encoding the NF-κB transcription factors themselves or in genes that control NF-κB activity (such as IκB genes). NF-κB also affects cancer progression by controlling epithelial to mesenchymal transition and metastasis and controls vascularisation of tumours via VEGF and its receptors. NF-κB pathway mutations are rare in solid tumours but they do occur: increased IKKβ and NF-κB expression has been seen in prostate cancer; mutations in IκBα, and IKKβ have been seen in breast cancer. IKKβ induced NF-κB was found in intestinal epithelial cells to have an essential role in tumour formation in mice. NF-κB can act to stimulate or inhibit liver cancers. H-Ras mediated initiation of tumourigenesis requires IKKβ -mediated NF-κB activation in a mouse model of melanoma. IKKβ and NF-κB are crucial cofactors in lung cancer. NF-κB has also been shown to be activated in cancer stem cells, where it promotes a pro-inflammatory environment, inhibits apoptosis and stimulates cell proliferation but CSCs are a minor subpopulation of cancer cells. NF-κB induces Lin28 which inhibits processing of Let7 miRNAs which are down-regulated in cancer and usually act as tumour suppressors. In general NF-κB acts as a survival factor for transformed cells that otherwise would become apoptotic or senescent. Elevated NF-κB expression in cancer cells provides a survival mechanism for cells by up-regulating anti-apoptotic genes.

Tumourigenesis is a multistage process requiring the interaction of many mutated genes which also lessens the risk from delivery of a single oncogene or tumour suppressor gene to a target tissue. The principle route of transmission that could lead to transduction of laboratory workers by packaged viral particles is inoculation. Therefore, use of sharps will be prohibited except where essential for viral delivery to rats. Other possible routes of transmission such as inhalation, ingestion and eye splashes are less likely to lead to tumourigenesis because of the required very high titres, which will not be achieved under the given experimental conditions. Consequently, the risk of tumourigenesis is very low.

Evaluation of foreseeable effects

Advisory Committee on Dangerous Pathogens (ACDP) – no appropriate level from list but level 2 should be sufficient for this type of lentivirus because it is replication-incompetent and following injection, no new replication-competent virus can be produced, but instead results in "self-inactivation". The modifications made to this virus include VSV-G envelope protein incorporation which increases tropism conferring the capability to infect a wide range of mammalian cells. The virus does not express stable disabling mutations but see (b) below. Effects of the lentivirus itself are unknown but not considered to be serious as the gene delivery method has been developed with human gene therapy in mind.

These lentiviruses are adequately attenuated to be considered class 1 but the inserts contain oncogenic potential thus, pre-injection work and until the end of the quarantine period they should be considered as class 2 and appropriate control measures used for class 2 GMMs adhered to. For animal work following the quarantine period, containment level 1 would suffice (Karlen & Zuffery, 2007; Reuter et al, 2012). The waste brain tissues will be autoclaved and disposed of in the orange bag clinical waste stream.

i) Risks associated with virus vectors and virus handling, injection and during the quarantine period

The live virus would be able to transduce many tissues should it come in contact with them but is unable to replicate within them. The major hazard is therefore represented by the packaged virus prior to infection of the rats. The two potential transmission routes are by external exposure (either skin lesions or mucous membranes) and by accidental injection/inoculation using sharps. Given that the viruses are replication incompetent and will only infect at low efficiency in sub optimal conditions any potential harm would be extremely limited. The risks will be further minimised by control measures described below. The risks of harm from this virus type have been reduced through several modifications from the original HIV-1 virus. These include use of only three HIV-1 genes gag, rev and pol. Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids. All four plasmids have been engineered not to contain any regions of homology with components required for packaging the viral genome are separated onto four plasmids. All four plasmids have been engineered not to contain any regions of homology with

(a) The two potential transmission routes are by external exposure (either skin lesions or mucous membranes) and by accidental injection/inoculation using sharps. Where
a worker has active eczema, chapping or sepsis, they should consult a competent person (e.g., a medical professional or occupational health provider) before embarking upon, or continuing activities.

(b) Given that virus is replication incompetent and will only infect at low efficiency in suboptimal conditions any potential harm would be extremely limited. As described above, the risk of tumourigenesis is negligible and also difficult to ascribe to infection, so for these reasons health surveillance of people working on the project is not necessary.

Recombinant lentiviral vectors can only be produced in complementing cells such as HEK 293T that have been transfected with the three packaging plasmids. The vectors described here pose a low risk to animal/plant health and the environment. The virus is replication-incompetent and following infection, no new replication-competent virus can be produced and so adverse effects on other animals are negligible. The active virus would be expected to be cleared from the infected rats within 48-72 hours after which time the rats should have the gene stably integrated into the genomic DNA and would not cause harm to other animals. Lentivirus is an enveloped virus that is highly susceptible to dehydration and sensitive to UV light, unbuffered pH and is rapidly inactivated outside a host. The modifications made to this virus including VSV-G envelope incorporation are not thought to confer a significant increased risk of its survival or clinical stability as the virus remains highly susceptible to dehydration, pH and UV light, and so the virus is thought not to pose a risk to the environment.

Risk level: Low

ii) Risks associated with handling animals, bedding, carcasses, tissues or fluids and waste after the quarantine period for the GMMs.

Following the 72 hour quarantine period the animals can be treated as a normal lab animal where containment level 1 would be adequate. The bedding can be treated as uncontaminated but this and all waste, tissues, fluids and carcasses will be disposed of as described in the additional information section below.

Containment and control measures for GMOs that are not microorganisms (e.g., GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Soiled bedding, cages and any other contaminated materials from the quarantine period will be handled as infectious material in a biological safety cabinet and decontaminated by autoclaving and washing. Carcasses from this period will be considered as infectious and should be disposed of by incineration. Waste for removal by contractors for incineration should first be autoclaved then stored and transported in sealed bags or containers.

Surfaces and equipment will be cleaned by treatment with disinfectant e.g. Sodium hypochlorite (use 1-10% dilution of fresh bleach), or 1% VirKon S, and/or autoclaving for 30 minutes at 121°C and incineration or appropriate disposal for radioactive materials. Waste tissues will be autoclaved and incinerated. Animal carcasses will be incinerated, unless the animal has died within the quarantine period and then the carcass will be autoclaved before incineration. Rat bedding will be autoclaved. Cages will be autoclaved, washed and re-autoclaved before reuse.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The Foresterhill GM Committee approved this application at activity class two following lengthy discussions about how the lentiviral vectors would be safely injected into the rats without risk to the individual performing the surgery. The Committee are satisfied that the PI has evaluated the risks thoroughly and that all appropriate precautions and training will be employed throughout the course of the project.

Recipient or parental organism

**Sendai virus (SeV):** We will purchase the ready-to-use Sendai viral vectors from Life Technology. Sendai virus is an ACDP class 1 organism and is a murine parainfluenza virus that is non-pathogenic to humans, yet these genetically modified Sendai viral vectors can transduce human and animal cells. In the modified kit (CytoTune®-iPS 2.0), the virus can infect a wide range of cell types, but with the F gene deleted, they can’t produce infectious particles from infected cells. Importantly, human is not the natural host for sendai virus thereby the virus is non-pathogenic to human.

**Lenti-virus:** Pseudo-typed lentivirus will be used to achieve stable gene knockdown. We will purchase a third-generation packaging system, MISSION Lentiviral Packaging Mix from Sigma (SHP001) to produce virus particles. This packing system is based on multiple-plasmid approach and significantly lower the risk to produce replication competent viral particles by a single step. In addition, the vector contains a self-inactivating 3’ LTR that prevents the produce of infectious virus.

**Human lymphoblastoid Cell lines:** These cell line are immortalized human B cell lines which are currently used by the Wellcome funded UK10K and MRC UK epigenetic schizophrenia programmes.

Host/vector system

We will use the CytoTune®-iPS 2.0 Sendai Reprogramming Kit, which is newly released by Life Technology but has been rapidly used and well-referenced worldwide. The virus is non-integrating and only requires incubation as short as one overnight compared to multiple days of transductions required by other protocols. This kit is based on a modified, non-transmissible form of Sendai Virus, with the Fusion protein deleted. The viral vectors maintain full infectivity to a wide range of cells, however they are no longer capable of producing infectious particles from infected cells because the viral genome lacks the F gene. Additionally, the vectors and transgenes can be eliminated from the host cells which will lead to an integration-free reprogramming. Importantly, human is not the natural host for sendai virus thereby the virus is non-pathogenic to human.

We will also use a third-generation packaging system, MISSION Lentiviral Packaging Mix (Sigma, catalog number SHP001) to produce lenti-virus particles. This system has not been shown to produce replication competent viral particles because it only contains the minimal components (1+2, see following) and won’t work without co-transfection along with compatible lentiviral transfer vector. This unique design together with a lacking of 3’LTR assures very low risk of producing infective viral particles.

1. The packaging vector, which contains the minimal set of lentiviral genes required to generate the virus structural proteins and packaging functions.
2. The vesicular stomatitis virus G-protein (pCMV-VSV-G) envelope vector, which provides the heterologous envelope for pseudolyping.

Lentivirus transduction will served as a backup method of Sendai virus to derive human iPSCs. The ViraPower Lentiviral expression system (Invitrogen) will be used to produce recombinant lentivirus containing Yamanaka factors essential for iPSe derivation. Again, this multi-plasmid approach efficiently prevent the produce of packaged lentivirus which greatly increases biosafety.

Origin & function

The state-of-art CytoTune®-iPS 2.0 Sendai Reprogramming Kit developed by Life Technology ensures both the virus vector and transgene eliminated after integration and produce an "integration-free" re-programming. Sendai virus does not integrate in the host genome. Lenti-virus mediated transduction serves as a backup strategy. Due to the
vector structure, the produced lenti-viruses are replication incompetent, and could not produce viral particles in infected cells, thus preventing system wide effects.

The Yamanaka factors (Oct4, Sox2, Klf4, c-Myc) are a recognised cocktail genes to force the cultured human lymphoblastoid cells to acquire the properties of pluripotent stem cells. Oct4, Sox2, Klf4, and c-Myc will each be delivered in separate SeV vectors. Oct4 regulates the pluripotency of embryonic stem cells and under and overexpression has been associated with cell differentiation. Sox2 acts cooperatively with Oct4 to regulate pluripotency. Klf-4 is a transcription factor that regulates transcription factor expression during development. C-Myc, with roles in regulating cell proliferation and apoptosis, is a proto-oncogene and is overexpressed in many cancers.

Together, they are a recognised cocktail of genes required for reprogramming somatic cells to a stem cell phenotype. The expression of these genes results in cells adopting a phenotype whereby they have self-renewal capacity and the ability, under managed conditions to proliferate indefinitely.

Evaluation of foreseeable effects

Although human is not the natural host for the SeV, and the virus is non-pathogenic to humans, appropriate care must be taken to prevent the potential mucosal exposure to the virus. Similarly, the adopted strategy will ensure that the produced lentiviruses are replication incompetent, preventing subsequent production of lentiviral particles in infected cells. There would be a potential risk of mobilisation and transmission of the recombinant lentivirus to individuals with wildtype HIV virus by accidental injection. Thus, individuals known to be HIV-positive or to be immunocompromised will not be allowed to work on this project and these risks will be made clear to all personnel in the laboratory. In addition, sharps are strictly prohibited to use in this project. Another potential hazard associated with these vectors are as a result of the nature of the inserted genes. Overexpression of any of these genes can result in dysregulation of cell proliferation, differentiation and survival and therefore potentially transform the cells. Therefore, following centrifugation and for all handling, the tubes containing CytoTune sendai viral or lentiviral particles will be opened in the Class 2 safety cabinet to avoid exposure to aerosolised particles.

Serologically positive rodents (the natural host for sendai virus), animals that have already been infected with wild type SeV, may be able to make infectious CytoTune™-Sendai virus. Sendai virus affects the respiratory tract and causes severe respiratory disease in rodents. It can be spread by contact and airborne transmission including through air circulation systems. As a rule it is recommended that after handling sendai viral vectors or infected animals, a period of at least 3 hours should elapse before contact with other animals.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1. Solid waste including culture plates and disposable plastic ware will be inactivated with disinfectant (Precept, Johnson and Johnson, 29fl) for at least one hour prior to being rinsed with water and detergent and sent for wash and autoclave.
2. Glassware and non-disposable plastic ware will be treated with disinfectant (Precept, Johnson and Johnson, 29fl) for at least one hour prior to being rinsed with water and detergent and sent for wash and autoclave.
3. Liquid waste (i.e. cultured medium) will be treated with disinfectant (Precept, Johnson and Johnson, 59FL) for at least one hour prior to disposal down the sink.

Validation will involve regular testing of the autoclave to demonstrate, using independent thermocouples placed aile
centre of the load, that the correct time and pressure have been reached for the required time. Sendai viruses are inactivated at temperatures above 37°C. The "degree of kill" of chemical disinfectant is expected at 99.99%. At the start of the project and at monthly intervals, we will validate the inactivation of sendai viral and lentiviral vectors following autoclaving by incubating cultures of Hela cells with autoclaved liquid waste. We will then perform reverse transcription on RNA isolated from the Hela cells, followed by PCR using primers to specifically amplify the viral genome to determine whether any virus had been incorporated into the cells. Records will be kept of the results from each test.

Project Ref 490/16.1

Date Ackn'd 21/01/2016

CU2 Project Title Pattern recognition receptors in immunity and homeostasis: transduction of cell lines and primary murine cells using lentiviruses

Class Class 2

CultureVol Class 2 < 1 Litre

Consent Granted

Project notified under transitional arrangements
Project Additional Information

Purposes of the contained use

To safely and efficiently transduce genes, either unmodified, mutated and/or fused to tag sequences (see attached risk assessment for details) of C-type lectin receptors, pathogen recognition receptors, and phagosome maturation markers, using lentiviruses into murine and human cell lines and murine primary cells.

Recipient or parental organism

Cloning of the various genes into the lentiviral cloning vectors will require the use of the disabled K12-derivied E.coli. A fast growing version of the human embryonic kidney (HEK) 293T cell line, containing the large T-cell antigen, will be used as the packaging cell line for the production of the replication incompetent lentivirus vectors. The packaged ecotropic lentivirus vectors will then be used to transduce murine primary and cell lines, and packaged amphotropic lentiviruses will be used for human cell lines and both murine primary cells and cell lines.

Host/vector system

VSV-G (amphotropic) and MLV (ecotropic) pseudotyped lentiviral vectors will be produced using the ViraSafe lentiviral expression kit (Cell Biolabs) by co-transfecting the 293T cell line with the expression construct and a lentiviral packaging mix containing 3 plasmids, carrying the minimal number of genes encoding the necessary viral structural and replicatory proteins (to improve safety).

Origin & function

The lentivirus vectors expressing wild type or mutated genes from murine and human C-type lectin-like receptors of the Dectin-1 and Dectin-2 clusters, members of the scavenger receptor family, Collectins, Natural Killer lectin-like receptor family, the complement pathway and the Toll-like receptor family will be used to transduce primary murine and human cells and cell lines. These cells will then be assessed for functions involved in immunity and homeostasis. The interaction of the transduced cells with various pathogens, other cell types, and cellular or serum components will be examined. To evaluate the temporal dynamics of uptake of pathogens, inert particles, and cellular components, we will perform experiments using murine macrophage cell lines transfected with murine phagosome maturation regulators (e.g. members of the Rab GTPase family) fused to fluorescent tags (e.g. green fluorescent protein (GFP). All of these experiments are performed in vitro and will only be performed in primary murine cells and cell lines. To enable functional determination of the various receptor domains and identified polymorphisms we will transduce cells with wild-type and/or receptors carrying specific mutations, which may also be tagged or co-expressed with. Functional mutants of specific members of the Rab GTPase family will also be used. Various combinations of receptors and murine phagosome maturation markers may be simultaneously introduced into cells derived from wild type or genetically altered mice allowing the combinatorial effects on cellular function to be assessed.

Lentiviral transduction will result in stable integration of the receptors or phagosome maturation regulation encoding genes in murine primary cells and cell lines. Stable integration of only the receptor encoding genes, using the amphotropic lentivirus system, will be in human cell lines. None of the receptor genes under study are known to be oncogenic and their expression will not affect the tropism of the lentivirus. However, several studies have linked members of the Rab GTPase family and functional mutations of these proteins (mainly activating mutations) with cancer. In particular, there is evidence showing that the phagosome maturation regulators under study are overexpressed in certain types of cancer and associated with tumour development and/or metastatic ability. Consequently, only the murine ecotropic MLV based lentiviral system for the expression of the Rab GTPase and phagosome maturation markers will be used. These Rab GTPases and phagosome maturation markers are not
Evaluation of foreseeable effects

Accidental infection with the genetically modified micro-organisms described in this application are not expected to give rise to any specific symptoms since the lentiviral vectors are replication incompetent. There is a very small theoretical risk that, if the lentiviral expression plasmid was accidentally injected into an individual carrying wildtype HIV, the vector could recombine, via the truncated LTRs, with the wildtype virus to produce replication competent virus, carrying the immune recognition receptor genes. The likelihood of this occurring is extremely low since a) the use of sharps will be prohibited, b) plasmid DNA does not enter cells readily and c) the plasmid would have to be internalised by a CD4+, HIV infected T cell. Only the VSV-G containing lentiviral vectors (amphotropic viruses) are capable of transducing a broad range of cell types and therefore the expressed genes will be stably integrated into any cell type that the vectors are exposed to. However, this is not thought to pose a significant risk to human health due to the reasons described in section 6 above. In carriers of wildtype HIV there may be a theoretical risk of recombination of the lentiviral vector with wildtype virus. Thus, there would be the potential risk of mobilisation and transmission of the recombinant lentivirus to other individuals via the normal routes of HIV-1 transmission. Individuals known to be HIV-positive or to be immunocompromised will not be allowed to work on this project; these risks will be made clear to all personnel in the laboratory.

Lentiviruses require close contact for their transmission and their survival in the general environment is poor. Replication deficient lentivirus cannot propagate so therefore, after infection of a cell they are incapable of further replication. It will be possible to demonstrate that the lentiviral vectors are replication deficient by plating 5% of the vector stock supernatant into mitotically active indicator cells (eg 293FT cells) and monitoring for syncitia formation or by PCR analysis of cells that have been transduced with lentiviral vector stocks using primers specific for pro-viral components, such as the VSV-G.

All phagosome maturation genes, such as those from the Rab GTPase family, lysosomal-associated membrane proteins and proton transporter families will only be expressed in the MLV lentivirus vector system (ecotropic viruses specific for rat and mouse). This is due to the potential of these genes to cause phenotypic changes causing tumourogenesis.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste (from mammalian cell cultures) will be treated with 5% Chemgene (for high level disinfectant) before disposal down the sink. Plastics and other solid disposable waste will be collected in an autoclavable bag within the biological safety cabinet, sealed and then sprayed with Chemgene (2%). The bag will then be removed from the safety cabinet placed into a clean autoclave bag, sealed, and taken to the autoclave in a sealed container. The degree of kill following autoclaving will be 100% since there is a high expectation of killing of GM microorganisms exposed to 121ºC for 15 minutes. The autoclaved waste will then be disposed of by CFA processing. Glass bottles and other non-disposable vessels will be soaked in the appropriate concentration of Chemgene (2%, according to the manufacturer’s recommendation) in a bucket with a sealed lid, rinsed and then autoclaved for future use.

Validation will involve regular testing of the autoclave to demonstrate, using independent thermocouples placed at the centre of the load, that the correct time and pressure have been reached for the required time. At the start of the project we will validate the inactivation of lentiviral vectors following autoclaving. NIH3T3 cells (for the murine ecotropic lentiviruses) or HEK293T cells (for the amphotropic lentivirus) will be grown in the presence of increasing (10 fold) amounts of inactivated waste. The cells will then be selected for using the antibiotic puromycin and incubated for 10 days before being . The identification of any puromycin-resistant colonies demonstrates the presence of active lentiviral vector within the ‘inactivated’ waste.

The virucidal disinfectant, Chemgene, has been validated for inactivation of lentivirus at a concentration of 2%. Details of Chemgene testing can be accessed at http://www.medi-mark.co.uk/images/uploads/CHEMGENE_HLD4H_TEST_SUMMARY.pdf

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
This application was approved at Containment Level 2 (GM-15-010) by the local Genetic Modification Safety Committee.

- **Non-GMM Consent Granted**: Consent Granted
- **Project notified under transitional arrangements**: N
- **Withdrawn**: N

**Project Additional Information**
Cancers are heterogeneous tissues comprised of multiple components, including tumour cells and microenvironment cells. They arise from extensive mutation and deregulation of genes, leading to loss of control of key cellular processes. In addition, for tumours to grow, become invasive and metastasize they must develop a blood supply through the process of angiogenesis and evade the host immune system. The tumour microenvironment (TME) has a critical role in tumour initiation, promotion and progression. Fibroblasts are the predominant cell type in the TME. There is evolving evidence showing that in breast cancer, cancer associated fibroblasts (CAFs) contribute to tumorigenesis via bidirectional crosstalk with tumour cells, and actively involved with metabolic reprogramming, angiogenesis and therapy resistance of the tumour. Through transcriptomic screening of tumour and CAFs we have identified genes required for processes associated with carcinogenesis; cancer cell migration, invasion proliferation and angiogenesis. These include mediators of intracellular signalling events and cell-cell adhesion. The aim of our research is to understand the complex connections between breast CAFs and cancer cells/other TME component such as endothelial cells, and to explore their therapeutic potential in cancer.

Objectives:
- To identify and track CAFs and other relevant cell types present in multicellular culture models using reporter genes.
- To use hTERT overexpression to establish immortalized cell lines from primary fibroblasts and/or epithelial cells derived from patients which allows long term or more complex in vitro studies
- To use shRNAs/CRISPR and micro-RNA derivatives determined from on-going transcriptomics screens and bioinformatics mining of, for example, TCGA, to knock down expression of genes/microRNAs involved in carcinogenesis e.g. those associated with proliferation, invasion and migration

Recipient or parental organism

**E.coli**

We will use the E.coli strain One Shot Stbl3 (Invitrogen), XL-1 blue (Stratagene), one shot or subcloning Dh5α (Invitrogen), or related disabled E. Coli strains to amplify the plasmid vectors. The natural environment of E. coli is in the gut but these experimental strains are laboratory adapted E coli K-12, being classified as disabled hosts in the ACGM guidelines, and are unlikely to survive in the human gut or elsewhere.

- **Lentivirus**

Lentiviruses are a type of retrovirus. They are unique from other types of retroviruses because they can infect both dividing and non-dividing cells and are stably integrated into the host genome. This is because their pre-integration complex (or virus shell) encodes a localisation sequence that is recognised by the import machinery of the nucleus, enabling the virus to get through the intact membrane of the nucleus of a target cell. Lentiviral vectors that will be used in this project are HIV-derived viral vectors. HIV derives its virulence from 9 genes. Of these nine genes, five or six have been removed (depending on viral expression system used), leaving only the viral genes that are essential for its gene transfer ability. Furthermore, the provirus is broken into pieces, leaving the vectors replication defective.

Tropism of the lentiviral vector depends on the envelope (env) protein that is expressed. Lentivirus coated with e.g. the envelope protein from murine leukemia virus (MLV) is ecotropic, i.e. able to infect murine cells, but not human cells. Lentivirus coated with e.g. the envelope protein from vesicular stomatitis virus (VSV-G) is pantropic, i.e. able to infect both murine and human cells.

We will use pantropic virus. This will be used because i) pantropic virus is needed to infect human cells in culture, and ii) the pantropic VSV-G envelope protein brings stability to the lentiviral vector yielding higher functional titres following Lenti-X™ Concentrator and a standard speed centrifugation. We will avoid concentration of immortalisation viruses where possible by using viral supernatants directly.

- **In vitro target cells**

Host cells will include primary fibroblasts or cancer epithelial cells, generated in-house using well established protocols, commercially available HUVECs (https://www.cellapplications.com/human-umbilical-vein-endothelial-cells-huvec), plus established human cancer cell lines e.g. MCF-7, T47D, MDA-MB-231 and others
available from the European Collection of Authenticated Cell Cultures (https://www.phe-culturecollections.org.uk/collections/ecacc.aspx). The cell lines used are not capable of survival outside the laboratory and are non-transplantable due to immuno-incompatibility. They are therefore, considered to be highly disabled hosts.

Host/vector system

Replication-defective retroviral vector system:
The Phoenix ecotropic and amphotropic retroviral transduction systems (packaging producer line is derived from 293T human embryonic kidney cell-line), or equivalent, 3 plasmid packaging system will be used. The transducing particles produced are simple enveloped RNA virus vectors that consist of gag (coding for the core proteins), pol (coding for the viral RNA reverse transcriptase) and env (coding for the viral envelope). Long terminal repeats (LTRs) harbour sequences that aid viral genome integration and transcription of the inserted genes. The ecotropic particles cannot transduce human cells and are therefore categorized as ACDP Hazard group 1. The amphotropic particles can transduce human cells and therefore are categorized and Hazard group 2.

In the 3 plasmid packaging system one construct harbours gag and pol and a separate construct harbours env. A third construct is then transfected into the producer cells that contains: (a) the gene of interest plus the retroviral packaging signal to allow production of particles capable of transducing human target cells; and (b) sequences within the Long Terminal Repeats (LTRs) that aid viral genome integration and transcription of the inserted genes. Only sequences within the LTRs are integrated in the genome of target cells. In this packaging system, the functions required for production of transducing units are separated in three different plasmids making the potential for recombination and virus production in the target cells virtually impossible.

The retroviral vectors to be used with this system are pBABE and pBabe derivatives or equivalent MLV-derived retroviral vectors. The plasmids are non-mobilisable but are designed to be integrated into the host genome. Vectors carry drug resistance markers or reporter genes that are non hazardous to humans.

Replication-defective lentiviral vector system:
Where mitosis-independent transduction is required lentiviral systems will be used. These systems are based on HIV-1. However, viral genes such as vpr, vif, vpu and nef are deleted and the HIV envelope gene is replaced with Vesicular stomatitis virus G protein (VSV-G) to increase the host range of the virus. Replication defective transducing units are produced by co-transfection of a transgene vector harbouring the gene of interest together with at least two separate non-overlapping packaging constructs containing gag, pol and env making the potential for recombination virtually impossible. Biosafety is further increased by the use of self-inactivating vectors. The particles can transduce human cells therefore they are categorized and Hazard group 2 and will be handled under Containment level 2 conditions.

The plasmids to be used with the lentiviral system pLKO.1 (addgene), pGIPZ, pLEX (Open Biosystems) or equivalent self-inactivating (SIN) lentiviral vectors due to deletion of part of the HIV-1 3’ LTR – upon integration the provirus lacks a promoter so full-length vector sequence can no longer be transcribed. Vectors carry drug resistance markers or reporter genes that are non-hazardous to humans.

- Ready-to-use lentivirus
  - pCSII-CMV-hTERT-IRES-Hygro second generation lentivirus ready to infect human cells, will be used (provided by collaborators in Leeds or Glasgow). The lentivirus contains the hTERT gene under the control of a CMV promoter and an internal ribosome entry site (IRES) to allow simultaneous translation of a hygromycin resistance gene, flanked by 5’ and 3’LTR sequences, as well as an origin of replication and ampicillin resistance gene.
  - pGIPZ-tGFP (Dharmacon), a replication-incompetent lentiviral vector designed specifically for the expression of shRNAs in mammalian cells. The Human U6 promoter drives RNA Polymerase III transcription for generation of shRNA transcripts. Selection of shRNA expressing cells is possible using turbo GFP under the control of a CMV promoter.

- Production of lentivirus

Viral vectors will be transfected into a packaging cell line such as HEK293T-based Lenti-X™ HTX (Clontech; www.clontech.com), which has been modified to stably express the SV40 large T antigen under the control of the CMV promoter. This enables replication of the plasmids containing an SV40 origin of replication to high copy number in the transfected cell, thus achieving a high viral titre.
- 2nd generation lentivirus

This will NOT be used for production of lentivirus containing hTERT or other inserts that are potentially harmful.

Plasmids that are co-transfected into packaging cells to produce virus:
1. expression plasmid
2. packaging plasmid encoding gag, pol and rev viral genes
3. envelope plasmid

1. Lentiviral expression plasmids

Lentiviral expression constructs are created by cloning a gene of interest into a vector sequence that is flanked by LTRs and the Psi-sequence. The LTRs are needed for the integration of the gene of interest into the host genome and the Psi-sequence is required for packaging RNA transcribed from the gene of interest in virions.

- pLKO.1 vector, a replication-incompetent lentiviral vector designed specifically for the expression of shRNAs in mammalian cells. The Human U6 promoter drives RNA Polymerase III transcription for generation of shRNA transcripts. For stable selection in mammalian cells pLKO.1 contains the Puromycin resistance gene (PuroR) which is driven by the Human phosphoglycerate kinase promoter (hPGK).

2. Lentiviral packaging plasmids

- psPAX2 (Addgene plasmid #12260), encoding pol, gag and rev genes. Transcription of viral genes gag, pol and rev within psPAX2 is mediated via the human cytomegalovirus (hCMV). For bacterial selection psPAX2 contains the Ampicillin resistant gene.

3. Lentiviral envelope plasmids

- pMD2.G (Addgene plasmid #12259). This plasmid encodes the coding sequence for the envelope G glycoprotein from Vesicular Stomatitis Virus (VSV-G) to allow production of pseudotyped lentivirus with a broad host range. The human b-globin intron and polyadenylation (beta-globin pA) signal enhance expression of the VSV-G gene in mammalian cells and allows efficient transcription termination and polyadenylation of mRNA, respectively.

- 3rd generation lentivirus

This will always be used for production of lentivirus containing hTERT or other inserts that are potentially harmful, and may be used for any other gene to be modified.

Plasmids that are co-transfected into packaging cells to produce virus:
1. expression plasmid
2. packaging plasmid encoding gag and pol viral genes
3. packaging plasmid encoding rev viral gene
4. envelope plasmid

1. Lentiviral expression plasmids

Lentiviral expression constructs are created by cloning a gene of interest into a vector sequence that is flanked by LTRs and the Psi-sequence. The LTRs are needed for the integration of the gene of interest into the host genome and the Psi-sequence is required for packaging RNA transcribed from the gene of interest in virions.
A suitable expression plasmid will be used, such as:

- pLKO.1 vector, a replication-competent lentiviral vector designed specifically for the expression of shRNAs in mammalian cells. The Human U6 promoter drives RNA Polymerase III transcription for generation of shRNA transcripts. For stable selection in mammalian cells pLKO.1 contains the Puromycin resistance gene (PuroR) which is driven by the Human phosphoglycerate kinase promoter (hPGK).
- Other plasmids will be added as required and The Foresterhill Biological Safety Committee informed of the expression plasmids to be used.

2. Lentiviral packaging plasmid encoding gag and pol

- pMDLg/pRRE (Addgene plasmid #12251, Didier Trono) or equivalent. A 3rd generation LV packaging plasmid that includes gag, coding for the virion main structural proteins; pol, responsible for the retrovirus-specific enzymes; and RRE, a binding site for the Rev protein which facilitates export of the RNA from the nucleus. This plasmid does not include Rev.

3. Lentiviral packaging plasmid encoding Rev

- pRSV-Rev (Addgene plasmid #12253, Didier Trono) or equivalent. A Rev cDNA expressing plasmid in which the joined second and third exons of HIV-1 rev are under the transcriptional control of RSV U3 promoter.

4. Lentiviral envelope plasmid

- pMD2.G (Addgene plasmid #12259). This plasmid encodes the coding sequence for the envelope G glycoprotein from Vesicular Stomatitis Virus (VSV-G) to allow production of pseudotyped lentivirus with a broad host range. The human b-globin intron and polyadenylation (beta-globin pA) signal enhance expression of the VSV-G gene in mammalian cells and allows efficient transcription termination and polyadenylation of mRNA, respectively.

Origin & function

- hTERT (Human Telomerase Reverse Transcriptase), the catalytic subunit of the enzyme telomerase. Telomerase prevents shortening of telomeres at the tips of chromosomes during replication by adding TTAGGG sequence repeats to maintain telomeres. Overexpression of TERT is widely used to immortalise cells.
- Reporter genes such as EGFP and derivatives, dsRed and derivatives, Firefly luciferase (Fluc), β-galactosidase under the control of mammalian or viral promoters (e.g. CMV or MLV 5' LTR) to enable tracking of cells.
- Inserts encoding wild-type or mutant genes involved in normal development, cell signalling, angiogenesis or cancer. cDNAs may be expressed as fusions with a fluorescent molecules EGFP or dsRed; in non-tagged or tagged form (N- or C-terminal MYC, HA, FLAG, or HIS-tag); cDNA libraries may be used. Expression will be constitutive via mammalian or viral promoters (e.g. CMV or MLV LTR) or inducible (e.g. TET ON or TET OFF systems).
- Small hairpin RNA molecules (shRNAs) or derivatives of microRNAs to knockdown genes involved in normal development, cell signalling, angiogenesis or cancer under the control of U6 or H1 promoters. shRNA and miRNA libraries may be used.
- Inserts encoding function-blocking peptides or antibody fragments to inhibit the function of proteins involved in normal development, cell signalling, angiogenesis or cancer. Mammalian expression vectors harbouring cDNAs and reporter genes will be obtained from commercial sources and collaborators. Lentiviral vectors will be obtained from commercial sources and collaborators (lentiviral vectors will be SIN vectors. Plasmids will be propagated in E. coli K-12 derivatives.
- Inserts encoding reporter genes such as EGFP and derivatives, dsRed and derivatives, Firefly luciferase (Fluc), β-galactosidase under the control of mammalian or viral promoters (e.g. CMV or MLV 5' LTR) to enable tracking of cells.
- TERT (Telomerase Reverse Transcriptase), is the catalytic subunit of the enzyme telomerase. Telomerase prevents shortening of chromosomes during replication by adding TTAGGG sequence repeats to maintain telomeres. Cell immortalization is typically achieved through the overexpression of TERT, particularly for cells that are most affected by telomere length, such as human cells (Lundberg AS. 2000; Fridman AL, 2008).

Evaluation of foreseeable effects

(a) hazards associated with the recipient organism including ACDP hazard group and the effects of any stable disabling mutations

- Bacterial expression
The bacterial organisms are E. coli K12 derivatives and are unlikely to survive in the human gut or elsewhere. None of the genes expressed here would be expressed in...
these bacterial cells since the genes lack a bacterial promoter. Even if expression did occur, it would not be anticipated to confer any pathological advantage to the bacterial host.

- Lentiviral vectors
  (i) Second (pre-made in the PI’s former lab) or (ii) ready-to-use third generation lentiviral systems will be used for generation of pantropic virus.

Second generation lentiviral system carry the following safety features:
1. The number of lentiviral genes necessary for packaging, replication and transduction is limited to four (Gag/Pol/Rev/Tat) all lacking packaging signals. The plasmids share no significant homology to the expression vector, preventing the generation of replication-competent virus.
2. None of the Gag, Pol, or Rev genes will be present in the packaged viral genome, thus making the mature virus replication-incompetent.
3. The packaging plasmids share no significant homology to any of the expression lentivectors, the pVSV-G expression vector (pMD2.G), or any other vector, to prevent generation of recombinant replication competent virus.
4. An enhancer deletion in the U3 region of 3′ΔLTR ensures self-inactivation of the lentiviral vector following transduction & integration into the target cell’s genomic DNA.

Third generation lentiviral expression systems include the following additional safety features:
1. The number of lentiviral genes necessary for packaging, replication and transduction is further reduced to three (Gag/Pol/Rev). It utilizes a chimeric 5′ LTR to ensure transcription in the absence of Tat.
2. Gag/Pol and Rev are encoded on separate plasmids.

All of these safety features mean that there is no likelihood of this work resulting in the production of replication competent lentiviruses.

Third generation lentiviral systems are considered safer than second generation systems but may be more difficult to use because they require transfection with four separate vectors in order to create functional lentiviral particles.

Our current protocol employs a 2nd generation lentiviral system (Addgene) to modify TERT and insert GFP/RFP, generated by the PI at her former lab. A supply of pre-made virus exists and when exhausted, we will use a 3rd generation commercial ready to use system (e.g. from OriGene, Dharmacon, ThermoFisher) for TERT, shRNA and CRISPR modification in future.

- Target cells
  None of the target cells have inherent pathogenic properties and they would be unable to survive if introduced accidentally into non-immunocompromised lab workers. The risk associated with accidental injection of target cells is therefore negligible in immune-competent individuals, since the cells would be eliminated by the host’s immune system.

(b) hazards arising directly from the inserted gene
- TERT
  This may cause pathogenic effects, since TERT is considered an oncogene. It is expressed in around 90% of malignant cancer. While telomerase does not drive the oncogenic process, it is permissive and required for the sustained growth of most advanced cancers.
- Non-mammalian reporter genes, such as GFP/RFP and other fluorescent variants are non-pathogenic proteins. The gene products would not be expected to cause any hazard to human health.

(c) hazards arising from the alteration of existing pathogenic traits
It is not thought that the inserted genes will alter the tropism of the lentiviral vectors. Thus, they will not be able to infect additional cell types and will stay non-replicative.
Pathogenic traits are not present in commercially available disabled strains of E coli K12: they do not have the type of glycocalyx required for the attachment to the mucosal surface of the human colon and they do not express capsular (K) antigens which are important for colonisation and virulence. The genes in the plasmids will not introduce pathogenic traits into the bacteria.

(d) likelihood and effects of natural gene transfer to other organisms

Bacterial strains are multiply disabled and therefore there is no foreseeable risk of gene transfer to workers or the environment. Should plasmid DNA accidentally enter the body it is highly unlikely that it would lead to expression since the DNA is not readily taken up by cells and will be degraded rapidly.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

The following precautionary measures will be used for work with lentivirus:

- Lab users are made aware of the risks when receiving lab induction/training and through Local Rules and Risk Assessments.
- Individuals carrying the HIV virus, or any other immuno-compromised individuals, will not be allowed to work on the project. There is a very small risk that, if the lentiviral expression plasmid was injected into an individual carrying wildtype HIV, the vector could recombine, via the truncated LTRs, with the wildtype virus to produce replication competent virus. Lab users are asked to contact the Occupational Health Service if (s)he has any medical condition or takes any medication that causes his/her immune system to be compromised.
- The risk of accidental injection, inhalation or ingestion will be minimised by wearing gloves, handling stocks and cultures containing viral particles in a Class II safety cabinet. No needles and sharps will be used.
- For transduction of human cells with genes such as TERT known to have potential pathogenic effects, ready-to-use lentivirus will be collected from collaborators and used.
- The operator will use appropriate CL-2 safety equipment, such as coat, gloves, sleeves, protective goggles (during the lentivirus handling).

Factors such as congenital immunodeficiency and secondary immunodeficiency caused by serious illness or chemotherapy would increase the susceptibility to infection by micro-organisms, including the genetically modified micro-organisms described in this application. In carriers of wild-type HIV there may be a theoretical risk of recombination of the lentiviral vector with wildtype virus. Thus, there would be the potential risk of mobilisation and transmission of the recombinant lentivirus to other individuals via the normal routes of HIV-1 transmission. Individuals known to be HIV-positive or to be immunocompromised will not be allowed to work on this project, these risks will be made clear to all personnel in the laboratory.

We would not expect any specific symptoms as the result of an infection with the genetically modified micro-organisms described in this application since the lentiviral vectors cannot replicate.

All liquid waste (from mammalian and bacterial cell cultures will be treated with Virkon (1:50, following manufacturer’s recommendations) and left for at least 30 minutes before disposal down the drain with copious amounts of water. This is from the first media change after transfection and for 10 days (or two passages) after target cell infection.

Plastics and other solid disposable waste will be collected in an autoclavable bag within the biological safety cabinet, sealed and then sprayed with Chemgene (1:50, following manufacturer’s recommendations). The bag will then be removed from the safety cabinet into a clean autoclave bag, sealed, and taken to the autoclave in a sealed container.
Glass bottles and other non-disposable vessels will be soaked in the appropriate concentration of Chemgene (1:50 dilution, according to the manufacturer’s recommendation) in a bucket with a sealed lid, rinsed well and then autoclaved.

Validation will involve regular testing of the autoclave to demonstrate, using independent thermocouples placed at the centre of the load, that the correct temperature and pressure have been reached for the required time.

To validate the inactivation of lentiviral vectors, a standard viral culture test will be used after each transduction procedure. Cells able to be transduced by the virus will be grown in the presence of increasing (10-fold) amounts of inactivated waste. Any transduced cells will then be selected for using appropriate antibiotic treatment for 10 days prior to detection of colonies e.g. by staining with Crystal Violet. The identification of any antibiotic-resistant colonies demonstrates the presence of active lentiviral vector within the ‘inactivated’ waste.

100% expectation of kill of GM microorganisms exposed to 121ºC for 15 minutes.

Liquid and solid waste will be disposed of according to the normal Foresterhill waste procedures as described.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The committee were happy that the hazards of the project have been correctly identified, and that appropriate safe systems of work will be used to control those risks identified. This application was approved at Containment Level 2 by the local Genetic Modification Safety Committee.

Project Ref 490/20.2

Date Ackn’d 11/11/2020  CU2 Project Title Investigation of molecular and cellular mechanisms regulating neurogenesis and Development

Class 2  CultureVolClass2 Class 2  CultureVolumeClass3-4 < 1 Litre

02/03/2022  Page 7883 of 1532
The main goal of this project is to examine the functions of risk genes for brain developmental disorders or RNA metabolism related genes in regulating neural stem cell and brain development. GM micro-organisms will be used to manipulate the expression of risk genes genetically and to label neural stem cells and their progenies. We will infect cells with virus (Lentivirus, retrovirus, AAV, Adenovirus) carrying shRNA or cDNA, and fluorescence protein by micro injection into the embryonic or adult mouse brain, or human brain organoids.

Bacteria: K12 derivative E. coli strains such as DH5α, Stella or XL10-gold
Replication incompetent recombinant Retrovirus
Third-generation, replication incompetent, recombinant Lentivirus
Replication incompetent recombinant Adenovirus (serotype 5)
Replication incompetent recombinant Adeno-associated virus (AAV)
Mammalian cell lines and organoids: HEK293T, HEK293GP, Adult mouse neural stem cells, human iPSCs induced forebrain organoids.
Animal: Mouse

For knockdown experiments, retroviral vector pUEG-shRNA (Human U6 promoter-shRNA, Ef1α promoter and EGFP), lentiviral vector cFUGW-shRNA (Human U6 promoter-shRNA, human Ubiquitin C promoter-EGFP), or adeno associated viral vector AAV-CMV-GFP (CMV promoter- EGFP) will be used. For overexpression experiments, retroviral vector cUXIE (Ubiquitin C promoter-cDNA-IRES-EGFP), lentiviral vector cFUGW (Ubiquitin promoter -EGFP – IRES- cDNA) will be used. EGFP in all vector can be replaced by different colour of fluorescence protein such as mCherry, RFP, Tdtomato. All vectors contain ampicillin resistance for selection in E.coli.
Each virus will be packaged as follows:

*Retrovirus: retroviral transfer plasmid, and plasmid expressing envelope gene VSV-G will be co-transfected into HEK293GP packaging cell line (stably expressing Gag-Pol). Virus will be concentrated using ultra-centrifugation and stored at -80 °C.

*Lentivirus: 3RD generation lentiviral transfer plasmid (FUGW), packaging plasmid (pMDLg/pRRE and pRSV-Rev) and envelope plasmid (for expressing VSV-G) will be co-transfected into HEK293T packaging cell line. Virus will be concentrated using ultra-centrifugation and stored at -80 °C.

*AAV: AAV transfer plasmid, helper plasmid (pAD) and Rep/Cap plasmid (Serotype 5 or 2/9) will be co-transfected into HEK293T packaging cell line. Virus will be purified using chloroform treatment, PEG/NaCl precipitation and chloroform extraction method, and then be stored in -80°C

* Replication incompetent recombinant Adenovirus (serotype 5) will be purchased.

**Origin & function**

The following genes will be modified to knockdown or overexpress their expression.

**Genes implicated in brain developmental disorders, including:**

*Cyfip1: This gene encodes a protein that regulates cytoskeletal dynamics and protein translation. This protein also interacts with the Fragile X mental retardation protein (FMRP) and translation initiation factor 4E to inhibit protein translation. A large chromosomal deletion including this gene is associated with increased risk of schizophrenia and epilepsy in human patients. Reduced expression of this gene has been observed in various human cancers and the encoded protein may inhibit tumour invasion.*

*Fnbp1l: The protein encoded by this gene binds to both CDC42 and N-WASP. This protein promotes CDC42-induced actin polymerization by activating the N-WASP-WIP complex and, therefore, is involved in a pathway that links cell surface signals to the actin cytoskeleton. Diseases associated with FNBP1L include Malignant Breast Melanoma and Familial Hypocalciuric Hypercalcaemia. Intelligence genes. High expression during early development.*

**Genes involved in RNA metabolism, including:**

*Mettl5 (Methyltransferase Like 5) linked to Intellectual Developmental Disorder, Autosomal Recessive 72 and Epilepsy, Familial Temporal Lobe, 4. Implicated in intellectual disability disorder;*  

*PTBP1: associated with pre-mRNAs in the nucleus and appear to influence pre-mRNA processing and other aspects of mRNA metabolism and transport. Diseases associated with PTBP1 include Human T-Cell Leukaemia Virus Type 2 and Spastic Ataxia 4;*  

*hnrNPG: RNA-binding protein that plays several roles in the regulation of pre- and post-transcriptional processes. Implicated in tissue-specific regulation of gene transcription and alternative splicing of several pre-mRNAs. Diseases associated with RBMX include X-Linked Hereditary Ataxia and Fragile X-Associated Tremor/Ataxia Syndrome;*  

*Pus7: PUS7 (Pseudouridine Synthase 7) Diseases associated with PUS7 include Intellectual Developmental Disorder With Abnormal Behaviour, Microcephaly, And Short Stature and Non-Specific Syndromic Intellectual Disability. Among its related pathways are Gene Expression and tRNA processing. Gene Ontology (GO) annotations related to this gene include nucleic acid binding and RNA binding*  

*Adat3: This gene encodes a subunit of a tRNA-specific adenosine deaminase. This heterodimeric enzyme converts adenosine to inosine in the tRNA anticodon. A mutation in this gene causes a syndrome characterized by intellectual disability and strabismus. This gene shares its 5’ exon with the overlapping gene, secretory carrier membrane protein.*  

*NSUN2: This gene encodes a methyltransferase that catalyzes the methylation of cytosine to 5-methylcytosine (m5C) at position 34 of intron-containing tRNA(Leu)(CAA) precursors. This modification is necessary to stabilize the anticodon-codon pairing and correctly translate the mRNA. Diseases associated with NSUN2 include Mental Retardation, Autosomal Recessive 5 and Dubowitz Syndrome.*  

**Other genes, including:**

*Hopx: homeodomain protein that lacks certain conserved residues required for DNA binding. It was reported that choriocarcinoma cell lines and tissues failed to express this gene, which suggested the possible involvement of this gene in malignant conversion of placental trophoblasts. Studies in mice suggest that this protein may interact...*
with serum response factor (SRF) and modulate SRF-dependent cardiac-specific gene expression and cardiac development. Marker for quiet stem cell in many tissues; ChR2: Channelrhodopsin is a subfamily of retinylidene proteins (rhodopsins) that function as light-gated ion channels. They serve as sensory photoreceptors in unicellular green algae, controlling phototaxis: movement in response to light. Expressed in cells of other organisms, they enable light to control electrical excitability, intracellular acidity, calcium influx, and other cellular processes. We will overexpress this gene on organoids before transplantation to validate the functional connectivity.

Evaluation of foreseeable effects

Bacteria:
The K12 derivative bacteria are widely used in routine culture work for cloning and have a proven safe history. There will be no expression of functional proteins in bacteria and therefore the inserts should not confer any advantage to the bacterial host. The bacteria are disabled, and the plasmid vectors classified as non-mobilizable, and therefore are not transferred between organisms.

Viral vectors:
All retroviral, lentiviral (3rd generation), adenoviral and adeno-associated viral vectors that will be used in this project are replication incompetent and have a history of safe use. All viral vectors are designed with low homology to prevent recombination with the host. The multi-plasmid transfection system ensures minimal likelihood of recombination, and lentiviral vectors are self-inactivating. For the concentration of virus, a ultracentrifuge with sealable buckets will be used in case of spillage. These detachable buckets will be opened and closed inside category II tissue culture hoods. After concentration, virus will be aliquoted into sealed tubes.

Inserted genes:
Reduced expression of Cyfip1 has been observed in various human cancers. Therefore, CYFIP1 might have a function to inhibit tumour invasion. Other than knockdown of CYFIP1, there is no evidence that knockdown or overexpression of listed genes to increased risk of specific cancers.

Target cells:
The eukaryotic cell lines are standard cell lines with a long history of safe use. They cannot survive outside culture conditions. Genetically modified brain organoids will pose no hazard to human health or the environment since they are unable to colonise humans or survive outside of laboratory culture. For the mouse work, virus will be stereotaxically injected into the mouse brain using neurosyringe. Neuro syringes is ultrafine needle (32gauge) but has dull end and a protective sleeve of needle. Also, only 0.5-1 µl of virus will be injected, therefore there is limited risk of accidental sharp injury or spillage due to direct human handling of the virus. However, there is a possibility that virus aerosol is produced during loading of virus into syringe. Therefore, loading should be performed in the biosafety cabinet.

Effects of accidental inoculation of laboratory workers:
No specific symptoms are expected as the result of an infection with the genetically modified micro-organisms described in this application since the viral vectors cannot replicate. Any genetically modified cells would be eliminated by the immune system in immunocompetent individuals. In carriers of wild-type HIV there may be a theoretical risk of recombination of the lentiviral vector with wildtype virus. Thus, there would be the potential risk of mobilisation and transmission of the recombinant lentivirus to other individuals via the normal routes of HIV-1 transmission. Individuals known to be HIV-positive or to be immunocompromised are asked to contact Occupational Health before working on this project. This will be made clear to all personnel in the laboratory.

Infected mice will be housed in secure cages in a containment level 2 room in a full barrier facility.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be decontaminated with 10% chemgene (final concentration) within the microbiological safety cabinet for a minimum of 20 minutes prior to disposal through the laboratory waste sink. The treatment with 10% chemgene completely disrupts the virus thereby eliminating virus activity. Solid waste will be decontaminate by
immersion in 10% chemgene solution for at least 20 minutes. The solid waste will then be autoclaved under vacuum air extraction with rapid steam heating to 121°C for 25 minutes. 100% kill is expected to be achieved.

The autoclaves are tested regularly, using independent thermocouplers placed at the centre of the load, to ensure a sufficient temperature and pressure are maintained for the required time. Validation is performed by spreading samples from autoclaved solutions on agar plates and monitoring for bacterial growth. To check the lab autoclave is working correctly, indicator tape is included in the runs.

All infected liquid and solid waste will be sterilized by 10% chemgene. Validation by the manufacturer indicates that this will result in inactivation of all organisms detailed in this proposal.

Liquid and solid waste will be disposed of according to the normal Foresterhill waste procedures as described.

The committee were happy that the hazards of the project have been correctly identified, and that appropriate safe systems of work will be used to control those risks identified. This application was approved at Containment Level 2 by the local Genetic Modification Safety Committee.

Please enter comments on the GM safety committee on the risk assessment

Project Ref 490/21.1

Date Ackn'd CU2 Project Title Class CultureVolClass2 CultureVolumeClass3-4

03/06/2021 Deletion of duplicated metabolic genes of Staphylococcus epidermidis to explore their Class 2 < 1 Litre
Project Additional Information

Purposes of the contained use

Recipient or parental organism

Staphylococcus epidermidis (multidrug resistant clinical isolates).

Host/vector system

pMAD vector

Origin & function

To enable the targeted deletion of the 6 genes listed in section 6 we will utilise the pMAD shuttle vector for generating gene inactivation mutants in naturally non-transformable gram-positive bacteria. This vector was derived from the cloning of shuttle vector pE194ts:pBR322 and the NaeI-BglII DNA fragment containing the extended multiple cloning site from the pMTL22 plasmid (Arnaud et al., 2004). This vector features the bla and emrC genes for antibiotic resistance.

Evaluation of foreseeable effects

S. epidermidis strains used for this work are clinical isolates derived from blood cultures of patients who suffered from bloodstream infections during their admission in the intensive care unit of Aberdeen Royal Infirmary. These infections are largely the result of inevitable contamination during invasive procedures or insertion of medical devices (cannulation, intubation or catheterisation) in intensive care where patients are already susceptible to a range of opportunistic infections, all compounded by the ‘immune-paralysis’ associated with sepsis (McGahee and Lowy., 2000). S. epidermidis is otherwise one of the most predominant commensal microorganisms which colonises the skin and mucous membranes. Unlike S. aureus, S. epidermidis is not classified as Hazard Group 2 pathogen by the ACDP. However, S. epidermidis strains isolated in intensive care units are known to carry multiple resistance genes giving rise to Multidrug Resistant Staphylococcus epidermidis (MRSE). For this reason, precautionary measures for handling and disposal of S. epidermidis will be the same as those expected for HG 2 pathogens, notwithstanding that multidrug resistance in staphylococci does not necessarily result in increased bacterial fitness or virulence (Geisinger and Iseberg, 2017). For this project we will create targeted deletion mutants of wild-type clinical isolates of S. epidermidis (free of disabling mutations).

Selection of deletion mutants requires the insertion of use of a dominant selectable marker such as Spc (spectinomycin resistance). Spectinomycin is not used in clinical practice and therefore the use of this marker does not compromise antimicrobial therapies.

For this project we will create targeted deletion mutants of wild-type clinical isolates of S. epidermidis. To date there is no evidence to indicate that antimicrobial resistance...
or virulence of staphylococci can be increased through targeted deletion of any gene(s). If anything, these strains are expected to display antimicrobial resistance and virulence levels that are less than (or at worse equal) to the wild-type clinical isolates. It is important to note that multidrug resistance has been often associated with a reduction in pathogenicity in Staphylococcus and beyond. (Geisinger and Isberg, 2017).

The risk of DNA transfecting human cells is extremely low. In any event DNA replication and expression of genes borne on the shuttle vector cannot be expressed in human cells in the absence of eukaryotic origin of replications and promoters.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

| n/a |

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

| n/a |

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Small spills will be inactivated using laboratory disinfectant, Chemgene, according to the instruction of the manufacturer (https://www.starlabgroup.com/GB-en/gloves-safety/laboratory-disinfectant_WebPSUB-159946/chemgene-hld4l-conc-clear-unfragranced-5-litre_SLXTM309-C.html#tab=downloads).

Large cultures will be inactivated by adding neat Chemgene to a concentration of 10%.

Cultures on petri dishes will be inactivated by autoclaving (121°C, 15psi, 15-20min).

Our standard procedures for use of Chemgene have been validated experimentally to kill >99.99% of cells. Viability tests were performed on Chemgene-exposed cultures. Autoclaves are validated at least annually by means of biological indicators. In addition, we have validated killing at >99.99% by plating samples harvested from the centre of autoclaved samples. In daily use, monitoring is by thermocouple temperature recordings and autoclave strips included in the loads.

Once the genetically modified microorganisms have been inactivated, normal routes of disposal are used for liquid and solid waste: 1) solid waste is incinerated; 2) liquid waste is discarded down the sink.

**Is an emergency plan required according to regulation 20?** N

### Please enter comments on the GM safety committee on the risk assessment

The safety committee noted that activities associated with this work should be assigned to Class Activity 2 given the requirement for CL2 containment measures to control the risk (refer to section 7 for explanation of risk).

The safety committee noted that a higher concentration of laboratory disinfectant (10% Chemgene) is required for inactivation of GM S. epidermidis grown in larger cultures and also for routine bench top and equipment decontamination.

Maximum culture volume to be released at one time: 1 litre.
Waste deactivation: by autoclaving at 15 lbs/sq inch pressure and 121 degrees C for at least 20 minutes.
Validation of the deactivation method: colour change of autoclave tape.
Monitoring of deactivation method: all waste is labelled, autoclave tape attached, and placed in appropriate containers prior to deactivation in an autoclave room.

Maximum culture volume for disposal is between 500 ml to 1000 ml liquid LB media. Autoclaving is used for waste deactivation. Contaminated fluids are autoclaved before disposal at 126 degrees C, for 20 minutes. Contaminated LB plates and solid waste are placed in either yellow biohazard bags and incinerated, or autoclaved, wrapped and placed in the normal bins for disposal.

At regular intervals, to monitor the adequacy of a disinfectant or the disinfectant method, the Kelsey and Maurer in-use test is used. Whenever a new disinfectant, dilution, or deactivation procedure is brought into use, the Kelsey and Maurer in-use test is also performed.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The maximum culture volume for the class 1 activities in 50 litres. This is done occasionally (around 3-4 times per annum) but volumes are more typically 2 litres or less. The worst case scenario would occur if a 50 l fermenter were to break or leak its entire contents. In this unlikely event, the spill would be contained within the area and decontaminated in situ. Waste or spills would be deactivated by a variety of methods dependent on the situation. These range from heat inactivation by autoclaving in validated autoclaves to use of approved disinfectants such as sodium hypochlorite (presept tablets) or fumigation with formaldehyde gas for room sterilisation.

Deactivation is in accordance with published procedures, but the Murex GMSC agrees that it would be good practice to have internally validated these methods and has instigated a programme of experimental work to provide scientific backing to the practices adopted.

All genetically modified plant material must be disposed of by one of the following procedures:

1. Autoclaving on a waste cycle (30 minutes at 15 lbs/in², 121 degrees C). The inbuilt autoclave monitoring systems must be checked to ensure the cycle was completed and records of each run kept to the extent that it is noted such output was checked. All autoclaves must be correctly maintained and users appropriately trained. Service records for autoclave equipment must be retained.

2. Milling, grinding, or processing of material to such an extent that the organism is rendered non-viable. Where the non-viability cannot be judged by eye, e.g., in the case of small seed where the extent of destruction cannot be ascertained an appropriate germination test must be carried out using a recorded and approved protocol. All such disposals and assessments should be recorded.

# Project Additional Information

**Purposes of the contained use**

Probes are used to diagnose PSTVd in samples of imported and UK-derived potato material submitted for testing. These probes are produced from full length transcripts of PSTVd in E. coli.

**Recipient or parental organism**

The host organism is a disabled laboratory strain of E. coli (JM 109 or JM 101)

PSTVd is a non-indigenous viroid pathogen of potato, comprising approximately 359 nucleotides. It causes disease in potatoes and tomatoes and has been found in a number of other plants. It is not present in the UK and is a quarantine organism listed in EC Plant Health legislation. PSTVd is held under plant health containment for use as a positive control in diagnostic assays.

**Host/vector system**

For the RNA probe the plasmid pSP65 containing a full length dimmer of PSTVd is used. For the DNA probe an M13 bacteriophage cloning vector containing full length PSTVd is used.

**Origin & function**

The full length PSTVd sequences were produced in the USA and tyrailed in Peru.

**Evaluation of foreseeable effects**

The resulting PSTVd RNA and DNA sequences may be infectious, so present the same risk to potatoes and tomatoes as wild-type PSTVd.

There are no foreseeable effects on human health.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All material will be autoclaved or sterilised in 20% sodium hypochlorite (equipment that has been in contact with the GMM) prior to disposal. Both disposal methods are used in the laboratory to kill wild type PSTVd.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The work requires a GM Plant Health Licence.

The maximum culture volume for disposal of liquid waste is 2 litres. Solid waste is deactivated by autoclaving. Liquid waste is deactivated either by autoclaving or by addition of disinfectant Virkon. Validation and monitoring involves use of autoclave tape, and for disinfectant, reference to the manufacturer's instructions supplemented with testing for live micro-organisms post deactivation.

**Date Project Ceased** 02/03/2022

**Non-GMM Consent Granted** Not Applicable
### Project Additional Information

#### Purposes of the contained use

The aim is to investigate S. aureus and S. epidermidis adhesion, biofilm formation and development of antibiotic resistance. The project will examine the differential expression of S. aureus and S. epidermidis adhesins and intercellular adhesive mechanisms, the global regulatory circuits like agr, sigB and sar, and antibiotic resistance in relation to biofilm formation and infections associated with implanted biomaterials. The long-term objective is to improve our understanding of staphylococci infections which will lead potentially to the development of strategies for the prevention and improved treatment of such infections.

#### Recipient or parental organism

- **Staphylococcus strains; ADCP Group 2 micro-organisms:** S. epidermidis 1457, S. epidermidis 5179, S. epidermidis 1585 and clinical S. aureus and S. epidermidis isolates as the parental hosts.
- S. aureus RN4220 restriction deficient cloning host.
- S. carnosus TM300 cloning host for protoplast transformation.
- Escherichia coli K12 cloning strains; ADCP Group 1 micro-organisms: E. coli TOP 10 Cloning host; E. coli BL21AI Expression host; E. coli MC1061 Expression of erythromycin resistance of Tn917 in E. coli

#### Host/vector system

- pTVlts for transposon Tn917; pRN3208 for transposon Tn551; pBT1, pBT2 replicon in staphylococci for allelic exchange mutagenesis; pRB474 shuttle vector for cloning in E. coli/staphylococci; pASI shuttle vector for cloning in E. coli/staphylococci; pCX15 inducible gene expression in staphylococci under control of xylA promoter; pWBG636 conjugative mobilisation of plasmids; ClosTron system for allelic exchange mutagenesis; pBluescript II SK E. coli cloning vector; pCRII TOPO & pCR2.1 TOPO cloning vectors for PCR fragments in E. coli; pENTR/D-TOPO entry vector for Gateway technology in E. coli; pDEST1 7 expression vector: N-terminal His6-Tag.

#### Origin & function

DNA will derive from S. aureus and S. epidermidis. Genetic modification will be carried out to determine the function of genes involved in biofilm formation and antimicrobial resistance of these bacteria. Marked transposons will be mobilised from E. coli into S. aureus and S. epidermidis. Mutants which demonstrate either susceptibility to various agents or a diminished capacity for virulence will be selected using laboratory models of disease. The genes which have been disrupted by these transposon insertions will then be identified by genetic analysis. To determine if these disrupted genes play a role in the actual observed phenotype, the wild-type gene will be cloned back into the mutants; restoration of the parental phenotype will then be examined. In addition, the genes may also be mutated by site-directed mutagenesis to create unmarked, non-polar mutations, in order to clarify their role in virulence and resistance. This gene knockout and complementation approach will be used to elucidate the genetic basis for virulence, pathogenesis and overall environmental fitness in S. aureus and S. epidermidis.
S aureus and S. epidermidis are ACDP Hazard Group 2 bacterial species capable of causing opportunistic human infection. Likelihood of causing infection in healthy laboratory worker is low and therapy is available to treat any potential infections. The likelihood of escape of bacteria from the laboratory or transfer to susceptible individuals is low given the level of containment and disinfection procedures employed during handling of these bacteria. S. carnosus is used as starter for fermentation of sausages and has no hazards for human health, Escherichia coli K12 cloning strains to be used in the project have no associated hazard.

The plasmid vectors to be used are either: (i) narrow-host range E. coli vectors for DNA sequence analysis (ii) shuttle vectors for self-cloning of DNA in staphylococci which require electroporation or protoplast transformation or conjugation for their introduction, or (iii). These vector systems given the level of containment and disinfection procedures employed during handling of these vectors and recipient hosts carry a very low associated hazard. Genes involved in virulence, biofilm formation and antibiotic resistance are identified by a mutagenesis procedure which will stop expression of the recombinant gene. Self-cloning of DNA will be used to restore expression within the mutants and check the function of the encoded DNA. The genes explored are widely distributed in naturally occurring populations of staphylococci. All other sub-cloning of DNA will be performed in E. coli K12 cloning strains which are highly attenuated and will not represent an increased hazard risk after insertion of DNA from S. aureus and S. epidermidis.

Since mutagenesis and self-cloning of DNA will be the genetic modification performed, the recombinant strains will not present a pathogenicity hazard greater than the original host organisms, S. aureus or S. epidermidis. The only interspecies transfer of DNA to be performed will be from S. aureus or S. epidermidis to E. coli K12 cloning strains. The E. coli K12 cloning strains are harmless and transfer of DNA into them will not represent an increased hazard.

As outlined above the genetic modification performed, mutagenesis and self-cloning of DNA will not increase the hazard risk above that of the wild type parental strains. S. aureus and S. epidermidis are ACDP Hazard Group 2 micro-organisms capable of opportunistic human infection, but for which treatment exists in healthy individuals. Hence they pose a low level of risk.

### Evaluation of foreseeable effects

S aureus and S. epidermidis are ACDP Hazard Group 2 bacterial species capable of causing opportunistic human infection. Likelihood of causing infection in healthy laboratory worker is low and therapy is available to treat any potential infections. The likelihood of escape of bacteria from the laboratory or transfer to susceptible individuals is low given the level of containment and disinfection procedures employed during handling of these bacteria. S. carnosus is used as starter for fermentation of sausages and has no hazards for human health, Escherichia coli K12 cloning strains to be used in the project have no associated hazard.

The plasmid vectors to be used are either: (i) narrow-host range E. coli vectors for DNA sequence analysis (ii) shuttle vectors for self-cloning of DNA in staphylococci which require electroporation or protoplast transformation or conjugation for their introduction, or (iii) These vector systems given the level of containment and disinfection procedures employed during handling of these vectors and recipient hosts carry a very low associated hazard. Genes involved in virulence, biofilm formation and antibiotic resistance are identified by a mutagenesis procedure which will stop expression of the recombinant gene. Self-cloning of DNA will be used to restore expression within the mutants and check the function of the encoded DNA. The genes explored are widely distributed in naturally occurring populations of staphylococci. All other sub-cloning of DNA will be performed in E. coli K12 cloning strains which are highly attenuated and will not represent an increased hazard risk after insertion of DNA from S. aureus and S. epidermidis.

Since mutagenesis and self-cloning of DNA will be the genetic modification performed, the recombinant strains will not present a pathogenicity hazard greater than the original host organisms, S. aureus or S. epidermidis. The only interspecies transfer of DNA to be performed will be from S. aureus or S. epidermidis to E. coli K12 cloning strains. The E. coli K12 cloning strains are harmless and transfer of DNA into them will not represent an increased hazard.

As outlined above the genetic modification performed, mutagenesis and self-cloning of DNA will not increase the hazard risk above that of the wild type parental strains. S. aureus and S. epidermidis are ACDP Hazard Group 2 micro-organisms capable of opportunistic human infection, but for which treatment exists in healthy individuals. Hence they pose a low level of risk.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMM cultures (liquid and on plates), and contaminated plasticware, glassware, paper towels/spill material will decontaminated by autoclaving for 20 minutes at 134 degrees celsius in the designated autoclave in room 508. 100% of the GMMs will be inactivated using this method of heat/steam treatment.

The GMO authorised autoclave on the ground floor, room 026 will be used if the autoclave in room 508 breaks/out of order. The autoclaves will be tested/checked according to the regulations.

Hands will be disinfected after handling any cultures, and also before leaving the laboratory using disinfectant hand scrub, HDSIO, available at each sink.

The disinfectant for routine use is sodium dichloroisocyanurate (NaDCC) at 0.25% made up according to manufacturers' specification. All work areas will be disinfected using 0.25% NaDCC immediately after use. This is currently being reviewed as new products are being introduced to the market.

### Is an emergency plan required according to regulation 20? N

### If yes, tick to confirm that it is attached to this form N

### Tick to confirm that you have attached a risk assessment to this form Y

### Tick if you are claiming exemption from disclosure for section of the risk assessment N
A special meeting of the Working Group was convened:

TO CONSIDER

The GM Risk Assessment for the Institute of Life Sciences Building.

explained the requirements concerning the risk assessment of the ILS and tabled an assessment that detailed the control measures to be carried out for handling Containment Level II work in laboratories (ILS 5D, Floor).

The findings of the assessment were discussed, in particular the requirements of wearing appropriate and suitable personal protective clothing for laboratory staff undertaking Containment Level I and Containment Level II working within the same laboratory explained the minimum safety requirements.

It was agreed that there would be a need to slightly amend the ‘local safety rules’ to include new rules governing the need to wear designated laboratory coats whilst working on the th Floor.

Following further discussion the following ACTION was AGREED

1. Action: is to complete HSE Form cu2 2000 (rev 2005) Notification of intention to conduct individual contained use activities” and forward a completed copy to all Committee members.
2. Action: is to speak with MB to confirm who should sign the HSE form
3. Action: is to ensure that once the form has been signed it is sent to the HSE and that signed a copy be sent to the Group Secretary.
4. Action: to update local safety rules and disseminate to all staff.

**Project Additional Information**

### Purposes of the contained use

The aim is to investigate GM fungi of Candida spp., Fusarium spp. and Aspergillus spp. which have alterations (through methods such as gene insertion and gene knockout) in the pathways involved in, and associated with cytochromes P450, sterol biosynthesis and beta oxidation to study the pathways affected and to produce novel products. Azole drugs interact with cytochromes P450 and genetic modifications will address mode of action, susceptibility and resistance.

### Recipient or parental organism

<table>

</thead>
<tbody>
<tr>
<td>Candida spp., Fusarium spp. and Aspergillus spp.</td>
<td>2</td>
</tr>
<tr>
<td>E. coli – lab adapted strains with long history of safe use</td>
<td>1</td>
</tr>
</tbody>
</table>

### Host/vector system

Vectors used for transformation in Candida spp. will be episomal shuttle vectors. In Aspergillus spp., general use vectors, based on vectors such as pGEM-T easy or pCR2.1 will be used. In all cases, the vector can contain an origin of replication that allows for manipulation in E. coli, but there is no origin of replication for the host organism. Genetic manipulation will be via homologous recombination. Most recipient strains have pyr auxotrophy and pyrG from related fungi, e.g. A. nidulans, used as marker. A similar homologous integration system to Aspergillus is used in Fusarium.

### Origin & function

Genes associated with cytochromes P450, sterol biosynthesis and beta oxidation and related pathways from Candida spp., Fusarium spp. and Aspergillus spp.

Genes have the potential to be involved with anti-fungal drug resistance. Antibiotic/Antifungal selection genes such as kanMX and hgh/hgt will also be
No genes known to be involved with the pathogenicity of this organism will be modified as part of this project.

**Evaluation of foreseeable effects**

As similar genes to those in the host will be self-replicated within the fungi, the hazard risk will be similar to that of the wild-type or less. Genes will also be inserted to produce other products, such as hydroxy fatty acids, are currently not known to play a role in pathogenicity and are present no greater risk of hazard than the wild-type.

As only the sterol and beta-oxidation pathways (and pathways associated with them) are to be altered, the recombinant strains will not present a pathogenicity hazard greater than the original hosts.

The genetic modifications to Candida spp., Fusarium spp. and Aspergillus spp. performed will not increase the hazard of each species above that wildtype.

As outlined previously, each fungal species is an ACDP Hazard Group 2 pathogen and represent a low risk to healthy individuals. There are also antifungal treatments available to treat infection in said individuals. Therefore the risk posed by exposure to these GMM is low.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid waste will be contained in sealed containers and inactivated by autoclave prior to disposal to foul waste. Solid waste will be autoclaved prior to disposal in appropriate skip (for subsequent incineration)

**Is an emergency plan required according to regulation 20?**

**If yes, tick to confirm that it is attached to this form**

- N

**Tick to confirm that you have attached a risk assessment to this form**

- Y

**Tick if you are claiming exemption from disclosure for section of the risk assessment**

- N
The committee thought this was a well thought out and detailed risk assessment. The panel agreed that modification of the pathways listed would not be expected to alter virulence of the pathogens or the hazards posed.

With respect to the environmental risk – the review panel noted that there is a site of special scientific interest near to the University but that Fusarium are not expected to be a pathogen of these wild plants (and the modified form no more than wild type), there are no significant crops of maize or wheat in the immediate area and that the GMMs are not expected to be more harmful than wild-type.

The panel requested the following clarifications:
- In the event of a spillage during centrifugation – rotors should be opened within a microbiological safety cabinet.
- Once autoclaved, waste will be placed in designated skip for final disposal via incineration

The review panel were satisfied that the control measures in the proposal were appropriate to minimise the risk and approved the assessment subject to minor modification.

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

Previous research done in our research group identified key genes involved in extra-intestinal spread, which is where Campylobacter leaves the gut and infects organs such as the liver. Genes responsible for increased invasion have also been studied. The key genes will be knocked out of C. jejuni strain M1, this should make the strains less invasive in vitro. The strains will be compared to the wild type and the significance of the genes determined. If invasion is reduced then in the future a vaccine could be developed using the information obtained from these experiments.

**Recipient or parental organism**

Campylobacter jejuni M1.

**Host/vector system**

Vectors being used are:

- pUC19-pGEMT easy
- pRDH315==� contains CAT cassette and H pylori rpsl gene (sensitive to streptomycin)
- pRDH316==� contains kanamycin cassette and H pylori rpsl gene (sensitive to streptomycin)
- pKM46==� contains kanamycin cassette with flanking region of CJ 0046 pseudogene
- pCM46==� contains CAT cassette with flanking region of CJ 0046 pseudogene

**Origin & function**

Genes thought to be involved in invasion and/or inflammation are being knocked out individually. The genes identified are involved in movement/chemotaxis, metabolism and membrane association.

**Evaluation of foreseeable effects**

Campylobacter is a class 2 bacterium, and the knock-out mutants will be less invasive than the wild-type. There is no greater risk than any other class 2 bacteria and the mutants are not more harmful than the wild type. The genetic modifications performed to Campylobacterspp. will not increase the hazard of each species above that wild-type. As outlined previously the risk of a healthy individual becoming infected with Campylobacter is low and any if infected the majority of infections are self-limiting. Therefore, the risk posed by exposure to these GMM is low. When the appropriate selections are used, cassettes and plasmids introduced to the recipient are highly stable. Throughout experimentation and the handling of GM bacteria, the selection will be maintained, therefore, any hazard as a result of phenotypic or genetic instability is low.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be contained in sealed containers and inactivated by autoclave. Solid waste will be autoclaved. All waste will be autoclaved promptly. The degree of kill is 100% by autoclaving. Following autoclaving, waste is placed into tiger bags (yellow/black striped) and disposed into a locked autoclave only skip. The skip is collected by Veolia and is taken to Viridor, Trident Park Cardiff where it is incinerated.

The autoclaves are serviced, as well as calibrated and validated, yearly. Test strips and tubes are used to test the efficiency of the autoclaves and autoclaved samples.
have been sent to the waste contract company to test and have been shown to be negative. Any spills should be dealt with in the same manner as bacterial spills in containment level 2, flood the area with disinfectant (2% Distel solution) and mop up with paper towels, dispose of in autoclave bags.

**Please enter comments on the GM safety committee on the risk assessment**

GMO PANEL – 3rd July 2019
Review and consideration of GMO1903
1. The Sub-Committee asked for clarification in the risk assessment who the project partner was and which elements of work are taking place on site or off site. They also requested clarification of how knock out strains would be transported between the partner lab and Singleton campus.
2. Clarification on whether cells would be centrifuged following infection was requested.
3. The panel commented the likelihood of illness is in fact high if a person becomes infected and requested details of control measures to prevent exposure to reduce the potential of exposing people to a ‘low’ risk. They also requested details of the disinfectant procedures.
4. There is a need to detail how the control measures prevent the exposure, resulting in the potential exposure of people to a low risk. Information on disinfectant procedures and what is being used was also requested.
5. More detailed information on containment measures was requested.
6. Further information on the average culture volume and frequency e.g. no of experiments per week was requested.
7. The panel felt that more detail was required in relation to the disposal of waste and how reporting of any spills or accidents would be completed.

GMO PANEL - 2nd October 2019
Review and consideration of GMO1903
The panel noted the updated risk assessment, following comments provided from the previous panel and approved the project to proceed.

### Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

Laboratory | Animal Unit | Growth Room | Glass House | Large Scale
---|-------------|-------------|-------------|-------------|
Level 1 (GMMs) | Level 2 (GMMs) | Level 3 (GMMs) | Level 4 (GMMs) | Non-microbial
Maximum culture volume used - 1 litre.

Waste deactivation - cultures are autoclaved at 121 degrees C, 1 atmosphere steam pressure to obtain a suitable and calculated Del.

Monitoring - digitally controlled cycle with two independent thermocouples to control, including a printout of each temperature cycle for each sterilisation.

Validation - periodic use of spore strips.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

Project Ref 510/20.1

Date Ackn'd: 12/03/2020

CU2 Project Title: Identification and functional analysis of virulence determinants from enteric bacterial and Microsporidia pathogens

Class: Class 2

CultureVolClass2: < 1 Litre

CultureVolumeClass3-4: Non-GMM

Consent Granted
**Project Additional Information**

**Purposes of the contained use**

This project will involve identifying new virulence genes in the following enteric pathogens and also characterise the functions of known virulence genes. The overall purpose is to determine the role of newly-discovered and established pathogen genes in virulence and pathogenicity of important human pathogens.

Pathogens that will be used in this study:

- All pathogens used in this project are hazard group (HG) II pathogens and their use will be strictly regulated under containment II guidelines. The pathogens being investigated are:
  - Pathogenic E.coli strains including enteropathogenic E.coli (EPEC) E2348/69 0127:H6 which is the causative agent of infantile diarrhoea, predominantly in developing countries; and Class I shiga-toxin-minus enterohemorrhagic E. coli 0157:H7
  - Salmonella enteric serovar typhimurium SL344 - which causes non-typhoid gastroenteritis in humans
  - Trachipleistophora hominis - a microsporidian parasite that may infect immunocompromised patients
  - Encephalitozoon cuniculi - a microsporidian parasite that may infect immunocompromised patients

Genetic modification of the last two Microsporidian parasites will be attempted but currently no GM is possible as these parasites only exist within larger host cells and are dependent on host cells for their survival.

Pathogen genes will routinely be expressed in non-pathogenic disabled E.coli K12 and BL21 strains or mammalian cell lines that are classified as Hazard Group I, but will be manipulated and treated as Class II.

**Recipient or parental organism**

The recipient and parental organisms are as following

(i) Pathogenic species

The GMM in this study are all ACDP Hazard Group (HG) II pathogens and their use will be strictly regulated under containment II guidelines. Typically, these pathogens produce a self-limiting non-lethal diarrhoea in adults, lasting just a few days. The pathogens being investigated are:

- Pathogenic E.coli strains including enteropathogenic E.coli (EPEC) E2348/69 0127:H6 which is the causative agent of infantile diarrhoea, predominantly in developing countries; and Class I shiga-toxin-minus enterohemorrhagic E. coli 0157:H7
- Salmonella enteric serovar typhimurium SL344 - which causes non-typhoid gastroenteritis in humans
- Trachipleistophora hominis - a microsporidian parasite that may infect immunocompromised patients
- Encephalitozoon cuniculi - a microsporidian parasite that may infect immunocompromised patients

Genetic modification of the last two Microsporidian parasites will be attempted but currently no GM is possible as these parasites only exist within larger host cells and are dependent on host cells for their survival.
(ii) Laboratory-strain E. coli K12 which as defined by the Compendium of Guidance (Part 2) are non-colon ising and cannot survive for long outside the laboratory. They can be considered as equivalent to ACDP Hazard Group 1.

(iii) E. coli BL21 and derivatives: The same arguments for K12 broadly exist for BL21 expression strains. Stemming from a HSE-commissioned study, ACGM Newsletter 30 (Nov. 2001) states (in para 3) that "BL21 can be considered broadly equivalent to K12 strains and that in most cases work which uses this host can be considered as a class 1 activity ....... but the cloning of a bacterial pathogenicity determinant into BL21 will need careful consideration and may in some cases warrant classification as class 2". Since this project involves cloning genes from ACDP Hazard Group 2 pathogens, their expression in BL21 will require CL2.

(iv) Mammalian hosts: Cultured mammalian cells used in this study include: HeLa, Caco-2, RAW 264.7, T84, J774, Cos-7 and HEK293T. These cell lines are highly unstable and require stringent conditions for growth. They cannot reproduce outside of controlled laboratory conditions and the transfected pathogen genes will not alter this susceptibility. In addition, as defined in the SACGM compendium of Guidance; section 2.5, para 5) in the unlikely event of injection of mammalian cells into a lab user, the immune system would rapidly reject the cells. Therefore, no additional hazards have been identified beyond those associated with the cloned gene products themselves. All cell lines will be treated as ACDP Hazard Group II.

Host/vector system

For pathogen expression the following vectors will be used - pACYC184, pSK(bluescript) and ptrc99a
Gene knockouts will be made with the suicide vector such as - pCVD442
For K12 and BL21 expression - common expression vectors such as pET expresion vectors will be used

Origin & function

Most of the genes cloned and expressed in the pathogens used in this project and in K12 strains will be of pathogen origin. When expressed in the pathogen (usually a deletion mutant) the complemented gene will be from the same species. Therefore, for almost all experiments, no unforeseen genetic interactions are predicted. In addition, the complemented genes are almost exclusively under the control of inducible promoters and hence would only be expressed weakly outside of the lab.

The intended function of the genetic material will be to either complement a deficient gene in the same strain or carry where mutagenesis of the gene may be performed to understand the genes functions. In addition, in disabled E.coli cloning or expression strains, and mammalian cells, the virulence genes will be expressed to purify the protein or understand the cell biological effects of the proteins in these class I cells.

Origin of genetic material:
Genomic DNA or RNA extracted from pathogenic strains as indicated in the above descriptions
Manipulations
(i) Cloning, expression, and manipulation of known or putative virulence genes in E. coli non-pathogenic strains such as K12
(ii) Expression of defined virulence genes in E. coli BL21 or BL21 -derived strains, from standard vectors where the cloned gene is expressed from a phage T7 promoter only upon IPTG induction of a chromosomally inserted T7 RNA polymerase gene.
(iii) Use of suicide plasmid vectors to construct genetically-defined mutants of pathogenic strains by either gene inactivation or allelic replacement.
(iv) Complementation of defined mutants of mutants by reintroducing the corresponding wild-type gene on
mobilisation-defective vectors. Some experiments may express defined genes in the wild-type strains, to examine multicopy effects.

(v) Examining the effects of mutant strains and purified gene products on standard cultured mammalian cells, such as HeLa, Caco-2, T84, HEK293, and J774 cells. Knockout mammalian cells with defined defects in particular pathways will be used in some experiments.

(vii) Expression of pathogenic genes in mammalian cells by transfection of non-mobilizable plasmids to investigate the virulence gene function.

**Evaluation of foreseeable effects**

While most of the work in this project will involve expression of virulence genes in disabled lab-strains of E. coli, the pathogens used in this project may be genetically altered by gene knockout, expression of virulence genes from a plasmid or in-cis or in-trans mutagenesis of virulence genes to elucidate their functions. These pathogens all belong to ACDP Hazard Group 2 and since only genes from the same or very closely-related strains will be introduced into these hosts, it is difficult to envisage how the proposed work could increase the virulence of these species. The plasmids used in this study are all non-mobilisable and therefore the risk of transfer of the plasmids to other bacteria is very small.

Where a gene is overexpressed from a plasmid, the gene will be typically under the control of an inducible promoter, and would only be weakly expressed outside of the lab. Therefore, no additional risks above and beyond those involved in handling ACDP Hazard group 2 pathogens have been identified.

Pathogenic Microsporidia, Microsporidia are weakly pathogenic towards healthy humans but can pose a threat to immuno-compromised patients. At present no methods are available to genetically modify microsporidia species, including those species used in this study. Attempts will be made to design protocols to make gene deletion possible with Microsporidia. The risks of increasing virulence of a Microsporidia species following genetic modification are extremely low as these pathogens are highly dependent on host cells for survival and have a finely tuned evolutionary relationship with the host. Gene deletion in Microsporidia will target important genes and will likely decrease virulence while gene expression studies will involve tagging pre-existing genes. Thus, the any attempted genetic manipulation will likely have little effect on Microsporidia pathogenicity compared with the parent strain.

In all cases, the pathogens and GM-modified class I organisms will be treated under Class II containment procedures and therefore given the low inherent risk of these GMMs, combined with the containment procedures in place, the overall risk is extremely low.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

The procedures in place are suitable for ACDP Hazard group II material

GM waste is of 2 types: liquid and solid.

All contaminated materials, including waste destined for incineration, will be inactivated as follows:

Liquid GMM waste:

[1] Treatment with a disinfectant, e.g. Distel™ or Virkon™ at 5x the recommended concentration, diluted 1:10 (final
concentration 10,000ppm available chlorine, 100% kill, contact time> 2 hours).
[2] Followed by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware.

Solid GMM waste:
[1] is autoclaved at 134 degrees C for 15 minutes at 27 psi pressure. This gives 100% kill.
All clinical waste is sealed in bags and transported on robust trays from the containment facility to the autoclave. This waste is handled by authorised personnel only. After autoclaving, the material is transferred to yellow bags for incineration

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

CU2 Project Title  The Study of The Kinetoplastid Lipid Biosynthesis: Regulation of Virulence and Host-Pathogen Interactions

Class  Class 2

CultureVolClass2  < 1 Litre

CultureVolumeClass3-4  

Class  Non-GMM

Consent Granted  

Project notified under transitional arrangements  N
Sphingolipids are essential signalling molecules and integral structural components of eukaryotes plasma membranes. Differences in the sphingolipid metabolism between protozoan parasites and host cells have received major attention as a promising drug target towards the development of selective and safe new anti-protozoa Is. While many protozoan parasites can synthesise their own sphingolipid, there is strong evidence that they rely on salvaging host cell sphingolipids as well. The proposed work will look systematically into the enzymes involved in sphingolipid metabolism and attempt to decipher the mechanism of host-pathogen interactions and exploit differences for drug discovery projects.

The proposed projects will utilise genetic manipulation to knock out essential and semi-essential genes involved in lipid metabolism with direct impact on the virulence of the parasite; these genetic manipulations result in genotypic and phenotypic parasites of less capacity to induce infections while remaining a subject of interest of the experimental systematic studies.

Purpose of GM: Reverse genetic methods will be used to identify and characterise parasite proteins involved in lipid biosynthesis and trafficking, which will then be functionally analysed in transgenic Trypanosoma, using both molecular and biochemical methods.

The work will focus on the use of the following protozoan parasite:

[1] Kinetoplastid, Trypanosoma brucei brucei (a separate SAPO licence application has been submitted)

Recipient or parental organism

Escherichia coli, Saccharomyces cerevisiae and Schizosaccharomyces pombe are all are standard laboratory strains and approved hosts in widespread use for cloning and expression studies.

[1] E. coli K12 strains: BL21, JM101

Host/vector system

1) E. coli K12 strains: pUC or pAT153 based, e.g. pGEX and pET
2) S. prombe strains: pUC based, e.g. REP series
3) S. cerevisiae strains: pRS or pESC based
4) T. brucei pXS, p2T7

Origin & function
Genetic material:
Genomic DNA or RNA extracted from T. brucei brucei using conventional techniques.
The strains to be used will be:
T. brucei brucei (Lister 427, transgenic lines 29-13 and BF-4)
Genetic manipulation:
The open reading frames of target T. brucei genes (i.e. those encoding enzymes in the sphingolipid and other lipid biosynthetic pathways) will be amplified by PCR and cloned into unique restriction sites downstream of vector promoter signals, prior to transfection into E. coli.
Plasmid vectors will be pUC or pA T153 based such as the pGEX or pET series for the production of fused and nonfused recombinant proteins. The replicon is from colE1. The plasmids are non-mobilisable and include a selectable marker for resistance to ampicillin. Cloning in the pGEX vectors introduces target genes downstream of a glutathioneS-transferase gene for expression of a C-terminal fusion peptide. Transcription is inducible from the upstream tac promoter. Cloning in the pET vectors places target genes under the control of strong bacteriophage T7 transcription and translation Signals. Expression is induced by providing a source of T7 RNA polymerase in the host cell, under the control of the inducible lacUV5 promoter.
In practice, plasmids are cloned into JM101 (F'traD36 for no transfer of F, lacZDM15 for blue/white selection of recombinants, supE44 amber suppressor) and selected recombinants transferred into a lambdaDE3 lysogen of BL21 (F' ompT rB-mB-) containing the T7 polymerase gene cassette for expression.
The amplified fragments will be used to create null/non-functional DNA constructs that will be used to create the mutant strains of the T. brucei for further investigations to ascertain function in growth and infectivity. T. brucei brucei will only be grown in suspension.

Evaluation of foreseeable effects
T. brucei brucei is a cattle pathogen.
T. brucei brucei is not a plant pathogen.
The risk of infection and dissemination is effectively zero due to the absence of the intermediary insect vectors and containment.
accidental self-injection is minimal as the use of sharps prohibited. Safety protocols described within Code of Practice and Standard Operating Procedures.
Transgenic T. brucei will also be resistant to one or more antibiotics but this is irrelevant as T. brucei is non-infective to man. The objective of the project is directed towards the down regulation of specific endogenous gene expression which is more likely to make the transgenic organism less virulent and less able to survive in a host.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GM waste is of 2 types: liquid and solid.
All contaminated materials, including waste destined for incineration, will be inactivated as follows:
Liquid GMM waste:

CU2 Project Title The Study of The Apicomplexan Biosynthesis: Regulation of Virulence and Host-Pathogen Interactions

Class 2

CultureVolClass2 < 1 Litre

Class 3-4

Consent Granted Not Applicable

Project notified under transitional arrangements N
Purposes of the contained use

Sphingolipids are essential signalling molecules and integral structural componenets of eukaryotes plasma membranes. Differences in the sphingolipid metabolism between protozoan paraSites and host cells has received major attention as a promising drug target towards the development of selective and safe new anti-protozoa Is. While many protozoan paraSites can synthesise their own sphingolipid, there is strong evidence that they rely on salvaging host cell sphingolipids as well. The proposed work will look systematically into the enzymes involved in sphingolipid metabolism and attempt to decipher the mechanism of host-pathogen interactions and exploit differences for drug discovery projects.

The proposed projects will utilise genetiC manipulation to knock out essential and semi-essential genes involved in lipid metabolism with direct impact on the virulence of the parasite; these genetiC manipulations result in genotypic and phenotypic parasites of less capacity to induce infections while remaining a subject of interest of the experimental systematic studies.

Purpose of GM: Reverse genetiC methods will be used to identify and characterise parasite proteins involved in lipid biosynthesis, which will then be functionally analysed in transgenic Toxoplasma, Neospora and Sarcocystis, using both molecular and biochemical methods.

The work will focus on the use of the following protozoan parasites:

1. Toxoplasma gondii: Nicolle and Manceaux (ATCC® 50174) RH and RHdeitaku80
2. Neospora caninum: Nc-LiV [NC-Liverpool]

Recipient or parental organism

Escherichia coli, Saccharhormyces cerevisiae and Schizosaccharomyces pombe are all are standard laboratory strains and approved hosts in widespread use for cloning and expression studies.

1. E. coli K12 strains: BL21 , JM101
2. S. prombe strains: LH 121 , THTS 18 and THTS22
3. S. cerevisiae strains: YPH499, YPH499-HIS-GAL-AUR1, AGO, RCD113, ISC1
4. Toxoplasma gondii: Nicolle and Manceaux (ATCC® 50174) RH and RHdeitaku80
5. Neospora caninum: Nc-LiV [NC-Liverpool]
8. Bovine Turbinate (ATCC): BT (ATCC® CRL-1390™)
E. coli K12 strains: pUC or pAT153 based, e.g. pGEX and pET
S. prombe strains: pUC based, e.g. REP series
S. cerevisiae strains: pRS or pESC based
Toxoplasma, Neospora and Sarcocystis: pEXP, pminiHXGPR, p5RT70tetR

Genetic material:
- Genomic DNA or RNA extracted from Toxoplasma, Neospora and Sarcocystis using conventional techniques.

Genetic manipulation:
- The open reading frames of target Toxoplasma, Neospora and Sarcocystis genes (i.e. those encoding enzymes in the sphingolipid and other lipid biosynthetic pathways) will be amplified by PCR and cloned into unique restriction sites downstream of vector promoter signals, prior to transfection into E. coli.
- Plasmid vectors will be pUC or pAT153 based such as the pGEX or pET series for the production of fused and nonfused recombinant proteins. The replicon is from colE1. The plasmids are non-mobilisable and include a selectable marker for resistance to ampicillin. Cloning in the pGEX vectors introduces target genes downstream of a glutathioneS-transferase gene for expression of a C-terminal fusion peptide. Transcription is inducible from the upstream tac promoter. Cloning in the pET vectors places target genes under the control of strong bacteriophage T7 transcription and translation signals. Expression is induced by providing a source of T7 RNA polymerase in the host cell, under the control of the inducible lacUV5 promoter.
- In practice, plasmids are cloned into JM101 (F'traD36 for no transfer of F, lacZDM15 for blue/white selection of recombinants, supE44 amber suppressor) and selected recombinants transferred into a lambdaDE3 lysogen of BL21 (F' ompT rB-mB-) containing the T7 polymerase gene cassette for expression.
- The amplified fragments will be used to create null/non-functional DNA constructs that will be used to create the mutant strains of the Toxoplasma, Neospora and Sarcocystis for further investigations to ascertain function in growth and infectivity. The parasites will be grown in human foreskin fibroblasts (toxoplasma) or bovine turbinate (Neospora and Sarcocystis).

Evaluation of foreseeable effects
- Theoretically, laboratory infections with the animal and human pathogens Toxoplasma, Neospora and Sarcocystis could be caused accidentally if large numbers of proliferative parasites were inoculated through the skin or via an open wound. To avoid this the use of sharps is to be avoided. Ingestion of cysts could also result in infection, to avoid this, encysted forms will not be studied.
- Safety protocols are described within the Code of Practice. Adherence to these render the risks of infection and dissemination effectively zero. Notably, Toxoplasma is endemic to the U.K. The down regulation of specific endogenous gene expression by the reverse genetics proposed is most likely to make the organism less able to survive in the environment.
- The risk of infection and dissemination is effectively zero due to the absence of the definitive hosts and containment. Toxoplasma, Neospora and Sarcocystis are not plant pathogen.
- No known potential and in the absence of infection of host cells, risk of transfer of genetic material must be regarded as very low or negligible.
- The objective of the project is directed towards the down regulation of specific endogenous gene expression which is more likely to make the transgenic organism less virulent and less able to survive in a host.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GM waste is of 2 types: liquid and solid.
All contaminated materials, including waste destined for incineration, will be inactivated as follows:

Liquid GMM waste:
1. Treatment with a disinfectant, e.g. Distek™ or Virkon™ at 5x the recommended concentration, diluted 1:10 (final concentration 10,000ppm available chlorine, 100% kill, contact time > 2 hours).
2. Followed by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware.

Solid GMM waste:
1. Is autoclaved at 134 degrees C for 15 minutes at 27 psi pressure. This gives 100% kill.
All clinical waste is sealed in bags and transported on robust trays from the containment facility to the autoclave. This waste is handled by authorised personnel only. After autoclaving, the material is transferred to yellow bags for incineration.

Project Ref 510/20.4
To determine the underlying mechanisms responsible for influenza A (H1 N1) virus induced asthma exacerbation by assessing epithelial cell damages.

Madin-Oarby Canine Kidney (MOCK) cells will be used for H1 N1 propagation. Mammalian cells which will be infected with dilution of H1 N1 include, immortalised epithelial cells (A459 and BEAS-2B), and primary epithelial cells obtained from bronchial brushing of healthy and asthmatic donors.

Origin & function
Influenza A virus (H1 N1), which is going to purchased from ATCC, was obtained from Nasopharyngeal specimen from a patient positive for Flu A in Virginia, 2009. Epithelial cells will be infected with H1 N1 at different dilutions (max Mal 5).

Evaluation of foreseeable effects
Cell Pathologic Effect (CPE) of include rounded refractile cells with cell degeneration. H1 N1 will be manipulated in a Class II Microbiological safety cabinet. Written records of staff training will be obtained and checked before commencement of work by individuals. Disposable plasticware (pipettes especially) will be used for mammalian cell culture. Precausions are full personal protective equipment including laboratory gowns, gloves and safety google.
Virus stock and virus-infected cells will be securely stored in -80°C freezer and locked after hours. All virus-contaminated wastes are disposed of in virkon solution and autoclaved for destruction. It is highly unlikely that any higher pathogenic strains will arise as a result of the use of these GMO strains.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All virus-contaminated wastes are disposed of in virkon solution and autoclaved for destruction.

This project assesses the biological function of putative cancer driver genes by lentiviral transduction, and also involves identifying potential oncogenes and tumour suppressors by genome-scale screen in human cancer cell lines. Typically the methodology will involve a gene highly over or under-expressed in cell lines, and reversing the expression by either over-expressing the gene or expressing a small hairpin RNA (shRNA) or CRISPR single guide RNA (sgRNA) to silence expression of the gene in question. Lentiviral particles will be generated on site containing either a cDNA, appropriate shRNA or sgRNA. cDNAs may occasionally contain a mutation where a dominant negative or constitutively active version of the gene is required. Cells will be infected by titrated lentiviral particles followed by antibiotic selection or sorting by flow cytometry. Downstream analysis may involve proliferation, apoptosis and/or cell cycle assays at the NHC, and development of in vivo xenograft models in collaboration with external collaborators with appropriate animal licence and facilities. RNA, DNA and protein would typically be extracted from infected cells in each case to verify appropriate infection and to validate cDNA/shRNA expression or CRISPR/Cas9 gene editing. For genome-scale screen, a CRISPR library with various sgRNAs or pooled shRNA library is used to create a pool of cells which will then undergo in vitro selection to screen for constructs which either promote or inhibit cell proliferation. The purpose is to perturb the natural state of target genes identified from our OMICS screens and to assess the functional effects on cancer cells.

Packaging cell line 293T is derived from the well-characterised 293 cell line (Pear et al., PNAS 1993; 80; 8392; ATCC CRL-11268). This cell line stably and constitutively expresses a temperature-sensitive version of the SV40 large T antigen. Lentivirus is produced by co-transfection of the 293T cell line with transfer, packaging and envelope plasmid vectors. Human cancer cell lines will be transduced with the supernatant generated by the packaging cells. These cell lines originally derived from cancer patients, and are purchased from cell-line bank such as DSMZ. The cell-line cells are only able to survive if maintained in tissue culture in the NHC laboratory or if injected into immunodeficient animals (in collaboration with external collaborators).
Lentiviral packaging system (2nd generation) derived from HIV is going to be used to produce lentiviral particles. This recombinant lentivirus has pseudotyped with the VSV-G envelope protein and its tropism has a broadened host range. This system was specifically engineered for biosafety by separating lentiviral genes into three plasmid vectors, with packaging and envelope genes away from viral LTR on the transfer plasmid. The plasmids remain in the packaging cell line, effectively precluding the production of replication competent virus in target cells or should the viral vector escape containment. The plasmids have been engineered not to contain any regions of homology to each other, to prevent undesirable recombination events which might result in replication competent virus being produced. The viral vector cannot produce any new viral particles after the initial infection in host cells, without genes encoded in the envelope and packaging vectors. Also self-inactivation (SIN) is achieved by deleting a large portion of the viral 3' LTR. The deleted 3' LTR of the viral genome is transferred into the 5' LTR after one round of reverse transcription, and this deletion abolishes transcription of the full-length virus after it has incorporated into host cells and minimizes, the risk of generating replication-competent lentivirus.

Origin & function

cDNA sequences of human origin, appropriate shRNA or sgRNA sequences will be cloned into lentiviral vectors to assess potential contribution to tumourigenesis of candidate genes identified from our OMICS screens. cDNA sequences may include partial or entire gene sequences, or mutant forms of the gene sequences. shRNAs and sgRNAs are smaller than 100 bases in length, which are designed to target specific DNA. Target genes in cancer cell lines include proto-oncogenes and tumour suppressors such as FOX01, TP53 and other candidate genes. In genome-scale screen, many of the target genes will have unknown function but may include known oncogenes and tumour suppressors regulating cell proliferation and apoptosis. In CRISPR/Cas9 gene editing, Cas9 nuclease enzyme and a sgRNA are integrated into host genome, causing single or double-stranded breaks on target genetic locus. Genetic breaks are then repaired with a template for precise gene editing, or by non-homologous end joining mechanism leading to silencing of the target genes. The aim is to use either overexpression or knock-down/knock-out or gene editing to assess the potential contribution to tumourigenesis of each candidate gene identified from our genomics screens. Once a stably infected cell line is produced, experiments performed will depend on the particular gene selected but will typically involve a panel of proliferation, apoptosis and/or cell cycle, as well as collection of RNA/DNA/Protein for further profiling analysis at the NHC and potentially in vivo engraftment in collaboration with external collaborators.

Evaluation of foreseeable effects

The lentivirus is capable of transducing a wide range of mammalian cells, but it would not transfer genetic material to microbial organisms. Release of the viral vector into the environment is very unlikely due to the standard procedures employed in the tissue culture facility. Even should such an event occur the virus is replication incompetent and self-inactivating. It is highly unlikely that the genetically modified cell lines could transfer the viral vector into the environment since they have very limited ability to propagate outside of the cell culture facility, and no means to mobilise the transfected DNA sequences to other organisms. The transfer vector contains sequences that will incorporate into the host cell genome, but cannot produce functional viral particles without the genes encoded in the envelope and packaging vectors. With replication-competency and SIN it is not possible for viruses to replicate and produce more virus after the initial infection. Potential hazard of harmful sequences within the virus being transferred to related viruses is negligible, since there are only very small regions of homology between the viral vector and wildtype viruses, making recombination events unlikely. The lentivirus would have the ability to infect human tissues should it come in contact with them. The major hazard is therefore represented by the packaged lentivirus prior to infection of the target cells, and residual virus in the medium of transfected cells. The main potential transmission routes are by external exposure to high tit res (either skin lesions or mucous membranes). In addition, oncogenic effects could arise if tumour suppressor genes are silenced by certain
shRNAs or sgRNAs, particularly in genome-scale screens, as well as the over-expression of potentially oncogenic cDNAs. Therefore there is a theoretical possibility that they could render the cells neoplastic. If shRNAs, sgRNAs or cDNAs were to be transfected directly into living human tissue, the detrimental effects that they could cause are uncertain but unlikely on their own to transform affected cells. Tumourigenesis is a multistage process requiring the interaction of many mutated genes which also lessens the risk from delivery of a single genetic change to a target tissue.

The virus is generally weak and does not survive long outside of buffered solutions. Infection requires optimal conditions and the use of supplements in cell culture. Likelihood of harm is low as the virus is non-replicable and self-inactivating. With lab procedures for avoiding contamination, in particular no sharps, risk is generally no greater than handling human tissue. Reversion to replication-competent lentivirus is extremely unlikely given that several recombination events would be needed to reconstitute an active viral genome, the viral genes are present on three different plasmids which have minimal sequence homology and the viruses are self-inactivating following insertion. Given that the lentivirus is replication incompetent and SIN, and will only infect at low efficiency in sub-optimal conditions, potential harm would be extremely limited.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste (culture and media) will be decontaminated by autoclaving or by Virkon solution (>1% w/v final working concentration of Virkon for at least 2 hours prior to disposal to sewers). All contaminated plasticwares and materials will be properly disinfected by autoclaving or by 2% w/v Virkon solution for at least 2 hours prior to incineration. Spillages will be soaked with tissue paper, which will afterwards be decontaminated with 2% w/v Virkon solution for at least 2 hours. Contaminated surfaces will be decontaminated with 1% w/v Virkon solution followed by 70% Ethanol.

Project Containment

Laboratory Activities | Glass Houses | Growth Rooms

02/03/2022
Trypanosomiasis and leishmaniasis are caused by parasites which belong to the genera Trypanosoma and Leishmania, respectively. These diseases affect a large number of people across the world, and could be fatal if not properly treated. These diseases are also animal infective, where they also cause weight loss and significant number of deaths in domestic and wild animals, posing a restraint on agricultural outputs and economic prosperity, especially in resource poor communities. Trypanosomiasis and leishmaniasis require an insect vector, tsetse fly and sand fly respectively for disease transmission.

There is yet no known vaccine for these diseases. Both diseases can be treated with available chemotherapy, however, this approach is faced with many challenges, including drug resistance, toxicity, high treatment cost and the lack of guaranteed supply. Hence, there is a need for new strategies to combat these diseases.

Membrane-bound phosphatases (also called ectophosphatases) such as acid phosphatase are type I membrane protein that is, single span transmembrane proteins that have their N-terminus exposed to the extracellular space and C-terminus cytosolic. They catalyse the hydrolysis of orthophosphate monoesters and generate Pi as final product.

The roles of the ectophosphatases in parasite-host interactions during the trypanosomatids infections have been predicted but largely understudied.

A multidisciplinary approach will be used to investigate the unique roles of Trypanosoma and Leishmania ectophosphatases, and attempt to decipher the mechanism of...
host-pathogen interactions and exploit differences for drug discovery.

The proposed projects will utilise genetic manipulation to knock out or overexpress essential Trypanosomatid ectophosphatase genes with direct impact on parasite viability and virulence.

This research will focus on the use of the following protozoan parasite:

[1] Leishmania
[2] Trypanosoma (a separate SAPO licence application has been submitted)

**Recipient or parental organism**

Standard laboratory strains of host organisms approved and widely used for cloning and expression studies will be deployed throughout this research.

**E coli:**
- XL1 blue strain of Escherichia coli (E. coli)
- Top 10 E. coli
- Chemically competent Rosetta (DE3) cells

Leishmania Mexicana:
- (MNYC/BZ/62/M379 strain and various transgenic lines)

Trypanosoma brucei brucei and various widely used transgenic lines:
- Wild type T. b. brucei, strain Lister 427 (s427; MiTat 1.2/BS221)
- s427-WT derived TbAT1 knockout (tbat1−/−)
- B48 which was derived from a TbAT1-KO strain
- Aquaporin (aqp2/aqp3, aqp1-3) null strains

**Host/vector system**

Standard and approved laboratory vectors will be used. For example:

- pET151D/TOPO expression vector system
- pHD1336
- Leishmania pX, pTEX

**Origin & function**

All materials that will be used for genetic manipulation in this research will come from the open reading frames of Trypanosoma and Leishmania ectophosphatases, which will be amplified using the polymerase chain reaction-based techniques, the product will be cleaned before cloning into the restriction sites downstream of the promoter signals of the appropriate vector. This assembly (vector plus inserted gene) will be used for the transformation of E. coli.

The nature of modification is as follows. The pET system will be used for the cloning and expression of recombinant proteins in E. coli. Briefly, plasmid vectors (pET System) with selectable antibiotic cassette will be used for the production of fused and non-fused recombinant proteins. The insert (target) ectophosphatase gene will be cloned in the pET vector under the control of a strong bacteriophage T7 transcription and translation signals, expression of this gene will be induced by providing a source of T7 RNA polymerase in the host (E. coli) cell.

The T7 RNA polymerase should convert all of the cell's resources towards expression of the target ectophosphatase gene after a few hours of induction. In order to clone the target ectophosphatase gene, non-expression hosts that do not contain the T7 RNA polymerase gene will be initially used, thus eliminating plasmid instability caused by the production of proteins that are potentially toxic to the host cell. Once established in the non-expression host, the plasmid will then be transferred into the expression hosts, which contain a chromosomal copy of the T7 RNA polymerase gene under lacUV5 control, and IPTG will be added for the expression of the target ectophosphatase gene.
This will enable the over-production of the corresponding protein (ectophosphatase) of interest. The protein will be purified for onward chemical and molecular characterization.

In addition, for proof of concept, the amplified fragments will also be used for the transfection of the appropriate Trypanosomatid to create either an overexpressed or null/non-functional construct that will be used to create the mutant strains of the appropriate Trypanosomatid for further investigations into the essentiality in terms of its function and chemical inhibition.

**Evaluation of foreseeable effects**

There is a possibility of laboratory infections with Leishmania due to accidental skin or open wound inoculation with a large population of infective parasites, but considering that the use of sharps is prohibited in this work, the chances of this kind of accidental infection happening is effectively zero.

- T. brucei on the other hand is a cattle pathogen. Also, both Leishmania and T. brucei, require a vector (sand fly and tsetse fly respectively) for disease transmission; the absence of these parasite vectors in the UK makes the risk of infection by these parasites effectively zero.

- There will be a strict adherence to safety protocols described within the Code of Practice and Standard Operating Procedures operational at the NHC.

- Moreover, the absence of these tropical insect vectors makes it impossible for these parasites to disseminate within the environment.

- In addition, there is no known report of similar genetic modifications resulting in the capacity of similar organisms to survive, establish, and disseminate with and or displace other organisms.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

- Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

- Not applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

GM waste is of 2 types: liquid and solid.

All contaminated materials, including waste destined for incineration, will be inactivated as follows:

**Liquid GMM waste:**

1. Treatment with a disinfectant, e.g. Distel™ or Virkon™ at 5x the recommended concentration, diluted 1:10 (final concentration 10,000ppm available chlorine, 100% kill, contact time > 2 hours).
2. Followed by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware.

**Solid GMM waste:**

Solid wastes will be autoclaved at 134 degrees C for 15 minutes at 27 psi pressure. This gives 100% kill.

All clinical waste is sealed in bags and transported on robust trays from the containment facility to the autoclave. This waste is handled by authorised personnel only. After autoclaving, the material is transferred to yellow bags for incineration.

**Bacteria inoculation.**
GM E. coli will be disinfected with the appropriate solutions e.g. 100% ethanol followed by sterilization of inoculating loops with naked flame, autoclaving of GM E. coli and contaminated lab equipment like glassware, culture flask, etc. These will ensure 100% kill. UV light on the microbiological safety cabinet will be turn on upon completion of each task.

02/03/2022
RNAi knockdown and expression of protein kinases and phosphatases and associated proteins involved in intracellular signalling pathways in mammalian cells using retrovirus vectors

Commonly used tissue culture cell lines (HEK293, HeLa, COS cells) or embryonic stem cells, hepatocytes, fibroblast and myoblast cells derived from rodents.

The retroviral vectors to be used for the studies are called pHR-SIN-CSGW, pLK0.1 (Stewart et al., 2003), pMKO.1puro (Masutomi et al 2003) or pRS (commercially available origene vector). Please use full risk assessment for more information on these systems.
The inserts will be either RNAi constructs designed to remove intracellular mRNAs for their target genes or the cDNAs coding for the normal intracellular versions of kinases, phosphatases, etc. All these proteins are components of signalling pathways and so could affect cell growth. However, none will be known oncogenic versions of the proteins and so should not lead to cellular transformation. It is not known whether any of the proteins are capable of altering the properties of any naturally occurring viruses in any way that would increase their pathogenicity. However, from the known properties of the proteins this would not be predicted. The transfected cultured cell lines will not survive outwith the culture medium and all liquid and solid waste will be autoclaved on site. This rules out the possibility of escape into external environment and survival, establishment or dissemination therein.

**Evaluation of foreseeable effects**

The RNAi constructs are designed to remove intracellular mRNAs for their target genes and so the predicted direct effect of this will be the removal of the corresponding protein from the cells infected with the virus. This is predicted to interfere with the signalling pathway and this will what will be tested. In the majority of cases it is predicted that the removal of a component from the signalling pathway will lead to the loss of ability for that signalling pathway to function. In some cases it might be that the loss of an inhibitory component could lead to an upregulation of that pathway. Both effects are likely to be deleterious to the cell in the long run and it is not predicted that cell infected with the viruses will beat a selective advantage relative to their parent cells.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Autoclaving is by validated (internal temperature probe linked to printout) autoclave, in the same building, reserved only for inactivation of waste (effective 100% kill). The autoclave undergoes annual testing tyo ensure correct operation. Waste will be transferred to the autoclave in covered containers.

**Project Additional Information**

**Purposes of the contained use**

The aim of this project is to investigate the role of N-acyl homoserine lactone (AHL) bacterial signalling molecules in the development of microbial communities. This work does not involve the creation of new GMMs, but will utilise GM bacteria constructed at Nottingham University (UK) and Umea University (Sweden). The GMMs will be used in studies of the involvement of AHLs in biofilm formation of mixed species microbial communities.

**Recipient or parental organism**

- E. coli JM109 (recA1 supE44 and A1 hsdR17 gypA96 relA1 thi D (lac-proAB)).
- C violaceum wild type strain ATCC31532 was obtained from the American Type Culture Collection (Rockville, MD USA).
- V anguillarum NB 10, serotype 01, is a clinical isolate from the Gulf of Bothnia, Sweden.

**Host/vector system**

- pSB401 - AHL reporter plasmid; luxR "::luxCDABE (Apr) in pACYC184 (Winson et al., 1998)
- pSB536 - AHL reporter plasmid; ahyrR "::luxCDABE (Apr) in pUCP18 (Swift et al 1997))
- pSB1075 - AHL reporter plasmid; lasR "::luxCDABE (Apr) in pIC18 (Winson et al., 1998)
- pNQflaC4-gfp27 - gfp labelled plasmid; lac::gfp mut-s (CmR) from pJBA88 (pUC18-based plasmid)
- pDM42 - AHL reporter plasmid; pNQflaC4 derivative carrying luxR-Plux+RBSII::gfp+mut3*-TO; CmR- from pJBA88
- pDM44 - AHL degrading plasmid; pNQflaC4 derivative carrying a PA1/04/03::aaiA gene fusion; CmR - from pJBA27

**Origin & function**

- C. violaceum CV026 is defective in AHL production due to a mini-T5 insertion in the AHL synthase gene, creating an AHL reporting strain (McClean et al., 1997).
- Mutations to V. anguillarum are inframe deletions of quorum sensing genes. (DM21 (vanl); DM35 (vanR) CmR; DM27 (vanM); DM28 (VanlM); DM34 (vanN) CmR; DM59 (vanU); AC11 (vanO) CmR; AC10(vanT)

**Plasmid carrying strains are:**

- JM109/pSB401; JM109/pSB536; JM109/pSB1075 - AHL reporter strains
- NB10/pNQflaC4-gfp27; DM21/pNQflaC4-gfp; DM27/pNQflaC4-gfp - wild type and mutant gfp-labelled strains
- NB10/pDM442; DM21/pDM42; DM27/pDM42; DM28/pDM42 - wild type and mutant AHL reporter strains
- NB10/pDM44 - wild type strain with AHL degrading enzyme

**Evaluation of foreseeable effects**

The E. coli strain used in classified as a ‘disabled or non-colonising host’. Work to date with these GMMs has suggested that the insertion of AHL reporter plasmids into this strain has not affected the pathogenicity of this organism.

Chromobacterium are ACDP hazard group 1, rarely causing disease in humans. Again, work to date with CV026 has suggested that the mutation to the AHL synthase gene has not affected the pathogenicity of this organism.

Vibrio sp. (except V. cholerae) only rarely causes disease in humans.
Deletion of genes vanI, vanM, vanN, vanR and vanIR were found to have no effect on the virulence of the bacteria in a fish infection model; there was no increased nor decreased virulence (Milton et al., 1997; 2001).

VanT is not essential for virulence (Croxatto et al. 2002).

In a separate study of brine shrimp, there were no significant differences between the virulence of the wildtype NB10 and GMMOs containing mutations in vanl, vanR, vanM, vanN and vanO (Defoirdt et al., 2005).

From these studies, it seems that the alterations made to V. Anguillarum are unlikely to increase the level of risk over an equivalent to hazard group 2.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

After growth, cultures (liquid, agar, biofilm material) will be killed by autoclaving prior to disposal. Autoclaves are situated within the GM laboratory, and are tested on a yearly basis.

Any spillages will be contained within the laboratory and dealt with using an appropriate disinfection procedure.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The genetic modification safety committee agree with the applicant that the risk assessment should stand as class II, for the benefit of the individuals involved with the project, and to the institution.

## Project Additional Information

### Purposes of the contained use

Organism used is E.coli serotype 0157:H7 atcl 4388 does not possess shiga-like toxin I or II, does not possess the genes for these toxins - therefore is not pathogenic - considered equivalent to ACDP Hazard Group 2

### Recipient or parental organism

E.coli serotype 0157:H7 ATCC Thy - auxotroph, non-reverting. (See sheet attached to notification)

### Host/vector system

Non-mobilicable PUC-BASED plasmids containing luciferase - encoding genes
- PSB311
- PSB100
  (See sheet attached to notification)

### Origin & function

To allow bioluminescent monitoring of the organism by virtue of the luciferase genes borne by the plasmid

### Evaluation of foreseeable effects

The plasmids under use have an extensive history in being used by workers and are not considered to have human health risks associated with them. They are non-mobilisable.

The E.coli strains have been specifically disabled, are toxin-less, are not pathogenic to humans or animals and have limited survival in the environment. The cloned DNA is unlikely to alter the pathogenicity of the host.

Overall in terms of severity or consequence of harmful effect were it to occur: It is considered that any unforeseen events will have no environmental impact.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Materials are bagged and autoclaved. Autoclave's activities are charted autoclave is regularly checked for efficiency using bacillus spore check. Waste is removed as clinical waste for subsequent incineration.

### Project Ref 515/17.1

**Date Ackn'd**: 14/06/2017

**CU2 Project Title**: High throughput drug screening assay using Green Flourescent Protein (GFP) expressing Leishmania spp.

**Class**: Class 2

**CultureVolClass2**: < 1 Litre

**Non-GMM Consent Granted**: Consent Granted

**Project notified under transitional arrangements**: N

**Withdrawn**: N

**Tick if notifying a connected programme of work**: N

### Project Additional Information

**Purposes of the contained use**

The project aim is to utilise the GFP expressing Leishmania spp to screen novel drug treatments for this parasite. Drug assays will be performed against the extracellular promastigote stage of the parasite and the intracellular amastigote stage that have been allowed to infect a human THP-1 cell line in in vitro culture.
Recipient or parental organism

Leishmania mexicana (MNYC/BZ/62/M379) – ATCC PRA-416
Leishmania aethiopica (MHOM/ET/72/L100) – ATCC PRA-417
Leishmania tropica (MHOM/SU/58/OD) – ATCC PRA-418
Leishmania major (MHOM/SU/73/5ASKH) – ATCC PRA-419

Host/vector system

Host cells: Human acute monocytic leukaemia cells (THP-1)

Cell lines are to be used in tissue culture and as such are only capable of replicating in culture. If accidentally injected into the operator they would be antigenically incompatible and rapidly destroyed.

Origin & function

The insert included in pRib1.2αNeoGFP encodes for protein that confers resistance to the aminoglycoside G418 (Geneticin) allowing for the selection of the GFP expressing organisms

pRib1.2αNeoGFP encodes for GFP protein.

The GFP protein fluoresces under blue light.

The proteins expressed may be considered to have little chance of causing harmful reactions in laboratory workers.

The inserted gene product; GFP do not have any oncogenic, cytotoxic or allergenic effects as far as the author is aware. So the risk for human health of transfer to related microorganisms is not significant.

Evaluation of foreseeable effects

The hosts; THP-1 monoytic leukaemia cell lines are to be used in tissue culture and as such are only capable of replicating in culture. If accidentally injected into the operator they would be antigenically incompatible and rapidly destroyed.

The cell lines have been provided by ATCC and are well characterised.

The cloned DNA inserts are unlikely to alter the pathogenicity of the cloning host and therefore containment level 2 is appropriate throughout the procedures.

Leishmania is a BSL-2 organism and care must be taken when handling this parasite. Infection is usually transmitted by the bite of an infected sandfly although laboratory transmission is possible through needle stick injury. The work has been risk assessed and no sharps will be used during the culture of the organism.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Solid waste will be disposed of in an appropriate container in the tissue culture lab and destroy by autoclaving. A complete degree of kill is expected when carrying out these procedures. This will be validated by re-culturing the autoclaved organisms to confirm complete kill. Waste will then be disposed of via special clinical waste collection.

Liquid waste will be disinfected with Trigene disinfection solution. Disposed disinfected liquid waste in container located in MB418 for disposal by technical staff. A complete degree of kill is expected when carrying out these procedures. This will be validated by re-culturing Trigene treated organisms to confirm complete kill. Waste will then be disposed of via special clinical waste collection.

The Genetically Modified Organisms Safety Committee has approved your risk assessment containment level 2 for the project "High throughput drug screening assay using GFP expressing Leishmania spp." subject to the following conditions:

- This project requires containment level 2 and therefore, it requires notification to the HSE. Before starting the project, the Principal Investigator, Dr Wayne Heaselgrave, must notify to the HSE the intention to carry out this project in the University of Wolverhampton. Dr Heaselgrave must present to the GMO safety committee (by e-mail to the secretary Dr Armesilla) evidences of the notification and the acknowledge of notification from the HSE before starting any work.
- Work can begin 45 days after acknowledgment from the HSE of receiving the notification, unless HSE require that work does not begin.
- The Principal Investigator (Dr Wayne Heaselgrave) must report to the GMO safety committee (by e-mail to secretary Dr Armesilla) any correspondence with the HSE.
- No work on this project will be carried out by undergraduate or master students.
- PhD students or other members of staff should not undertake any work on this project until receiving appropriate training from the PI. The PI should get approval by the GMO safety committee for PhD students or other members of staff to work in this project by providing to the committee in writing the names of new researchers required to work in the project and the training provided. Moreover, Dr Wayne Heaselgrave should submit to the committee (by e-mail to secretary Dr Armesilla) a risk assessment including the additional worker/s, indicating the nature of the training. This risk assessment must be approved by the G MOSC before any new staff or PhD students start working on the project.
- The project can only be carried out in the containment level 2 laboratory MB418.

Project Additional Information

**Purposes of the contained use**

CABI's responsibilities as an international Depository Authority (IDA) within the Budapest Treaty (1977) require the acceptance of organisms, which fall within the remit of the GRC, for safe deposit and/or patent storage. This means that CABI may accept Hazard Group 1 or 2 organisms (provided that they are considered no more hazardous than the wild type) from third parties for long-term secure storage. Microbes will be handled according to relevant Standard Operating Procedures (SOPs) and Technical Operational Procedures (TOPs) and the culture plates/vials of the relevant organisms only opened within a suitable Class 2 biological safety cabinet. We will not be undertaking genetic manipulation, per se, we are only going to be "handling" organisms that have been genetically manipulated by third parties who wish CABI to process the samples for optimal long-term storage.

**Recipient or parental organism**

All GMMs to be accepted will be limited to ACDP (UK) Hazard Group 1 & Group 2 organisms. Appropriate GMM risk assessments will be required from the depositor to demonstrate that the organism belongs to ACDP (UK) Hazard Group 1 or group 2 and that the GM is no more hazardous than the wild type of that organism.

**Host/vector system**

This will be dependent on the specific case.

**Origin & function**

Not known currently: i.e. the nature of CABI's position as a signatory of the Budapest Treaty means that anyone can request to send a strain for safe deposit and/or patient storage. At the point of receiving the request, CABI will require the submission of an appropriate GMO RA in order to determine whether, or not, the strain will be accepted for preservation. Clear records will be maintained and the Biological Safety Officer will be informed (where appropriate the BSO will convene a meeting of the Biological Safety Committee in order to assess the request). CABI's current class 1 licence is for a GMM that was created through a specific project. This upgrading of the licence is not with an aim to undertake actual GMM work. As described above, it is purely in recognition that advances in biotechnology mean that we are increasingly likely to be asked, by third parties, to accept (and process) their GMMs for optimal long-term storage.

**Evaluation of foreseeable effects**

As we only accept GMMs of hazard group 1 & 2 carrying supporting documentation that specifically states that they are no more hazardous than the relevant wild type, there should be no adverse effects. Further, the plates/vials of the isolates will only be opened within an appropriate Class II biological safety cabinet - and by trained staff (and in accordance with relevant SOPs and TOPs) wearing appropriate PPE - so those undertaking the work (and anyone else should not be exposed to the organisms).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste material to be autoclaved after use and clearly marked for disposal by incineration, where appropriate, and in accordance with existing TOPs and SOPs

Is an emergency plan required according to regulation 20? 

Tick if you are claiming exemption from disclosure for section of the risk assessment

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

The risk assessment review noted the potential handling of hazard category 2 GMM and although agreeing they shall not be manipulated per se, concurred an application for hazard class 2 activities is to be made. TO's and SOP's to be updated to reflect additional training and procedures required where appropriate. Staff nominated for class 2 works shall be trained and their records updated.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Details of waste management are as follows:
All bacterial cultures and tissue culture flasks are autoclaved at 121°C with a 20 minute holding time before disposal by incineration. The autoclaving process is monitored by Browne's tubes or autoclave tape. Autoclaves are serviced annually. Some tissue culture fluid is inactivated by Chloros (10000 ppm free chlorine) overnight, monitored by colour change of the medium, before disposal via the sink. All animal waste is incinerated at source.

**Historical Significant Changes**

PROJECT TRANSFERRED TO GM 14 & GM CENTRE CLOSED
Project Additional Information

Purposes of the contained use
To prevent the exposure of humans to risks associated with the Eukaryotic expression of human oncogenes. It is not likely that DNA or cells will infect humans and therefore there is no foreseeable effect. All activity will be Class 2 with special provisions of "no shards".

Recipient or parental organism
Disabled strain of E.Coli and tissue culture cell lines as detailed below.

Host/vector system
pBI-EEFP, pIIRES type bicostronic vectors, pTREX toruse in Eukaryotic cells.
In cell lines, Hela, MCF7, HRIE7, ARPE19, CAL02, A431, MRC5, HOP2.cos-1, cos 7. MDCK, CHU, CHUKI, NIH3T3, SWISS 3T3, EPNT.
For prokaryotes pBluescript, pCRII, pBLUNJ, pRSET, TrCHISA, pGEX, pUBEX in TOP10F, E.Coli XL-Blue, E.Coli JM83, BL21, DHSx

Origin & function
Human oncogenes have originally been cloned from human tissues, the precise function of which are largely unknown. They will be studied during this project.

Evaluation of foreseeable effects
So long as DNA or transfected cells are not introduced directly to humans there are no foreseeable effects. Class 2 activity is determined due to the expression of human (potential) oncogenes. We will not use any vectors which will directly infect human or animals such as viruses. We will in all instances adhere to precautions and procedures described in 'Guidance and Construction of Recombinants containing potentially oncogenic nucleic acid services.' Para 13-15 GMAC Category 2 containment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
None

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All end waste from this project will be autoclaved. Autoclave indicator tape will be used to determine that effective autoclaving has taken place. We have previously determined that autoclave is 100% effective in killing all tissue culture cell lines and all strains of E.Coli used.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
Similar work to that described in this notification and in the accompanying risk assessment is currently being undertaken by the Institute. See GM 521/01.1 and is happy that the work can be carried out safely.

**Project Additional Information**

**Purposes of the contained use**: To prevent the exposure of humans to risks associated with the eukaryotic expression of human oncogenes. It is not likely that DNA or Cells will infect humans and therefore there is no foreseeable effect. All activity will be Class II with specific provisions of "no sharps".

**Recipient or parental organism**
Disabled strains of E.coli and tissue culture cell lines as detailed below

### Host/vector system

**HOST:**  pCDNA3  Tet on/off E1A-deleted (replication deficient) adenovirus expressing GFP pGST, pMBP, pBS, pUC, pSP, pGL2, pCAT, pCH110  
**VECTORS:**  E.coli DH5alpha, BL21.  Drosophila SL2 cells HeLa, OSH50T, jurkat, A20, WEHI, raji, RJ225, jijoye, C113, 293, HEK, Y79, WERI, mel202, 270, 285, 290, OCM-1, OCM-3, OCM-8, OMM-1-3, 92.1SUM520E, SUM 159, MCF - 7T47DD, MDA231, 435, 468, HBL, FRTL-5, PRL

### Origin & function

Human oncogenes have originally been cloned from human tissues. The precise function of which are largely unknown

### Evaluation of foreseeable effects

So long as DNA or transfected cells are not introduced directly to humans there is no foreseeable effects. Class II activity is determined due to the expression of human (Potential) oncogenes. We will not use any vectors which will directly affect human or animals such as viruses. We will in all instances adhere to precautions and procedures. Described in "Guidance and construction of recombinants contains potentially oncogenic nucleic acid sequences“ Para 13 - 15 GMAC Category II Containment.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

None

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMO waste from this project will be autoclaved. Autoclave indicator tape will be used to determine that effective autoclaving has taken place. We have previously determined that autoclaving is 100% effective in killing all tissue culture cell lines and all strains of E.coli used.

**Project Title** USE OF RECOMBINANT LENTIVIRAL VECTORS TO EXPRESS A RANGE OF NON-ONCOGENIC SIGNALLING PROTEINS AND ADHESION MOLECULES IN EUKARYOTIC CELLS

**Class** Class 2

**Consent Granted** not applicable

**Project notified under transitional arrangements** N

**Recipient or parental organism**

Strains of E. coli bacteria and a range of human and tissue culture cell lines as detailed below.

**Host/vector system**

Hosts.
- E. coli DH5 alpha
- E.coli DB3.1

**Purposes of the contained use**

Purpose of contained use is to minimise/prevent the exposure of humans to risks associated with the eukaryotic expression of a variety of signalling proteins expressed through a human lentiviral gene transfer system. It is not likely that transduced cell lines will produce viable progeny and therefore only handling of the producer cell line with expression vectors and isolated viral particles can be considered a risk. All this activity will be carried out in class II biological safety cabinets and in category containment laboratory facilities.
293FT kidney epithelial cells (producer cell line) supplied from invitrogen
Target cell lines
Primary cultures of rat brain and retinal endothelial. Primary aortic and lung rat endothelial cells. Cells. GP8/3.9, RBE4 and GPNT cells (rat endothelial cell lines). LD7.4 rat RPE cell lines. ARPE19, hRPE7 human RPE cell lines.
CHO cells. COS cells.

Vectors
pENTR4 (invitrogen)
pLENT16/V5 (invitrogen)

Origin & function
A range of cell adhesion molecules and signalling proteins have originally been cloned from human/rat tissues. The functions of all the proteins are generally known. No human oncogenes will be used.

Evaluation of foreseeable effects
As long as the DNA or transfected cell are not directly introduced to humans there is no foreseeable effects. Class II activity is determined to minimise exposure to virus-producing cell lines.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All GMO waste from this project will be autoclaved immediately. Autoclave indicator tape will be used to determine that autoclaving has reached correct temperature and pressure. We have previously determined that autoclaving results in 100% kill of the GMO used in this project.

Project Containment

02/03/2022
**Project Ref**: 521/03.1

**Date Ackn’d**: 14/11/2003

**CU2 Project Title**: TRANSFECTION AND EXPRESSION OF POTENTIAL HUMAN ONCOGENES IN EUKARYOTIC CELLS

**Class**: Class 2

**CultureVol**: 1-50 litres

**Non-GMM**: not applicable

**Consent Granted**: Project notified under transitional arrangements

**Withdrawn**: N

**Historical Significant Changes**: PROJECT TRANSFERRED TO GM 14 & GM CENTRE CLOSED

**Recipient or parental organism**: Tissue culture cell lines as detailed below.

**Host/vector system**: The vector is the pLNC-cmyc ER virus. The virus will be used to transduce primary epithelial cells.

**Origin & function**: Human c-myc was originally cloned from human cells, but its precise functions are largely unknown. The virus will be destroyed during the project.

**Purposes of the contained use**: The purpose of the contained use is to prevent the exposure of humans to risk associated with the eukaryotic expression of c-myc. It is not likely the DNA or cells will infect humans and therefore there is no foreseeable effects, all activity will be class II with specific provisions of "no sharps".
Evaluation of foreseeable effects

So long as the DNA or transfected cells are not introduced directly to humans there are no foreseeable effects. Class II activity is determined due to the expression of human (potential) oncogenes. We will not use any vectors which will directly infect humans or animals. We will in all instances adhere to precautions and procedures described in "evidence and construction of recombinants containing potentially oncogenic nucleic acid sequences" PARA 13-15 GMAC category II containment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

None

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid cultures of viruses, or cells infected with viruses including all tissue culture plasticware will be autoclaved for 30 mins at 121 degrees C under 115lb/sq in pressure. This is effective in producing 100% kill of viruses as assessed by replating 10(6) CFU of autoclaved viruses on indicator cell lines and observing the appearance of no transduced cells. Each autoclaved sample will be marked with autoclave indicator tape. Each load will not be regarded as safe unless indicator tape shows that correct autoclaved parameters have been achieved. In addition we will also include thermosticks with each load to ensure the centre of the load has reached the correct working temperature and pressure. Autoclaves are routinely serviced to ensure correct working temperatures and pressures. Autoclaved material will be marked "inactivated GM waste" discarded to clinical waste and removed from the site by an authorised contractor.

The purpose of the contained use is to prevent the exposure of humans to risks associated with the expression of human signalling molecules - some with a potential transforming activity. It is not likely that DNA or cells will infect humans and therefore there are no foreseeable effects. All work will be carried out according to class II rules as specified further in the accompanying risk assessment.

Recipient or parental organism
Replicon-deficient Ad5 vectors and tissue culture cell lines as detailed below.

Host/vector system
Vectors code for Adenovirus 5 which are replication deficient since they lack the E1 gene. Target gene sequences will be inserted at its place. Production of recombinant virions will be done in HEK293 cells which complement the genes required for replication. Final experiments will be undertaken in endothelial, epithelial and fibroblast cell lines of human or rodent origin, and primary rodent endothelial cells.

Origin & function
All target sequences to be used encode signalling molecules involved in the transmission of extracellular signals to the cytoskeleton, nucleus or the junctions of the cell. The molecules to be used are dominant-negative mutants of the small GTPases. Furthermore, we are going to use dominant-negative versions of MAP kinase pathway components which again are generally characterised by a growth-attenuating effect. We also envisage the occasional use of activated versions of these molecules, some of which have been shown to exhibit mid transforming activity in a 3T3 foci assay.

The precise function in the target cell lines is unknown and should be determined during the course of this project.
Evaluation of foreseeable effects
As long as target DNA is not stably introduced into the human genome there are no foreseeable effects. Class II has been applied due to the expression of a potential human oncogene (e.g. activated rac1).
The Ad5 vectors to be used stay episomal in host cells; therefore - even in the unlikely event of infection - target sequences cannot be integrated into the human genome. The Ad5 vectors to be used are also replication deficient; therefore no amplification of virions can take place in the unlikely event of the recombinant virus being taken up by humans.
We will in all instances adhere to precautions and procedures described in 'Guidance and Construction of Recombinants Containing Potential Oncogenic Nucleic Acid Sequences' Para 13-15 GMAC category II containment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
None

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Solid waste will be collected separately in bins and then autoclaved. Autoclave indicator tape will be used to determine that effective autoclaving has taken place. Liquid waste will be kept to a minimum, treated with 1% Virkon and hypochloride for a 12h period before being discarded. This mixture is highly effective against all 18 virus families affecting man and animals. Phenol red in the media will change to colourless and indicate that the inactivation procedure is effective.

The identification of novel targets for treating neovascular eye disorders

In most cases, mammalian gene sequences will be used. Polyomavirus represents the only pathogenic donor organism, the middle T antigen being its transforming oncogene.

Cultured mammalian cells will be transfected with bacterial plasmids containing mammalian gene sequences or transduced with viral vectors containing mammalian gene sequences.

ViraPower Lentiviral expression systems (Invitrogen) will be used for cloning/expression of VEGF120/121, VEGF164/165 and mutant variants, VEGF188/189, PIGF and mutant variants, VEGFR-1/2, neuropilin-1/2, notch ligands and notch receptors and their mutant variants, PV-1 and mutant variants, moesin and mutant variants, polyoma middle T antigen and mutant variants.
Vectors will be introduced into bacteria by heat transformation or by electroporation using a BioRad GenePulser Xcell electroporator. Vectors will be introduced into yeast cells by electroporation. Vectors will be introduced into mammalian cells in a class 2 safety cabinet either by electroporation using an Amaxa Nucleofector II, or by chemical transfection using lipid based transfection reagents.

Origin & function

Of the inserts to be used, VEGF, PIGF and Notch ligands are growth factors, and VEGFR1/2, neuropilin-1/2 and notch are growth factor receptors; Hey-1 and Hey-2 are nuclear proteins and downstream genes of the notch pathway; moesin, PV-1, radixin and caveolin are structural proteins, linked to the actin cytoskeleton, and it is thought that certain mutant variants of moesin and PV-1 may disrupt cytoskeletal arrangements and affect cell structure; integrins are involved in cell-cell and cell-matrix interactions; C5α, LFA1, CD46, CD55 and Mac-1 are involved in the immune system, C5α Mac-1, CD46 and CD55 in the complement cascade, LFA1 in immune cell recruitment RBP4 is a specific retinol-binding protein; polyoma middle T antigen is a transforming oncogene, and Src, PI3K and Ras are components of the polyoma middle T signalling pathway, and it is thought that mutant variants of polyoma middle T, Src, PI3K and Ras may disable aspects of their activity and therefore affect cell transformation. MicroRNA sequences are designed with the aim of causing reduced expression of a target gene.

Evaluation of foreseeable effects

VEGF is a pro-angiogenic and pro-inflammatory growth factor which may exert harmful effects if over-expressed at high levels in the tissue, but with low severity because of the short half-life of the protein. VEGFR1/2 and neuropilin-1/2 are receptors and co-receptors, respectively, which mediate VEGF signalling. Notch ligands and Notch receptors are growth factors and receptors, respectively, and unregulated expression of their mutants variants has been linked to tumorigenesis, but with low severity and a self-limited localisation. C5α, LFA1, CD46, CD55 and Mac-1 may cause transient local inflammation if expressed at high levels locally, but with low severity. Polyoma middle T-antigen is a transforming oncogene with the potential to induce tumour growth, although the severity would be likely to be low and limited to immune-deficient individuals. Src, PI3K and Ras are involved in the Polyoma middle T-antigen signal transduction pathway and may be involved in its transforming ability, indicating a potential for harm, but effects would be limited, localised and transient with low severity. The use of low volumes of culture medium and replication-deficient lentivirus reduce the risk to humans. Sharps will not be used when handling potentially harmful sequences; this will significantly reduce the risk of DNA transfer through needlestick or other puncture injury. Other proteins including the structural proteins such as PV-1 and nuclear proteins such as Hey-2 have no documented risk of causing diseases in humans.

pPICZ yeast expression vectors contain the TEF1 and EM7 promoters, which drive the expression of the gene coding for resistance to the antibiotic Zeocin in yeast and prokaryotes, respectively. Insert expression in pPICZ vectors is controlled by the AOX1 promoter, which is induced by methanol. Gene expression is therefore suppressed in the absence of methanol. Bacterial plasmid vectors contain the prokaryotic lac, EM7, T7 and SP6 promoters, and the cytomegalovirus (CMV) immediate-early promoter and the simian virus (SV) 40 promoter for expression in mammalian cells. All bacterial plasmid vectors used are non-mobile, and are therefore unable to transfer into wild-type bacteria in the environment.

The ViraPower Lentiviral expression systems which will be used are derived from HIV-1 but have a number of inbuilt safety features. There are no longer terminal repeats (LTR) in the packaging plasmids, so that HIV-1 structural genes are only expressed in the producer cell and never packaged into virions. Secondly, viral particles are replication incompetent, and they only carry the gene of interest, so that no other viral proteins are produced. Additionally, these viruses have a deletion in the 3' LTR which makes the virus “self-inactivating”; transduced and integrated lentiviral vectors are no longer capable of producing a packagable viral genome. The insertion of genes would be unlikely to affect the behaviour of the viral vectors.

Cultured mammalian cells transfected with bacterial plasmids containing mammalian gene sequences or transduced with viral vectors containing mammalian gene sequences may display altered signalling, growth or viability but due to the fact that these cell lines rely on specific culture conditions and would be unlikely to survive outside the laboratory culture conditions, this would not pose a risk to humans. The insertion of genes would be unlikely to alter the recipient organisms' ability to survive in the environment, compete with other organisms or transfer to them the inserted sequences.

The majority of materials used in this project are not considered hazardous to handlers. The transforming oncogene polyoma middle T antigen and the VEGF isoforms and receptors have a potential to cause harmful effects. In the case of the vectors used for VEGF, the risk of natural gene transfer is very low. The most hazardous GMM is disabled lentivirus containing the polyoma middle T sequence, and any procedure in which this construct is handled, particularly with a view to transducing cells, is likely to
be the most hazardous

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The inactivation measures which will be used, as appropriate, are chemical disinfection with a 1% solution of Virkon disinfectant for 10 minutes or a 105 bleach (sodium hypochlorite) solution, treatment with UV light, and autoclaving. Virkon disinfectant has been proven to kill 99.999% of microorganisms in less than 10 minutes, and is the disinfectant of choice for inactivating viruses. Sodium hypochlorite is a commonly-used wide-spectrum disinfectant. Autoclaving involves treatment with high pressure steam at 121°C for 15-20 minutes, which kills all bacteria and viruses. The inactivation of bacteria and yeast should be confirmed by spreading treated liquid waste onto the appropriate solid growth medium, incubating overnight at the optimum temperature and checking for micro-organism growth. The inactivation of virus should be confirmed by attempting to infect host cells and testing for infectivity or expression of proteins coded by the viral vector. Inactivated contaminated solid waste should be disposed of in Biohazard bags, and inactivated contaminated sharps in Biohazard sharps bins. Inactivated contaminated liquid waste may be disposed of in normal waste water drains.

Production and use of recombinant lentiviral (rLV) vectors.

Our group aims to contribute to the development of novel methodologies of human disease treatment through identification of novel targets of diseases and their characterisation using in vitro and in vivo systems. We are particularly interested in cancer and ocular disorders. Recently our studies have identified that the small leucine rich proteoglycan family members may inhibit tumourigenesis. To examine this possibility, it is essential to analyse the effect of their activation in in vitro and in vivo cancer models. To this end, the third generation lentivirus system is ideal because it is very safe and can easily produce stable expression. So far, there is no effective treatment of many types of cancer. If the activation is effective, this may provide a novel strategy of cancer treatment.

Virus:
The third generation lentiviruses such as Lenti-X system (Clontech), SIN third generation (Gentarget, OpenBiosystem),

Cells:
Non-transformed cells 293, NHU-hTERT

ATCC supplied established human cancer cell lines such as Hela, EJ28, J82, RT112, 253 JBV, and MCF7.

Corneal cells: epithelium, endothelium, and fibroblast

Animals: mouse

To construct viral vectors, the following intermediate constructs will be made using general lab strain of E. coli. There is no potential for harm to health and/or harm to the
Commercially available packaging vectors are used such as pMDL, prev, and pVSVG.

Lentiviral transfer vectors containing inserted genes of interest will be constructed using commonly used safe vectors such as pLVX-Tight-Puro (Clontech), LT-Exp1 (Gentarget), plenti vectors (Invitrogen), and Express-In™ (Openbiosystem).

**Origin & function**

Origin: human, mouse, Xenopus (OMD, PRELP), P1 bacteriophage (Cre recombinase), E.coli (Tet-on)

Functions:
OMD and PRELP are secreted proteins in the small elucine rich proteoglycan family. These proteins regulate cellular signalling from extracellular space. We expect that overexpression of these genes show negative effect on tumour cell growth.

Cre recombinase has the activity to induce recombination through the Cre-lox system.

Tet-on (for inducible system) is used for suppression of spontaneous expression of introduced genes.

**Evaluation of foreseeable effects**

The third generation lentivirus system has been recognized as a very safe system. The inserted DNA and virus are unlikely to be pathogenic. However, the most hazardous GMO is recombinant lentivirus. There is the possibility of mutagenesis caused by random insertion of viral sequences, but the risk of foreseeable adverse effects is very low.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Infection of mice will be performed in the animal facility. The protocols are set out in the Home Office Animal Project Licence (PPL70/6750). The mice will be always kept in the animal facility.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

The viruses, cells and animals cannot survive in natural conditions. They will be killed by standard methods.

E. coli and eukaryotic cells are inactivated by treatment with Virkon. Also, all waste and used glassware are autoclaved. The autoclaved waste will be discarded using plastic bags. We expect to kill 100% of cells and mice. The conditions are approved to kill E. coli, mammalian cell lines, and mice. Mammalian cells are confirmed by lysis of structure. Death of mice is confirmed by eye. The dead mice will be packed in plastic bags. The bags are temporarily kept in designated -20 freezer in the animal facility. Then, the dead animals are incinerated by the designated special facility.

**Is an emergency plan required according to regulation 20?**

Y

**If yes, tick to confirm that it is attached to this form**

N

**Tick to confirm that you have attached a risk assessment to this form**

Y
Prof O has submitted a new Class 2 risk assessment using third generation lentiviruses. The risk with this proposal lies in the possibility of random positional integration into the genome and the unpredictable effects this could have. The committee reviewed the risk assessment forms and the following points were raised.

GMM1 & 2
- Section 1.11 mentions xenopus but not section 1.13
- Section 2.06 states there is no risk. Clearly there is a risk but this is controlled.
- Section 2.09 - The risk should be low not zero

HSE Risk assessment
- As the form will be submitted to the HSE it must be accurate.
- Section 2.13 needs to be more specific. It is not acceptable to state "such as Virkon" or "suitable bags".
- Section 2.07 again states there is no risk. This needs to be amended
- We need to make it clear in the risk assessment why we believe the proposal is Class 2, i.e. because of the level of virus titre being used and the injection into animals.

CU2 form
- The sentences relating to the Home Office need to be removed. The HSE are interested in the disposal of the carcasses not how the animals will be killed

Project Additional Information
### Purposes of the contained use

The purpose of this project is to develop strategies to improve the in vitro and in vivo function of viral vectors for potential use in cancer gene therapy.

### Recipient or parental organism

Well characterised, ACDP Class 1 mammalian cell lines (e.g. A549, CaLu 6, CT26, B16-F10, HeLa) well characterised, ACDP Class 2 mammalian cell lines (e.g. HEK293, COS-7, SVEC 4-10, 2F2B) Murine embryonic stem cell line (El4Tg2a) and murine primary cell C57B16, Oalt/b/c and CD1 immunocompetent mice

Athymic (nude) immunodeficient mice

### Host/vector system

1. Wild-type Reovirus is replication competent. However, its replication is selective to cells that have an activated Ras signalling pathway (Curr Opin Mol Ther. 2006 Jun; 8(3):249-60)

2. Tumour-replicating Adenovirus. ICOVIR-5 (Ad-DM-E2F-K-Delta24RGD) is an optimised oncolytic adenovirus that combines Ela transcriptional control by an insulated form of the E2F promoter with Delta24 mutation of Ela to improve the therapeutic index of AdDelta24RGD (Mol Ther. 2007 Sep; 15(9): 1607-15)

### Origin & function

Reovirus will be provided by Oncolytics Siotech Inc. Calgary, Canada (Reolysin). This product is currently being used in clinical trials and we wish to investigate its oncolytic potential in cancer gene therapy. The virus is not genetically modified.

ICOVIR has an Ela gene deletion in the retinoblastoma (Rb) protein-binding region, substitution of the Ela promoter for E2F-responsive elements and an RGD-4C peptide motif inserted into the adenoviral fibre to enhance adenoviral tropism.

### Evaluation of foreseeable effects

Reovirus will infect human cells however, it is only replication competent in cells with an activated ras signalling pathway therefore, the risk to human cells is minimised. Ras mutations and overexpression of the ras signalling pathway are most frequently associated with a transformed phenotype and the development of malignancy. However, there is a theoretical risk that ras signalling may be activated in growth factor-stimulated cells, cells that proliferate (wound healing) or in people with cellular proliferative disorders. Therefore we cannot exclude the possibility that Reovirus (Reolysin) might infect and replicate in apparently normal cells, causing lysis. Furthermore, the release of tumour associated antigens following lysis may modify the host immune system to infected cells. However, this is unlikely to result in adverse disease. Reovirus will also be readily transmitted via aerosols. Therefore, to protect people from the potential risk of infection all work associated with the virus will be carried out at Class 2.

ICOVIR is replication defective in normal, healthy cells, However, if ICOVIR were to recombine resulting in replication competence it would be comparable to wild type adenovirus since it contains no additional genetic material. All strains of adenovirus 5 are non-oncogenic. Wild-type Ad5 may cause mild respiratory diseases in children. Primary infection of adenovirus is thought to generate life-long immunity and it is thought that the majority of the adult population are likely to have antibodies to the wild-type virus. Although replication has been shown to occur in the lungs of experimentally infected cotton rats administered with high doses of virus, there is no evidence that adenoviruses can naturally colonise non-human hosts and therefore pose no significant harm to animals, plants or ecosystems.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Wild type Reovirus or Adenovirus-infected animals may excrete (shed) adenovirus (especially in the first 72 hours after infection). Precautions must be taken not to create aerosols when emptying animal waste material, washing cages or cleaning the room.

Handling is carried out in Class 2 microbiological cabinet.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
No derogation required.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be treated with a 1% Yukon solution for at least 3 hrs. It can then safely be disposed of in the laboratory sink. All surfaces coming in contact with liquid waste will be washed with 1% Virkon and/or 70% isopropanol and/or a mild detergent (e.g. SDS).

Plastic tips, simplettes, syringes, etc or glassware that was used to hold or dispense virus will similarly be soaked in a: 1% Virkon solution for at least 3 hrs, but overnight in most cases. The liquid will be disposed of in the laboratory sink, and the remaining solid waste will be collected in the laboratory solids bins.

1% Virkon has activity equivalent to 1000 p.p.m. chlorine without hazards, corrosion potential and loss of activity due to organic challenge.

(Altvirai Res. Inactivation of adenovirus types 5 and 6 by Virkon S. 2004 Oct;64(1):27-33.)

All other solid waste will be inactivated by autoclaving. The autoclave will be validated by external contractors at least once per year and the day to day operation monitored using the instrument readouts of temperature, pressure and time. The autoclaves used for waste also indicate a failed cycle if the required parameters are not met.

Please enter comments on the GM safety committee on the risk assessment

The committee feel that the proposed research using replication deficient viruses and tumour replicative competent viruses that are dependent upon ras signaling for adenoviral infection are safe. This research is a continuation of work currently being conducted within other UK institutions, using similar protocols. In these proposed experiments reporter genes are used as markers for transfection efficiency and translation. All cell lines used in these experiments are well characterized and if handled correctly, according to well developed protocols, will not pose any difficulties concerns, even for those cell line assigned at class 2 containment. The proposed experiments are very timely and need to be conducted without undue delay. There are no additional unknown risks associated with using nude mice in these proposed studies as similar studies have been carried out using the very similar experimental protocols as outlined in this proposal.

What happens if humans with cancer (in early stages people might not know that they have cancer) would work with tumouronly replicative viruses? The worst case scenario would be that of the wild-type viruses.

Is it really likely that all of these cell lines will be used? Yes, cell lines held by this laboratory have been acquired ‘specifically for their different properties/species specificity.

The School requires double HEPA filters for Class II Microbiological Safety Cabinets used for GM work.

Other points of clarification were dealt with at the draft stage for the Risk Assessment.

We aim to identify the molecular targets for our small antibacterial molecules using a multicopy suppression strategy. This requires the creation of a shot-gun library of Clostridium difficile DNA in specific vectors. These will then be transferred back into Clostridium difficile with the aim of identifying clones that are resistant to our molecules. Further to this our potential targets will be cloned to confirm their role in resistance. An alternative approach to this will be by creating a transposon library of random mutants and testing these for sensitivity against our compounds.

Clostridium difficile strains are ACDP hazard category 2. Clostridium difficile R20291 is regarded as the PCR ribotype 027 reference strains. Strains produced in this study are not likely to be more virulent than this. Clostridium difficile 630 and 630 delta erm will also be used in this study but are known to be less virulent than strain R20291. Initial cloning will take place in E.coli and plasmids will be screened to ensure those containing toxin genes will not be placed in C.difficile as the additive effect is unknown. C. difficile only presents a hazard when the normal bacterial flora is compromised and is carried by 25% of the population with no effect to health.

Recipient or parental organism

Clostridium difficile strains are ACDP hazard category 2. Clostridium difficile R20291 is regarded as the PCR ribotype 027 reference strains. Strains produced in this study are not likely to be more virulent than this. Clostridium difficile 630 and 630 delta erm will also be used in this study but are known to be less virulent than strain R20291. Initial cloning will take place in E.coli and plasmids will be screened to ensure those containing toxin genes will not be placed in C.difficile as the additive effect is unknown. C. difficile only presents a hazard when the normal bacterial flora is compromised and is carried by 25% of the population with no effect to health.

Host/vector system

The disabled E.coli strains TOP10, JM109 and CA434 will be used as the plasmid host and are not pathogenic. Due to the differences in codon usage between E.coli and C.difficile, it is very unlikely that expression of C.difficile genes will occur in E.coli. Also due to the random fragmentation of the genomic DNA the required elements for
expression may not be cloned with the genomic DNA. The pMTL vectors based on the CoE1 replicon will be used as shuttle vectors in E.coli and C.difficile. These plasmids are nic mob minus and are derived from Gram positive and negative components, many of which (except the Gram positive replicon) do not function in clostridia. These plasmids will also contain antibiotic resistance markers which are regularly used in the laboratory environment and E.coli. The plasmids are not self-transmissable.

**Origin & function**

Genomic DNA will be extracted from the Clostridium difficile sequence strains CD630 and R20291. Fragmented segments of this DNA will then be cloned into pMTL80000 series vectors for propagation in E.coli and conjugation into Clostridium difficile. The approach of creating mutants for testing, either by deletion of a gene or insertion of a transposon will make the GMM less virulent. The majority of the genes to be expressed are innocuous bacterial enzymes used for basic metabolic functions and they are unlikely to function in isolation or in E.coli.

**Evaluation of foreseeable effects**

**C.difficile:**
The duplication of metabolic genes in the multicopy suppression studies are highly unlikely to increase virulence or survival in the environment. The effect of gene dosage on the only known virulence determinants of C. difficile, toxins A and B is unknown. Expression levels of the genes encoding toxin A and B vary widely in clinical strains and the experiments here are unlikely to exceed clinical levels even in the worst case scenario. Random mutagenesis or directed gene deletion may increase or decrease virulence factor expression. None of the antibiotic markers used correspond to antibiotics that are routinely used to treat C. difficile infection.

**E.coli:**
The strains used are disabled, non-pathogenic laboratory strains which are unlikely to cause disease even with the addition of fragmented clostridial DNA or genes. As such infection with recombinant E.coli or survival in the environment is deemed highly unlikely.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Waste will be autoclaved to achieve 100% kill and will then be sent to landfill after processing by approved waste disposal contractors.

Please enter comments on the GM safety committee on the risk assessment
The GMSC has considered the proposal for work with C. difficile, and after initial discussion to clarify the text of the risk assessment we have no concerns about the genetic modification as planned, and note that it is highly unlikely that a GMO more hazardous than the host will be generated. The main concerns expressed were regarding the safe transport, handling and disposal of the pathogenic host organism. Acceptable safe working practices have been cited in the risk assessment, and reference has been included to indicate the expertise and experience of the key post-doc who has safely and successfully worked with C. difficile, and with other Level 2 and 3 pathogens for 11 years. One committee member has extensive experience of pathogen work including MRSA and has no problem with this straightforward application using category 2 bacteria. The GMSC has approved this proposal.

For activities involving GMMs, describe the waste management measures which will apply to the activity.

Full heat sterilisation facilities eg autoclaves available and always used for live organisms. Typical waste cycles are 90 mins at 121 degrees C.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Liquid waste is inactivated either by overnight incubation with hypochlorite (primarily 20 litres spent fermentor media) or by autoclaving (0.25 litres in shake flasks). The efficacy of the waste treatment is confirmed by plating representative samples.

**Project Additional Information**

**Purposes of the contained use**

The aim of the project is to characterise the function of genes encoded by Mycobacterium tuberculosis. In order to achieve this in as closely related organism as possible to the virulent M. tuberculosis we will utilise a highly attenuated and genetically validated M. tuberculosis generated by Prof W Jacobs (Albert Einstein College of Medicine, New York). The M. tuberculosis mc(2)7000 strain is an unmarked derivative of the mc(2)6306 M. tuberculosis strain harbouring disabling deletion mutations in RD1 region (associated with the attenuation of bacilli Calmette-Gurin (BCG) vaccine) and panCD (associated with pantothenate synthesis). RD1 mutations limit the ability of M. tuberculosis to grow within animal tissue and have been validated in humans through the use of the BCG vaccine, panCD mutations limit growth in vivo by restricting the availability of essential nutrients to the bacteria. Evidence supporting these statements is to be found in the supporting documents. Additional parallel studies will be performed in Mycobacterium bovis BCG, an avirulent strain of M. bovis, and similar HG2/1 mycobacteria (e.g. Mycobacterium smegmatis, Mycobacterium marinum, Mycobacterium thermoresistibile).

We will exploit these background strains in phenotypic screens. Nulling deletion mutations will introduced in protein coding genes within M. tuberculosis and additionally complement with a mycobacterium specific inducible expression vector. The mutants will enable us to identify the function of these genes using basic phenotypic characterisation studies. Potential foreign genes, which are exploited already within the field as validation markers and reporters, will be cloned into mycobacterium specific vectors to create viable test strains (e.g. luxAB genes from Vibrio harveyi). Antimicrobial testing and mutant generation using these strains will assist our efforts in mode of action studies of novel anti-tuberculosis compounds. Additionally genes of interest will be expressed at high levels in disabled host bacterium (E. coli) to enable further biochemical and biophysical analysis of the target protein.

**Recipient or parental organism**

The parental Mycobacterium tuberculosis H37Rv strain is a fully sequenced laboratory strain of TB classified as a HG3 organism. The route of transmission is via aerosol but can also infect via oral routes. This strain will not be used in the notified activities. The highly attenuated M. tuberculosis mc(2)7000 strain and its derivatives, classified as hazard group 2, will be used. The GM activities in this notification are growth in vivo, complementation, and storage of GM mc(2)7000 strains.

Other Mycobacterium related strains with potential opportunistic activities will also be used;
- Mycobacterium marinum (HG2)
- Rhodococcus equi (HG2)
- The vaccine strain;
- Mycobacterium bovis BCG
- Non-pathogenic;
- Mycobacterium smegmatis
- Mycobacterium thermoresistibile (HG2)
- (HG1)
- Disabled laboratory strains of E. coli including K12/MC1061 or similar/derivatives thereof will be utilised in construction of genetic elements using standard protocols.TOP10, XL-10 Gold (host for routine cloning); BL21, C41, BL21 star (for protein expression).
The pJV53 and pAL70 series of vectors for generating marked and unmarked mutants in Mycobacterium spp. including M. tuberculosis mc(2)7000 will be used (van Kessel JC, Hatfull GF Nat Methods. 2007. 4(2):147-52, Cascioferro et al., Appl Environ Microbiol. 2010; 76(15): 5312-5316). These vectors carry a hygromycin resistance gene for selection which can be removed by successive passaging of the organism in the absence of the selective marker.

phaE181 phage is a recombinant phage that contains a derivative of the mariner-based Tn5371. The recombinant phage phAE181 is derived from a temperature sensitive mutant of the lytic Mycobacteriophage TM4, which can infect many slow and fast growing Mycobacterium species, including M. tuberculosis, M. bovis, M. smegmatis and M. marinum. The phage can replicate inside a mycobacterial host (with a productive lytic cycle) at 30°C, but not at the non-permissive temperature of 37°C. Tn5371, which contains a hygromycin resistance gene (hyg), can thus be delivered by infecting the target Mycobacterium host at 30°C, followed by selection of Tn-mutants on hygromycin-containing plates at 37°C (Kriakov et al., 2003 J Bacteriol 185(16):4983-91).

DNA sequences will be introduced into Mycobacterium spp. including M. tuberculosis mc(2)7000 using well characterised and harmless non-mobilisable (Parsons et al., 1998 Mol. Microbiol. 28: 571-582) shuttle vectors that can replicate in E. coli and mycobacteria (e.g. pJEM15, pMV261, pMV306, pW16, pPR27 and their derivatives). These vectors contain an E. coli origin of replication (e.g. pJEM15, pMV261, pMV306, pW16, pPR27 and their derivatives). Additionally pMIND and pMEND derivatives will be used in complementation and overexpression studies (Blokpoel et al. Nucleic Acids Res. 2005.33(2):e22. 10.1093/nar/gni023). pNV18 and pNV19 are constructed by inserting a 1.8 kb DNA fragment carrying the pAL5000 origin of replication (Snapper et al. 1990 Mol. Microbiol. 4:1911-1919; Stolt 1997 Nucl. Acids Res.25:3840-3846) into the unique Nhel site of pK18 or pK19 (Pridmore 1987 Gene 56:309-312) for expression in Rhodococcus equi.

E. coli recombinant protein expression for crystallographic and biochemical studies will utilise the non-mobilisable pET expression systems.

Origin & function
Source: M. tuberculosis H37Rv
Genetic material: DNA fragments encoding various well defined genes involved in cell wall metabolism and function, e.g. transferases, fatty acid biosynthesis, polyketide biosynthesis, siderophore biosynthesis, p450 enzymes, core biosynthetic genes, regulatory enzymes and shock response genes. The intention is not to work with any sequences where insertion or deletion could be reasonably foreseen to increase the hazardous characteristics of the organism.
Source: Depending on marker - E. coli for B-galactosidase, luminescent vibrios for luciferase, jellyfish for GFP, Streptomycyes for agarases.
The genetic material that are to be expressed are marker protein which are highly unlikely to have any biological effect, eg GFP, luciferase, B-galactosidase, agarase.
Antibiotic resistance genes expressed from their native promoters.

Evaluation of foreseeable effects
1. Hazards to human health:
The parental strain M. tuberculosis H37Rv is capable of causing TB, the deletions of RD1 and panCD are well documented in peer-reviewed papers as attenuating the ability of these strains to colonise and cause infection in mammals (see accompanying summary of relevant literature). Furthermore, there is no reduction in the susceptibility of the GMMs to frontline treatments for TB. The likelihood of the 10 disabling gene deletions being overcome is
extremely unlikely. The possibility of generating a fully infectious TB strain is therefore effectively zero. Subsequent genetic modifications by over-expression of potential target gene candidates by plasmid expression or through further gene deletions are unlikely to modify the bacteria's virulence or infective route as long as the mutations are not rescuing or reverting the original RD1 and panCD deletion genotype. The majority of GMMs will render the strains less efficient at causing disease. It is not anticipated that any GMMs will show increased virulence.

2. Possible impact on the environment:
The disabling mutations were introduced by multiple gene replacement events in the H37Rv chromosome. The likelihood of mobilisation of the genetic modification from the mc(2)7000 derivatives, or transfer into other species in the environment in the event of a release is diminutive. This is reduced further still when the waste control measures are taken into consideration. All potentially infected material is autoclaved prior to disposal. 100% killing of GMMs is required. Disinfectants such as 2% Trigene and 10% Chloros are available for spills/disinfection of contaminated surfaces. Potential modes of transmission to the environment: Drains, aerosols, faulty autoclaves, and carried on individuals. These risks are reduced to moderated/unlikely, firstly by the disabling mutations within the bacteria, which reduce the likelihood of survival outside the laboratory (panCD) and the control measures used in the contained environment (see BioCOSHH and risk assessment).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not Applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The parental Mycobacterium tuberculosis H37Rv strain is a fully sequences laboratory strain of TB classified as a HG3 organism. This strain will not be used in any part of this notification. The HG2 classified M. tuberculosis mc(2)7000 strain and its derivatives will be used at our premises. The M. tuberculosis mc(2)7000 strain is an unmarked derivative of the mc(2)6306 harbouring disabling deletion mutations in RD1 region (associated with the attenuation of bacilli Calmette-Gurin (BCG) vaccine) and panCD (associated with pantothenate synthesis). RD1 mutations limit the ability of M. tuberculosis to grow within animal tissue and have been validated in humans through the use of the BCG vaccine, panCD mutations limit growth in vivo by restricting the availability of essential nutrients to the bacteria. Therefore we seek a derogation to allow the reclassification of the M. tuberculosis mc(2)7000 strain to HG2. Similar derogations for work with mc(2)7000 and its parental strain have been granted to existing projects in the GM public register, including project Ref 8/15.2 & Ref 552/13.2.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All materials used in the CL2 facility are to be regarded as potentially contaminated and disposed of accordingly to ensure 100% killing. All solid waste will be autoclaved in a validated autoclave before leaving the laboratory and disposed of in clinical waste bags for clinical waste disposal. Liquid waste is pre-treated with Surfanios at 5% final concentration and left overnight before autoclaving and disposal of as clinical waste. Minimum 126°C degrees for 45 minutes, 10 minutes free-steam. Activities will be separated from those which use Virkon for chemical disinfection, as Virkon is documented as being ineffective against Mycobacteria.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

**Purposes of the contained use**

The aim of our work is to develop two novel molecular genetic strategies to treat or prevent prion diseases, by interfering with the prion protein (PrP) conversion process, during which the cellular prion protein (PrPc) undergoes conformational changes transforming it into an abnormal, protease-resistant isoform (PrPsc). PrPc is encoded by the cellular PRNP gene and is co-translationally translocated into the lumen of the endoplasmic reticulum (ER), trafficking through Golgi and trans-Golgi network to reach the outer face of the cell membrane, from where it is internalised into endosomes and targeted to lysosomes for degradation. The conversion of PrPc into PrPsc is thought to occur on the cell membrane or in early endosomes. Replication of the agent causing transmissible spongiform encephalopathies is tightly associated with this post-translational conversion step and according to the now widely accepted “prion hypothesis” PrPsc itself represents the infectious agent. One of our strategies of interfering with conversion is creation of a "phenotypic knockout" of PrPc by expression of mini-genes encoding PrPc-specific single-chain antibodies fused with an ER-retention signal, thereby depleting the cell surface of PrPc molecules, and the other is overexpression of mini-genes encoding dominant negative mutants of PrPc that follow the identical pattern of subcellular trafficking and are capable of blocking the conversion of wild-type PrPc into PrPsc.

**Recipient or parental organism**

Initial cloning hosts will be disabled E. coli K12 derivatives such as XL1-blue and HP101. These are non-colonising and have auxotrophic and/or other mutations that limit their survivability outside laboratory media in the very unlikely event of escape (Compendium of Guidance 2000, Part 2A, Annex II). As such, they are equivalent to ACDP hazard group 1.

The host for expression of genetically modified material (anti-PrP single chain antibodies; dominant negative PrP mutants) is the mouse neuroblastoma cell line Neuro2a, which is not known to have any associated pathogens and has a long history of safe use. These cells are not known to contain any adventitious agents and they have pracitically no survivability outside tissue culture medium and do not colonise humans. For some experiments, Neuro2a cells will be infected with the Chandler strain of mouse scrapie agent (Bosque & Prusiner [2000] J Virol 74:4377). Hazards associated with infection of cells by mouse scrapie have been assessed in a COSHH risk assessment. Transfection of scrapie-infected cells with the GM sequences that are expected to inhibit production of pathogenic PrP isoforms are expected to result in a lower hazard than that involved in scrapie infection of non-transfected cells. Even if the GM sequences lack the predicted inhibitory activities, it is difficult to envisage how they could result in a greater hazard than those associated with infection of cells with scrapie, and therefore no additional GM hazards have been identified in relation to infection of cells with scrapie.

The host for introduction of the foreign genes in the germline of mammals is the mouse (Mus musculus).

**Host/vector system**

The phagemid vector pSEX81 (http://www.ncbi.nlm.nih.gov/entrez/viewer.cgi?val=2462915) is a pUC119 derivative comprising a ColE1 origin but is Bom-/(Nic-), Mob- and Tra- and therefore non-mobilisable (ACGM compendium of Guidance, Part 2A, Annex II). The mammalian expression vector plasmid pCMV/myc/ER comprising the HCMV promoter (http://www.invitrogen.com/content/vectors/pcmvmycer.pdf) is a pUC18 derivative and therefore non-mobilisable (ACGM compendium of Guidance, Part 2A, Annex II). The mammalian expression vector plasmids pL15TK (Holscher et al, J Virol 1998; 72:1153-9) and MoPrP.Xho (Borchelt DR et al, Genet Anal 1996; 13:159-63) comprising the HCMV promoter or the Prnp promoter, respectively are pUC19 and pBluescript derivatives, respectively, and therefore non-mobilisable (AC GM compendium of Guidance, Part 2A, Annex II). All the vectors are widely used in many laboratories and no specific hazards have been identified in relation to any of the vector sequences.

The GM mice will be constructed in a collaborating institution abroad (German Cancer Research Centre, Heidelberg, Germany) and then imported. The gector plasmid MoPrP.Xho (Borchelt DR et al, Genet Anal 1996; 13:59-63) allows for targeted expression in brain and myocardial cells of transgenic mice and is designed to give an expression level and pattern matching that of the endogenous Prnp gene.

**Origin & function**

The mini-genes encoding single-chain antibodies will be based on the variable regions of heavy chain and light chain immunoglobulin cDNA segments of murine hybridoma cells producing monoclonal antibodies directed against PrPc. Heavy chain and light chain segments will be joined via a flexible linker peptide. Expression of such single-chain antibodies fused with M13 pIII coat protein should enable recombinant phage to bind to the epitope of the parent monoclonal antibody, thus...
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Tissues will be collected (on death of the animal) and any unused material will be destroyed by incineration, using the services of a hospital-approved clinical waste contractor.

Records will be kept of numbers in each cage. All control measures required for Animal containment level 1 (Compendium of Guidance, Part 3E).

The mice will all be identified by earmarks and will be checked daily. The containment described below as well as the operator protection to be used when working with the live animals or derived tissues will render the risk of any putative harmful effects from the transgene product to humans effectively zero.

The containment level is required according to Compendium Part 2A, Annex III, Table 5A. The assessment is that containment level 1 is suitable for this work. Mice will be housed at all times in secure cages in a lockable room, minimising the risk of release. Appropriate facilities and procedures are in place to prevent any escape of animals, such as door guards, use of a closed-cage "mini-barrier" system (Fittlinger Co., Hockenheim, Germany), providing SPF-like conditions via closed-circuit ventilation of individual plastic cages operating at sub-atmospheric pressure, and the absence of floor drains and windows in the room. The mice will all be identified by earmarks and will be checked daily. Records will be kept of numbers in each cage. All control measures required for Animal containment level 1 (Compendium of Guidance, Part 3E).

Tissues will be collected (on death of the animal) and any unused material will be destroyed by incineration, using the services of a hospital-approved clinical waste contractor.

Codes of Practice under the Animals (Scientific Procedures) Act 1986 which equate at least to containment level 1 as described in the Compendium of Guidance, Part 3E.

Evaluation of foreseeable effects

Published data on Prnp null mice and derived cells as well as other cell culture studies demonstrate that deletion of PrPc, as intended in the present project, does by itself lead to the de novo creation of PrPsc but actually prevents the formation of PrPsc, infectivity and pathology that is typically seen in wild-type cells and animals upon scrapie agent inoculation (Sailer A et al, Cell 1994;77:967-968). Furthermore, PrPc depletion by Prnp gene knockout is not directly cytotoxic but may render cells slightly more vulnerable to oxidative stress (Brown DR et al, Exp Neurol 1997;146:104-112). Based on this, it is anticipated that depletion of PrPc by expression of mini-genes encoding ER-anchored anti-PrP single chain antibodies in transfected mammalian cell cultures, as intended in the present project, will not lead to cellular toxicity or de novo creation of PrPsc but will rather protect cells from scrapie agent replication and pathology.

Evaluation of foreseeable effects

Published data on Prnp null mice and derived cells as well as other cell culture studies demonstrate that deletion of PrPc, as intended in the present project, does by itself lead to the de novo creation of PrPsc but actually prevents the formation of PrPsc, infectivity and pathology that is typically seen in wild-type cells and animals upon scrapie agent inoculation (Sailer A et al, Cell 1994;77:967-968). Furthermore, PrPc depletion by Prnp gene knockout is not directly cytotoxic but may render cells slightly more vulnerable to oxidative stress (Brown DR et al, Exp Neurol 1997;146:104-112). Based on this, it is anticipated that depletion of PrPc by expression of mini-genes encoding ER-anchored anti-PrP single chain antibodies in transfected mammalian cell cultures, as intended in the present project, will not lead to cellular toxicity or de novo creation of PrPsc but will rather protect cells from scrapie agent replication and pathology.

Published data on Prnp null mice and derived cells as well as other cell culture studies demonstrate that deletion of PrPc, as intended in the present project, does by itself lead to the de novo creation of PrPsc but actually prevents the formation of PrPsc, infectivity and pathology that is typically seen in wild-type cells and animals upon scrapie agent inoculation (Sailer A et al, Cell 1994;77:967-968). Furthermore, PrPc depletion by Prnp gene knockout is not directly cytotoxic but may render cells slightly more vulnerable to oxidative stress (Brown DR et al, Exp Neurol 1997;146:104-112). Based on this, it is anticipated that depletion of PrPc by expression of mini-genes encoding ER-anchored anti-PrP single chain antibodies in transfected mammalian cell cultures, as intended in the present project, will not lead to cellular toxicity or de novo creation of PrPsc but will rather protect cells from scrapie agent replication and pathology.

It is also anticipated that expression of novel dominant negative PrP mutants in mammalian cells or mouse brain will inhibit conversion of wild-type PrPc into PrPsc, as has been the case with the previously characterised prototype mutant PrPc - 114-121 (Holscher et al, J Virol 1998; 72:153-9), thus protecting from scrapie agent replication and pathology. The likelihood of the expressed products leading to (rather than inhibiting) production of pathogenic isoforms of PrP is extremely low and even if this could occur the likelihood of the expressed product reaching a target tissue (CNS) and causing a pathogenic effect is so remote as to be almost negligible. Nevertheless, because it is not possible to be 100% certain about predicted functions prior to performing experiments, combined with the consequences that could be involved in the extremely unlikely event of a hazard arising, to err on the side of caution the risks are assessed as medium/low rather than effectively zero. This is consistent with the recommended containment level 2 in the Compendium of Guidance, Part 2A, Annex III, Table 5A, for work involving expression of modified human or animal PrP genes where there is no expectation that the modified protein will have the ability to convert human PrP to pathogenic isoforms.

For introduction into the mouse germline only such PrP deletion mutants that have been well characterised and shown to lack harmful effects in cultured cell lines will be considered, greatly reducing the likelihood that any harmful effects will arise in vivo. The transgene products are unlikely to be secreted with saliva, urine or faeces. Furthermore, it is anticipated that the transgene products will not display any toxic or allergenic potential, nor induce any behavioural changes or act as a disease reservoir. There is some risk of allergenicity associated with mouse work in general and workers showing an allergic response to the animals are not required to come into contact with them although the expressed sequence is unlikely to be allergenic in itself since it is only expressed in muscle or CNS (Borchelt DR et al, Genet Anal 1996; 13:159-163). The containment described below as well as the operator protection to be used when working with the live animals or derived tissues will render the risk of any putative harmful effects from the transgene product to humans effectively zero.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The transgenic mice expressing dominant negative versions of PrPc under the control of the Prnp gene promoter will be maintained to the standards prescribed in the Codes of Practice under the Animals (Scientific Procedures) Act 1986 which equate at least to containment level 1 as described in the Compendium of Guidance, Part 3E. This containment level is required according to Compendium Part 2A, Annex III, Table 5A. The assessment is that containment level 1 is suitable for this work. Mice will be housed at all times in secure cages in a lockable room, minimising the risk of release. Appropriate facilities and procedures are in place to prevent any escape of animals, such as door guards, use of a closed-cage "mini-barrier" system (Fittlinger Co., Hockenheim, Germany), providing SPF-like conditions via closed-circuit ventilation of individual plastic cages operating at sub-atmospheric pressure, and the absence of floor drains and windows in the room. The mice will all be identified by earmarks and will be checked daily. Records will be kept of numbers in each cage. All control measures required for Animal containment level 1 (Compendium of Guidance, Part 3E).

Tissues will be collected (on death of the animal) and any unused material will be destroyed by incineration, using the services of a hospital-approved clinical waste contractor.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

02/03/2022
Inactivation of any liquid waste or any contaminated plasticware or glassware will be by autoclaving at 121 degrees C for 20 minutes in a laboratory autoclave. The autoclave will be serviced on a 6 monthly basis and on an annual basis will be tested by thermocouple mapping employing a representative typical load. All autoclave runs will be monitored using TST (Time, Steam, Temperature) indicator test strips (Albert Browne Ltd, TST class 6 emulating indicator 121 degrees C for 20 min) meeting international standard ISO11140 part 2 to verify temperature and time.

In the event of spillage of possibly contaminated material, the area will be disinfected using 1% Virkon. The used paper towels will be autoclaved as above. As all work is performed in a separate laboratory, the wider environment is unlikely to become contaminated.

Control measures relating to TSE infectivity: As explained above, it is extremely unlikely that any TSE infectivity will be created as a result of the GM work to be performed in this project. Nevertheless, in view of the theoretical risk of spontaneous formation of PrPsc and scrapie infectivity by expression of the PrP deletion mutants (expected to behave as dominant negatives) and in view of using scrapie-infected mouse cell cultures in some of the experiments, disinfection of any remaining cellular material cell culture medium and plastic dishes will be carried out using methods approved for inactivation of TSE agents (incubation in sodium hypochlorite with release of 20,000 ppm chlorine for 1 hour, known to lead to 100% kill; joint ACDP/SEAC 1998 publication "Safe working and the prevention of infection") followed by incineration using an approved hospital contractor. In addition to the controls already mentioned, use of sharps will be avoided whenever alternatives exist.

In the event of spillage from the flasks, the area can be effectively disinfected and the wider environment is unlikely to become contaminated. The disinfectant used will be sodium hypochlorite with release of 20,000 ppm chlorine to be applied for all spillages for a period of 1 hour, after which this will be collected into a suitable container for disposal via the yellow bag route for incineration.

Tissues from transgenic mice will be collected (on death of the animal) and any unused material will be destroyed by incineration, using the services of a hospital-approved clinical waste contractor.

Project Additional Information

**Purposes of the contained use**
The aim of the project is to identify antimicrobial activity in vertebrate gastro-intestinal (GI) tract material, using a sensitive assay involving a mutant of S. typhimurium.

**Recipient or parental organism**
Salmonella typhimurium strain CS015 (phoP102::Tn10d-Cam)

**Host/vector system**
No vectors will be used in this study. The GM strain CS 015 (phoP102::Tn10d-Cam) will be supplied to us from our collaborator (SI Miller). Ref: Gunn SS & Miller SI (1996) J of Bacteriology 178 6857-6864

**Origin & function**
Origin: Transposon Tn10d-Cam is a 1.5kb DNA element specifying chloramphenicol resistance (cam) and is defective for transposase (d). Ref: Elliott T and Roth JR (1988) Mol Gen Genet 213:332:338

Nature of modification: The GMM has been generated by our collaborator by insertion of the transposon Tn10d-Cam into phoP of wild type Salmonella typhimurium. This modification increases the sensitivity of the strain to killing by anti-microbial peptides. Ref: Miller SI, Kukrai AM, Mekalamos JJ (1989) PNAS 86 5054-5058.

Intended function: The detection of anti-microbial activity.
Evaluation of foreseeable effects

The recipient organism wild-type Salmonella typhimurium is classified as ACDP hazard group 2 that is very widely distributed in nature, infecting a wide range of zoonotic hosts. It is a very commonly encountered pathogen that causes infection via the oral route, involving in the vast majority of cases a self limiting gastroenteritis that resolves within 5-7 days without treatment, particularly in otherwise healthy individuals. Except in rare cases where bacteremia or other complications may occur, treatment with antibiotics is usually not advised but if necessary ampicillin or amoxicillin is usually recommended. As outlined below, the mutant S.typhimurium strain to be used in this project is very likely to be strongly attenuated in virulence and is therefore likely to be less hazardous than the parent wild-type strain. However since this has not been directly tested in humans, the mutant strain will be treated as equivalent to ACDP hazard group 2.

Salmonella strain CS015 has acquired chloramphenicol resistance but carried a mutation in phoP. This alteration has resulted in a strain with reduced pathogenicity ie the strain is attenuated for virulence in mice (and by extrapolation in humans), is unable to survive within macrophages and is sensitive to killing by antimicrobial cationic peptides. Ref: Miller SI, Kukrai AM, Mekalamos JJ (1989) PNAS 86 5054-5058. It is difficult to envisage how the phoP::Tn10d-Cam mutation could increase the ability of S.typhimurium to survive, disseminate or displace other organisms in the environment. Although the inserted transposon carries a Cmr marker, Cmr is already widely encountered among enteric bacteria in nature (Gallardo et al (1999) J Med Microbiol 48 367-374; Liberti and Loiacono (2000) Int J Antimicrob Agents 16 347-8). Moreover, any possible advantage that might be conferred by the Cmr marker, would probably be vastly out-weighed by the increased sensitivity of the mutant strain to killing by cationic peptides, which would likely to place it at a selective disadvantage in competition with wild-type strains in the guts of animals or poultry. S.typhimurium does not infect plants.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Control measures to protect human health and the environment.

Since the GMM is classed as activity Class 2, they will be handled at containment level 2 (small scale, laboratory activities), as defined in ACGM Compendium of Guidance.

Contaminated Material (plastics, gloves, paper waste, bacterial cultures, agar plates, sharps, glassware).
All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored using TST (Time, Steam, Temperature) test strips (Albert Browne Ltd, TST class 6 emulating indicator 121 degrees C for 20 min) meeting international standard ISO11140 part 2.

Approved 1 October 2001.
The objectives of this programme are to construct and characterise mutants of Mycobacterium bovis BCG. These mutants will be used to analyse well-defined, non-toxic, mycobacterial cell wall components (proteins, lipids, etc) and genes that contribute to the basic physiology of mycobacteria. This project is of special interest because Mycobacterium tuberculosis, the causative agent of tuberculosis, is a major cause of death worldwide. The use of M. bovis BCG as a model organism to study M. tuberculosis coelocal genetics and physiology is well documented and will aid in the development of new classes of drugs against tuberculosis.

M. bovis BCG (Pasteur) will be the recipient organism. This is a widely used live attenuated vaccine strain used to protect against tuberculosis. The ACDP categorisation
of pathogens classifies M. bovis BCG as hazard group 2; although under clinical conditions for immunisation laboratory Containment Level 2 is not necessary. Staff working on the programme have previously been immunised with BCG. Studies to identify the genetic determinants of attenuation of virulence in M. Bovis BCG (Pasteur) have revealed two large tandem duplications and 14 large unlinked genome deletions in M. Bovis BCG (Pasteur), totalling c. 200 kb and encompassing 119 open reading frames. These deletions reflect a progressive adaptation of M. bovis BCG to laboratory conditions resulting in their compromised ability to survive within the host.

Host/vector system

DNA sequences will be introduced into M. bovis BCG using well characterised and harmless non-mobilisable shuttle vectors that can replicate in E. coli and mycobacteria (eg pJEM15, pMV261, pVV16, pPR27). These vectors contain both an E. coli and mycobacterial origin of replication (from the pUC cloning vector series and plasmid pAL5000, respectively) and antibiotic resistance markers (eg kanamycin and gentamycin). Only antibiotic resistances that are already present in very widely used bacterial cloning vectors will be exploited. Some of the vectors also contain the mycobacterial hsp60 promoter, the reporter genes lacZ (encoding B-galactosidase), phoA (encoding alkaline phosphatase) and gfp (encoding green fluorescent protein) or the counter-selective amrnker sacB (causing sucrose sensitivity to mycobacteria).

Origin & function

Only DNA sequences encoding non-toxic products of known function will be inserted into the vectors for introduction into M. bovis BCG. These products will be involved in the synthesis of cell wall components (eg. B-keto-acyl synthase and mycolyl transferase) and/or contribute to basic cellular physiology (eg essential metal ion homeostasis). The latter will include metal transporting P-type ATPases and SmtB-related metal-sensor proteins that occur in a wide range of bacteria, including non-pathogenic strains.

All sequences will be well characterised prior to introduction into M. bovis BCG and will be generated by PCR using specific primers designed to amplify known DNA sequences (no random sequences will be introduced). The DNA sequences will include defined sequences, amplified by PCR, from M. tuberculosis (ACDP hazard group 3) DNA which has been provided by Colorado State University (USA) through the Tuberculosis Research Materials Contract of The National Institutes of Health and M. smegmatis (ACDP hazard group 1) DNA. The sequence of the M. tuberculosis genome is complete and contains no toxin-life genes.

Introduced DNA sequences will either (i) remain on self replicating plasmids to drive reporter gene expression or for expression from the mycobacterial hsp60 promoter, or (ii) be used to direct allelic replacement mutagenesis and hence generate gene deletion mutants of M. bovis BCG.

Evaluation of foreseeable effects

M. bovis BCG is a widely used live attenuated vaccine strain used to protect against tuberculosis. Staff working on this programme have previously been immunised with BCG. We will only introduce very short (<4kb) DNA sequences into M. bovis BCG using well characterised harmless vectors. Introduced DNA will be well defined genes (or parts of genes) that encode non-toxic cell wall components and that contribute to basic physiology (such as the sensing and transport of essential metal ions). It is therefore very unlikely that these sequences would restore virulence to M. bovis BCG which has numerous unlinked genetic alterations. Only non-mobilisable vectors will be used to introduce DNA sequences and hence it is highly unlikely that these sequences will be transferred to another organism. For reasons outlined above, the likelihood of harm in the event of exposure would be no greater than that with non-GM M. bovis BCG.

Environment

It is difficult to envisage how either the vectors or the inserts could confer a harmful phenotype or competitive advantage to M. bovis BCG. The environmental hazards associated with the project are therefore considered no greater than those associated with handling non-GM M. bovis BCG. The project involves small-scale work for research purposes and all contaminated material will be completely inactivated by autoclaving prior to disposal. In the highly unlikely event of release into the environment no risks are envisaged.

Class 2

USE OF RECOMBINANT REPLICATION-COMPETENT SENDAI VIRUS (SEV) AS A NEW GENE TRANSFER AGENT FOR GENE THERAPY OF INHERITED DISEASES

Class CultureVolClass2 CultureVolumeClass3-4

Class 2 < 1 litre

Number of pages: 1

02/03/2022
### Project Additional Information

**Purposes of the contained use**

Recombinant SeV will be used to transfer reporter and therapeutic genes to different cell types in vitro and compared to currently available gene transfer vectors.

**Recipient or parental organism**

Sendai virus (SeV) is an enveloped virus with a nonsegmented negative-strand RNA genome of 15384 nucleotides and is a member of the family Paramyxoviridae. The SeV genome contains six major genes: nucleoprotein (NP), phosphoprotein (P) and large protein (L) from a ribonucleoprotein (RNP) with the SeV genomic RNA. The matrix protein (M) engages in the assembly of viral particles. Two envelope glycoproteins, hemagglutinin-neuraminidase (HN) and fusion protein (F) mediate the attachment of virions and penetration of RNPs into infected cells. SeV replication is independent of nuclear functions and does not have a DNA phase. Therefore, it does not transform cells by integrating its genetic information into the cellular genome. SeV has been reported to naturally infect rodents (causing upper respiratory tract infections) and has never been reported to infect humans.

**Host/vector system**

Transgenes are normally inserted immediately before the ORF of the viral 3'-proximal nucleocapsid (NP) protein gene in a full-length SeV cDNA copy. The inserted gene is flanked by "gene start signal" and polyadenilation/stop sequences and recognised by the viral RNA polymerase.

**Origin & function**

The Sendai genome derives from the Z-strain. The recombinant virus has been developed by a Japanese biotech company, DNAVEC.

The recombinant SeV will carry different transgenes:
1. Bacterial transgenes, such as beta-galactosidase or CAT;
2. Eukaryotic transgenes such as luciferase (from Photinus pyralis) and GFP (from jellyfish);
3. Therapeutic genes

**Evaluation of foreseeable effects**

1. Recombinant SeV does not have an altered tropism compared to wild type virus. However, insertion of a transgene reduces the replication speed as well as the final virus titre in a way that is proportional to the size of the transgene, carried. In vivo a remarkably attenuated replication and pathogenicity were generally seen (Sakai et al., FEBS Lett 1999; 456: 221-226).
2. Virus replication and transmission to neighbouring cells has been demonstrated in the host species (rodents). SeV has never been reported to infect humans.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Recombinant Sendai virus is stored at -80 degrees C in 1-2ml vials. In vitro transfection experiments of cultured or primary cells will be carried out in a class II safety cabinet. After use the cabinets are routinely UV irradiated. Single-use plasticware is used. All GM contaminated material (including materials destined ultimately for incineration) will be completely inactivated by autoclaving before final disposal. This will allow a 100% degree of virus "kill", according to manufacturer's guidelines. The work involves standard laboratory protocols and there are no unusual procedures that require additional containment measures. Personnel will wear labcoats and gloves.

02/03/2022
USE OF ATTENUATED SALMONELLA TO DELIVER RECOMBINANT YERSINIA F1 PROTEIN IN THE LABORATORY AND FOR IMMUNISATION OF MICE.

Purposes of the contained use

To study the immune response to Yersinia F1 protein by infection of mice and cells in tissue culture to evaluate the potential of F1 protein as a candidate vaccine antigen.

Recipient or parental organism

Attenuated AroA Salmonella typhimurium SL3261 (vaccine strain).

Host/vector system

The vector system consists of the low copy number plasmid pLG339(Kan) into which the 4 genes of the caf operon of Yersinia pestis (caf1 structural gene, the caf1A and caf1M export and assembly genes and the regulatory caf1R gene) has been cloned to create the plasmid pAH34L.

Origin & function

The caf1 operon was derived from Yersinia pestis strain MP6 and codes for the capsule structural F1 protein which is a surface capsular structural protein whose function in virulence is thought to be conferring resistance to phagocytosis. Recombinant Salmonella typhimurium SL3261/pAH34L express the F1 protein on the surface and it has been reported that infection of mice has been shown to induce immunity that protects the mice against challenge with virulent Yersinia pestis. The recombinant Salmonella typhimurium SL3261/pAH34L has been used previously as a vaccine strain to protect mice against a lethal challenge with Yersinia pestis with no untoward side effects in the mice so vaccinated (Titball, RW, et al., (1997) Infection and Immunity 65: 1926-1930).

Evaluation of foreseeable effects

Salmonellae, including SL3261, that are attenuated by mutations in genes such AroA of the aromatic amino acid biosynthetic pathway are safe vaccines in animals and have been used in trials in humans. No wild-type strains will be used for this work. The likelihood that the expression of recombinant proteins such as F1 protein by the host strain will alter the strain and lead to pathogenic traits is negligible. No untoward side effects were observed in mice vaccinated with the recombinant Salmonella typhimurium SL3261/pAH34L strain, cf. Titball, RW, et al., (1997) Infection and Immunity 65: 1926-1930.

The only host strain that will be used will be attenuated Salmonella typhimurium strain SL3261, which is defined as disabled in the Compendium of Guidance (Part 2A, Annex II, para 11). This strain has been used as a live oral vaccine strain in mice. It has a non-revertible AroA deletion mutation (as well as other auxotrophic mutations) that confers a requirement for nutrients that cannot be supplied by mammalian hosts. Consequently, inoculation of mice with even a large infective dose results in a mild
self-limiting infection that can persist for only a limited period (usually < 2 weeks) before the organism is cleared completely. During this time no signs of distress are apparent and the host mounts an effective immune response to SL3261. The strain has been widely used as a safe live oral candidate vaccine delivery system for various recombinant antigens. Moreover, very similar AroA attenuated S. typhimurium strains have been used in human vaccine trials with no adverse reactions. Therefore, even infection with a very high dose would be unlikely to produce a symptomatic infection in normal healthy adults. However, the possibility that a more prolonged or even symptomatic infection might occur in immunocompromised individualxs cannot be excluded, since such data are not available.

In nature, S. typhimurium infections occur via the oral route (eg in contaminated food) and it has never been documented to be transmitted by an aerosol route. During infection experiments in mice, the recombinant SL3261 will be shed in faeces. Infection of laboratory or animal house personnel by contaminated faeces would require direct transmission of faeces to the mouth and it is highly unlikely that a sufficiently high infective dose would be transmitted unintentionally by this route (particularly in the case of the attenuated SL3261 strain) to establish an infection.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The recombinant attenuated S. typhimurium SL3261 strain will be grown in carefully controlled conditions in a containment level 2 laboratory. All contaminated material will be completely inactivated by autoclaving (100% kill). All autoclave cycles are validated by monitoring with a chart recorder. The autoclaves are serviced twice annually and their efficiency validated annually by thermocouple testing. Waste will consist of contaminated laboratory glassware as well as discarded residues from small scale culture media or solid media cultures and contaminated disposable plastics such as centrifuge tubes and pipettes.

Mice infected with the recombinant attenuated S. typhimurium strains are maintained in the airborn infection suite in the Comparative Biology Centre which equates to containment 2 to the standards prescribed in the Codes of Practice under the Animals (Scientific Procedures) Act 1986. The animals are maintained in closed cages in rooms with self closing doors. Access is by two-keypad controlled doors and through a further two doors. The doors are all flush to the floor. The floor drains are screwed down to the floor and have very small drainage holes, much too small for a mouse. Records are kept of the numbers of mice in each cage. Dead mice and other animal waste (eg bedding) are treated as clinical waste and are disposed of by autoclaving within the airborne infection suite followed by incineration, in accordance with Comparative Biology Centre standard practice for dealing with infected carcasses. Cages used for infected mice are also autoclaved prior to washing.

Approved 19 December 2002.

Project Containment
### Project Additional Information

**Purposes of the contained use**

The production of conditionally immortal human cell lines for use in drug discovery and development. Primary cells derived from muscle, fat, liver and microvascular endothelial cells will be infected with a replication incompetent retrovirus containing a combination of immortalising genes.

**Recipient or parental organism**

Non-self human muscle, fat, liver and microvascular endothelial cells obtained from volunteer subjects and covered by ethical permission and appropriate consent, or purchased from a supplier company.

**Host/vector system**

Viral transduction of primary human cells in Newcastle will involve their infection with up to two amphotropic retroviruses (produced in London) based on murine leukaemia virus (MLV) A strain. One vector was constructed using the pZipNeoSV(X)1 backbone, which additionally confers resistance to neomycin (G418), while another vector was.
constructed using the pBabe-Hygro backbone, which additionally confers resistance to hygromycin B. Both viruses are disabled so incapable of producing infectious virus.

All virus stocks will have been tested to confirm absence of replication competent virus before transfer from London.

**Origin & function**

The shuttle vectors employed in the immortalisation process will encode either temperature-sensitive simian virus (SV40) large T antigen (designated U19ts58) or the catalytic component of human telomerase (hTERT), and will be transduced into human cells as either LT alone or as LT + hTERT. The product of each of these genes is capable of extending the lifespan of and/or immortalising human cells. The SV40 large T antigen gene (LT) contains two mutations: tsA58 point mutation renders the T antigen thermolabile and severely attenuated at the physiological temperature 37 degrees C but wild-type at 33.5 degrees C, while the U19 double mutation ablates binding to SV40-origin DNA sequences present in the vector, and thus prevents autonomous viral replication. The hTERT and LT viruses encode resistance to hygromycin B and G418 respectively, and thus infected cells can be selected on the basis of resistance to these antibiotics.

**Evaluation of foreseeable effects**

The overall level of risk is low - the viruses are infectious to humans and human cells in vitro, but no competent virus would be produced in the event of infection since the recombinant virus is replication defective. Work at containment level 2 will be sufficient to prevent infection. All procedures involving use of virus will be performed in a designated class 2 containment hood within a secure exclusively designated laboratory containing its own equipment. In normal individuals, the LT virus would be recognised as foreign on inoculation, would be readily complement-inactivated, and therefore would not be allowed to integrate into the genome and produce the LT product. However, the hTERT virus is not inactivated by complement. Therefore, neither metal sharps nor glassware will be used in working with these viruses, to minimise the risk of inoculation into the bloodstream. The highest (although still low) risk associated with this type of virus is probably insertional mutagenesis and the subsequent activation or inactivation of host genes proximal to the insert that regulate cell growth in a positive or negative manner. Provided that human cells transduced with such virus are free of helper activity and are tested for the absence of replication-competent genetically modified virus, they pose no/low risk.

Transduced cells will be maintained under containment level 2 conditions and segregated from untransduced cells. Absence of active virus in transduced cells will be confirmed prior to use and at intervals of 3 months during continuous culture.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

All Class 2 activities will be performed using full containment level 2.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All plasticware contaminated with GMMs will be decontaminated by soaking in 1% Virkon for at least 24 hours, drained and transferred to a segregated autoclave bag. Virkon has been demonstrated to be an effective virucidal agent against related retroviruses showing the same protein, sugar and membrane lipid content as MLV, as dilutions ranging from 1/100 to 1/1400. However, the efficiency of Virkon action can be decreased by the presence of organic matter (ACGM Compendium of Guidance 2000, Part 3A, Annex III). Therefore, all detergents will be made fresh daily, their correct preparation being ensured by the strict following of standard operating procedures adhering to the manufacturer's guidelines. Additionally, a record of the preparation of all disinfectant solutions will be kept. All paper, gloves etc. will be collected in a segregated autoclave bag. Once each bag is full, or 2-weekly if this time is shorter, the bag will be removed by autoclaving at 121 degrees C for 20 min (100% kill) in the discard validated autoclave within the Xcellsyz Ltd facility. Autoclaving at 121 degrees C for 20 min has been found to inactivate all organisms encountered.

Date Ackn'd: 14/04/2003

CU2 Project Title

IMMORTALISATION OF AVIAN CELLS BY RETROVIRAL TRANSFER OF THE TELOMERE MODIFYING GENES TELOMERE REVERSE TRANSCRIPTASE (TERT) AND A TELOMERASE RNA (TR)

Class 2

CultureVolClass2 < 1 litre

Non-GMM: not applicable

Consent Granted

Project notified under transitional arrangements N

Tick if notifying a connected programme of work N

Project Additional Information
Purposes of the contained use

Telomeres are necessary for chromosome stabilisation and their maintenance determines the mortality of a cell. The aim of this work is to manipulate telomere size and maintenance in avian cells in vitro by constitutive expression of the TERT and TR genes. We will examine the effects of the transfected genes on telomere length, telomerase activity, cell growth and cell immortality. We will use the Pantrophic Retroviral Expression System (BD Biosciences, Clontech), which provides a highly efficient gene delivery system.

Recipient or parental organism

1. Avian primary cell lines. These cell lines are primary cell lines established from embryonic tissues. They are non-self lines, which cannot colonise humans and therefore pose no hazards to human health.

2. Packaging cell lines GP2-293 and GP2-293Luc. Both lines are human embryonic kidney (HEK 293) based cell lines. These human cell lines are established non-self lines, which cannot colonise humans and therefore pose no hazards to human health.

The GP-293Luc packaging cell line is a cell line that has been modified to encode luciferase activyr. This cell line functions as an experimental control to verify that the viral transfection system is functioning properly and that the avian cells can be infected.

Host/vector system

1. The avian cell lines are primary cell lines established from avian embryonic tissues.

2. The packaging cell lines, GP2-293 and GP2-293Luc, employed during these procedures are commercial cell lines and purchased from BD Biosciences, Clontech.

3. The viral vectors pLXRN, pLNHX, pLPCX and pVSV-G are commercial vectors purchased from BD Biosciences, Clontech. The viral vectors are propagated in the disabled Escherichia coli host DH5a, using ampicillin selection. The copy number is low.

Origin & function

Origin: The pLXRN, pLNHX and pLPCX viral vectors contain elements from Moloney murine leukaemia virus (MoMuLV) and Moloney murine sarcoma virus (MoMuSV). These viral vectors are disabled in that they lack the genes env, gag and pol necessary for viral particle formation and replication. It is unlikely that introduction of the TERT or TR genes into these vectors will decrease their stability. Plasmid VSV-G encodes the G envelope glycoprotein of the vesicular stomatitis virus and lacks the genes gag and pol.

The hTERT cDNA was a gift of the Geron Corporation, USA; the avian TR cDNA sequence was a gift of JL Chen, John Hopkins University, Baltimore (Chen JL et al 2000 Cell 100 503-514); the avian TERT cDNA is being cloned in the laboratory from an avian cDNA library.

Intended Function: Immortalisation of avian cells by retroviral transfer of the telomere modifying genes TR and TERT.

Evaluation of foreseeable effects

The Pantrophic packaging cell line (GP2-293 produces virus that can infect both mammalian and non-mammalian cells (Burns et al 1993, PNAS 90 8033-8037). This is due to the fact that virions are pseudotyped with the envelope glycoprotein from the VSV-G virus. VSV-G mediates viral entry through lipid binding and plasma membrane fusion (Emi et al 1991 J Virol 65 1202-1207). It is therefore possible that non-replicating virus could infect the target cells of organisms other than humans, transmit the TERT and TR genes and cause a biological effect.

The health risks associated with the inserted genes are low. This is because:
(i) the virus cannot replicate in cells that lack the viral structural genes gag and pol, necessary for viral particle formation and replication. Thus virus would be confined to the original infected cell;
(ii) the TERT or TR genes do not induce a transformed phenotype and do not render cells tumorigenic (Morales et al 1999 Nat Gen 21 115-118; Franco et al 2001 Exp Cell

Nonetheless it is possible that if the transfected cells are already pre-disposed to tumour formation eg by a separate oncogenic sequence, then a tumour may result. However, pathogenicity is extremely unlikely as the virus cannot replicate in target cells that lack the viral structural genes.

The virions produced by co-transfection of GP-293 with recombinant vector and pVSV-G can infect and transmit the TERT and TR genes to the avian (target) cells. However, the virions cannot replicate because the avian cells lack the viral genes.

The probability of the virus reverting to wild type is low because the viral gag and pol genes are supplied only from the genome of the packaging cell line GP-293, and the viral envelope protein env, is expressed by a separate vector pVSV-G. Thus at least two independent recombination events are necessary for reversion to wild type. The chance of producing replication-competent virus is also reduced by the use of minimal viral sequences.

We will however test for the presence of replication-competent virus by a) using indicator cell lines for plaque estimation and b) monitoring the supernatant of the cultures infected with the recombinant retroviral particles for reverse transcriptase activity. In the unlikely event of replication competent virus being detected, the stock will be inactivated by autoclaving as described in Section 12.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Control measures to protect human health and the environment:
All work will be done under full containment level 2 facilities.
Production of virus particles and viral infection of host cells is performed at small scale (<10 (to the power of 7) cells) under sterile conditions in closed plastic tissue culture vessels. All cell culture work will be done in a Class ii safety cabinet with HEPA microfilter. Needles will not be used during the procedures and protective clothing (laboratory coats and gloves) will be worn at all times.

Contaminated material:
All material that is possibly contaminated with virus will be collected in closed vessels for transfer to the autoclave and will be inactivated by autoclaving at 121 degrees C for 20 min. This will result in 100% kill. All autoclave runs will be monitored using TST (Time, Steam and Temperature) test strips (Albert Browne Ltd., TST class 6 emulating indicator 121 degrees C for 20 min) meeting international standard ISO11140 part 2. The autoclave is tested on an annual basis using an independent thermocouple mapping employing a representative typical load.
In the event of spillage of possibly virus-contaminated material the area will be disinfected using 1% Virkon. All paper material used in the clean-up will be autoclaved as above.

Streptococci of the "viridans group" are normal commensal organisms found in the mouths of humans and other mammals. S. mutans and S. sobrinus are known to be associated with dental caries in humans and this project is concerned with investigations of features of these organisms that may contribute to disease, with the aim of developing novel preventive or therapeutic approaches. The pathogenesis of dental caries relates to the ability of the organisms to colonise dental plaque and, when present in sufficient numbers and exposed to a carbohydrate source, to damage tooth enamel by reducing the local pH. The project is thus principally concerned with
structural and regulatory genes for enzymes and proteins associated with the adhesion of streptococci, metabolism of carbohydrates and formation of sucrose-derived polymers.

Recipient or parental organism

“Viridans streptococci” are generally considered of low pathogenic potential and normally exist in the mouth and naso-pharynx as commensals. They do not normally multiply or survive outside the body. They are occasional opportunistic pathogens and have been associated with cases of infective endocarditis but are regarded as being of low pathogenic potential. Available information indicates that infections in otherwise healthy individuals are readily treatable with antibiotics, with penicillins being the antibiotics of first choice. The project will be focused on the mutans group of streptococci that are associated with dental caries, specifically S. mutans, S. sobrinus and S. downei. It is believed that the pathogenesis of this disease is due to the ability of these organisms to form organic acids at low pH. A number of surface proteins and extracellular enzymes are known to polymerise glucose and fructose using sucrose as the substrate (GTFs and FTFs) have been linked with the potential of S. mutans and S. sobrinus to cause caries in experimental animals. The mutans streptococci are not known to produce any toxins. Some experiments will be performed with other oral streptococci for purposes of comparison. In particular, S. gordonii strain Challis, which has been used extensively for genetic manipulation in other laboratories. It is also anticipated that certain experiments will involve expression in Lactococcus lactis, an organism that is not considered a human pathogen and is approved as Generally Regarded as Safe (GRAS) for use in the food industry. All streptococci are placed in ACDP Hazard Group 2.

Host/vector system

Insertional inactivation experiments in oral streptococci will utilise either linear PCR amplicons incapable of replication or plasmids incapable of replication in streptococci. Insertional inactivation and cloning experiments will utilise markers for resistance to antibiotics that are not of clinical importance for treatment of infections caused by the bacteria. Specifically, resistance to penicillin will not be introduced to streptococci. Vectors used for complementation experiments will be those based on naturally-occurring streptococcal replicons.

Origin & function

The project is principally concerned with structural and regulatory genes for enzymes and proteins associated with the adhesion of streptococci, metabolism of carbohydrates and formation of sucrose-derived polymers.

Experiments will be undertaken to inactivate genes of species of oral streptococci by insertional inactivation or gene replacement and to transfer DNA between bacteria for expression of complementation of inactivated genes.

Evaluation of foreseeable effects

Natural isolates of oral streptococci shown considerable variation in properties such as acidogenicity and production of extracellular enzymes. It is difficult to envisage how the inactivation of specific genes or alterations in their regulation could enhance the ability of the host strains to colonise humans or otherwise cause disease. Furthermore, the risk of infection with the host bacteria is low. Therefore the level of risk is identified as low.

**Purposes of the contained use**

Candida albicans is a human pathogen in ACDP Hazard Group 2. C. albicans causes superficial infections of mucosal epithelia (thrush) (Odds [1988] Candida and Candidosis, Balliere Tindall). C. albicans can also cause systemic infections which can be fatal, but these only occur in severely immunocompromised patients. To keep things in perspective, it is important to realise that C. albicans is carried commensally in 50% of the healthy population and most Candida infections arise as an overgrowth of the strains resident in the normal microflora of the gut and vaginal tract. It is a micro-organism of low pathogenic potential that rarely affects healthy individuals. It only becomes a potential medical problem when the immune system of an individual is significantly impaired. Furthermore, as with most pathogenic micro-organisms, the virulence of C. albicans strains is likely to become attenuated rather than enhanced after prolonged laboratory culture. The organism does not form spores, therefore there is no transmission by air-currents. C. glabrata is closely related to C. albicans, and generates similar types of infections in humans, but undergoes the yeast-hypha morphogenesis less efficiently, and is considered to be less virulent than C. albicans. Furthermore, genetically disabled C. glabrata strains will be used in these experiments, and it will be entirely appropriate to use similar precautions to those used for our C. albicans experiments.

The C. albicans strains CA14 (ura3) and RM1000 (his1, ura3) are the standard host for DNA transformation world-wide. These auxotrophies makes C. albicans avirulent (Leberer et al. [1996] PNAS, 93, 13217). Transformation with URA3 plasmids partially restores the virulence of CA14, but this restoration is not complete because the genes neighbouring URA3 remain inactivated. This is enough to partially (but not completely) attenuate virulence. The ura3 marker is recycled for subsequent rounds of transformation (Fonzi, & Irwin (1993) Genetics, 134, 717). Therefore by necessity, some of the transformants we will create are not genetically disabled, although their virulence is slightly lower than the wild type strains of C.albicans carried by most individuals. C.albicans strain CA18 (ura3, ade2) will also be used in some experiments. CA18 is transformed with ADE2 or URA3 containing plasmids, leaving one remaining disabling mutation in the transformants. This is sufficient to render all of the transformants completely avirulent.

Pathogenicity in C. albicans and C.albicans and C.glabrata is a polygenic trait involving numerous physiological characteristics (e.g. rapid growth, cell wall, morphogenesis, secreted hydrolases, phenotypic switching). Therefore, (i) no single Candida gene (or combination of genes) will turn E.coli, S.cerevisiae or S. pombe into a pathogen, (ii) a reduction in any one of these parameters can attenuate C.albicans or C.glabrata virulence, and (iii) an increase in any one of these parameters is very unlikely to increase C.albicans/C.glabrata virulence. Furthermore, C.albicans strains that have been cultured in the laboratory tend to display reduced pathogenicity compared to strains carried commensally by most individuals.

The likelihood of natural gene transfer to other species is essentially zero. The plasmids that will be used are not mobilisable and the GMMs are highly unlikely to come into contact with other micro-organisms under the experimental conditions to be used. Furthermore, despite the recent discovery of sex in C.albicans strains mate very inefficiently in vivo (Hull et al., (2000) Science 289, 307-310), probably because the specific growth forms that mate most efficiently aren't maintained at 37 degrees (Miller & Johnson (2002) Cell 110, 293-302). In addition, C.albicans must be homozygous at the mating type locus for them to be competent for mating, and the vast majority of clinical isolates are heterozygous at the mating type locus.

E.coli, S.cerevisiae and S.pombe. Only disabled E.coli strains (E.coli K12-Compendium of Guidance 2000, Part A, Annex ii; BL21-ACGM Newsletter 30, Nov 201) and especially disabled S.cerevisiae and S.pombe strains which are unable to colonise humans and are non-pathogenic will be used. In addition, pathogenicity in C.albicans and C.glabrata is a polygenic trait involving numerous physiological characteristics (e.g. rapid growth, cell wall, morphogenesis, secreted hydrolases, phenotypic switching). Therefore, no single Candida gene (or combination of genes) will turn E.coli, s.cerevisiae or S.pombe into a pathogen.

Vector system
1. Non-mobilisable or mobilisable defective E.coli vectors (including pBR322, pUC18/19, pBluescript, pGEMT, pGEX; lac-based expression plasmids such as pET vectors (Compendium of Guidance 200, Part A, Annex II).
2. Non-mobilisable S.cerevisiae vectors (including multicopy 2um vectors; single copy Ycp replicating vectors; single copy integrating Yip vectors; single copy GAL-based expression vectors).
3. Non-mobilisable S.pombe vectors (low copy replicating and integrating vectors (Rep/Rip).
4. Non-mobilisable C.albicans vectors (low copy replicating and integrating vectors (YPB1, Cip and Clp20); low copy replicating and integrating vectors for ectopic expression (YPB-ADHpt, pACT1); integrating expression vectors regulated by methionine (pEXPa is a MET3 vector), or maltose (pMRP is a MAL2 vector). These vectors are routinely used in by methionine (pEXPa is a MET3 vector), or maltose (pMRP is a MAL2 vector). These vectors are routinely used in many Candida laboratories.

Origin & function
The genetic material involved in this project is of yeast (C.albicans and C.glabrata) origin. In most cases we will simply express specific native yeast genes or mutant versions, cloned from genomic sequences, or express native or mutant yeast genes where the genes have been fused with standards tags (eg. MYC, 6 histidine residues, HA, FLAG, GFP, YFP). Candida genes involved in stress responses will also be deleted or disrupted to assess their role in stress responses. In addition, well characterised reporter genes will be fused to yeast promoters to allow studies of expression in yeast. In some cases we will use #Candida genomic and cDNA libraries. Candida genes will also be expressed in the yeasts S.pombe and S.cerevisiae to adress whether any of the proteins involved in stess responses are conserved. Candida genes involved in the project include
1. Stress-signalling genes (e.g. HOG1)
2. Transcription factor genes (e.g. SK01)
3. Auxotrophic markers (e.g. URA3, ADE2, LYS2)
4. Regulated promoters (e.g. MET3, MAL1, MAL2) and "constitutive" promoters (e.g. ACT1, ADH1),
5. Reporter genes (e.g. yEGFP, Renilla luciferase, StLacZ, SaLexA)
6. Candida genomic and cDNA libraries.

Evaluation of foreseeable effects
As described above pathogenicity in C.albicans and C.glabrata is a polygenic trait involving numerous physiological characteristics (e.g. rapid growth, cell wall, morphogenesis, secreted hydrolasis, phenotypic switching). Therefore, (i) no single Candida gene (or combination of genes) will turn E.coli, S.cerevisiae or S.pombe into a pathogen, (ii) a reduction in any one of these parameters can attenuate C.albicans or C.glabrata virulence, and (iii) and increase in any one of these parameters is very unlikely to increase C.albicans/C.glabrata virulence. Furthermore, C.albicans strains that have been cultured in the laboratory tend to display reduced pathogenicity compared to strains carried commensally by most individuals.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GMM contaminated waste will be inactivated and disposed of as follows:
Liquid waste: Presept tablets (1 tablet per 500ml)
Solid waste: autoclaved
Glassware: Soaked with Presept tablets (1 tablet per 500 ml) or autoclaved
Standard procedures for use of Presept have been established in the laboratory.
Plasticware; autoclaved
Sharps: Contaminated sharps are placed in CinBins, bagged and incinerated.
Validation and Monitoring of Inactivation

The use of Presept has been validated experimentally in many major Candida laboratories to kill >99.99% of cells. We will validate this procedure in our laboratory by performing viability tests on killed cultures. We will monitor this procedure monthly by repeating viability tests on killed cultures. We will also re-validate the procedure should the conditions of use change, for example if the volumes to be inactivated increase, larger amounts of protein material are involved, or if we need to switch to a different chemical.

Upon autoclaving GMM waste samples are subjected to autoclaving at 134 degrees C for 30 min (100% kill). This procedure has been validated to completely inactivate all organisms encountered. We will again validate this procedure for Candida as above. The autoclaves are validated by annual thermocouple mapping and each run is to be monitored by continuous chart recording of the temperature/time profile.

Once GMMs have been inactivated, normal routes of disposal are used for liquid and solid waste. Killed liquid waste is discarded down the sink. Inactivated solid waste is discarded by CFA processing.

If spillage were to occur the contaminated area will be flooded with Virkon (peroxyenic acid) (freshly diluted 1 in 50), mopped up with paper towels, and reswabbed with Virkon (freshly diluted 1 in 50). Killing at >99.99% has been validated experimentally. Contaminated material is autoclaved. In addition Virkon will be used for routine cleaning of bench tops and laboratory equipment. Virkon is preferred to Presept for swabbing benches, because it is less nasally invasive.

Project Ref 540/04.2
The purpose of this project is to provide a system for the high-level expression (mg quantities from a litre) of proteins from Listeria species for protein structure and function studies. As part of this project recombinant plasmids containing the Listeria genes of interest will be supplied by collaborating laboratories. These genes will then be sub-cloned, where necessary, into more vectors that support high-level protein expression, and introduced into suitable E. coli hosts. Proteins will be expressed in these hosts for the purpose of in vitro protein structure and function studies only. No live wild-type Listeria strains will be used or stored. In order to characterise the relevant protein's sturcture and function some PCR-induced site-directed mutagenesis may also be undertaken as part of this project.

Listeria have been classified as ACDP hazard group 2 organisms. They are, however, very commonly encountered pathogens in nature that very rarely, if ever, cause disease in normal health adults, implying low levels of virulence compared to many other group 2 organisms. However, they are capable of causing serious infections in individuals with certain predisposing conditions (very young or very elderly, immunocompromised individuals, and pregnant women), and therefore caution is warranted in dealing with any potentially pathogenic factor from these organisms.

The recipient organisms for this study are E. coli strains K12 and its derivatives and BL21 and its derivatives. Use of these organisms is discussed in the Host/Vector system section that follows this.

The parental organisms for this study are the pathogenic species of the Listeria genus, Listeria monocytogenes and Listeria ivanovii. As mentioned previously, at no time in this project will wild-type strains of Listeria be handled or stored. All genetic material from Listeria will be cloned into non-mobilisable or mobilisation-deficient plasmids by collaborating laboratories prior to entry into the laboratory.

E. coli strains K12 and its derivatives and BL21 and its derivatives only will be used as hosts during this project. All cloning and plasmid amplification will be done using E. coli K12-derivative hosts. These hosts are classed as disabled, non-pathogenic, and have minimal colonisation potential. For protein expression both K12-derivative hosts and BL21-derivative hosts may be used. BL21-derivatives can be broadly considered equivalent to disabled K12-strain. However, special consideration is required in the case of cloning bacterial pathogenicity determinants into BL21, as is described in this notification. More detail is given below (foreseeable effects).
Only vectors that are non-mobilisable or mobilisation-defective in bacteria will be used. For cloning this includes pGEM-T (Promega), and for expression this includes vectors of the pET (Novagen) and pGEX (Amersham) series. Given that gene products to be studied in this project are potentially biologically active, only plasmids that specifically support expression of protein to an intracellular location will be used. Vectors that specifically support secretion of gene products from the host organism will be excluded from this study.

**Origin & function**

Cloned sequences will initially be derived from Listeria genomic DNA, by PCR. This work will be conducted in collaborating laboratories. All DNA sequences to be handled in this project will already be cloned into non-mobilisable or mobilisation defective plasmids and maybe transformed into a K12-derivative or BL21-derivative bacterial strains. Specific modifications and intended functions will vary depending on the particular experiment, but at all times they will be restricted to facilitating standard, routine, well established molecular biology procedures with the intent of expressing recombinant proteins for biochemical and biophysical structure and function studies.

**Evaluation of foreseeable effects**

1. **Risk to Human Health**
   The use of only K12-derivative and BL21-derivative hosts, which have limited ability to survive outside the laboratory environment, combined with non-mobilisable or mobilisation-deficient plasmids that are in common use limits the risks to human health from the host/vector system. However, some of the gene products to be studied have specific roles in the pathogenic/virulence mechanisms of Listeria species. Whilst it is difficult to envisage how any of the gene products could enhance mammalian cell invasion by the disabled E. coli strains to be used as hosts in this study, the possibility that some of the gene products may pose a hazard when expressed at high levels cannot be excluded. Of particular concern are proteins that may be secreted during expression in E. coli. To minimise the likelihood of any such hazard, sequences encoding recognisable secretion signals will be removed from Listeria genes sub-cloned into expression vectors. This will avoid active secretion and minimise release of product from disabled E. coli hosts.

2. **Environmental Harm**
   The details of the host/vector system in reference to human health implications also applies here. In the very unlikely event of GMM escape, the use of only K12-derivative and BL21-derivative hosts, which have limited ability to survive outside the laboratory, combined with non-mobilisable or mobilisation-deficient plasmids that are in common use, limits any possible environmental impact. As also noted above, some of the gene products to be expressed might have detrimental effects if they are delivered in sufficient quantities to mammal cells/tissues or other eukaryotic cells, but the biological containment measures noted will minimise the likelihood of any hazard arising and therefore the previsionally assigned containment level 2 will be sufficient to contain the risk.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All work will be conducted in accordance with the requirements for containment level 2, as described in the Compendium of Guidance 2000, Part 3A Section 1.

All contaminated waste, disposable plastics, laboratory glassware, or other contaminated materials, including waste destined for incineration, will be autoclaved at 121 degrees C for at least 30 min to inactivate GMMs (100% kill) prior to disposal or cleaning and recycling. Autoclaves, available within the building the work is taking place, will be validated by annual thermocouple mapping and each run will be monitored by continuous recording of the temperature/time profile.

Project Additional Information
Purposes of the contained use

The objectives of the project are to understand the pathogenic mechanisms of members of the family of attaching and effacing pathogens involving closely related species that infected humans - enteropathogenic E. coli (EPEC) and enterohaemorrhagic E. coli (EHEC; but see below), rabbits (REPEC), pigs (PEPEC), dogs (DEPEC) and mice (Citrobacter rodentium) which for convenience are hence forth described collectively 'A/E bacteria'. Please note that the description 'A/E bacteria' as used here specifically excludes verotoxigenic E. coli strains. Genetically attenuated derivatives of EHEC strains where the Shiga-like (Vero) toxin genes have been deleted will be used in some experiments, but wild-type EHEC or other verotoxigenic strains will not be used.

Recipient or parental organism

(i) Disabled E. coli K12 strains as defined by the Compendium of Guidance (Part 2, Annex II Para 11): these are non-colonising and cannot survive for long outside the laboratory. They can be considered as equivalent to ACDP Hazard group 1. It is difficult to envisage how any of the cloned genes could increase the virulence of these strains. Therefore no additional hazards have been identified beyond those associated with the cloned gene products themselves.

(ii) E. coli BL21 and derivatives: Stemming from a HSE-commissioned study, ACGM Newsletter 30 (Nov. 2001) states (in para 3) that "BL21 can be considered broadly equivalent to K12 strains and that in most cases work which uses this host can be considered as a class 1 activity……, but the cloning of a bacterial pathogenicity determinant into BL21 will need careful consideration and my in some cases warrant classification as class 2". Since this project involves cloning genes from ACDP Hazard group 2 pathogens, their expression in BL21 will require CL2. Use of expression vectors dependant on the T7 RNA polymerase will greatly minimise the likelihood of expression in the very unlikely event of transfer to other hosts.

(iii) The 'A/E bacterial' hosts that will be used are either non pathogenic for humans or ACDP Hazard group 2 pathogens. Since only genes from very closely strains of the same species, or the very closely related ACDP Hazard Group 1 species C. rodentium, will be introduced into these hosts. Therefore, no additional risks above and beyond those involved in handling ACDP Hazard group 2 pathogens have been identified.

(iv) Yeast hosts: Only non-pathogenic yeast species as defined by the Compendium of Guidance (Part 2, Annex II, para 7) will be used. It is diffic ult to envisage how any of the cloned genes could, in isolation, confer these species with pathogenic traits. Therefore no additional hazards have been identified beyond those associated with the cloned gene products themselves.

(v) Mammalian hosts: Cultured mammalian cells are highly unstable and are rapidly inactivated in the absence of controlled laboratory conditions and the transfected genes will not alter this susceptibility. Therefore no additional hazards have been identified beyond those associated with the cloned gene products themselves.

(vi) Other GMOs: Genetically attenuated strains of Shigella flexneri, Yersinia pseudotuberculosis, Y. enterocolitica and Salmonella typhimurium will be used in some experiments, but not as hosts for cloned EPEC genes. The hazards associated with handling these strains are no greater (indeed significantly less) than those associated with handling the wild-type parent strains, which are ACDP hazard group 2 pathogens.

Host/vector system

Various hosts will be used, as described in section 7 above. Most of the vectors to be used are standard vectors with a long history of safe use in the laboratory. These include non-mobilisable or mobilisation-defective E. coli vectors such as pSK (bluescript), pACYC184, pLG339, pBR332 and derivatives including, for example, the pET expression vector series. The non-mobilisable yeast vector pREP-1 and standard nonmobilisable or mobilisation defective mammalian expression vectors such as pcDNA-3. Drug resistance markers used in these vectors are already widely distributed in nature. Moreover, the use of nonmobilisable or mobilisation defective vectors minimised likelihood of transfer to other species.

Some experiments will employ the non-self transmissible but mobilisable 'suicide' vectors pCVD442, pKNG101, and pTnMod-RCm. These vectors will be maintained only
in disabled E. coli K12 hosts containing a chromosomally-inserted Lambda gene, which is required for replication of these plasmids. These suicide vectors are used to construct mutants in 'target' strains to which they are mobilised by transfer functions encoded by chromosomally-inserted genes in the donor, disabled, E. coli K12 host. Thus, in the very unlikely event of unintended mobilisation to a different strain or species these vectors would be incapable of replicating in most cases. In the even more unlikely event of unintended mobilisation to another E. coli strain already carrying a Lambda phage actively expressing the gene that permits plasmid replication, it is difficult to envisage any detrimental effects arising from expression of the cloned genes in isolation from other 'A/E bacterial' genes. Moreover, horizontal transfer of genes between different E. coli strains already occurs in nature.

### Origin & function

| (i) | Cloning, expressing, and manipulating 'A/E bacterial' genes in disabled E. coli K12 strains. |
| (ii) | Expressing defined 'A/E bacterial' genes in E. coli BL21 or BL21-derived strains, from standard vectors where the cloned gene is expressed from a phage T7 promoter only upon IPTG induction of a chromosomally inserted T7 RNA polymerase gene. |
| (iii) | Expressing defined 'A/E bacterial' genes in the non-pathogenic yeast hosts Saccharomyces cerevisiae or Schizosaccharomyces pombe. |
| (iv) | Use of standard transposon (Tn) mutagenesis procedures to construct Tn mutant libraries of 'A/E bacterial' strains and screening these to identify potentially novel factors involved in interactions with mammalian cells (see below). |
| (v) | Use of suicide plasmid vectors to construct genetically defined mutants of 'A/E bacterial' strains by either gene inactivation or allelic replacement. |
| (vi) | Complementation of defined mutants of the 'A/E bacterial' strains by reintroducing the corresponding wild-type gene on mobilisation-defective vectors. Some experiments may express defined genes in the wild-type 'A/E bacterial' strains, to examined multicopy effects. |
| (vii) | To explore potential strain-specificities of particular interactions, complementation of mutant strains may include corresponding genes from the various 'A/E bacterial' strains, as well as hybrid genes encoding proteins with domains from different 'A/E bacterial' strains. |
| (viii) | Examining the effects of mutant strains and purified gene products on standard cultured mammalian cells, such as HeLa, CaCo-2, T84, HEK293, and J774 cells. Mutant mammalian cells with defined defects in particular pathways will be used in some experiments. |
| (ix) | Transfecting mammalian cells with defined plasmids transiently expressing defined EPEC or mammalian proteins, or defined mutants of these. |
| (x) | For comparative purposes only, some experiments may examine the effects of the ACDP Hazard group 2 pathogens Shigella flexneri, Yersinia pseudotuberculosis, Y. enterocolitica and Salmonella typhimurium SL1344 in mammalian cells. These experiments will employ mutant strains that were attenuated by Drs P Sansonetti (Pasteur Inst, France), H. Wolf-Watz (Umea, Sweden), G. Cornelis (Brussels, Belgium) and B. Finlay (Vancouver, Canada), using genetic manipulation to inactivate key virulence genes. Consequently, these GMOs are also included in this risk assessment. |

### Evaluation of foreseeable effects

1. **Risk of human health**
   Most of the GMMs will be incapable of causing harm to animals, either because they will be unable to survive outside the laboratory and/or are non-pathogenic for animals. However some of the GMMs constructed in 'A/E bacterial' hosts may be capable of inducing A.E lesions and diarrhoea in humans. The 'A/E bacterial' hosts that will be used are either non pathogenic for humans or ACDP Hazard group 2 pathogens. Moreover, giventh requirement for the concerted action of many different 'A/E bacterial' genes products in disease (Deng et al., 2004 PNAS 101:3579) it is difficult to envisage how any of the cloned genes could significantly increase the virulence of the GMMs above that associated with wild-type human-specific strains, which are highly prevalent in nature. Therefore, the hazards associated with these GMOs will be the same as those associated with corresponding wild-type 'A/E bacteria' strains.

2. **Environmental Harm**
   GMMs constructed in disabled E. coli K12 strains, E. coli BL21-derived strains (which can be considered broadly equivalent to K12 strains) and mammalian cell hosts are very unlikely to survive for long outside the laboratory and will be unable to establish, disseminate and/or replace other organisms to any significant extent. In cases where large quantities of a particular gene product will be expressed to facilitate protein purification, the likelihood of unusually large quantities being delivered to a target tissue will be minimised by the pET expression vector system that will be used (ie expression from a phage T7 promoter in non-colonising BL-21 derived hosts that require the addition of IPTG to induce the chromosomally-inserted T7 RNA pol gene required for high level expression of the cloned gene product). GMMs constructed in non-pathogenic yeast hosts or in 'A/E bacterial' hosts could survive in the unlikely event of escape from the laboratory. However, it is difficult to envisage how any of the cloned gene products could increase the virulence of these hosts, or confer novel virulence traits, and it is equally difficult to envisage how any of the cloned gene products could increase the fitness of these hosts and their abilities to compete with or displace other organisms. While some of the gene products to be expressed might have...
detrimental effects if they are delivered in sufficient quantities to mammalian cells/tissues or other eukaryotic cells, but the biological containment measures noted will minimise the likelihood of any hazard arising and therefore the provisionally assigned containment level 2 will be sufficient to contain the risk.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
only the bacterial, yeast or mammalian cell lines described in section 7 will be used as hosts.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All work will be conducted in accordance with the requirements for containment level 1, as described in the Compendium of Guidance 2000, Part 3A Section 1.

All contaminated waste, disposable plastics, laboratory glassware, or other contaminated materials, including waste destined for incineration, will be autoclaved at 121 degrees C for at least 30 min to inactivate GMMs (100% kill) prior to disposal or cleaning and recycling. Autoclaves, available within the building the work is taking place, will be validated by annual thermocouple mapping and each run will be monitored by continuous recording of the temperature/time profile.

Is an emergency plan required according to regulation 20?  N

Project Additional Information

Purposes of the contained use

This project will involve the study of the regulation of protein secretion by regulatory factors during flagellar assembly in S. typhimurium. The project will involve the use DNA recombinant technologies to create targeted deletions, insertions and point mutations directly on the bacterial chromosome.

Recipient or parental organism

The organisms to be used in this study are Salmonella enterica a ACDP Hazard group 2 organism, Escherichia coli K12 strains which are equivalent to ACDP hazard group 1 and are in the ACGM ‘disabled’ hosts category. The majority of work to be performed will use wild-type strains of S. enterica serovar Typhimurium including LT2, SL1344 and 14028s. Although these strains were originally natural isolates, they have been maintained and passaged in the laboratory for many decades and are likely to have adapted to laboratory conditions. Moreover, LT2 is known to be an attenuated strain of S. typhimurium attributed to a mutation in the stationary phase sigma factor o (-5) (Wilmes-Riesenberg, Foster and Curtis (1997) Inf. And Imm. V 65 p 203-210). Nevertheless, LT2 is formally classified as an ACDP Hazard Group 2 organism along with SL1344 and 14028s. However, taking into consideration the high dose required for S. typhimurium to cause symptomatic infections, the hazard risks associated with the strains LT2, SL1344 and 14028s are considered to be low.

Host/vector system

Mobilisable suicide vectors derived from the R6K vector are dependent upon the RP4 mob functions encoded on the chromosome of E. coli strain SM10 pir, these vectors are unable to replicate in recipient cells which do not provide this essential protein, or be mobilised if the recipient cell is unable to provide the RP4 transfer functions. Examples of mobilisable vectors to be used in this study are derivatives of the vectors pACYC184, pSC101, pBR322, R6K. Other vectors to be used such as pUC19 and pET28 are non-mobilisable requiring manipulation to achieve transfer to other strains. Chromosomally located genetic markers will be mobilised using bacteriophage P22-mediated transduction. The bacteriophage P22 derivative HT105 int201 packs at a higher frequency than wild-type P22, chromosomal DNA allowing for the transfer of selectable genetic markers by transduction into other strain backgrounds. No hazard to human health has been identified in using any of these vector systems or P22 mediated transduction.

Origin & function

The work during this project will involve the genetic manipulation of genes of interest on the bacterial chromosome. The majority of genes to be worked with are to be found in S. typhimurium LT2. Introduction of the reporter genes such as lacZYA from E. coli and the lux operon from P. luminescens will be used to monitor gene expression.
The lacZYA genes will be introduced into S. typhimurium strains using the Mu derived transposons MudJ and MudK while the lux operon will be introduced using a transposon system derived from the transposon Tn5. Antibiotic markers to be used during this study are all widely used in microbiology laboratories world-wide and are all derived from naturally occurring sources. The recombinant in vitro generated sequences to be used are also found naturally in a number of prokaryotes and are routinely used in DNA recombinant technology to overexpress proteins to high levels. During this study these sequences will be used to "tag" proteins of interest on the bacterial chromosome and purify these proteins from S. typhimurium LT2 under normal expression conditions avoiding overexpression. These reporter genes, antibiotic markers and recombinant sequences are widely used and no role in pathogenicity of micro-organisms has been established, leading to the conclusion that there associated hazards are low.

Evaluation of foreseeable effects

The worst case scenario, in the event of a laboratory infection of Salmonella enterica serovar Typhimurium, strains SL1344 and 14028s, is a self-limiting gastroenteritis. The individual will have diarrhoea, vomiting and a slight fever for 3-5 days. However infection will only result with the ingestion of the bacteria in excess of 10 (to the power of 6) bacteria. Full recovery would be expected. Strain LT2 is known to be an attenuated strain of S. enterica serovar Typhimurium. Therefore infection is highly unlikely and if it was to occur an extremely high dose, greater than that required for strains SL1344 and 14028s, would be required for any symptoms to develop.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

02/03/2022
The aim of the project is to investigate trace metal ions homeostasis in the pathogenic fungus Cryptococcus neoformans. Trace metals are linked to capsule and melanin production, which are essential for the survival of this organism within humans. The sensing and acquisition of trace metals must therefore be a fundamental aspect of the ability of C. neoformans to cause infection. These studies will define metal homeostasis pathways in C. neoformans so that their role in the pathogens interaction with the host can be determined.

Cryptococcus neoformans (serotypes A and D) will be the recipient organisms that are classified as pathogens in ACDP hazard group 2. C. neoformans is a free living saprophytic yeast that has been isolated from a variety of environmental sources such as the soil, avian excreta and decaying wood. The life cycle of this fungus does not require human infection and is not a commensal organism. It can, however, cause serious disease in immuno-compromised individuals such as those with AIDS and patients receiving steroids or organ transplant therapies.
DNA sequences will be introduced into C. neoformans using the standard techniques of plasmid transformation or conjunct using the bacterium A. tumefaciens. C. neoformans cDNA will also be expressed in E.coli for protein purification purposes. All vectors are well characterised, widely used and contain standard antibiotic resistance markers. These include mobilisable defective C. neoformans vectors (pCnTel1, pM8), non-mobilisable S. cerevisiae vectors (pRS series) and non-mobilisable or mobilisable defective E.coli vectors (pBluescript, pUC and pET series).

Origin & function

Candidate genes within the C. neoformans genome will be mutated, tagged and/or deleted to determine the role of these genes in metal ion homeostasis. Genes will be tagged with various well characterised epitopes (eg. FLAG, GFP) to facilitate cellular localisation, detection via western blotting and isolation using immunoprecipitation techniques. The deletion of C. neoformans genes and the introduction of epitope coding sequences will involve the introduction of widely used dominant antibiotic resistance markers such as the nourseothricin and neomycin resistance cassettes. Mutated C. neoformans genes will be generated by amplifying and ligating the relevant sequences into E.coli vectors so that they can be modified before being reintroduced into the C. neoformans genome. Tagged and mutated genes will usually be expressed from their native promoters and occasionally from a constitutive promoter (eg. ADH promoter). Tagged and mutated C. neoformans genes will usually be integrated into the C. neoformans genome but will sometimes be expressed from a self-replicating plasmid. Reporter genes (such as lacZ) will also be introduced into the C. neoformans genome to analyse metal dependent gene regulation. In some cases, the ability of the C. neoformans genes to complement homologous genes in the yeast S. cerevisiae will be tested by expressing those genes in S. cerevisiae using standard yeast expression vectors.

Evaluation of foreseeable effects

Human infection occurs by inhalation of aerosolised particles from environmental sources. In healthy individuals, the resulting pulmonary infection initiates an inflammatory response that eliminates the yeast. If the pulmonary infection cannot be contained, significant disease can occur with dissemination of the yeast throughout the body. Infection of the central nervous system results in meningoencephalitis that is fatal if not treated. The anti-fungal drugs, amphotericin B, flucytosine and fluconazole are recognised effective treatments for cryptococcosis. The only documented cases of human to human transmission have involved organ transplantation with infected tissues.

The genetic manipulation of C. neoformans will involve the disruption of individual genes and the integration of coding sequences that allow for the identification and visualisation of proteins. It is highly unlikely that these integration events will generate a variant with increased virulence. Gene disruptions are likely to have a negative influence on the trafficking of metal ions and therefore on those virulence factors that depend on metal enzymes. In addition, any imbalance of trace metal metabolism will likely result in a reduction in the fitness of C. neoformans. The majority of experiments will be carried out using genetically disabled strains that will be unable to survive for long periods outside the laboratory. In addition, as with many laboratory-cultured organisms, C. neoformans becomes attenuated for virulence by laboratory growth. In any event, the accidental release of a non-disabled strain from a laboratory would not be predicted to add to the level of C. neoformans that humans are exposed to from the environment.

This study will also use genetically disabled strains of the yeast S. cerevisiae and the bacteria E.coli and A. tumefaciens to express and amplify C. neoformans DNA. These are non-pathogenic organisms and are unable to colonise humans. The pathogenicity of C. neoformans is a ploygenic trait so that the expression of a single C. neoformans gene is not going to convert to S. cerevisiae or E.coli into pathogenic organisms. In addition, C. neoformans genes will only be expressed using mobilisation defective plasmids.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All work will be carried out at containment level 2. C. neoformans strains will be maintained as non-desiccated haploid yeast. Any procedures that may result in aerosols will be carried out using sealed containers or carried out in designated Class II safety cabinets.
All materials contaminated with GMM's, including liquid waste, solid waste, glassware, plastic ware and sharps in CinBins will be autoclaved. Autoclaved sharps in CinBins will then be incinerated. Autoclaving involves the GMM's contaminated waste being subjected to 121°C for 30 min, which kills 100% of the contaminating organisms. The autoclaves are validated by annual thermocouple mapping and each run is monitored by continuous chart recording of the temperature/time profile. Following sterilisation, normal routes of disposal are used for liquid and solid wastes. Liquid waste is discarded in the sink and solid waste by CFA processing.

Accidental spills of GMM's will be treated with Virkon (peroxycetic acid) (freshly diluted 1 in 50), wiped up and retreated with Virkon. Contaminated material will be autoclaved. Virkon will be used for routine cleaning of bench tops and laboratory equipment.

characterisation of the virus, virus infected cells and products.

We intend to study the assembly of the J6/JFH hepatitis C virus in cell culture, to investigate the interaction of virus and host cell lipoprotein synthesis and to assess the influence of lipid modulating agents on the infectious process.

Huh7.5 cells. This cell line was derived from the human hepatoma cell line Huh7 following transfection with an HCV replicon. A clone supporting high level replicon replication, Huh7.5, was selected. The replicon was cleared from the cells by interferon treatment (Blight, K.J., McKeating, J.A. and Rice, C.M. 2002, J Virol 76, 13001-14).

Recipient or parental organism

Recipient or parental organism

pFLHCV J6/JFH1 is a pUC19 vector bearing a DNA copy of the J6/JFH1 recombinant hepatitis C virus as an insert (Kato et al.,2003 Gastroenterology 125. 1808; Lindenbach et al., 2005 Science, 309, 623)

Host/vector system

The recombinant pFL J6/JFH1 was produced by Lindenbach et al (Science. 2005;309(5734):623-6). It is a pUC19 plasmid which contains as an insert a DNA copy of a full length copy of HCV hepatitis C virus (HCV) genome which is a hybrid containing the non-structural protein genes of the HCV JFH1 strain and the structural protein genes of HCV J6 inserted downstream of a T7 promoter. JFH1 is the only known HCV strain capable of producing infectious progeny virus in human cells in culture. J6 is capable of replication in Huh7.5 cells but does not produce infectious progeny virus.

Origin & function

The recombinant pFL J6/JFH1 was produced by Lindenbach et al (Science. 2005;309(5734):623-6). It is a pUC19 plasmid which contains as an insert a DNA copy of a full length copy of HCV hepatitis C virus (HCV) genome which is a hybrid containing the non-structural protein genes of the HCV JFH1 strain and the structural protein genes of HCV J6 inserted downstream of a T7 promoter. JFH1 is the only known HCV strain capable of producing infectious progeny virus in human cells in culture. J6 is capable of replication in Huh7.5 cells but does not produce infectious progeny virus.

The three plasmids are identical except that in pFL-J6/JFH(GND) a point mutation has been introduced changing amino acid 2476 from H to L. This is an “adaptive mutation” which increases colony formation when the plasmid is transfected into cells.

HCV has a single stranded positive sense RNA genome and the pFL J6/JFH1 DNA plasmid is not capable of generating infectious virus in the absence of a T7 polymerase, to transcribe an RNA copy, and a mechanism of cutting the transcribed RNA precisely at the 3’ end of the HCV genome. However an in vitro generated RNA copy of the cDNA insert, cut out of the plasmid with the endonuclease Xba-1 followed by mung bean nuclease to generate the correct 3’ end and transfected into Huh7.5 cells, has
been shown to replicate and the cells release infectious, recombinant HCV (Kato et al., 2003, Gastroenterology125, 1808). We intend, therefore, to generate RNA copies of the virus genome in this manner and transfect them into Huh7.5 cells in order to generate a replicating system in order to study virus assembly and interaction with the host lipoprotein export system.

Evaluation of foreseeable effects

An RNA copy of the hybrid virus genome has been shown to replicate well when transfected into Huh7.5 cells. Huh7.5 cells are the only cell type known to support the replication of this virus in culture. The recombinant virus has been inoculated into chimpanzees and SCID mice and produces infections which are similar to those produced by wild type virus strains (Lindenbach et al. PNAS. 2006 103, 3805-9). In these experiments the virus has exhibited neither attenuation nor enhanced virulence and consequently the risks are similar to those associated with the wild-type virus, which is an ACDP hazard group 3 organism. The pFL-J6/JFH (GND) and pFL-J6/JFH (H2476) products are each attenuated by point single mutations, which could revert to produce a wild-type phenotype. The risks associated with such reversions would be similar to those associated with the wild-type virus.

Hepatitis C virus is a blood borne pathogen and the risks of infection have been intensively studied and are well characterised. We have established and approved protocols for the handling of hepatitis C virus in containment level 3. The replication of this recombinant clone in cell cultures presents no additional risk. The maximum titres expected from published studies with J6/JFH1 ((Lindenbach et al. PNAS. 2006 103, 3805-9). are one thousand-fold lower than the wild type material we routinely handle (Nielsen et al., 2004, Journal of General Virology 85, 1497-1507).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The project (risk assessment section 2.1) requires the determination of the density of cell culture derived J6/JFH HCV by density gradient ultracentrifugation. The containment level 3 laboratory does not contain an ultracentrifuge and is not equipped with the necessary power supply to run one. An ultracentrifuge is available in the adjacent containment level 2 virology laboratory. We request a derogation to allow ultracentrifugation to be carried out in this machine. The machine will be restricted for HCV use for the duration of this project. A label indicating that the use of the machine is restricted for HCV work will be posted on the machine and staff using the laboratory, all of whom work under the jurisdiction of will be acquainted with the restriction.

Material to be centrifuged will be loaded into sealed plastic centrifuge tubes and loaded into a dedicated sealed rotor within the microbiological safety cabinet within the containment level 3 laboratory. The sealed rotor will be disinfected with 1% Virkon prior to removal from the cabinet. The disinfected ultracentrifuge rotor will be placed into a lidded metal box for transport to and from the ultracentrifuge and under no circumstances will the rotor be opened outside of the microbiological safety cabinet in the containment level 3 laboratory. After centrifugation the rotors will be washed in 1% Virkon and will be housed within the category three laboratory at all times. The centrifuge chamber will be swabbed with 1% Virkon after each use.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The waste generated will be contaminated plasticware, paper, gloves and other soft discard which will be accumulated in Cin Bins. When full the bins will be closed but not sealed and transferred into an en suite autoclave and killed off. On occasion, use will be made of small quantities of disinfectant (1% Virkon) for swabbing surfaces. In all such cases the paper towels used will then be autoclaved. Waste disinfectant and container will also be autoclaved.

All waste will be inactivated by en suite autoclaving (100% kill) prior to disposal by incineration. The autoclave will be validated by annual thermocouple mapping and each run will be monitored by continuous chart recording of the temperature/time profile and the records retained for inspection.

### Project Ref 540/07.2

**Date Ackn'd** 15/05/2007

**CU2 Project Title**

The Use of Herpes Virus Saimiri vectors to investigate the role of HF-kB transcription factor family in the pathogenesis of liver diseases in vitro and in vivo.

**Date Project Ceased** 26/02/2016

**Class**

- Class 2

**CultureVolClass2**

- < 1 Litre

**Consent Granted**

- Not Applicable

**Project notified under transitional arrangements**

- N
**Project Additional Information**

**Purposes of the contained use**

We intend to use the Herpes Virus Saimiri as a vector system to deliver protein components of a family of proteins called NF-κB to investigate the functions of these proteins in the development of inflammation driven chronic liver disease.

**Recipient or parental organism**

Disabled E. coli K12 will be used in cloning work to generate the necessary viruses. Viruses will be used on human, rat and mouse primary liver myofibroblasts as well as on the human cell lines LX2 and Cos. In addition, the viruses generated will be used on fibroblastic cell lines of mouse and human origin. In addition, the virus will be used to infect mice to study the effects on liver disease using in vivo models. Control C57/Black 6 strain male mice as well as various mice that have knockouts of the various NF-κB family members (supplied by Birmingham University and JAX lab, Maine, USA) will be used in these experiments.

**Host/vector system**

Herpes Saimiri virus strain A11-S4 – this infects squirrel monkeys persistently without causing disease. (Griffiths et al Current Gene Therapy, 2006, 6, 1-15)

**Origin & function**

NF-κB proteins come in 5 different forms; namely p65 (RelA), RelB, c-Rel, p50/p105 (NF-κB1) and p52/p100 (NF-κB2). These proteins bind in different combinations to gene promoters and regulate gene transcription. They are often bound in the cytoplasm by inhibitory proteins known as inhibitors of NF-κB or IκBs. There are seven IκB proteins namely IκBa, IκBβ, IκBγ, IκBε, Bcl-3 and the precursor proteins p100 and p105. NF-κB dimers are released from IκB proteins when the latter are phosphorylated by the actions of the Inhibitor of NF-κB Kinases (or IKKs). There are three IKKs namely IKKa (IKK1), IKKβ (IKK2) and NEMO (IKKy). For a general review of the NF-κB pathway please see Hayden and Ghosh 2004, Genes and Development, 18, 2195-2224.

The human cDNAs for the various NF-κB family members along with functionally inactive mutants (with inert tags such as FLAG, green fluorescent protein (GFP) or hemagglutinin (HA) epitope tag added for identification) will be inserted into Herpes Virus Saimiri using a Bacterial Artificial Chromosome (BAC) system. Examples of these will include but not be restricted to FLAG tagged p50 in addition to a mutated form of p50 (where residues 267, 269, 308, 310 are all mutated to alanine) that does not bind DNA in addition to GFP-tagged p65 and various mutated forms where serine residues have been mutated to alanine thereby restricting the ability of these proteins to activate gene transcription. These different forms of the proteins will enable us to dissect out subtle regulatory pathways that would otherwise be impossible to study.

The HA tag used consists of 9 amino acids of the much larger hemagglutinin protein (containing more than 550 amino acids) from the influenza virus. This epitope is highly unlikely to have the biological activity of the full length protein and is routinely used by researchers around the world for the purpose of identifying and tracking proteins. We, therefore, do not envisage that the addition of this epitope will alter the biological properties of the virus in any way and the risk assessment below will not, therefore, make any special reference to this.

**Evaluation of foreseeable effects**

The inserted genes will encode for the human forms of the various NF-κB family proteins and their inhibitors listed above. In addition, functionally inactive forms of the proteins will be used as controls. We do not expect these genes to fundamentally alter the biology of the attenuated virus strain A11-S4. It is difficult to be precise about the properties of the final genetically modified viruses that will be produced. However, what is known is that p50, for example, has both anti-inflammatory and pro-inflammatory properties (Bonizzi and Karin 2004, Trends in Immunol, 25, 280-288) and there is no evidence that it can act as a proto-oncogene (Karin 2006, Nature, 441, 431-436). We, therefore, cannot accurately predict the overall effects of an attenuated virus strain A11-S4 carrying the p50 protein. The attenuated virus strain A11-S4 carrying the mutated form of p50 should be inactive. On the other hand the attenuated virus strain A11-S4 carrying the p65 form of NF-κB may have the opposite effect and act to
promote the production of various inflammatory genes. However, the various mutants of p65 that we plan to use should have attenuated effects. It is impossible to predict in
detail what the biological properties of viruses carrying all the different members of the NF-κB family will be as the exact functions of many of the subunits and inhibitors in
different cell types has not been studied in detail. Indeed this is the aim of the current project in the context of liver fibrosis. In terms of the in vivo arm of the project, the
exact forseeable effects are again difficult to define in detail. Although NF-κB subunits are frequently increased in many cancers none of the NF-κB subunits are known to
be proto-oncogenes per se (Karin 2006, Nature, 441, 431-436). Over expression of the p50 subunit may lead to defects in the production of pro-inflammatory cytokines
such as TNF-α and this may lead to immunosuppression of the animal. On the other hand, over expression of the p65 subunit may have the opposite effect and lead to
increased inflammation. Ikβα over expression may lead to general inhibition of NF κB in the animal, which again may be anti-inflammatory. However, the effects in terms of
morbidity and mortality of the animals with each of the subunits and inhibitors and IKKs are impossible to predict. Of note mice infected with the virus expressing luciferase
in the Smith et al 2005 study were Nude mice that were naturally immunosuppressed. These mice were alive and well at 10 weeks when the study was terminated. We,
therefore, do not anticipate any major problems from the over expression of NF-κB family members or for that matter the mutated forms (which should be inert). However,
all animals infected with the virus will be carefully monitored for signs of toxicity and animals will be euthanized if there are significant

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Animals will be maintained in accordance with the Codes of Practice under the Animals (Scientific Procedures) Act 1986 which equate at least to containment A as

Mice will be maintained in closed cages in rooms with self-closing doors. Access to the facility is via two swipe card and key pad controlled doors. The doors are all flush to
the floor. The floor drains are screwed down to the floor and have very small drainage holes, much too small for a mouse. The mice are all checked daily and records are
kept of the numbers in each cage.

Animals infected with GM virus will be stored and handled only inside Containment Level 2 animal room and laboratory suite in the animal facility. Isolators will be used for
additional safety. The animal facility is isolated from the rest of the university and access is by card and keypad. Rooms will be maintained at negative pressure relative to
the surroundings.

All personnel dealing with the animals will be required to wear protective clothing including but not limited to lab coats, gloves and removable footwear. They will also be
expected to have read and understood any risk assessments pertaining to this project.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All contaminated materials including animal waste and carcasses and any waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of
waste or cleaning and recycling of reusable laboratory equipment, such as glassware. All waste material will be transported in robust leak proof containers. Autoclaves will
be validated by annual thermocouple mapping and each run will be monitored using TST (Time, Steam, and Temperature) test strips (Albert Browne Ltd., TST class 6
emulating indicator 121ºC for 20 min). Records will be kept.

Is an emergency plan required according to regulation 20?

Purposes of the contained use

Deletion of stress response genes in ACDP Hazard group 2 organisms Salmonella enterica serovar Typhimurium strains LT2, SL1 344 and SL14028s. After passage in the laboratory for many years these strains have mutations that adapt them to these in vitro conditions and the risk for any hazardous effects is considered low.

Recipient or parental organism

The organisms used and generated here are the enteric bacterial strains Salmonella enterica serovar Typhimurium strains LT2 s [Wilmes-Riesenberg, Foster and Curtis (1997) Inf. and 1mm. v. 65 p. 203-210], SL1344 and SL14028s. Both the parental strains used and the derivatives thereof can be considered non-hazardous to humans and to the environment.

Host/vector system

The hosts organisms used in this study are the Salmonella enterica serovar Typhimurium strains LT2, SL1344 and SL14028s. Vectors to be used are derivatives of the plasmid vectors pACYC184, pSCI 01, pBR322, R1 and R6K. Other vectors to be used such as pUC19 and pET28 are non-mobilisable plasmids requiring manipulation to achieve transfer to other strains. Chromosomally located genetic markers will be mobilised using bacteriophage P22-mediated transduction. No hazard to human health has been identified in using any of these vector systems or P22 mediated transduction.

Origin & function

The organisms to be used in this study are Salmonella enterica a ACDP Hazard group 2 organism, Escherichia coli K-12 strains which are equivalent to ACDP hazard group 1 and are in the ACGM “disabled” hosts category. The majority of work to be performed will use wild-type strain S. enterica serovar Typhimurium including LT2, SL1344 and 14028s. Although these strains were originally natural isolates, they have been maintained and passaged in the laboratory for many decades and are likely to have adapted to laboratory conditions. Moreover, LT2 is known to be an attenuated strain of S. typhimurium used widely in bacterial genetic studies. The attenuation of LT2 has been attributed to a mutation in the stationary phase sigma factor (Sigma 5) (Wilmes-Riesenberg, Foster and Curtis (1997) Inf, and 1mm. v. 65 p. 203-210). Nevertheless, LT2 is formally classified as an ACDP Hazard group 2 organism along with 1344 and 14028s.

The intention is to synthesize with PCR chromosomal DNA fragments and combine the DNA fragment with a DNA fragment that encodes for a resistance gene such as aphA or cat, such that the assembled DNA fragments can be integrated into the chromosomes of the wild-type strain S. enterica serovar Typhimurium including LT2, 5L1344 and 14028s by direct selection. Furthermore, the DNA fragments contain a recognition sequence of the FLP site-specific DNA recombinase that allows for, by site-specific recombination, the deletion of the resistance cassette, as devised by Datsenko and Wanner (Proc. Nati. Acad. Sci. U S A. 97, 6640-5, 2000). After deletion of the relevant genes, such as ppk, ppx, relA, spoT, relBE, dinJ yafQ, yefM yoeB, priF yhvA, hicAB, mazEF or chpB, the resulting strains will be analysed for changes in physiological traits, such as levels of translational errors (Kramer EB, Farabaugh PJ. RNA 13: 87-96, 2007) and levels of carbonylated proteins (Oncor Oxyblotting method).

Evaluation of foreseeable effects

Salmonella enterica serovar Typhimurium host strains LT2, SL1344 and SL14028s have been approved as ACDP Hazard group 2 organisms and will be handled in accordance with the requirements for containment level 2 as described in the SACGM Compendium of Guidance 2007. The derivatives of the host strains constructed in this project will carry deletions of genes coding for stress response elements. These stress response elements are thought to help the cells cope with environmental stress. Therefore, the deletion of the corresponding genes are likely to debilitate further the survival of the bacterial cells in the environment. Therefore, we foresee that the mutations constructed in this project will reduce the potential health or environmental hazards connected with the use of the above-mentioned host strains.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All work will be conducted in accordance with the requirements for containment level 2 as described in the SACGM Compendium of Guidance 2007.
All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile.

Project Ref 540/08.2

Date Ackn'd 15/02/2008

CU2 Project Title Differentiation of primary human stem cell lines.

Class 2

CultureVolClass2 < 1 Litre

CultureVolumeClass3-4
The purpose of this project is to obtain a series of cell lines from various organs, in particular the developing nervous system. These lines will be used to identify which genes and gene products are required to promote differentiation into an adult cell phenotype. Ultimately these cell lines will be used in developing strategies for the development of stem cell therapies for CNS disorders and additionally so that we can study the effects of various environmental and endogenous chemicals in the development of neuropsychiatric disease. We are therefore aiming to isolate ventral midbrain (mesencephalon), cortical plate (early forebrain), early hippocampus (memory in the adult), hindbrain, spinal cord, early muscle, liver, heart, spleen, kidney, early lung, skin, and early gonadal tissue.

Whilst these cell lines show a capacity to divide short term, they are only likely to divide a finite number of times and in order to prevent us having to re-derive cell lines we wish to generate cell lines capable of long term division. Transfection of a single gene of human telomerase (bTERT) provides a cell with the capacity to undergo infinite cell divisions without causing the cell to become transformed into a cancerous phenotype. In addition, expression of hTERT provides a level of genomic stability and a capacity to resist cell stress. We will therefore transfect the primary cell lines at low passage number with hTERT under the control of a Tet operon using a disabled lentiviral vector along with the Tet repressor to conditionally immortalise the cell lines. This will allow us to use tetracycline to switch on hTERT expression in stock cells allowing the immortalised phenotype. Removal of tetracycline will switch off hTERT expression reverting the cells to essentially wild type for biochemical study.

In order to determine those factors which control cellular differentiation of stem cells a functional genomic approach will be used. Using siRNA libraries and an ORF library in lentiviral vectors, cells will be transfected and functional and morphological assays used to identify those genes that promote or inhibit differentiation. To achieve this, cells will have been first transfected with viral vectors containing Green Fluorescent Protein (or its derivatives) under the control of cell specific promoters (e.g. CNPase for oligodendrocytes) to allow the cells to be imaged using fluorescence microscopy, or sorted using FACS. These cells will also be used for biochemical and morphological analysis in order to determine how similar they are to adult tissues and the original primary lines. Following the establishment of the cell lines we will then determine the effects of various chemicals on how these cells respond under optimal growth conditions, and under conditions of stress. Cells will be exposed acutely to high levels of specific chemicals and also to low levels over a prolonged period. A variety of the above methods used will then be used to determine how the cells respond to chemical exposure from simple cell survival to determining the levels of specific genes.

Recipient or parental organism

Different primary human stem cell lines derived from early human embryos. Virus will be produced in human 293 cells and its derivatives. The 293FT Cell Line in which the viral particles will be produced is derived from the 293F Cell Line, and stably expresses the SV40 large T antigen. Expression of the SV40 large T antigen is controlled by the human cytomegalovirus (CMV) promoter and is high-level and
constitutive. Studies have demonstrated maximal virus production in human 293 cells expressing SV40 large T antigen (Naldini, L. (1998). Lentiviruses as Gene Transfer Agents for Delivery to Non-dividing Cells. Curr. Opin. Biotechnol. 9, 457-463.). The 293 Cell Line is a permanent line established from primary embryonal human kidney transformed with sheared human adenovirus type 5 DNA (Graham, F. L., et al (1977) Characteristics of a Human Cell Line Transformed by DNA from Human Adenovirus Type 5. J. Gen. Virol. 36, 59-74). The E1A adenovirus gene is expressed in these cells and participates in transactivation of some viral promoters, allowing these cells to produce very high levels of protein. The 293FT Cell Line is derived from the 293F Cell Line which is a fast growing variant of the 293 cell line, adapted to grow in serum free media.

Host/vector system

The vector system will be restricted to “third generation” HTV-1 based vectors where the structural genes and genes for replication of the virus are placed on separate plasmids for co-transfection or are stably integrated into the packaging cell lines. For most of the work we will use lentiviral HIV-1 derived Virapower vectors based on those developed originally by Naldini and colleagues (Dull, T., Zufferey, R., Kelly, M., Mandel, R. J., Nguyen, M., Trono, D., and Naldini, L. (1998). A Third-Generation Lentivirus Vector with a Conditional Packaging System. J. Virol. 72, 8463-8471.). Other viral vectors with a similar composition will be used as necessary.

The basic pVirapower vectors contain:
- Rous Sarcoma Virus (RSV) enhancer/promoter for Tat-independent production of viral mRNA in the producer cell line (Dull et at, 1998)
- Modified (zU3) HIV-1 5’ and 3’ Long Terminal Repeats (LTR) for viral packaging and reverse transcription of the viral mRNA (Dull et at, 1998)
- HIV-1 psi (NI) packaging sequence for viral packaging
- CMV promoter for high-level expression or the human Ubiquitin promoter, UbC, for constitutive but physiological expression of the gene of interest.
- Two recombination sites, attRI and attR2 downstream of the RSV promoter for recombinational cloning of the gene of interest from a clone
- Chloramphenicol resistance gene (CmR) for counterselection
- The ccdB gene located between the attN. sites for negative selection
- Ampicillin resistance gene for selection in E. coli
- uc origin for high-copy replication of the plasmid in E. coli

Origin & function

hTERT will be obtained from Invitrogen as isolated plasmid DNA of human origin encoding a full length h-TERT cDNA (isoform 1). This will be cloned by Invitrogen to add a—V5 epitope tag for detection purposes by cloning into the viral vector pLenti6.2/V5-DEST or pLenti4/TO/V5-DEST. The hTERT sequence will provide unlimited cell replication on transfer and expression in cells.

The vector pLenti6/TR contains a tandem tetracycline repressor gene (Tet) that binds to tet operator sequences to repress transcription of the gene of interest in the absence of tetracycline (Postle, K., Nguyen, T. T., and Bertrand, K. P. (1984). Nucleotide Sequence of the Repressor Gene of the Tn10 Tetracycline Resistance Determinant. Nuc. Acids Res. 12, 4849-4863.). This will allow control of target gene (i.e. hTERT) expression.

The siRNA library will consist of short 30-50bp small interfering RNA sequences designed to inhibit gene expression, each siRNA species having been designed by computer programs to inhibit a specific gene. These sequences do not encode any proteins but provide a library of sequences designed to inhibit all potential genes in the genome. The siRNA library will be carried in a third generation lentiviral vector.

An ORF library in a lentiviral vector system will be used. Each clone represents a unique full length human coding sequence. As such, given the size of the library of over 5,000 ORFs, it is very likely that human oncogenes will be present in the library. These are however the normal cellular coding sequences that are expressed in a wide variety of cell types in the body, particularly during cell division. The purpose of this library will be to induce differentiation of cells to an adult phenotype by the presence of
the gene. The reporter genes will include green fluorescent protein (GFP) from Aequorea Victoria, and its various derivatives including proteins such as enhanced (EGFP), red fluorescent protein (RFP), yellow fluorescent protein (YFP), normally under the control of a CMV promoter. In certain instances these proteins will be under the control of a specific human gene promoter (for example the tyrosine hydroxylase gene). These fluorescent protein expressing viral stocks will be directly obtained from commercial suppliers such as Invitrogen as a custom service. The purpose of these will be to provide simple non-invasive detection of transfected cells in culture.

**Evaluation of foreseeable effects**

The major routes of transmission are through accidental inoculation via needle stick injury, exposure to open wounds and aerosolisation of high titre virus stocks (SACGM Compendium of Guidance). If delivered by these routes the virus will produce limited infection of cells if sufficiently high titres of virus are delivered.

Transfection with hTERT, the gene for the catalytic subunit of human telomerase, immortalises normal human cells and permits continued cell division. It does not induce a transformed phenotype and does not render cells tumorigenic (Morales et al., 1999 Nature Genetics 21: 115-118). The hTERT gene is expressed naturally in human germ line cells, stem cells, lymphocytes and other tissues. It does not induce genomic instability, and it is not an oncogene. Therefore, hTERT overexpression is not considered to pose a hazard to human health. The V5 epitope is not considered to be functional. The final viral vector will therefore be capable of infecting a wide range of dividing and non-dividing cells and providing continued expression of hTERT. Reporter gene constructs based on green fluorescent protein, (GFP from Aequorea Victoria) and similar safe, non-toxic fluorescent proteins from other organisms (e.g. Discosoma spp. mCherry (Shaner et al Nature Biotechnology 22, 1567 - 1572 (2004)) will be used. Transfection with GFP and other similar proteins is considered safe as there is widespread use of these proteins both in Vitro and in VIVO with no deleterious effects. These will be coupled to genomic fragments coding for the promoter regions of various genes which will provide specific markers of cellular differentiation (e.g tyrosine hydroxylase gene promoter). This will provide a series of viral vectors able to transfect a wide range of cell types and produce fluorescent protein expression only in specific cell types to non-invasively monitor cell differentiation.

The siRNA genomic library is composed of short 30-30mer oligonucleotide sequences, each designed to inhibit a specific human gene. The insertion of these sequences into a lentiviral vector will allow knockdown of a specific gene in a very broad range of dividing and non-dividing cells.

The ORE lentiviral library contains the full length coding sequence of a broad range of genes each single gene under the control of the viral or mammalian promoter contained within a lentiviral vector. As such, given the size of the library of over 5,000 ORFs, it is possible that human oncogenes will be present in the library. These are however the normal cellular coding sequences that are expressed in a wide variety of cell types in the body, particularly during cell division. These clones will deliver a specific gene to the target cell and provide constitutive expression of the ORF.

In summary, all inserted genes code for proteins with known or suspected physiological effects with the exception of the reporter constructs (e.g. GFP). However, pathological or pharmacological effects are neither known nor suspected. The siRNA sequences will reduce the expression of the specific gene that they target. In the event of exposure, the GM virus could gain access to human cells. However, direct consequences to human health of exposure to the virus are low, and the risk of transfer is very low (see SACGM Compendium of Guidance, Part 2 “Risk assessment of genetically modified microorganisms (other than those associated with plants)”, 2.11, and above). The health risks of the inserted genes are expected to be minor and self limiting due to the use of replication incompetent virus (see SACGM compendium of guidance, Section 2.11.7 and 2.11.9). The overall likelihood of hazard is therefore low.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**not applicable**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**not applicable**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All work will be carried out at Containment Level 2: All work will be done in accordance with the rules of good microbiological practice and only fully trained and competent individuals will be permitted to work. A “signing off” procedure will be used to monitor staff and their ability to work safely and within the directions of the risk assessment.
and this will be monitored on a regular basis. Production of virus particles will be provided by an external supplier, viral stocks being shipped to Newcastle from the supplier (e.g. Invitrogen). Viral infection of primary cells will be performed at small scale (< 1 o pfh) under sterile conditions in closed plastic tissue culture vessels and all work will be done in a Class 2 microbiological safety cabinet within a Containment Level 2 room, in order to control hazards associated with possible adventitious agents and to avoid contamination of cells. Protection levels provided by the flow cabinet are monitored on a 6 monthly basis in accordance with the appropriate legislation (BSEN 12469:2000). No hypodermic needles will be used. Used “sharps” (pipette tips, serological pipettes) will be collected in a yellow “CinBin” type container placed within the plenum of the MSC immediately after use. The container and all sharps content will be autoclaved prior to disposal by the clinical waste route. The cells will be harvested by protease digestion and centrifugation, and DNA, RNA and protein will be isolated for analysis. Certain transfected cells will be fixed in paraformaldehyde to visualise GFP etc. All waste that is possibly contaminated with virus will be inactivated by incubation with a final concentration of at least 1% Virkon for 30 minutes and all of this waste will be collected in dedicated bags and these transferred to an autoclave using closed containers and will be inactivated by autoclaving at 121°C for 20 mm. This procedure will ensure 100% killing efficiency. Autoclaving will be done at the end of each working day or on completion of work, whichever is the earliest. The temperature and time during each autoclave run will be monitored using indicator strips (TST control integrator, class 6 claiming indicator 121°C for 20 mm, Albert Browne Ltd, UK). The autoclave will be serviced and tested on an annual basis using an independent thermocouple mapping test. The viral killing activity of the autoclave can be tested using GFP-expressing indicator viruses. Cells will be transduced with the indicator viruses autoclaved as above, and green fluorescence will be monitored in an inverted fluorescence microscope or using green fluorescence in a FACS analyser. In the event of spillage of possibly virus-contaminated material, the area will be disinfected using 1% Virkon. The used paper towels and any other disposable material will be collected in dedicated bags and autoclaved as above. As all work is performed in a separate small tissue culture room the wider environment is unlikely to become contaminated. A spill kit will be available in the Containment Level 2 Laboratory for this purpose. All autoclaved waste will be incinerated using the yellow bag route as-cluval waste using an approved contractor.

The University GM Safety Committee has approved the GM Risk Assessment: Local GM reference: GM 07/30.
Principal Investigator: Project Title: Differentiation of primary human stem cell lines.
**Project Additional Information**

**Purposes of the contained use**

Research into the molecular mechanisms of ageing via the production of reactive oxygen species. We wish to establish which pathways are involved in mitochondrial dysfunction in cellular senescence. To this end, we intend to monitor mitochondrial function and intracellular signalling pathways in living cells during the onset of senescence.

**Recipient or parental organism**

1. Bacterial strain Stbl3 and Top10 (Invitrogen) for amplification of constructed plasmids. Both bacterial strains are E.coli K12 strain derivatives.
2. Producer cell line 293FT for the generation of lentiviral virus (Invitrogen).
3. Human fibroblast cell lines MRC-5 (from ATCC), MRChTERT (Saretzki G. et. al., Oncogene 1999, 18:5148-5158) and fibroblasts and neurons derived from aging mice. All human cell lines are established non-self lines, which cannot colonise humans.

**Host/vector system**

ViraPower™ Lentiviral Expression System from Invitrogen

**Origin & function**

This project will construct lentiviral expression plasmids to express:

1. Mitochondrially targeted photoactivateable GFP (mt-PAGFP, Karbowski et al., Nature 2006, 443: 658-662). This is a mutated (T203H) form of codon enhanced GFP (EGFP; Patterson and Lippincott-Schwartz, 2002, Science 297 1873-1877) fused to a human COX VIII mitochondrial targeting sequence.
2. Mitochondrially targetted calcium sensor, D3cpv (4mt-D3cpv, Palmer et al., 2006, Chem & Biol. 13; 521-530). This is a 'cameleon' probe consisting of 4 tandem repeats of the human COX VIII mitochondrial targeting sequence fused to ECFP (a cyan coloured variant of EGFP) which is fused to a circularly permuted 173 Venus (an
engineered yellow fluorescent protein) via an engineered calmodulin binding peptide (initially derived from smooth muscle light chain myosin) and calmodulin peptide binding domain (initially based on Calmodulin sequence). The expressed protein enables live cell monitoring of changes in calcium levels in the mitochondria.

3. Cytoplasmically expressed calcium sensor, D3cpv (Palmer et al., 2006, Chem & Biol. 13; 521-530). This engineered gene is the same as that described in 2. above, except it has no mitochondrial targeting sequences.

4. AmCyan and mCherry- PGC1α fusion proteins. AmCyan is an engineered fluorescent protein derived from Anemonia majano cyan fluorescent protein (Matz et al, Nature Biotechnology, 17: 969-973). mCherry is an engineered version of dsRed, a red fluorescent protein from Discosoma species (Shaner et al., 2004, Nature Biotechnology 22, 1567-1572). PGC1α is a transcriptional coactivator which is involved in activating mitochondrial biogenesis and expression of ROS-detoxifying genes. It is expressed in heart, skeletal muscle and brown fat, where its expression is greatly enhanced in cold exposure, leading to expression of uncoupling proteins which increase proton leak and thermogenesis (Puigserver et al., 1998, Cell 92, 829-839).

5. mCherry- UCP2 fusion protein. UCP2 encodes an uncoupling protein which when expressed lowers mitochondrial membrane potential and subsequently mitochondrial ROS production. It is widely expressed in adult human tissues (Fleury et al., 1997, Nature Genetics, 15; 269-272)

Evaluation of foreseeable effects

The viral vector would be able to transduce many tissues should it come in contact with them. The major hazard is therefore represented by the packaged virus prior to infection of the target cells and residual virus in the medium of transfected cells. The two potential transmission routes are by external exposure (either naked skin or mucous membranes) and needle-stick injury. Both are made extremely unlikely by the standard procedures employed in the tissue culture facility. The DNA in the packaged virus vectors have been modified to be “self-inactivating” (Yu et al., 1986, PNAS 83(10):3194-3198). A deletion has been made in the 3’LTR (called “delta U3”) which generates integrated viral genomes with defective 5’ and 3’ LTR’s. Thus, there is no transcription of the viral sequences in the target cell and no packagable viral genome is produced (Invitrogen).

Therefore, the foreseeable effects upon release of the packaged virus into the environment would be infection of the cells it came into contact with and expression of the transgene in those cells only.

Regarding the transgenes themselves, no health risks have been described or suspected to arise from UCP2 or PGC1α expression, and fluorescent proteins have been used in overexpression studies for more than a decade and are generally regarded as safe.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not Applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not Applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored using TST (Time, Steam, and Temperature) test strips (Albert Browne Ltd., TST class 6 emulating indicator 121°C for 20 min).

All autoclaved material will be disposed of via an approved contractor by the clinical waste route.

Date of Significant Change

**Project Additional Information**
We discovered recently (Ahmed et al., JCS 2008, in press) that hTERT, the catalytic subunit of human telomerase protects mitochondria by decreasing oxidative stress and lowering apoptosis levels. That could have potentially important implication for the sensitivity of cancer cells to different drugs and treatments. As telomerase has both telomere-dependent and —independent functions we don’t know whether the effect we see is, at least partially, dependent on its catalytic and telomere-maintaining function. That’s why we want to employ different mutants with either a defect telomere binding, lacking catalytic activity or various import signals for the shuttling between organelles. Most of these mutants are cloned into retroviral vectors and include the use of retroviral particles for high transfection efficiency.

The GMM’s will be human diploid fibroblasts transfected with wildtype and different mutants of the catalytic subunit of human telomerase (hTERT). The wildtype TERT greatly extends the lifespan and the cells continue to proliferate beyond their Hayflick limit (replicative lifespan). As telomerase stabilises and continuously maintains telomeres protects the cells from any genomic instability. These cells are therefore highly stable but do not pose any major risk for human health or the environment. They are not viable outside their special growth medium and culturing conditions. The mutants that are not able to bind telomeres will have telomerase activity but the telomeres will not be maintained and these cells will have the same replicative lifespan as the parental fibroblasts. We will analyse whether these mutants are still able to enter the mitochondria and protect these from oxidative stress and apoptosis. The same will be done with the 2 mutants that have either a defective nuclear or mitochondrial localisation sequence. The former, again, as the previously described mutants, are not able to enter the nucleus and maintain telomeres and will be analysed regarding their mitochondrial localisation and functions. The latter mutant is not able to enter the mitochondria. It can maintain telomeres but will be excluded from the nucleus upon oxidative stress. cannot, however, enter mitochondria. These transfected fibroblasts will be phenotypically (regarding replicative lifespan) similar to those transfected with the wild type hTERT. Transfection with telomere binding proteins increases the level of these proteins with no major phenotypes expected, whereas the dominant-negative telomere binding proteins (TRF1 and TRF2) change the structure of telomeres and lead to a DNA damage response and growth arrest resembling senescence. No adverse effects of any of the described GMMs on human health or for the environment are expected.

The expression of wt-hTERT in normal diploid fibroblasts maintains telomeres and increases the replicative lifespan of cells. The various mutants have mutations in different localisation domains or the catalytic function. The dominant-negative mutant suppresses any endogenous telomerase and cells go into senescence in long term. Any fl5fàtective effects of the mutant for mitochondrial function will be assessed. With the help of the mutants with missing localisation domains the subcellular shuttling of the protein and its protective function in mitochondria (Ahmed et al., J of Cell Science 2008, in press) will be analysed. No adverse effects on human health or for the environment are expected from these GMOs.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The GMMs are human somatic fibroblasts that are not able to survive or spread outside their defined laboratory conditions as they need special growth medium, adhere to plastic and need special tissue culture incubators. Protective clothing and gloves will be worn at all times, class 2 safety cabinets will be used, the access for the tissue culture facility is restricted to specially trained and supervised personnel only and no sharp instruments will be used. All GMMs will be disposed of using special waste containers and autoclaving. All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile.

02/03/2022  Page 8113 of 15326
Cloning and expression of genes encoding proteins localized and functioning in the mitochondrial homologues of Entamoeba histolytica, Giardia lamblia and Trichomonas vaginalis.

Entamoeba histolytica, Giardia lamblia and Trichomonas vaginalis are parasites of the digestive tract (Entamoeba and Giardia) or urogenital tract (Trichomonas). Entamoeba and Giardia are transmitted through the fecal-oral route by cysts. Only the mature cysts are infectious as they need to survive passage through the highly acidic gastric juice. T. vaginalis has no cyst stage and must be transmitted by direct intimate physical contact, as in sexual intercourse, to allow transfer. All of these are wild type infectious parasites of hazard group 2.

Recipient or parental organism

Entamoeba histolytica, Giardia lamblia and Trichomonas vaginalis are parasites of the digestive tract (Entamoeba and Giardia) or urogenital tract (Trichomonas). Entamoeba and Giardia are transmitted through the fecal-oral route by cysts. Only the mature cysts are infectious as they need to survive passage through the highly acidic gastric juice. T. vaginalis has no cyst stage and must be transmitted by direct intimate physical contact, as in sexual intercourse, to allow transfer. All of these are wild type infectious parasites of hazard group 2.

Host/vector system

Hosts will be infectious parasites of hazard group 2. All vectors are non-mobilisable and shuttle vectors between E. coli and named parasites. These include, E.histolytica: pAS'A3'NEO and pEhHYG-tetR; G. lamblia: pNLop*-GltetR and CWP1 containing vector; and T. vaginalis: TagVag-47. None of these represent a risk to human or other organisms.

Origin & function

All of the cloned DNA will be derived from Entamoeba histolytica, Giardia lamblia and Trichomonas vaginalis. Inserted DNA will compromise PCR amplified genes which encode proteins that are candidates to function in the mitosomes of Entamoeba or Giardia, or the hydrogenosomes of Trichomonas. These proteins include mitochondrial Hsp70, Cpn 60, proteins involved in iron sulphur cluster assembly, proteins involved in energy generating pathways, and candidate organelle transport proteins. These genes will be cloned to provide material for sequencing to verify gene identity, and sub-cloned into the respective vectors for investigating the cellular localisation of recombinant tagged proteins (analysed by microscopic studies) and other functions. The goal of the project is to understand how the Entamoeba, Giardia or Trichomonas mitochondrial homologous function. None of our work is linked to the pathogenicity of the three species and none of the genes encode known virulence determinants. We will be using this genetic material to make mutants to facilitate localization and analyses of expression including cellular localization, inducible expression, loss of function and gain of function.
Evaluation of foreseeable effects

These will be genetically modified organisms of wild type infectious parasites of hazard group 2. It is not envisaged that the mutants will modify the pathogenicity of the host strains. All of the cloned genes are associated with very specific structural or metabolic functions, none of which are known to be linked with pathogenicity. They are involved in central metabolic pathways and have no known deleterious effects on humans, animals or the environment. The genes to be cloned are already universally found in eukaryotic cells where they mediate housekeeping and metabolic functions in mitochondria. None of these mutations are expected to modify the host range nor tissue specificity. None of the GMOs are expected to increase the virulence of these strains.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**Project Additional Information**

**Purposes of the contained use**

We aim to understand the molecular mechanism(s) of the enlargement of the bacterial cell envelope during cell's growth and division in the human pathogen Streptococcus pneumoniae (the pneumococcus). Bacteria have a cell envelope of a highly complex structure. In Streptococcus pneumoniae the cell envelope contains a multi-layered peptidoglycan (murein) sacculus to which several surface polymers (teichoic acid, capsular polysaccharide, surface proteins) are covalently attached. So far 91 different capsular polysaccharides have been identified in clinical isolates (giving rise to the same number of serotypes) and their structures are known. Capsule genes are not essential for pneumococcal growth, as non-encapsulated strains are viable without any growth defect in the laboratory. However, capsule genes are required for pneumococcal virulence and survival in the host.
Within this project we are particularly interested in the biosynthesis of capsular polysaccharides and their attachment to the cell wall peptidoglycan. Although all steps in capsular biosynthesis will be addressed, the focus will be on the membrane-associated steps including attachment the capsule to the cell wall. We aim to determine the chemical structure of the linkage unit residing between the repeating units of the capsular polysaccharide and the peptidoglycan. We also want to identify and characterize the so far unknown enzyme(s) catalyzing the attachment of capsule polysaccharides to peptidoglycan (named "capsule ligases" in this application), enzyme(s) for the polymerization of the capsular polysaccharides and transporters for the capsule precursors.

To reach our goals we will perform the following experiments:
- Inactivation of potential capsule genes in S. pneumoniae. The presence of a capsule is not essential for pneumococcal growth; therefore capsule genes are not essential for pneumococcal growth in the laboratory. Inactivation of capsule genes will be done using standard procedures. For this, either part of a pneumococcal capsule gene or the upstream and downstream regions of will be amplified by PCR and will be cloned into a shuttle plasmid transformed into E. coli. Plasmids will isolated and transformed into S. pneumoniae to interrupt the target gene by single or double cross-over (the plasmids cannot replicate in S. pneumoniae).
- Testing for capsule attachment and capsule structure in the mutants. Cell wall of encapsulated pneumococcal strains will be isolated by a standard procedure at the beginning of which cells are boiled in SDS solution. This will kill the bacteria. The purified cell wall and cell wall fragments will be analyzed by high-pressure liquid chromatography (HPLC), mass spectrometry (MS) and nuclear magnetic resonance spectroscopy (NMR). The attachment of capsular polysaccharides to cell wall will also be analyzed by detection of capsular polysaccharides by specific antiserum in culture supernatants and on bacteria after SDS-PAGE and Western-Blot. Also the lipid-linked capsule polysaccharide precursors will be extracted from cells and will be analyzed by HPLC, MS, and NMR spectroscopy. These will also be used as substrates in enzyme assays.
- We will also express candidate genes for capsule genes (for example, capsule ligases) in Escherichia coli. E. coli cells expressing the capsule enzymes will be lysed and the enzymes will be purified for in vitro enzyme assays and biochemical characterization.

Recipient or parental organism

1) Streptococcus pneumoniae is an ACDP hazard group 2 pathogen. It is currently a leading cause of pneumonia, meningitis and bloodstream infections in elderly persons, and among the main pathogen causing middle ear infection in young children under the age of 3 years. The bacterium is carried asymptotically in the nasopharynx of healthy children (20-40%) and, less frequently (5-10%), of healthy adults, with colonization beginning shortly after birth (Austrian, 1986, J. Antimicrob. Chemother. 18:35-45). It has been very well established form many decades that the capsule is a crucial virulence factor of S. pneumoniae as the capsule is essential for survival in vivo. To date at least 91 different capsular types have been described and their structures as well as the genes responsible for their biosynthesis are known. In all serotypes, the production of capsule requires the presence of multiple genes which are most often clustered at a single locus on the pneumococcal chromosome. A serotype 2 S. pneumoniae strain called strain D39, which was originally isolated in 1916, has been widely used for studies on S. pneumoniae virulence. The complete genome sequence of strain D39 has been reported (Lanie et al., 2007, J. Bacteriol. 189:38-51). The use of the S. pneumoniae strains with other capsular types would be limited to comparative analysis. Although non-encapsulated strains have been associated with superficial infections, such as conjunctivitis, clinical isolates from other infection sites are encapsulated, and spontaneous non-encapsulated derivatives of these strains are largely avirulent (Kadioglu et al., 2008, Nature Reviews Microbiology 6: 288-301; and references therein). The prevailing animal model for pneumococcal virulence is the intraperitoneal mouse model of infection which has been used in numerous studies for more than 60 years. The virulence of S. pneumoniae is related to the thickness of capsule in a particular strain and serotype (MacLeod and Krauss, 1950, J. Exp. Med. 92:1-9). Moreover, defined mutants in which less capsular polysaccharide is attached to the bacterial cell wall show markedly reduced virulence (Morona et al., 2006, Proc. Nat. Acad. Sci. USA 103:8505-8510). Thus, our proposed inactivation of capsule genes will most likely reduce the virulence of the bacterium.

2) E. coli strains: E. coli K12 strains and derivatives (e.g. DH5(alpha), XL1-Blue or MC1061) are defined as disabled or non-colonising in the SAGCM Compendium of Guidance (Part 2.2, point 33) and is therefore equivalent to an ACDP hazard group 1 organisms. E. coli BL21 and derivatives are described in ACGM Newsletter 30 (Nov. 2001, para 3) as being “broadly equivalent to K12 strains and that in most cases work which uses this host can be considered as a class 1 activity………, but the cloning of a bacterial pathogenicity determinant into BL21 will need careful consideration and may in some cases warrant classification as class 2”. In this project potential single capsule genes will be introduced into E. coli strains. The products of capsule genes are not toxic. The introduction of a single pneumococcal capsule gene into E. coli cannot result in capsule formation in E. coli.
The following host strains will be used, or derivatives thereof:
S. pneumoniae: we will use mainly strain D39 (capsule type 2), but also strains with other capsule type for comparison.
Escherichia coli: K12, BL21.
The following vector systems will be used:
E. coli plasmid vectors based on pUC, pBAD, pBR322, pET, pQE.

Origin & function
Standard resistance markers (cat, kan, spc, tet, erm), epitope tags (such as HA, c-myc, 6xHis, etc.), artificial promoter constructions (e.g. Pxyl or Pspac) for insertion duplication mutagenesis or for expression plasmids. Capsule genes will be derived from host organism, introduced either on a plasmid or inserted directly into the host genome. The organisms that will provide the DNA to be PCR amplified will be from any of the host organisms mentioned above.

Evaluation of foreseeable effects
1. Effects on Human Health
Characteristics of the vector system and any hazards associated with it
Most of the vectors to be used are standard vectors with a long history of safe use in the laboratory. All plasmids used are mobilisation minus. These include E. coli-S. pneumoniae shuttle vectors (pJDC9, pBT2, pPP2, pLSE4) and E. coli expression vectors such as pUC, pBAD, pBR322, pET, pQE, pJDC9 and derivatives. Genetic markers (cat, bla, kan, spc, tet, erm) will involve the disruption or manipulation of specific genes involved in capsule biosynthesis, as such is unlikely to pose any increased hazard above the handling of the wild type strain.

Source and characteristics of the inserted gene product and any hazards arising directly from its use.
Drug resistance markers used in these vectors are already widely distributed in nature.
Strain construction will involve plasmid derivatives passing through E. coli for amplification prior to reintroduction into the host bacterium. It is therefore possible that these constructs could have biological effects on E. coli, but it is difficult to envisage the hazard being significantly greater than the handling of the parent strains from which the DNA was isolated. In general the GMs proposed fall into two categories; firstly, gene disruptions where no functional gene product should be produced. These plasmids will then be used to generate chromosomal disruptions in the chromosomes of the host bacterium, in so doing the plasmid replicon will either be destroyed, or will be non-replicating in the target host, where they will integrate into the genome and lie dormant. Secondly, genes will be cloned in plasmids in such a way as to be controlled by artificial promoters, e.g. T7 or Pspac. These will then be used as expression systems to allow the purification of the encoded gene product.

The genes of interest encode proteins involved in capsule biosynthesis in S. pneumoniae. Since capsular genes are generally not present in the E. coli hosts used, it is highly unlikely that introduction of single pneumococcal capsular genes into E. coli will have any effect on pathogenesis.

Hazards arising from the alteration of any existing pathogenic traits
Since capsular polysaccharide represent a virulence determinant in S. pneumoniae it is highly unlikely that the inactivation of capsular genes will lead to significantly increased virulence, the reverse is more likely.

Potential hazards of sequences within the GMM being transferred to related micro-organisms
It is difficult to envisage how any of the cloned gene products could confer or increase the virulence of a recipient strain. Transfer of the GMMs to related organisms where possible is unlikely to represent any significantly increased hazard. If any GMM were to be transferred the most probable outcome would be the selective loss of this marker as it would either be redundant or more probably deleterious to the new host.

The overall likelihood that, in the event of exposure, the GMM could cause harm to human health
The likelihood of the GMMs causing harm to humans should be no greater (and in most cases significantly less) than that associated with the parent organisms. As outlined above S. pneumoniae is wide-spread among healthy persons. The bacterium could potentially cause infections in young children and immuno-compromised persons (for example, in elderly persons). The greatest risk would be to introduce S. pneumoniae into the blood-stream which could potentially cause systemic infection. To reduce
this risk the use of sharp items will be minimized.
The genetic manipulations that are to be performed in the project will predominantly involve the deletion or disruption of specific genes functioning in capsular biosynthesis. These are expected to result in the reduction in the amount of cell wall capsular material, and as such are unlikely to enhance virulence.

2. Environmental Effects
Capacity of the GMM to survive, establish, disseminate with and or displace other organisms
In the case of E. coli the strains used are genetically marked by multiple mutations leading to at least auxotrophy such that they are unlikely to be able to survive outside the laboratory environment. S. pneumoniae strains colonize the nasopharynx of humans. There are very few reports on animals, e.g. horses, with pneumococcal infections, and the pneumococci are not known to be living free in the environment. The GMMs derived from this project are likely to be even less able to persist outside the laboratory environment than the parent strain, as they will have lost genes which function to optimise viability, this also would mean that the strains are unlikely to be more hazardous than the parent.

Ability of GMM to cause harm to animals, plants or other organisms
As detailed above [Characteristics of the GMO(s)], the GMMs are likely to be less able to cause harm than the parent strains. None of the hosts to be used are known to be significant colonisers or cause harm to other organisms. It is therefore difficult to envisage how the cloned gene products would alter this.

Potential for transfer of genetic material between the GMM and other organisms
The genetic manipulations proposed are designed to be stable in the host genome, thus transfer of the manipulated genes is very unlikely to occur due to the absence of a direct route of transmission to other species, incompatibility of DNA restriction modification systems and finally the low likelihood of expression of the genetic material outside the intended organism. In some instances it may be necessary to use plasmids to introduce the genetically manipulated material, the potential for transfer of these markers will be minimised by the used of narrow host range plasmid replicons. It is however unlikely that the gain of the markers by another organism would provide a sufficient advantage for it to be maintained in the population for a significant period of time.

Potential hazard as a result of phenotypic or genetic instability
It is difficult to identify any hazard that would be increased by genetic instability; the most likely result being that the strains would revert to the parental state or would be further damaged in function. The E. coli strains and S. pneumoniae strains D39 that are contained in this proposal are well-documented strains with a long history of safe use, thus instability is unlikely to result in pathogenic strain creation. The use of the remaining S. pneumoniae strains with other capsular types would be limited to comparative analysis.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste containing GMM includes bacterial cultures and supernatants of bacterial cultures present in or at glass or plastic lab equipment. 1% virkon, 1% chloros, 1% chlorosan or 70% ethanol disinfectant will be used to clean up spillages and all of the waste materials will be autoclaved.

All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile.
The University GM Safety Committee has approved the GM Risk Assessment:

Principal Investigator: Dr Waldemar Vollmer.

Genetic manipulation of Streptococcus pneumoniae capsule biosynthesis: construction of S. pneumoniae mutants and heterologous capsule gene expression in Escherichia coli.

Project Ref 540/09.2

Date Ackn’d 28/05/2009

CU2 Project Title Generating induced pluripotent stem cells (iPSCs) using lentiviral vectors

Class 2

Culture Vol Class 2 < 1 L

Non-GMM Consent Granted

Project notified under transitional arrangements N

Tick if notifying a connected programme of work N

02/03/2022
Project Additional Information

Purposes of the contained use

Induced pluripotent stem cells (iPSC) with properties similar to embryonic stem cells can be generated from skin fibroblasts by co-expression of various combinations of transgenes (for instance OCT4, SOX2, NANOG and LIN28; or OCT4, SOX2, KLF4 and c-MYC). We will obtain or produce replication deficient lentiviral vectors encoding the cDNAs (OCT4, SOX2, NANOG, KLF4, c-MYC, KLF4, TERT). These vectors will be used to transduce human primary cells with the aim of deriving iPSC from them. The factors we are going to introduce into the primary cells and cell lines are novel and their biological effects are not fully investigated. Some of the factors (c-MYC) are known to induce tumorigenesis upon activation in somatic cells. There is therefore at this stage a possibility that they could render the cells neoplastic and hence the reason for containment under level 2.

Recipient or parental organism

Primary human cells for transduction will include those obtained from the cornea, hair follicle, oral mucosa, blood, cord blood, muscle or skin biopsies, full-term human placenta or other tissues. Human cell lines will include well established fibroblast cell lines (BJ foreskin fibroblasts from ATCC, and others), BJ fibroblasts immortalised by the expression of telomerase, as well as standard laboratory cell lines like HT1080, HeLa, HEK293T, NIH3T3 fibroblasts, lymphoid, myeloid lines and others.

Host/vector system

For cloning, sequencing and prokaryotic expression of recombinant DNA sequences, disabled E. coli K12 derived bacterial host strains (e.g. TOP10, SURE, JM109, DH5, etc) will be used in conjunction with non-mobilisable vector systems e.g. Lambda gt and charon-based bacteriophage vectors and pUC/M13mp-based plasmid, filamentous phage or phagemid vectors. These host/vector systems have been widely used over many years and have a long history of safe application.

Replication-defective lentiviral vectors (rLVs) will be constructed based on the human immunodeficiency virus type-1 (HIV) genome, but they have been specifically engineered for biosafety by separating the packaging signals and viral LTR’s on the expression plasmid from the viral structural and expression genes (gag, pol and rev from HIV-1 and the VSV-G gene from Vesicular Stomatitis Virus in place of HIV-1 env) encoded on three separate plasmids which remain in the packaging cell line, effectively precluding the production of replication competent virus in the target cell or should the viral vector escape containment. The plasmids expressing these gene products carry no packaging signals or LTRs and so cannot themselves be mobilised with the vector and have been engineered not to contain any regions of homology to each other or to the viral vector, to prevent undesirable recombination events which might result in replication competent virus being produced. Additionally, we will use non-integrating variants of these lentiviral vectors, produced by using mutations affecting the catalytic active site of integrase. Such non-integrating lentivectors have a much reduced risk of causing insertional mutagenesis.

Origin & function

We will obtain or produce replication deficient lentiviral vectors encoding the cDNAs (OCT4, SOX2, NANOG, KLF4, c-MYC, KLF4, TERT). These vectors will be used to transduce human primary cells with the aim of deriving iPSC from them. The factors we are going to introduce into the primary cells and cell lines are novel and their
biological effects are not fully investigated. Some of the factors (c-MYC) are known to induce tumorigenesis upon activation in somatic cells. The function of the genetic material will be transduction of primary cell types highlighted above with the aim of producing iPSC.

**Evaluation of foreseeable effects**

Two potential risks to humans may arise from the hazards of working with the naked plasmid vector + insert DNA containing the potentially oncogenic DNA and the supernatant containing the viral particles from the packaging cell line. The amount of DNA is relatively low and it is envisaged that the risk of naked DNA entering the human body is relatively low. Linearized cloned DNA is usually introduced into the cells using different transfection techniques, however the transfection efficiency even under optimal culture conditions is not high, therefore transfection of researcher’s cells with naked DNA under accidental/non-optimal conditions would be rather low.

The viral vector would be able to transduce many tissues should it come in contact with them. The major hazard is therefore represented by the packaged virus prior to infection of the target cells and residual virus in the medium of transfected cells. The two potential transmission routes are by external exposure (either naked skin or mucous membranes) and needle-stick injury. Some of the genes that will be studied are novel and potentially could have oncogenic effects or interfere with the ability of the cells to survive in culture. If those genes were to be transfected directly into living human tissue any detrimental effects that they might cause are uncertain. However, the genes will only be transfected into cell lines or primary cells which have no ability to survive outside tissue culture environment. Even in the event of needle stick injuries or aerosol exposure, these cells (which will exist in very low numbers) will be destroyed by the human immune system.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not Applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All GMO waste materials including all tissue culture fluid etc generated in this project MUST be autoclaved. No other inactivation or waste disposal routes will be used. Spillages must be cleaned up with disinfectant but the tissues and other waste materials must then all be autoclaved.

All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored using TST (Time, Steam, and Temperature) test strips (Albert Browne Ltd., TST class 6 emulating indicator 121°C for 20 min).

Purposes of the contained use

We are interested in examining the role of various genes in the development of type 2 diabetes. In order to understand how the functions of these genes may contribute to the pathogenesis of type 2 diabetes it is necessary to examine the downstream effects of these proteins, by overexpression of certain proteins using the adenovirus system in cultured human skeletal muscle cells. One of the problems associated with genetic manipulation of these cells is the low level of transfection efficiency, a problem which can be overcome by using adenoviral-mediated overexpression of the proteins of interest. This will allow us to assess the contribution of these proteins to insulin signalling and action in this cell type.

Recipient or parental organism

Recombinant adenovirus will be transduced in non-self cultured human skeletal muscle cells. The recombinant adenovirus will be propagated in HEK293 cells, a human embryonic kidney cell line.

Host/vector system

Adenovirus vector (E1-deleted) using the freely available AdEasy system. The gene of interest will be cloned into the shuttle vector, pAdTrack-CMV. This vector does not contain any of the components of the adenovirus. The recombinant plasmid will be co-transformed into E.coli with the adenoviral backbone plasmid, AdEasy-1, allowing homologous recombination to occur. The AdEasy-1 adenoviral vector is derived from the human adenovirus serotype 5 (Ad5) and is an E1 and E3 double-deletion vector. E3 is not necessary for viral production therefore, AdEasy-1-derived recombinant adenoviruses can be propagated in packaging cells which express E1, ie. HEK293.

Origin & function

cDNA sequences originating in humans will be cloned into the adenoviral vectors. Some examples include:
- TCF7L2, full-length and tagged with GFP. This is a transcription factor involved in the Wnt signalling pathway. It has been implicated in blood glucose homeostasis through regulation of proglucagon. While the Wnt signalling pathway has been implicated in cancer, it has been demonstrated that TCF7L2 itself, appears to act as a transcriptional repressor that restricts colorectal cancer cell growth (Tang W et al, Proc Natl Acad Sci 2008. 105; 9697-9702.). Therefore it is not believed to be oncogenic. This will be obtained as an adenovirus from our collaborator, Dr Guy Rutter.
- GLUT4, full-length and tagged with GFP. This is an insulin-regulated glucose transporter required for insulin-stimulated glucose disposal and is naturally expressed at relatively low levels in cultured human skeletal muscle cells.
- CDKAL1, full-length and tagged with GFP. This is a novel gene, identified through genome-wide association studies as being associated with the development of type 2 diabetes.
- FTO, full-length and tagged with GFP. This is a novel gene, associated with obesity and the development of type 2 diabetes. Bioinformatic analyses have shown that FTO shares sequence motifs with Fe(II)- and 2-oxoglutarate-dependent oxygenases implying that it may play a role in nucleic acid demethylation (Gerken T et al, Science 2007. 318: 1469-1472). Studies are ongoing to determine how nucleic acid methylation status may be linked to increased fat mass. There is no evidence that FTO may be oncogenic.

The properties of each gene which will be expressed in the adenoviral vector will vary significantly. However, from the published literature and our own previous laboratory experience, they are not anticipated to be hazardous when used within this system. The final genetically modified viral vector will be infection competent but replication incompetent. All new stocks of recombinant adenovirus will be screened by PCR to ensure that replication competent virus particles have not been generated by recombination in the packaging cell line.

Evaluation of foreseeable effects

The properties of each gene which will be expressed in the adenoviral vector will vary significantly. However, from the published literature and our own previous laboratory experience, they are not anticipated to be hazardous when used within this system. The final genetically modified viral vector will be infection competent but replication incompetent. Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not Applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The GMM will be inactivated by the following:

i. Plasticware:
   Disposable plastics to be put in CinBins to be autoclaved prior to incineration. Autoclaving will be done after each packaging.

ii. Glassware
   Glassware will be swabbed with Virkon before autoclaving in Denley boxes. Swabs will be disposed of in a CinBin and autoclaved prior to incineration.

iii. Liquid Waste
   Liquid waste to be treated with Virkon and autoclaved prior to disposal down sink.

iv. Paper, gloves and other soft discard
   This will be put in a CinBin and autoclaved after each packaging.

All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves are validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile.

02/03/2022
Familial cylindromatosis (FC-OMIM 132700) is an autosomal dominant inherited, cutaneous tumour syndrome that occurs due to mutations in a tumour suppressor gene named CYLD. Recent advances in the understanding of the function of CYLD have raised possibilities of medical treatments such as aspirin, but these have not been validated in keratinocyte models.

We plan to use lentiviral transfection techniques that have been shown to be effective in transfecting keratinocytes for the development of in vitro models for drug screening:

a. CYLD deficient keratinocyte lines:
   • We plan to compare cell survival, proliferation, and apoptosis in a human keratinocyte cell line (HaCat) with and without functional CYLD in the presence of different aspirin-like compounds. Lentiviral delivery of short hairpin RNA targeting CYLD will be used to knockdown CYLD in the keratinocyte line.

b. Primary tumour cell lines:
   • We intend to reintroduce CYLD into primary human cylindroma tumour lines that are CYLD deficient. Cell survival, proliferation, and apoptosis will then be compared in the presence of different aspirin-like compounds with and without CYLD. Lentiviral delivery of CYLD cDNA will be used on the primary tumour cell lines.
Cell lines in culture: Human embryonic kidney cell line 293T carrying the SV40 large T (packaging cell line, hereinafter referred to as "HEK-293T"), Human keratinocyte cell lines (HaCat), primary keratinocyte tumour lines and human epidermal neural crest stem cells will be used. We will only use samples, or cells obtained from biopsies of volunteers or patients not known to carry infectious diseases, or with a history of safe use in laboratories.

Host/vector system

There are two types of lentiviral vectors that we intend to use: Trans-Lentiviral™ GIPZ for knockdown work and Trans-Lentiviral™ pLEX for overexpression work. (The term "trans" is used to emphasise the separation of the genes used for the packaging virus across multiple plasmids as a safety measure to reduce the likelihood of a recombination event). These are similar in structure, with pGIPz illustrated below, and are obtained from Openbiosystems. The Trans-Lentiviral packaging mix - contains an optimized mixture of five packaging plasmids (pTLA1-Pak, pTLA1-Enz, pTLA1-Env, pTLA1-Rev and pTLA1-TOFF) to facilitate viral packaging of the transfer vector following co-transfection into HEK-293T producer cells. These plasmids supply the helper functions as well as structural and enzymatic proteins in trans required to produce the lentivirus. The transfer vector will contain short hairpin RNA sequences, specific to the gene being targeted, CYLD, in the context of knockdown work, and cDNA (again CYLD) in the context of overexpression work. Empty vectors will be used for matched controls. These sequences are linked via an internal ribosomal reentry site (IRES) to green fluorescent protein (GFP), allowing monitoring of transfection efficiency.

Origin & function

Knockdown of CYLD in keratinocyte cell lines

CYLD, a ubiquitin hydrolase enzyme, is a tumour suppressor gene and therefore at this stage a remote possibility that they could render the cells neoplastic. Short hairpin RNA targeting human CYLD will be obtained in a pGIPz vector from Openbiosystems. This will be used to knockdown CYLD expression in keratinocyte lines such that it serves as CYLD deficient keratinocyte model in which potential therapeutic agents can be tested. pGIPz with a non silencing vector will be used in matched controls. The best candidates will be tested in the cylindroma cell lines below, which are a relatively precious resource.

Overexpression of CYLD in cylindroma cell lines

CYLD DNA sequences originating in humans or other eukaryotes will be purchased already cloned into replication deficient lentiviral transfer vectors described above and expressed in the primary cylindroma cell lines also described above. This will enable us to have an isogenic control of the cylindroma cell line with CYLD that is important for finding drugs that target CYLD deficient cells. CYLD is a tumour suppressor gene, and reintroduction of CYLD into the tumour cells should diminish their existing neoplastic status.

Evaluation of foreseeable effects

CYLD is a tumour suppressor gene and knockdown of this gene in HEK-293T cells using liposomal methods previously has not significantly altered the proliferation of such cells in tissue culture. We do not anticipate oncogenic transformations occur when these genes are singly knocked down in the neural crest cells or keratinocyte lines that we describe in this proposal. Only cells in tissue culture will be infected with the viral construct. These cells have no ability to survive outside tissue culture environment. Even in the event of a sharps injury, these cells (which will exist in very low numbers) will be destroyed by the human immune system.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not Applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Keratinocytes and neural crest stem cells, like any mammalian cells are extremely sensitive to rapid and complete inactivation by the disinfectants specified below which will be used in accordance with the manufacturer's instructions. Only disposable plastic pipettes will be used in the tissue culture facilities. Extra precautions will be taken by
disposing all liquid and solid contaminated waste in Virkon, prior to autoclaving.

All GMO waste materials including all tissue culture fluid etc generated in this project will be autoclaved. No other inactivation or waste disposal routes will be used. Spillages must be cleaned up with disinfectant and the tissues and other waste materials must then all be autoclaved prior to incineration. All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored using TST (Time, Steam, and Temperature) test strips (Albert Browne Ltd., TST class 6 emulating indicator 121°C for 20 min).

</table>
Recently new optogenetic methods have been developed that make it possible to target and modulate the activity of endophenotypically distinct groups of neurons with pulses of light. Viruses that encode for light-activated molecules can be injected into the CNS of rats and/or mice to target specific key cell types such as the parvalbumin-expressing interneurons that are critical for the generation of certain types of cortical network activity (Cardin et al 2009; Han et al 2009; Sohal et al 2009). Slices can then be prepared from treated animals after a few days and electrophysiological experiments performed. The key advantage of this technique is that specific cell types are genetically labelled so it is possible to directly control the activity of individual cell types in the network.

Rattus norvegicus/Mus musculus
It is essentially impossible for the modified genetic material to be transferred to other rats/mice if mating occurred.
The only phenotypic differences between the GMO and the wild type animal are that, upon exposure to focused, intense light (~10mW/mm²) the infected neurons will fire action potentials, and that the infected neurons will express fluorescent proteins (e.g. eGFP, mCherry).
Given the nature of the modification, it is unlikely that the GM animal poses any greater risk than wild type mice/rats.

Host/vector system
HEK293FT human embryonic kidney cell lines will be used as hosts for viral production.
E.coli strains such as DH5α will be used for plasmid production.
NB Production of plasmids and virus will be provided by a secondary supplier outside of Newcastle in all instances.
MIT (Boston) create self-inactivating lentiviruses by performing triple-transfection of HEK293FT cells with:
- a plasmid encoding for the gene of interest embedded in the lentiviral main backbone (e.g., FCK-hCmC for lentivirus).
- a plasmid encoding for packaging proteins for viral synthesis (e.g., pCMV-dR8.74 or pCMV-dR8.91 for lentivirus).
- a plasmid encoding for the viral coat protein (e.g., VSV).
No virus-producing cell lines are enduringly kept; we have found it most convenient, safe, and efficient to acutely triply-transfect fresh HEK293FT cells with plasmids each time we need to produce virus. No helper virus is needed for any of these protocols. The host range of the virus includes mice, rats, primates, and humans. We expect there to be no replication-competent virus.
MIT will, if required, periodically test for the presence of replication-competent lentivirus in producer cells by the following method: After 3 washes to remove original virus, supernatant that has been in the dishes for at least 12 hours with 293FT cells that have been infected with replication-defective virus expressing a measurable reporter
gene (GFP, dsRed2, neomycin, puromycin, or others) will be used to infect a second set of 293FT cells. These cells will be maintained for several weeks and screened for drug resistance or for expression of marker gene by flow cytometry. These highly sensitive assays are capable of identifying a single infected cell. These tests will be performed once for each construct used, since it is expected that the properties of each plasmid will be stable. The lentivirus constructs we use originated from the labs of Didier Trono and David Baltimore, and represent some of the safest and easiest-to-use vectors available for the delivery of genes into mammalian tissue. The resultant lentiviruses are replication-deficient, and are used in many labs at MIT and around the world, at this time. Furthermore, they are designed to be extraordinarily unlikely to become replication competent, with >2/3 of the viral genome deleted from the final packaged vector (including the abolition of all virus-production genes). These viruses have self-inactivating properties to prevent integrated genes from being repackaged, in the event a subsequent infection ever occurs. The lentivirus will be directly injected into target areas of the CNS of rats/mice under general anaesthesia using stereotactic surgery. 0.5-2 μl will be used, and the wound sutured. Virus and vectors will be injected (according the atlas of Paxinos and Watson) of adult rats/mice using a stereotaxic frame. Following local administration, animals will be allowed to recover. Animals injected with virus will be maintained in the CBC until transfer under deep anesthesia to labs within the Institute of Neuroscience (rooms MG144, MG183).

REFERENCES
Lentivirus

Origin & function
The lentiviral vector employed is based on HIV and has been attenuated by removal of over 2/3 of the viral genome along with parts of the 3'UTR (SIN type virus) and by having any viral packaging proteins and other proteins coded by up to three separate plasmids e.g.: a plasmid encoding for the gene of interest embedded in the lentiviral main backbone (e.g., FCK-hCmC), a plasmid encoding for packaging proteins for viral synthesis (e.g., pCMV-dR8.74 or pCMV-dR8.9), and a plasmid encoding for the viral coat protein (e.g., VSV). The nature of the modifications to the virus are such that it stable as both the parental vector and also the recombinant vector. The vector therefore does not present a major risk of homologous recombination (SACGM 2.11.14).

Ion channels/pumps to be employed are based on either rhodopsins from the unicellular green alga Chlamydomonas reinhardtii (Chr-1, Chr-2, ChiEF)(Boyden et al. Nat Neurosci. 2005 Sep;8(9):1263-8) or on the light-driven chloride pump halorhodopsin from the archaeabacterium Natronomas pharaonis (Han and Boyden, PLoS One. 2007 Mar 21;2(3):e299).

The modifications made to the naturally-occurring opsin are meant to optimize their expression and trafficking to the cell membrane in mammalian cells. These include: codon optimization for expression in mammalian cells, addition of an ER trafficking sequence. Such opsins, which allow modulation of neuronal voltage and activity have been safely used in a variety of model organisms, from C. elegans to mouse to rat to non-human primates (NHPs) without evidence of toxicity (Han et al. 2009, in particular, tested for safety in NHPs).

Fluorescent reporter proteins based on green fluorescent protein (GFP from Aequorea victoria), and other similar safe, non-toxic fluorescent proteins from other organisms (e.g. Discosoma spp. mCherry (Shaner et al Nature Biotechnology 22, 1567 - 1572 (2004)) will be used.

Evaluation of foreseeable effects
The self-inactivating lentivirus vector systems to be used are such that they have been extensively modified and are regarded as being stable, as are the inserted sequences. The lentiviral vector system to be used is considered to be “Third Generation” as defined by the SACGM Compendium of Guidance 2.11.9 as the accessory genes (vif, vpr, vpu, and nef) have been deleted along with the tat gene. The risk of dissemination of the described vector is extremely low due to it being replication incompetent and self-inactivating (SIN) (SACGM Compendium of Guidance, Part 2.11). The extensive modification of the viral vector also prevents homologous recombination with other related viruses (see 3A). All cultures are maintained under sterile conditions and it is unlikely that any hazardous sequences if they were present could be transferred to related organisms.

In the event of exposure, the GM virus could gain access to a limited number of human cells. However, direct consequences to human health of exposure to the virus are
expected to be negligible, because of the benign nature of the inserted genes. As detailed in the SACGM “transformation has not been seen when using lentivirus systems in a broad range of in vitro studies and animal studies using both in vivo and ex vivo protocols. Liver tumours have been observed following administration of lentiviral vectors to foetal and neo-natal animals”. Furthermore, the use of replication incompetent virus (see SACGM compendium of guidance, 2.11.9) ensures that only limited cells will be infected. The overall likelihood of hazard is therefore low. The animals are maintained to the standards prescribed in the Codes of Practice under the Animals (Scientific Procedures) Act 1986 which equate at least to containment level 1 as described in General Provisions of Part 3D in the Guide to the Genetically Modified Organisms (Contained Use) Regulations, 2000. The assessment is that containment level 2 is suitable for this work. The overall likelihood of hazard is therefore low. The only risk of the animals is allergenicity which is no greater than normal non-GM animals. Workers showing an allergic response to the animals are not required to come into contact with them. Consequently, there is a low risk to human health. All staff involved are regularly assessed for signs of allergy.

Mit the supplier will periodically test for the presence of replication-competent lentivirus in producer cells by the following method: After 3 washes to remove original virus, supernatant that has been in the dishes for at least 12 hours with 293 cells that have been infected with replication-defective virus expressing a measurable reporter gene (GFP, dsRed2, neomycin, puromycin, or others) will be used to infect a second set of 293 cells. These cells will be maintained for several weeks and screened for drug resistance or expression of marker gene by flow cytometry. These highly sensitive assays are capable of identifying a single infected cell. These tests will be performed once for each construct used, since it is expected that the properties of each plasmid will be stable.

Hypodermic needles will be used and therefore suitable training and precautions will be taken to minimise the potential for self inoculation. Needles to be used are of very narrow gauge (<30G) and flexible to allow insertion into soft tissue and as such are of lower risk than standard needles. Viral vectors will be injected using blunt needles (They are the WPI 36 guage blunt needle (NF36 BL-2) and the Hamilton 33 or 30 blunt needle (7803-05/00)) therefore minimising the risk of accidental injury. However, work will be conducted under the same safety controls as if using sharps. Virus injection is conducted by a controlled microinjection unit and there is no direct contact with the syringe or needle during injection.

Used “sharps” (pipette tips, scalpel blades, staples) will be collected in a yellow “CinBin” type container placed within the plenum of the MSC immediately after use. The container and all sharps will be autoclaved prior to disposal by the clinical waste route. Blunt needles will be used for injection but will be handled as if sharps. Denley boxes will be used to transport all materials to the autoclave.

All waste that is possibly contaminated with virus will be inactivated by incubation with a final concentration of at least 1% Virkon for 30 minutes and all of this waste will be collected in dedicated bags and these transferred to an autoclave using closed containers and will be inactivated by autoclaving at 121°C for 20 min. This procedure will ensure 100% killing efficiency. Autoclaving will be done at the end of each working day or on completion of work, whichever is the earliest. Temperature and time during each autoclave run will be monitored using indicator strips (TST control integrator, class 6 emulating indicator 121°C for 20 min, Albert Browne Ltd, UK). The autoclave will be serviced and tested on an annual basis using an independent thermocouple mapping test.

In the event of spillage of possibly virus-contaminated material, the area will be disinfected using 1% Virkon. The used paper towels and any other disposable material will be collected in dedicated bags and autoclaved as above. As all work is performed in a separate room, the wider environment is unlikely to become contaminated.
will be available in the surgery unit and in all other locations where the work will take place.

Withdrawn No 02/03/2022
Recently new optogenetic methods have been developed that make it possible to target and modulate the activity of endophenotypically distinct groups of neurons with pulses of light. Viruses that encode for light-activated molecules can be injected into the CNS of rats and/or mice to target specific key cell types such as the parvalbumin-expressing interneurons that are critical for the generation of certain types of cortical network activity (Cardin et al 2009; Han et al 2009; Sohal et al 2009). Slices can then be prepared from treated animals after a few days and electrophysiological experiments performed. The key advantage of this technique is that specific cell types are genetically labelled so it is possible to directly control the activity of individual cell types in the network.

Rattus norvegicus/Mus musculus

It is essentially impossible for the modified genetic material to be transferred to other rats/mice if mating occurred. The only phenotypic differences between the GMO and the wild type animal are that, upon exposure to focused, intense light (~10mW/mm²) the infected neurons will fire action potentials, and that the infected neurons will express fluorescent proteins (e.g. eGFP, mCherry). Given the nature of the modification, it is unlikely that the GM animal poses any greater risk than wild type mice/rats.

HEK293FT human embryonic kidney cell lines will be used as hosts for viral production. E.coli strains such as DH5a will be used for plasmid production.

MIT (Boston) create self-inactivating lentiviruses by performing triple-transfection of HEK293FT cells with:
- a plasmid encoding for the gene of interest embedded in the lentiviral main backbone (e.g., FCK-hCmC for lentivirus).
- a plasmid encoding for packaging proteins for viral synthesis (e.g., pCMV-dR8.74 or pCMV-dR8.91 for lentivirus).
- a plasmid encoding for the viral coat protein (e.g., VSV).

No virus-producing cell lines are enduringly kept; we have found it most convenient, safe, and efficient to acutely triply-transfect fresh HEK293FT cells with plasmids each time we need to produce virus. No helper virus is needed for any of these protocols. The host range of the virus includes mice, rats, primates, and humans. We expect there to be no replication-competent virus.

MIT will, if required, periodically test for the presence of replication-competent lentivirus in producer cells by the following method: After 3 washes to remove original virus, supernatant that has been in the dishes for at least 12 hours with 293FT cells that have been infected with replication-defective virus expressing a measurable reporter gene (GFP, dsRed2, neomycin, puromycin, or others) will be used to infect a second set of 293FT cells. These cells will be maintained for several weeks and screened for drug resistance or for expression of marker gene by flow cytometry. These highly sensitive assays are capable of identifying a single infected cell. These tests will be
The lentivirus constructs we use originated from the labs of Didier Trono and David Baltimore, and represent some of the safest and easiest-to-use vectors available for the delivery of genes into mammalian tissue. The resultant lentiviruses are replication-deficient, and are used in many labs at MIT and around the world, at this time. Furthermore, they are designed to be extraordinarily unlikely to become replication competent, with >2/3 of the viral genome deleted from the final packaged vector (including the abolition of all virus-production genes). These viruses have self-inactivating properties to prevent integrated genes from being repackaged, in the event a subsequent infection ever occurs.

The lentivirus will be directly injected into target areas of the CNS of rats/mice under general anaesthesia using stereotactic surgery, 0.5-2 μl will be used, and the wound sutured. Virus and vectors will be injected (according the atlas of Paxinios and Watson) of adult rats/mice using a stereotoxic frame. Following local administration, animals will be allowed to recover. Animals injected with virus will be maintained in the CRC until transfer under deep anaesthesia to labs within the Institute of Neuroscience (rooms MG144, MG183).

**REFERENCES**

**Lentivirus**

**Origin & function**

The lentiviral vector employed is based on HIV and has been attenuated by removal of over 2/3 of the viral genome along with parts of the 3'UTR (SIN type virus) and by having any viral packaging proteins and other proteins coded by up to three separate plasmids e.g.:

- a plasmid encoding for the gene of interest embedded in the lentiviral main backbone (e.g., FCK-hCmC),
- a plasmid encoding for packaging proteins for viral synthesis (e.g., pCMV-ΔR8.74 or pCMV-ΔR8.9), and
- a plasmid encoding for the viral coat protein (e.g., VSV).

The modifications to the virus are such that it stable as both the parental vector and also the recombinant vector. The vector therefore does not present a major risk of homologous recombination (SACGM 2.11.14).

**Evaluation of foreseeable effects**

The self-inactivating lentivirus vector systems to be used are such that they have been extensively modified and are regarded as being stable, as are the inserted sequences. The lentiviral vector system to be used is considered to be "Third Generation" as defined by the SACGM Compendium of Guidance 2.11.9 as the accessory genes (vif, vpr, vpu, and nef) have been deleted along with the tat gene. The risk of dissemination of the described vector is extremely low due to it being replication incompetent and self-inactivating (SIN) (SACGM Compendium of Guidance, Part 2.11). The extensive modification of the viral vector also prevents homologous recombination with other related viruses (see 3A). All cultures are maintained under sterile conditions and it is unlikely that any hazardous sequences if they were present could be transferred to related organisms.

In the event of exposure, the GM virus could gain access to a limited number of human cells. However, direct consequences to human health of exposure to the virus are expected to be negligible, because of the benign nature of the inserted genes.

As detailed in the SACGM "transformation has not been seen when using lentivirus systems in a broad range of in vitro studies and animal studies using both in vivo and
The overall likelihood of hazard is therefore low.

The animals are maintained to the standards prescribed in the Codes of Practice under the Animals (Scientific Procedures) Act 1986 which equate at least to containment level 1 as described in General Provisions of Part 3D in the Guide to the Genetically Modified Organisms (Contained Use) Regulations, 2000. The assessment is that containment level 2 is suitable for this work.

The only risk of the animals is allergenicity which is no greater than normal non-GM animals.

Workers showing an allergic response to the animals are not required to come into contact with them. Consequently, there is a low risk to human health. All staff involved are regularly assessed for signs of allergy.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

The self-inactivating lentivirus vector systems to be used are such that they have been extensively modified and are regarded as being stable, as are the inserted sequences. The lentiviral vector system to be used is considered to be “Third Generation” as defined by the SACGM Compendium of Guidance 2.11.9 as the accessory genes (vif, vpr, vpu, and nef) have been deleted along with the tat gene. The risk of dissemination of the described vector is extremely low due to it being replication incompetent and self-inactivating (SIN) (SACGM Compendium of Guidance, Part 2.11). The extensive modification of the viral vector also prevents homologous recombination with other related viruses (see 3A). All cultures are maintained under sterile conditions and it is unlikely that any hazardous sequences if they were present could be transferred to related organisms.

In the event of exposure, the GM virus could gain access to a limited number of human cells. However, direct consequences to human health of exposure to the virus are expected to be negligible, because of the benign nature of the inserted genes.

As detailed in the SACGM “transformation has not been seen when using lentivirus systems in a broad range of in vitro studies and animal studies using both in vivo and ex vivo protocols.....liver tumours have been observed following administration of lentiviral vectors to foetal and neo-natal animals”. Furthermore, the use of replication incompetent virus (see SACGM compendium of guidance, 2.11.9) ensures that only limited cells will be infected.

The overall likelihood of hazard is therefore low.

Workers showing an allergic response to the animals are not required to come into contact with them. Consequently, there is a low risk to human health. All staff involved are regularly assessed for signs of allergy.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not Applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste that is possibly contaminated with virus will be inactivated by incubation with a final concentration of at least 1% Virkon for 30 minutes and all of this waste will be collected in dedicated bags and transferred to an autoclave using closed containers and will be inactivated by autoclaving at 121°C for 20 min. This procedure will ensure 100% killing efficiency. Autoclaving will be done at the end of each working day or on completion of work, whichever is the earliest.

Temperature and time during each autoclave run will be monitored using indicator strips (TST control integrator, class 6 emulating indicator 121ºC for 20 min, Albert Browne Ltd, UK). The autoclave will be serviced and tested on an annual basis using an independent thermocouple mapping test.

In the event of spillage of possibly virus-contaminated material, the area will be disinfected using 1% Virkon. The used paper towels and any other disposable material will be collected in dedicated bags and autoclaved as above. As all work is performed in a separate room, the wider environment is unlikely to become contaminated. A spill kit will be available in the surgery unit and in all other locations where the work will take place.
The University GM Safety Committee has approved the GM Risk Assessments:

Project Additional Information

Purposes of the contained use

We will prepare cultures of non-clinical strains of Staphylococcus aureus for biochemical analysis to identify proteins involved in metal homeostasis of this organism. S. aureus will be cultured in small quantities for the isolation and analysis of nucleic acids and proteins. This will involve liquid culture of S. aureus, centrifugation, gel electrophoresis, liquid chromatography, MALDI-TOF-MS mass fingerprinting. Genes encoding proteins involved in metal homeostasis will be genetically inactivated, followed by biochemical and phenotypic analysis.

Recipient or parental organism

The organism for study is the hazard group 2 biological agent Staphylococcus aureus, using the common lab strain 8325-4 and derivatives thereof (RN4220, SH1000). Strain 8325-4 is a derivative of the NCTC8325 parent strain that was UV-cured of prophages phi12 and phi13 (which encode virulence genes chip, scin & sak) and phi11 (Novick & Richmond, 1965, J. Bacteriol. 90, pp 467-480).

Host/vector system

Several non-mobilisable plasmid vectors will be used for allelic replacement and subsequent complementation:

Plasmid pOB (Horsburgh, MJ et al., 2002, Mol. Microbiol. 44, 1269-1286), a suicide vector derived from the E. coli plasmid pGEM3zf incorporating an erythromycin resistance cassette, can be used for integration of mutant alleles into the restriction-deficient strain RN4220.

Plasmid pAUL-A is an E. coli – S. aureus shuttle vector constructed (Chen, JD & Morrison, DA, 1987, Gene 55, 179-187) by fusion of a fragment from the E. coli vector pJDC9 containing a multiple cloning site, transcription terminators and erythromycin resistance cassette, with a fragment from the native S. aureus plasmid pE194 containing a temperature-sensitive Gram-positive replication origin. This plasmid can also be used for integration of mutant alleles into the host genome, as it can be maintained in S. aureus at permissive temperatures and integrants acquired by selection at nonpermissive temperatures.

Plasmid pMK4, an E. coli – S. aureus shuttle vector constructed (Sullivan, MA et al., 1984, Gene 29, 21-26) by fusion of fragments from the E. coli vector pUC9, containing E. coli replication origin and ampicillin resistance cassette, and the native S. aureus plasmid pC194, containing a Gram-positive replication origin and a chloramphenicol resistance cassette, is used for complementation of mutants.

Phi11 is a serogroup B bacteriophage native to S. aureus NCTC8325 that is used for transduction of the mutant allele from the restriction deficient RN4220 strain to the
Origin & function

The intended mutations will involve interruption of a gene through insertion of a selectable marker. DNA sequences flanking the target gene will be amplified by polymerase chain reaction from S. aureus genomic DNA and cloned into plasmid vectors. Resistance determinant gene will be sub-cloned from commercially available vector (e.g. kanamycin resistance gene from pUC4K) and integrated into the target gene on this vector. S. aureus RN4220 is transformed with this construct using standard protocols (see 'Staphylococcus: Molecular genetics,' 2008, Ed. Lindsay, JA) and the mutant allele incorporated into the genome by homologous recombination. The locus is transduced into the host 8325-4 strain by using the bacteriophage phi11. Integration site is confirmed by PCR methods. Selectable markers will consist of antibiotic resistance determinants.

The initial target genes for insertional inactivation are the two chromosomally-encoded isozymes of superoxide dismutase (MnSOD). Future gene targets for insertional inactivation will be determined from preliminary results with wild type and will encode metalloenzymes and/or metal homeostasis factors, allowing phenotypic analysis of mutant strains in order to elucidate gene function.

Evaluation of foreseeable effects

The initial target genes for insertional inactivation are the two isozymes of MnSOD, named sodA and sodM. Strains in which these genes have been inactivated have previously been generated and analysed elsewhere, leading to reduced virulence in a mouse abscess model (Karavolos, MH et al., 2003, Microbiology 149, 2749-2758). These genes will either be inactivated as described or the mutant strain acquired from a collaborator. Future gene targets for insertional inactivation will be determined from preliminary results with wild type and will encode metalloenzymes and/or metal homeostasis factors. Some of these metalloproteins have the potential to be virulence factors, either through the involvement of the encoded proteins in host recognition/attachment or immune defence (e.g. SodA/M), or as regulators of important bacterial processes (e.g. peroxide sensor PerR, iron regulator Fur). In most cases, due to the importance of effective metal homeostasis to cell survival, and the role of metal starvation as a mechanism of immune defence against pathogenic infections (Corbin et al., 2009, Science 319, 962), strains in which such genes are inactivated would be expected to exhibit equivalent or reduced virulence relative to the host strain. However, in a small number of cases, such as the inactivation of a negative regulator of virulence gene expression, the mutant strain has the potential for increased virulence.
The University GM Safety Committee has approved the GM Risk Assessment:

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
Human embryonic stem cells (hESCs) and induced pluripotent stem cells (iPSCs) are able to differentiate into any cell type of the body and hence are important tools for i) providing in vitro models to study the cellular effects of development and disease and ii) developing cell therapies in tissue regeneration strategies. We have derived hESC lines from surplus human embryos and wish to research the molecular mechanisms that regulate pluripotency and differentiation into particular cell lineages (with emphasis on generating chondrocytes (cartilage) and osteoblasts (bone) and researching the developmentally regulated mechanisms that enable germ cells to enter meiosis). We will also carry out comparative studies with induced pluripotent cells generated from somatic cell types. We will begin by assaying a diverse selection of somatic cell types in order to investigate i) those that are most conducive to genetic reprogramming and ii) identify if different genetic factors / experimental conditions are required for different cell types. For this programme of work we will need to genetically modify hESCs and somatic cells by transfection with relevant genes, lineage-specific promoter elements and reporter gene sequences. In parallel we carry out comparative experiments with embryonic and somatic cells obtained from mouse and equine sources as part of our programme to identify species differences of stem cell behaviour.

Because of the low efficiency of transfection associated with hESCs and the primary cell types that we are using, we will employ lentiviral transfection technology to achieve a satisfactory level of transfection efficiency. Whilst this work will be carried out in parallel and will be complimentary to our existing programmes investigating the clinical application of stem cells this is purely a research project and lentivirally-transfected cells will not be used in the clinic.

Aims:

1) To generate iPSCs by lentiviral transfection of somatic cells.

2) Lentiviral transfection of ESCs with genetic reporter constructs in order to monitor the live cell pluripotent / differentiation status of hESCs and their derivatives.

3) Lentiviral transfection of molecular components involved in the driving differentiation of hESC and iPSC to cell lineages.

4) To investigate the regulation of meiosis-specific genes.

Recipient or parental organism

Cell lines in culture:

Human embryonic kidney cell line 293FT are a human embryonic kidney cell line optimised for viral transfection.
http://tools.invitrogen.com/content/sfs/manuals/293ft_cells_man.pdf

hESC lines including NCL1-5 (available from the UK Stem Cell Bank), hESC lines that have been derived at Newcastle University and are yet to be banked in the UK Stem Cell Bank, hESC lines that will be derived at Newcastle University and banked in the UK Stem Cell Bank during the course of this project. Primary human chondrocytes, primary mesenchymal stem cells derived from bone marrow and haemarthrosis aspirates, primary human skin fibroblasts, human amnion fibroblasts (HAF006), primary...
keratinocytes. iPSCs which are generated from the above mentioned somatic cells.
Mouse embryonic fibroblasts, derived in house or purchased from a commercial source.
In-house derived equine umbilical cord, keratinocytes and skin fibroblasts
All of these cells are unable to survive outside tissue culture conditions and are antigenically incompatible if accidently introduced to humans.

**Host/vector system**

**Lentiviral Packaging Vectors:**

- **pMDLg/pRRE**
  - Genes: gag and pol. Encodes structural proteins (gag) and enzymes (reverse transcriptase, integrase & protease) for viral replication. There is also a rev response element (RRE) in the encoded RNA.
  - Promoter: CMV

- **pMD2.VSVG**
  - Gene: VSV-G. Encodes envelope glycoprotein from the vesicular stomatitis virus.
  - Promoter: CMV

- **pRSV-Rev**
  - Gene = Rev. Rev interacts with transcribed viral RNAs (via the RRE) to facilitate nuclear export such that translation may take place. Rev is therefore beneficial for the expression of structural proteins to make daughter virions.
  - Promoter RSV

**Lentiviral Transfer Vectors:**

- **pCCLsin.PPT.Prom.[insert].Wpre**
  - The insert and viral DNAs are engineered into sites downstream of strong constitutive promoters (designated as Prom) (RSV, CMV, CAG and SV40) for some experiments cell lineage-specific promoters will be engineered into the vector. In both cases there will be no attempt to maximise expression. Insert refers to the gene or reporter of interest.
  - All of the vectors are based on the pUC19 backbone, defective in transfer to other hosts and are Bom-, Tra-Mob- (Follenzi and Naldini 2002)

**Origin & function**
Either genomic or cDNA sequences originating in humans and reporter sequences will be cloned into the lentiviral vectors using standard laboratory techniques. These will include both entire gene sequences, partial gene sequences and promoter sequences. Some of the factors we are going to introduce into the cell lines are novel and their biological effects are not fully investigated and as such there is the possibility that they could render the cells neoplastic.

Generation of iPSCs: the following genes have been identified as being involved in the reprogramming of somatic cells to a pluripotent phenotype. As such as part of our optimisation experiments we will transfect somatic cells with combinations of these genes in order to assay the most appropriate protocol for each cell type:

- SOX2- is involved in the maintenance and self-renewal of hESC and is one of many factors that are involved in the reprogramming of somatic cells to a pluripotent phenotype (Yu et al 2007, Takahashi et al 2007). cDNA will be generated from pluripotent hESCs.
- OCT4- is involved in the maintenance and self-renewal of hESC and is one of many factors that are involved in the reprogramming of somatic cells to a pluripotent phenotype (Yu et al 2007, Takahashi et al 2007). cDNA will be generated from pluripotent hESCs.
- NANOG- is involved in the maintenance and self-renewal of hESC and is one of many factors that are involved in the reprogramming of somatic cells to a pluripotent phenotype (Yu et al 2007, Takahashi et al 2007). cDNA will be generated from pluripotent hESCs.
- LIN28- is involved in regulating the expression of genes that control cell cycle and is widely expressed during the early stages of embryogenesis and is one of many factors that are involved in the reprogramming of somatic cells to a pluripotent phenotype (Yu et al 2007). cDNA will be generated from pluripotent hESCs or mature oocytes.
- KLF4- is expressed in many cell types and is involved in regulating proliferation, terminal differentiation and apoptosis. Depending on the cellular context KLF-4 can act as an oncogene or a tumour suppressor. It is one of many factors involved in the reprogramming of somatic cells to a pluripotent phenotype (Takahashi et al 2007). cDNA will be generated from pluripotent hESCs.
- c-MYC- is involved in regulating cell cycle progression in stem cells and during development and tissue homeostasis. It is one of many factors involved in the reprogramming of somatic cells to a pluripotent phenotype (Takahashi et al 2007). cDNA will be generated from pluripotent hESCs.
- Tbx3- is involved in regulating stem cell pluripotency and has been shown to increase the efficiency of iPSC generation (Han et al 2010). cDNA will be generated from pluripotent hESCs.

Cell lineage-specific promoter sequences will be cloned from human genomic DNA (purchased from a commercial supplier e.g. Promega). Experiment-dependent promoter sequences will be used to drive reporter elements and hence will be indicative of the pluripotent / cell lineage status of the cell.

Meiosis-specific genes will be sourced from human oocytes
- E2F6 is a transcription factor involved in suppressing expression of the meiosis-specific cohesin proteins SMC1B and Stag3 (Storre et al, 2005).
- Rec8-myc: Rec8 is a meiosis-specific cohesin protein, which will be tagged with myc to facilitate detection
- Histone H2 is a core nucleosomal histone, which maintains its function when tagged with a fluorescent protein and thereby provides a means to visualise chromosome dynamics by live cell imaging.
- Histone H1foo is an oocyte-specific linker histone
- Stra8 is a transcription factor expressed by spermatogonia
- Sycp1 is expressed during early meiosis of spermatocytes
- Pgx2 is expressed during late meiosis
- Prm1 is a post-meiotic transcription factor
- SFRS10 (cDNA) is a splicing factor expressed in meiosis
- TRA2A (cDNA) is a splicing factor expressed in meiosis
- SAM68 (cDNA) is a splicing factor expressed in meiosis
- T-STAR (cDNA) is a splicing factor expressed in meiosis
- ASPP1 (cDNA) is an apoptosis factor expressed in meiosis
• RBMX (cDNA) is a splicing factor expressed in meiosis
• hnRNP G-T (cDNA) is a splicing factor expressed in meiosis

siRNA experiments specific to meiosis-specific genes will be carried out by designing short-hairpin (sh) sequences in conjunction using commercially available software (eg Ambion or Sigma-Aldrich) and cloning in to lentiviral vectors as described by Manjunath et al 2009.

Reporter elements will be:

• EGFP – Aequorea Victoria jellyfish
• Venus/YFP - Vibrio fischeri
• RFP – Discosoma species of coral

Reporter cassettes will be obtained from plasmids gifted by Dr Owen Jones (Manchester University). These and related fluores are non-toxic and have no biological activity.

• Luciferase cDNA cassette will be generated from cDNA of stably-transfected CHO/N2-luc cell line (Wong et al 2003, Oldershaw et al 2008) and engineered into the appropriate vector

Overexpression of cell lineage-specific transcription factors will be used to drive differentiation toward particular cell types:

• L-SOX5, SOX6 and SOX9 cDNA will be generated from primary chondrocytes.
• CBFA1 and OSTERIX cDNA will be generated from osteoblasts obtained by differentiation of human bone marrow mononuclear cells.
• Notch signalling transmembrane receptors, Notch1, Notch2, Notch 3 and Notch4 and transmembrane ligands, Jagged1, Jagged2 and Delta are involved in mediating cell fate decisions during embryogenesis (Brennan & Gardner). Overexpression of receptor and ligand sequences obtained from cDNA of cell lineages known to express specific components will be used to delineate the mechanisms by which ES cell differentiation is regulated by Notch signalling.

Evaluation of foreseeable effects

Bacterial hosts for cloning and sequencing:

Disabled E. coli K12 derived bacterial host strains (e.g. TOP10, SURE, JM109, DH5, etc) (non-pathogenic to human) will be used in conjunction with non-mobilisable vector systems. Vectors are based on a pUC19 backbone which is Tra- and Bom- and thus mobilisation defective. These host/vector systems have been widely used over many years and have a long history of safe application. ACDP classification of the host is containment level 1. Cloning, amplification and isolation of plasmids is necessary to later package the virus. The gene product will not be expressed because the vectors lack the necessary promoters for the genes to be expressed in E.Coli. Also, the absence of eukaryotic translation/post-translational modification system would prevent the formation of a functional protein.

Packaging cell line:

Human embryonic kidney cell line 293FT are a human embryonic kidney cell line optimised for viral transfection.
http://tools.invitrogen.com/content/sfs/manuals/293ft_cells_man.pdf

These cells are unable to survive outside tissue culture conditions and are antigenically incompatible if accidently introduced to humans.

Host cells to be transfected with lentiviral particles are:

1) hESC lines including NCL1-5 (available from the UK Stem Cell Bank)
2) hESC lines that have been derived at Newcastle University and are yet to be banked in the UK Stem Cell Bank
3) hESC lines that will be derived at Newcastle University and banked in the UK Stem Cell Bank during the course of this project
4) Primary human chondrocytes isolated from cartilage tissue obtained through ethical consent of patients undergoing surgical procedures
5) Primary mesenchymal stem cells derived from bone marrow and haemarthrosis aspirates. Bone marrow mononuclear cells will be purchased from a commercial supplier (eg Lonza) and used to derived mesenchymal stem cells
6) Primary human foreskin fibroblasts. FED1 was generated by Dr Mary Herbert's group at Newcastle University in conjunction with the Bio-manufacturing facility at Newcastle University, this line is HTA approved. NUFF1 was purchased from a commercial source.
7) Human amnion fibroblasts (HAF006)
8) Primary keratinocytes obtained by Dr Mary Herbert's group with ethical approval
9) iPSCs which are generated from the above mentioned somatic cells.
10) Mouse embryo fibroblasts
11) NIH 3T3 cells

All host cells are unable to survive outside tissue culture conditions and are antigenically incompatible if accidently introduced to humans.

It is possible that infection may occur should the virus come into contact with broken skin or mucous membranes and as such the greatest risk to the operator comes from needlestick injury or from inhalation of aerosols. It is possible that some of the genes that are transfected might have oncogenic effects and there is no guarantee on the detrimental effects that could be caused.

Overexpression of transcription factors expressed by differentiated cell types (e.g. L-SOX5, SOX6, SOX9, CBFA1 and OSTERIX) are involved in regulating the differentiation status of the cell and hence would be unlikely to render the cells neoplastic within the context of the experiments described in this proposal. Notch signalling components described can promote or suppress tumorigenesis depending upon the cellular context. The gene products will be biologically active when transfected into mammalian cells. However, the recipient transfected cells will either be embryonic or somatic stem cells that have a history of safe use and may be regarded as posing minimal risk. Meiotic-specific genes would unlikely have a physiological effect since they will not be presented in a cellular environment that will perpetuate the effects of their expression. These hosts can be considered especially disabled hosts because the cell lines are unable to colonise the worker (i.e. not their own cells)
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/a

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All genetically modified organisms including bacteriological and mammalian cells will be inactivated by Virkon® disinfectant. 2% (w/v) and then autoclaved before disposal.

The designated Microbiological Safety cabinet and centrifuge will be disinfected by thoroughly wiping down with 2% (w/v) Virkon® solution followed by 70% ethanol before and after every use. The Microbiological Safety cabinet will also be irradiated for 5 minutes with UV after every use.

Solid waste (e.g. cultureware, pipette tips, used gloves etc) will be autoclaved. Prior to autoclaving, waste will be stored in designated yellow waste bins. Autoclaving all of the waste will take place as soon as possible, in the nearest available autoclave (same building/floor) by an authorised person. Once autoclaved, all bags will be disposed of by incineration.

Liquid waste (e.g. cultures in flasks or spent media) will be sterilised in the culture flasks on in designated waste bins by addition of Virkon® to a concentration of 2% (w/v) and left overnight. Virkon®-disinfected solutions will be autoclaved and then disposed of through the incineration route.

Virally-treated cells, tissues and packaging cells (293 cells) will be disposed of (following the removal and appropriate disposal of culture medium) by addition of 2% (w/v) Virkon® solution. Cultureware will subsequently be disposed as per solid waste.

All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile.

The University GM Safety Committee has approved the GM Risk Assessments:

Local GM references: GM 10/08.

Principal Investigator: Dr Rachel Oldershaw.

GM 10/08 Application of lentiviral vectors in the characterisation of the pluripotent and differentiated state of induced pluripotent stem cells and human embryonic stem cells.
The aim of this project is to study the role of specific components from the polysaccharide utilisation systems of Bacteroides thetaiotaomicron (Bt), a prominent member of our indigenous gut microbiota. Bt is able to use a wide range of plant and animal derived polysaccharides as its major source of carbon and energy. The genes that encode the machinery to access and degrade these polysaccharides are organised into co-regulated polysaccharide utilisation loci (PULs), each of which is specific for a particular polysaccharide. The key features that define a PUL are a pair of outer membrane associated carbohydrate binding and transport proteins, a number of carbohydrate-active catabolic enzymes and a closely linked inner membrane spanning sensor-regulator system.

In this project we will study the role of specific genes within different PULs by creating ‘clean’ deletions of these genes and studying the phenotype of the these knockout strains. Complemented mutant strains containing a single copy of the deleted gene reinserted at a specific site in the genome will be also be made.
The protocol to be used to create the knockout strains is an adaptation of the standard counter-selectable allelic exchange procedure employed in bacterial genetics based on a series of two recombination events. The method of counter-selection is based on sensitivity of Bacteroides spp. that contain a functional copy of the tdk gene (BT2275 in B. theta VPI-5482), which encodes a thymidine kinase (Tdk) involved in the pyrimidine salvage pathway, to the nucleotide analogue 5-fluoro-2-deoxy-uridine (FUDR).

Briefly, FUDR is imported into the bacterial cell and phosphorylated by Tdk, forming 5-fluoro-2-deoxy-uridine monophosphate (FdUMP), an event that activates its ability to bind irreversibly to an enzyme in the de novo thymidine biosynthetic pathway, ThyA. Thus, in the presence of Tdk FUDR ‘poisons’ the de novo biosynthetic pathway for thymidine. In this gene deletion protocol, genetic recombination must be conducted in a B. theta parent strain that has a deletion of tdk. This strain although not truly ‘wild-type’ due to its deletion of tdk, does not exhibit any auxotrophies (i.e., it still has a functional de novo pyrimidine pathway, which it can use during in vitro or in vivo growth in the absence of pyrimidines).

**Recipient or parental organism**

Bacteroides thetaiotaomicron VPI-5482 (Type strain), lacking the tdk gene (see section 6 above for description of tdk gene product). Bacteroides thetaiotaomicron is a prominent member of our resident gut microbiota and is known to play a significant role in maintaining health and nutrition, but is also an opportunistic pathogen when outside its normal niche (colon) and as such is classified as ACDP hazard group 2. It can cause bacteremia, peritonitis, endocarditis and wound infections. Can invade tissues after surgical or accidental trauma or tissue destruction (from infection with other organisms or malignancies). Risk of infection from other routes is negligible.

**Host/vector system**

Cloning host: Escherichia coli S17-1pir (conjugal K12 lysogenized for pir)

Vectors: The vectors to be used are both mobilisable, but replication limited ‘suicide’ vectors (pExchange-tdk and pNBU2-bla-ermGa/b). Both vectors can be maintained only in disabled E. coli K12 hosts containing a chromosomally inserted Lambda pir gene, which is required for replication of these plasmids. Thus, in the very unlikely event of unintended mobilisation to a different strain or species these vectors would be incapable of replicating in most cases. In the even more unlikely event of unintended mobilisation to another E. coli strain already carrying a Lambda phage actively expressing the pir gene that permits plasmid replication, it is difficult to envisage any detrimental effects arising from expression of the cloned genes as; i) they are not involved in any harmful traits (they are polysaccharide utilisation genes); ii) would have limited activity when expressed in isolation i.e. without the other co-regulated genes that make up an individual polysaccharide utilisation locus.

In addition, the drug resistance markers used in these plasmids are already widely distributed in nature.

Details of vectors:

- **pExchange-tdk** comprises: an E. coli R6K replication origin, an E. coli RP4 mobilization region, an ampicillin resistance gene (bla) for selection in E. coli, an erythromycin resistance gene (ermB) for selection in Bacteroides spp., and a copy of the BT2275 tdk gene (encodes Bt thymidine kinase) and promoter region, which upon chromosomal integration restores FUDR sensitivity (see section 2.1 above) and allows eventual counter-selection against pExchange-tdk.
- **pNBU2-bla-ermGa/b**. Bacteroides species integrative vector. Derivative of pKNOCK-bla-ermGb (see below) into which a PCR-amplified intN2-att fragment was inserted using engineered SalI and KpnI ends (intN2 encodes a Bacteroides integrase gene). MCS sites can be used to insert fragments into pNbu2-erm-a/b and the entire plasmid construct can then be conjugated into B. thetaiotaomicron and insertions made into either of the two NBU2-targeted tRNAser attachment sites (Wang et al. 2000. J. Bacteriol. 182: 3559–3571). pKNOCK-bla-ermGb suicide vectors - Base suicide vectors contain ermG for selection on erythromycin in Bacteroides spp. and bla for selection on ampicillin in E. coli. Vectors are derivatives of pKNOCK-cm (Alexeyev, 1999. Biotechniques 26: 824-828). The pBR325 cat gene was removed from pKNOCK-cm by MluI digestion and replaced with a PCR-amplified, bla-ermG-containing fragment from pGERM (Salyers et al. 2000. Methods 20: 35-46). The added bla-ermG fragment, with MluI ends, was inserted into the pKNOCK-cm MluI sites in both possible orientations ("a" and "b" designation).

**Origin & function**

The genes to be deleted from B. thetaiotaomicron are involved in polysaccharide utilisation in this bacterium and other gut Bacteroides spp. and enable these organisms to use a wide range of plant and animal derived glycans as a source of carbon and energy in the gut. They are therefore pivotal to the bacterium’s ability to survive in its specific niche and thus it is difficult to envisage how deletion of these genes would create a GM bacterium that was more hazardous than the wild-type strain.
In terms of cloning of these genes in E. coli it could be argued that they could endow a recipient organism with the ability to survive in a non-natural niche such as the human gut. However, B. thetaiotaomicron requires at least 6 different genes to utilise each polysaccharide, and as only one gene will be cloned in E. coli at a time for the complementation studies it is highly unlikely that a single gene product would confer any enhanced survival traits on the recipient organism.

During the allelic exchange protocol to delete specific genes from B. thetaiotaomicron one of the steps involves selection for a single crossover event where the whole suicide vector is inserted into the chromosome, thus creating a Bt strain that carries both the ampicillin (bla) and erythromycin resistance genes (ermG). However this is selected against in the next step so that the final GM Bt strain contains no extraneous vector sequences.

**Evaluation of foreseeable effects**

The polysaccharide utilisation genes that are to be disrupted/deleted are not involved in the ability of B. thetaiotaomicron to cause disease and even if they were, the removal of these genes as proposed would be more likely to create a less pathogenic strain than the wild-type. The risk of these genes altering existing pathogenic traits of this organism is therefore negligible.

The use of suicide vectors that can only replicate in specific E. coli hosts for these experiments minimises the likelihood of transfer of the genes to other species. The mobilisable suicide vectors require the pir gene product for their replication and this would not be available in most other species, minimising the risks of transfer when using these vectors. Furthermore, in the unlikely event of transfer to another species it is difficult to envisage how a single polysaccharide utilisation gene could confer/increase virulence of the recipient organism.

The likelihood of the GMMs causing harm to humans should be no greater (and in most cases significantly less) than associated with the wild type B. thetaiotaomicron or E. coli strains. This is risk extremely low as the E. coli strain to be used (S17-1λpir) is non-pathogenic and while B. thetaiotaomicron is an opportunistic pathogen its ability to cause disease is limited to very specific circumstances such as gut injury where the number of bacteria getting into the bloodstream is very large.

## Purposes of the contained use

Recently new optogenetic methods have been developed that make it possible to target and modulate the activity of endophenotypically distinct groups of neurons with pulses of light. Viruses that encode for light-activated molecules can be injected into slices of acutely resected human brain tissue to target specific key cell types such as the parvalbumin-expressing interneurons that are critical for the generation of certain types of cortical network activity (Cardin et al 2009; Han et al 2009; Sohal et al 2009). Slices can then be incubated with the virus for 4-8h and electrophysiological experiments performed. The key advantage of this technique is that specific cell types are genetically labelled so it is possible to directly control the activity of individual cell types in the network.

## Resected brain tissue from patients with epilepsy or tumours.

The only phenotypic differences between the virus-infected tissue and normal brain tissue is that, upon exposure to focused, intense light (~10mW/mm^2) the infected neurons will fire action potentials, and that the infected neurons will express fluorescent proteins (e.g. eGFP, mCherry).

Given the in vitro nature of the modification, and the short life of the virus (c.2-4h in cerebrospinal fluid at room temperature) to be used it is unlikely that the GM tissue poses any risk.

## Host/vector system

**Host:**
Recombinant Herpes simplex virus. The bacterial host strains used to prepare the plasmids for recombinant HSV-1 generation are E. coli K12 derivatives such as DH5a, HB101, MC1061.

The cell lines used to generate recombinant virus are human 293 and 293T cells and derivatives, HeLa, VERO, and the VERO cell derivative 2-2, which contains the HSV IE 2 gene (Smith et al., Virology 1992; 186:74-86). None of this work will be performed at Newcastle.

**Vector system:**

The plasmid vectors are HSVPrpUC-based HSV amplicon vectors detailed in Neve et al., Biotechniques 2005; 39:381-391, which includes figures showing the map of their amplicon vector HSVPrpUC and an overview of the packaging procedure. They use 2-2 (VERO cells containing the HSV IE 2 gene) as a packaging line, and 5dl1.2 (partial IE 2 deletion mutant of HSV-1; McCarthy et al., J Virol 1989; 63:18-27)) as a disabled helper virus. Thorough characterization of each viral vector stock involves measuring helper plaque-forming units per ml (pfu/ml) on VERO 2-2 cells and wild type HSV-1 pfu/ml on VERO cells to ensure the absence of any wild type HSV-1. These methods are detailed in the following reference: Lim F, Neve RL. Generation of high-titer defective HSV-1 vectors. In: Current Protocols in Neuroscience. New York: Greene Publishing Associates and Wiley-Interscience, 1999, pp. 4.13.1-4.13.17.

Since using the 2-2/dl1.2 packaging system (from 1997), Neve and co-workers have never detected replication-competent viruses in their stocks. They have generated over 2000 ml of virus @ 108 lu/ml and have never observed any production of replication-competent viruses.

## Origin & function

The HSV.p1005 virus employed is a modified HSVPrpUC with an added cistron expressing eGFP. This dual-cistronic virus produces a separate transcript (separate promoter and an SV40 poly-A signal) for GFP. The cassettes are in a nose-to-tail orientation. The target gene is still driven by the IE 4/5 while the eGFP is driven by a CMV promoter. Co-expression is generally >90%. Therefore, this construct is good for electrophysiology.

Ion channels/pumps to be employed are based on either rhodopsins from the unicellular green alga Chlamydomonas reinhardtii (Chr-1, Chr-2, ChIEF)(Boyden et al. Nat Neurosci. 2005 Sep;8(9):1263-8) or on the light-driven chloride pump halorhodopsin from the archaebacterium Natronomas pharaonis (Han and Boyden, PLoS One. 2007 Mar 21;2(3):e299).

The modifications made to the naturally-occurring opsin are meant to optimize their expression and trafficking to the cell membrane in mammalian cells. These include: codon optimization for expression in mammalian cells, addition of an ER trafficking sequence. Such opsins, which allow modulation of neuronal voltage and activity have
been safely used in a variety of model organisms, from C. elegans to mouse to rat to non-human primates (NHPs) without evidence of toxicity (Han et al. 2009, in particular, tested for safety in NHPs).

Fluorescent reporter proteins based on green fluorescent protein (GFP from Aequorea victoria), and other similar safe, non-toxic fluorescent proteins from other organisms (e.g. Discosoma spp. mCherry (Shaner et al Nature Biotechnology 22, 1567 - 1572 (2004)) will also be used. While this technique cannot provide the degree of cell specific transfection possible with the use of cre transgenic animals, we will use partially cell subtype specific promoters targeting interneurons (DLX) and principal cells (CamKII and TH).

**Evaluation of foreseeable effects**

The bacterial host strains are E. coli K12: DH5α, HB101, MC1061 for production of plasmids (N.B. These will be held by our collaborators at MIT and no plasmids or bacteria will be held in Newcastle).

The cell lines are 293 cells and derivatives (e.g. 293T), HeLa, VERO (African green monkey), and the VERO cell derivative 2-2, which contains the HSV-1 IE 2 gene for the production of virus (none of these cells will be held in Newcastle).

Viruses to be used are replication incompetent (SACGM 2.9.10).

NB. Production of plasmids and virus will be provided by a secondary supplier outside of Newcastle in all instances (MIT). MIT will, periodically, test for the presence of replication-competent HSV-1 derivatives: Culture supernatants of VERO 2-2 cells which have been infected with a replication-defective virus (HSV-1 dl1.2) will be used to infect a second set of normal VERO cells. The second set of VERO cells will be grown for several weeks to identify infected cells by means of a plaque assay. This is a sensitive technique since a single colony, arising from a single replication-competent virus, can be detected readily.

The major routes of transmission are through accidental inoculation via needle stick injury, exposure to open wounds and aerosolisation of high titre virus stocks (SACGM Compendium of Guidance, part 2.6.1). If delivered by these routes the virus will produce a very limited infection of cells due to the replication incompetent nature of the virus. There is the potential for exposure of the eyes to viral particles due to aerosolisation in the event of a spillage, which would lead to infection of epithelial tissue. The external parts of the eye are however ectodermal in nature and do not directly connect to the neuroectodermal parts of the eye which connect to the central nervous system. Given that the replication incompetent nature of the recombinant virus and the lack of direct connection and isolated blood supply, CNS infection and therefore expression of viral gene expression products is highly unlikely. The insert sequence is also considered to be safe and therefore the likelihood of any hazard is low.

Given the high levels of infection of the population with wild type HSV-1 & 2, the potential for interaction is however unknown (SACGM 2.9.29). However, the extensive modification of the viral plasmid vector, the use of a replication incompetent helper virus and the presence of the packaging gene IE2 in the VERO 2.2 packaging cell line also prevents homologous recombination with other related viruses. All cultures are maintained under sterile conditions and it is unlikely that any hazardous sequences if they were present could be transferred to related organisms. Whilst there is the remote possibility that the recombinant virus could be recombined with wild type HSV-1 or HSV-2 from infected individuals, the nature of the insert and the limited expression would not produce any additional hazard over and above the wild type virus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not Applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Any waste that is possibly contaminated with virus will be initially inactivated by incubation with a final concentration of at least 1% Virkon for 1h and all of this waste will be collected in dedicated bags and autoclaved (100% kill) prior to being disposed of by the clinical waste route.
All other contaminated materials will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile.

Date Project Ceased

02/03/2022 Page 8152 of 15326
The purpose of this research is to examine the role of various Candida cell wall structures on signalling and activation of human immune cells in healthy individuals and patients with Chronic Mucocutaneous candidiasis – a primary immune deficiency with selective susceptibility to infections with Candida species.

The project will be conducted in the Musculoskeletal Research group (MRG) of the Institute of Cellular Medicine (ICM), with optimal available containment level 2 laboratory space, equipment and intellectual expertise. The project will be conducted on human blood mononuclear cells obtained from peripheral blood and buffy-coats of human blood donors. After separation, peripheral blood mononuclear cells and/or monocytes will be stimulated with a range of Candida albicans mutants (a kind gift from Professor Neil Gow, University of Aberdeen) defective in various cell wall structures such as mannan, glucan and chitin to assess their effects on cytokine production and cell signalling pathways mediated by various cells surface receptors. Toll-like receptors (TLR 2, 4, 6) and C-type lectin receptors (mannose receptor, beta-glucan, dectin-1, dectin-2) will be investigated by measuring production of relevant cytokines and signalling pathway activation. Results will be confirmed by competitive blocking using TLR ligands and anti-receptor antibodies where available. Results obtained on cells from normal human blood donors will subsequently be investigated on cells from patients with a primary deficiency coined Chronic Mucocutaneous Candidiasis, to assess underlying defects which predispose them to Candida infections.

The Candida strains listed below are a kind gift from Professor N G, Aberdeen University in whose Laboratory these strains were generated. Work on these strains has been extensively published (see references below). The host organisms is NGY152 Candida albicans CAI-4 serotype (Wild-Type Strain); the following Candida albicans mutant strains will be used:

- CDH15 (mnn4 delta + Clp10) = mnn4 mutant (absence of phosphomannan)
- CDH13 (mnn4 + Clp10-MNN4) = matched control strain
- NGY355 (pmr1 delta) = pmr1 mutant (absence of phosphomannan & reduced O- and N-linked glycans)
- NGY356 (pmr1 delta + Clp10-PMR1) = matched control strain
- NGY357 (och1 delta + Clp10) = och1 null (defects in outer chain N-linked mannosyl chains)
- NGY358 (och1 delta + Clp10-OCH1) = matched control strain
- NGY337 (mnt1-mnt2delta + Clp10) = mnt1 and mnt2 mutant (defects in O-mannosylation)
- NGY335 (mnt1-mnt2 delta + Clp10-MNT1) = matched control strain
- NGY336 (mnt1-mnt2 delta + Clp10-MNT2) = matched control strain
C. albicans is a human commensal and opportunistic pathogen in ACDP Hazard Group 2. C. albicans causes superficial infections of mucosal epithelia (thrush) (Odds [1988] Candida and Candidosis, Balliere Tindall). C. albicans can also cause systemic infections which can be fatal, but these only occur in severely immunocompromised patients. To keep things in perspective, it is important to realise that C. albicans is widely distributed. C. albicans is carried commensally by at least 60-80% of the healthy population and most Candida infections arise as an overgrowth of the strains resident in the normal microflora. It is a micro-organism of low pathogenic potential that rarely affects healthy individuals. It only becomes a potential medical problem when an individual’s immune responses are significantly impaired. Furthermore, as with most pathogenic micro-organisms, the virulence of C. albicans strains is likely to become attenuated rather than enhanced after prolonged laboratory culture.

The C. albicans strain CAI4 (ura3) is a standard host for DNA transformation world-wide. The special growth requirements (auxotrophy) makes this C. albicans avirulent (Leberer et al. [1996] PNAS, 93, 13217). Transformation with URA3 plasmids partially restores the virulence of CAI4, but this restoration is not complete because the genes neighbouring URA3 remain inactivated and their virulence is slightly lower than the wild type strains of C. albicans carried by most individuals. It is important to note that although a large number of C. albicans mutants have been analysed, including virulence attributes, metabolic and cell wall genes, there is NO report of a mutation that increases the virulence of this species. This is unsurprising, since all evidence to date indicates that virulence in C. albicans is a multi-factorial process at the molecular level, with no single virulence factor of over-riding importance. Therefore, mutations in wild isolates are expected to have a neutral or negative effect upon virulence. A limited number of experiments will examine antifungal drug responses in a commercially acquired Candida strain (ATCC 18804) which we have used in this Laboratory since 2004.

Our work with antifungal agents includes manipulation of antifungal-resistant isolates, but it is important to note that Candida species have no effective mechanism for horizontal gene transfer that might allow dissemination of resistance traits. This difference from antibacterial resistance is well reflected in the clinic, where increased prophylactic and therapeutic usage of antifungal agents has led to an increase in prevalence, but not incidence of infections due to species with low intrinsic antifungal susceptibility. No increase in resistant strains of C. albicans has been found.

To summarise:
The likelihood of hazard is low, since we are handling a commensal and opportunistic fungal pathogen and the C. albicans strains used in this project are all disabled host strains of lower virulence. Most individuals already harbour wild type C. albicans strains. The consequences of any hazard arising from accidental contamination is also low since C. albicans infections are of low severity with mild, treatable symptoms and serious infections only occur in individuals with severely compromised immune systems. Staff and students employed on this project are informed of this situation to eliminate any with a compromised immune system. The estimation of overall risk to human health is low.

Host/vector system

Vector: Clp10 (Candida Integrative plasmid 10) is a convenient and efficient integrating vector for C. albicans (Murad et al, Yeast 2000,16:325). The plasmid is based on pBluescript KS+ (Stratagene, Cambridge, UK). It carries the marker CaURA3, has numerous convenient cloning sites and lacks a C. albicans replication origin. The ribosomal protein 10 coding region (RP10) provides homology to target chromosomal integration. An artificial StuI site was introduced beside the natural NcoI site in the RP10 coding region to provide two alternative unique restriction sites for chromosomal integration. The sequence of Clp10 is available with the GenBank Accession No. AF181970.
Integration and expression: The RP10 locus was chosen to target genomic integration because there appear to be two closely related RP10 loci and as a result, the disruption of one RP10 allele in this diploid fungus does not significantly affect the growth of C. albicans Clp10 transformants on rich or defined media. As RP10 is expressed at high levels, Clp10 integrates relatively efficiently by homologous recombination. Consistent with this, Clp10 transformed C. albicans Cal4 and Cal8 about 20 times more efficiently than a control plasmid. Finally, chromosomal integration at a highly expressed locus promotes efficient expression of genes integrated using Clp10 by avoiding unfavourable position effects. The increased stability of plasmids such as Clp10 reduces population heterogeneity due to plasmid loss or copy number variance.

Hosts: Hazards associated with C. albicans are not anticipated to have harmful effects or only effects of low severity. This is because C. albicans is widely distributed, with most individuals already harbouring wild type C. albicans strain while serious infections only occur in individuals with severely compromised immune systems. Pathogenicity in C. albicans is a polygenic trait involving numerous physiological characteristics (e.g. rapid growth, cell wall, morphogenesis, secreted hydrolases, phenotypic switching) so that no single C. albicans gene (or combination of genes) will increase its pathogenicity. On the contrary, vectors such as Clp10 are known to attenuate C. albicans and reduce pathogenicity, thus reducing the risk of hazards which are not anticipated to have harmful effects or only effects of low severity.

Origin & function

The C. albicans transformations in the strains we will acquire have an inactivated specific target gene to create a null mutant. The target genes which have been attenuated affect cell wall components such as mannann, glucan and chitin content which influence the cell wall structure. In none of the cases in question is this likely to increase virulence. As described above, it has been shown in numerous cases that C. albicans virulence is either decreased or remains unaffected by gene knockouts. No null mutations have been described that increase the virulence of C. albicans.

The special growth requirements (auxotrophy) makes this C. albicans strain CA14 (ura3) avirulent (Leberer et al. [1996] PNAS, 93, 13217). Transformation with URA3 plasmids partially restores the virulence of CA14, but this restoration is not complete because the genes neighbouring URA3 remain inactivated, although their virulence is slightly lower than the wild type strains of C. albicans carried by most individuals. It is important to note that although a large number of C. albicans mutants have been analysed, including virulence attributes, metabolic and cell wall genes, there is NO report of a mutation that increases the virulence of this species.

There are few papers reporting the isolation of C. albicans from the wild, suggesting that C. albicans might be obligately associated with mammals. The risk of infection of wild mammals (such as rodents) through accidental release of C. albicans is very low because to succumb to such infections, immunocompetent animals must be injected intravenously with relatively high infective doses (>10^4 CFU/g body weight). Therefore, none of the strains used in this project are likely to present a hazard to the environment.

Evaluation of foreseeable effects

As described previously the C. albicans mutant strains that we will acquire have individual inactivated target genes to create a series of null mutants with defective cell wall structures. In none of the cases in question does this likely to increase virulence. As described above, it has been shown in numerous cases that C. albicans virulence is either decreased or remains unaffected by gene knockouts. No null mutations have been described that increase the virulence of C. albicans.

As indicated above, pathogenicity in C. albicans is a polygenic trait involving numerous physiological characteristics (e.g. rapid growth, cell wall, morphogenesis, secreted hydrolases, phenotypic switching). Therefore, (i) no single C. albicans gene (or combination of genes we will be working with) will turn E. coli or S. cerevisiae into a pathogen, (ii) a reduction in any one of these parameters is likely to attenuate C. albicans virulence, and (iii) an increase in any one of these parameters is highly unlikely to increase C. albicans virulence. Furthermore, C. albicans strains that have been cultured in the laboratory tend to display reduced pathogenicity compared to strains carried commensally by most individuals.

Our work with antifungal agents includes manipulation of antifungal-resistant isolates, but it is important to note that Candida species have no effective mechanism for horizontal gene transfer that might allow dissemination of resistance traits. This difference from antibacterial resistance is well reflected in the clinic, where increased prophylactic and therapeutic usage of antifungal agents has led to an increase in prevalence, but not incidence of infections due to species with low intrinsic antifungal
susceptibility. No increase in resistant strains of C. albicans has been found.

The likelihood of natural gene transfer to other species is essentially zero. Furthermore, despite the recent discovery of sex in C. albicans, the risk of transfer between C. albicans strains is very low. This is because C. albicans strains mate very inefficiently in vivo [Hull et al., (2000) Science 289, 307-310], probably because the specific growth forms that mate most efficiently aren’t maintained at 37°C [Miller & Johnson (2002) Cell 110, 293-302]. In addition, C. albicans must be homozygous at the mating type locus for them to be competent for mating, and the vast majority of clinical isolates are heterozygous at the mating type locus.

In summary, the modified Candida organisms are extremely unlikely to cause harm to human health for the reasons described above.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Emergency procedures for spillage of infectious materials.
- Instructions, spills kits, PPE must be used where required.
- Instructions on laminated sheet are available in the CL2 lab.
- Notify other workers and isolate the area (if required).
- Evacuate lab if risk of airborne infection.
- Allow aerosols to settle.
- Contain spills with tissues or granules.
- Cover with disinfectant (liquid or granules).
- Allow sufficient contact time before clean up.
- Sweep up debris gently (do not use brush).
- Pick up broken glass carefully (e.g. forceps or swabs).
- Put debris in a suitable container for safe disposal.
- Disinfect contaminated surfaces with 1% Virkon.

Spillage procedures for accidental exposure of infectious materials (eg injection, ingestion or inhalation).
- Remove contaminated clothing as quickly as possible and leave in lab.
- Remove contamination from skin, eyes and mouth by thorough washing with water.
- Minor cuts and small puncture wounds should be encouraged to bleed.
- Wash wounds with soap and water wiping away from the wound.
- Dress wounds.
- Use PPE if required when helping injured persons.
- Seek help where required - First aid, GP or Hospital.
- Emergencies should be taken straight to hospital and call ambulance if necessary (Security x 6666).
- Explain incident and biological agents or hazards to medical staff.
- Report all accidents immediately or as soon as practicable to the USO.

In the event of an accident or spillage the procedure will be immediately implemented. In the event of any injection injury or other significant accidental exposure seek medical attention immediately.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware.

Autoclaves will be validated by annual thermocouple mapping and each run will be monitored using TST (Time, Steam, and Temperature) test strips (Albert Browne Ltd., TST class 6 emulating indicator 121°C for 20 min).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Project Additional Information

Purposes of the contained use

This application encompasses several areas of research involving several groups within the Institute of Cellular Medicine (ICM) at Newcastle University that will utilise the same general principle of lentiviral gene delivery as a tool to understand disease pathogenesis.

We plan to use various commercial viral vectors (eg from Sigma-Aldrich, Thermo-Scientific), or similar vectors from collaborating laboratories to generate lentiviral vectors encoding the corresponding cDNAs for expression or shRNAs targeted to selected cell components including, but not limited to the examples mentioned below in the different programmes of research. These vectors will be used to obtain infectious, but replication-incompetent lentiviruses for the transduction of mammalian tissues, cells and cell lines. The resulting GMOs will be used for various applications as described below. The programmes of research covered by this notification (PIs; see section 16 for details) are:

- Matrix biology in arthritis (ADR & DAY)
- In arthritis, dysregulated cell signalling and/or gene expression can lead to cartilage damage, typically due to the action of proteolytic enzymes (proteinases) such as matrix metalloproteinases (MMPs) as well as serine proteinases. There is evidence that several cell signalling pathways that are activated by pro-inflammatory stimuli drive the transcriptional activation of genes that are involved in the degradative mechanisms of arthritis.

We wish to validate laboratory observations that specific molecules are important in the overall mechanisms of cartilage and bone destruction. This could be a protein within a signalling pathway or a specific receptor, proteinase, inhibitor or a microRNA. Some genes, and indeed proteins, are rapidly turned over making conventional siRNA problematic. To this end we need to create stable, inducible RNAi knockdown of selected target genes in connective tissues and cells to a) provide prolonged and sustained gene silencing; b) confirm the specificity of small molecule inhibitors for their target (i.e., an inhibitor of protein X should not have any additional effect in a cell lacking protein X); c) to define the cellular pathology following loss/inhibition of specific cell signalling, receptor proteinase or microRNA constituents. We will aim to validate identified genes/targets using lentiviral approaches to drive over-expression of genes and/or mutant versions (eg. Kinase-dead ver, both constitutive and conditional, in human primary cultures and cell lines, to identify downstream targets using molecular biology methods such as microarray and/or chromatin immunoprecipitation approaches. Where indicated, limited in vivo experiments in rats and mice will be performed to further validate target candidates.

- Function of antigen presenting cells in health and disease (AK/JP)
- In order to mount immune responses, specialised mammalian cells termed antigen presenting cells (APC) capture
components (antigens) of invading pathogens. These components are digested by limited proteolysis within the endocytic compartment of the APC and then re-expressed as small peptide fragments on the APC surface in association with MHC molecules. These peptide/MHC complexes are recognised by CD4+ T lymphocytes (T cells) which then differentiate and expand into a number of specialised effector cells capable of limiting or destroying the pathogen. In some diseases which are termed autoimmune, APC capture and present self-components initiating immune responses targeted to various tissues within the body.

One specialised APC type is the B lymphocyte (B cell). Unlike other APC, each individual B cell clone expresses a unique receptor (BCR) for pathogen recognition. Recent evidence suggests that B cells have a unique APC function which is essential for the initiation of several autoimmune diseases including Rheumatoid Arthritis and Primary Biliary Cirrosis. We have recently compared immune activation following antigen presentation by B cells and other APC. This has involved cloning and of several BCRs recognising different antigens and their expression in various immortalised B cell lines. We now wish to extend our findings by expressing various immune related gene products, including antigen-specific BCR (or constructs to silence immune related gene products) in various ex-vivo mammalian immune cells including APC, T and B cells.

Epithelial to mesenchymal transition (EMT)
The process of epithelial to mesenchymal transition (EMT) involving biliary epithelium occurs in some chronic liver diseases and contributes significantly to the organ fibrosis. Fibrosis within organs is triggered by the microenvironment consisting of various growth factors and cytokines which are upregulated during the ongoing disease state. One of the major profibrotic agents is transforming growth factor-beta (TGFβ) and thus we stimulate cell cultures with this cytokine to initiate and monitor EMT in vitro. We have used several markers of EMT to characterise the process however the most reliable one is S100A4 expression which is an early marker of the transition. S100A4 is not expressed in healthy epithelium but appears shortly after addition of TGFβ or in diseased tissue sections which we have shown on protein and mRNA level. The role of this protein is not entirely discovered but it regulates apoptosis (by interaction with p53), migration (it binds heavy chain of myosin and associates with cytoskeleton) and cell differentiation. S100A4 has been shown to play an important role during the process of EMT in renal fibrosis whereas there is very few data regarding the liver. We wish to knockdown S100A4 in our in vitro primary cell culture and study the behaviour of the cells after stimulation with TGFβ. It would be very interesting to know whether inhibition of this marker can prevent epithelial cells from becoming fibroblasts upon stimulation with a profibrotic agent. We would like validate targets like S100A4 via gene silencing or over-expression. It is anticipated that additional groups may want to use these materials for related or similar projects in the future, and appropriate amendments to this risk assessment will be made.

Recipient or parental organism

see below

Host/vector system

Cell lines in culture: 293T Human embryonic kidney cell line (packaging cell line; Pear et al., PNAS 1993; 90; 8392)
SW1353 human chondrocyte cell line. Human embryonic stem cells lines (Newcastle)Murine C3H10T1/2 cells
Primary human cells generated from various tissues including joint tissues (cartilage, bone, synovium), kidney, liver, and immune cells, Human mesenchymal stem cells, Immortalized mouse cell fusions, Primary rodent cells (Mice and Rats) including transgenic animals (Home Office Licence to ADR: PPL/604173 "Joint tissue remodelling in health and
We will be using second and subsequent generation lentivirus vectors derived from FIV and HIV. They are replication incompetent and self inactivating (SIN). The systems separate the packaging signals and viral LTRs on the expression plasmid from the viral structural and expression genes (gag, pol and rev from FIV or HIV and viral envelope glycoproteins such as the VSV-G gene from Vesicular Stomatitis Virus, in place of HIV or FIV env). The viral structural and expression genes and the envelope glycoprotein genes are separated on at least two additional plasmids. Examples of vectors to be used are listed below:

Lentiviral Vector 1 (LV1): the Open Biosystems TransLentiTM Viral GIPZ&TRIPZ Packaging System, allows creation of a replication-incompetent HIV-1-based lentivirus which can be used to deliver and express shRNA in either dividing or non-dividing mammalian cells (Ref.: Shimada et al., Development of Vectors Utilized for Gene Therapy for AIDS. AIDS. 1995; 4). It uses a replication-incompetent lentivirus based on the trans-lentiviral system developed by Kappes et al. (Ref.: Kappes J.C., Wu X. Safety considerations in vector development. Somat Cell Mol Genet. 2001; 26(1-6):147-58.).

Lentiviral Vector 2 (LV2): pHR-SINcPPT-SIEW replication incompetent lentiviral system, obtained from Dr Heidenreich (NICR) (Ref.: Demaison et al., High-level transduction and gene expression in hematopoietic repopulating cells using a human immunodeficiency virus type 1-based lentiviral vector containing an internal spleen focus forming virus promoter. Hum Gene Ther. 2002, 13:803-13). This vector will be cotransfected together with pCMV8.9.1 (carrying HIV-1 gag, pol and rev/tat genes) and pVSV-G (carrying the VSV-G gene for pseudotyping).

Lentiviral Vector 3 (LV3): MISSION shRNA Lentiviral particles, Sigma-Aldrich. The Mission vector system represents a 2nd generation lentiviral system and will be used as an alternative especially when only limited work is envisaged. MISSION TRC transfer vectors contain a modified, self-inactivating 3’ long terminal repeat (SIN/LTR) which renders the resulting lentiviral particles replication incompetent. Specific features include: 1) multiple plasmids are used such that no single plasmid contains all the genes necessary to produce packaged lentivirus. Resultant particles are replication-incompetent. 2) Deletion in U3 portion of 3’ LTR which eliminates the promoter-enhancer region. This avoids promoter interference issues and further negates the possibility of viral replication. 3) Key virulence genes vif, vpr, vpu and nef are deleted. To monitor transfection efficiency we wish to also use a green fluorescent protein, from copepoda Pontellina plumata, expressing lentivirus pLKO.1-puro-CMV-TurboGFP.

Lentiviral Vector 4 (LV4): miRIDIAN shMIMIC Lentiviral microRNAs, Thermo Scientific. The miRIDIAN shMIMIC microRNA designs are created for each human microRNA described in the miRBase database. A CMV promoter drives strong transgene expression, a TurboGFP(nuc) Marker helps to visualize transduction. The SIN-LTR is a Selfinactivating long terminal repeat that results in replication-incompetent viral particles. Puromycin resistance permits antibiotic selective pressure and propagation of stable integrants whilst an IRES (internal ribosomal entry site) allows expression of TurboGFP and puromycin resistance genes in a single transcript.

Lentiviral Vector 5 (LV5): pDBR. (Calderon-Gomez et al 2011, Eur. J. Immunol. 41, 1696-1708.) This is is modified version of pL3.7 (Rubinson et. al 2003. Nature Genetics. 33, 401-6) in which the U6-shRNA/CMV-GFP cassette has been removed and replaced with a multiple cloning site. This replication incompetent vector will be cotransfected with the commercially available, 2nd generation packaging vector (containing TAT; psPax2; http://www.addgene.org/mammalianmrii/Packaging/) and VSV-G (carrying the VSV-G gene for pseudotyping) outlined in LV2.

New Lentiviral Vectors: We will also employ new generation, commercially available vectors systems with improved properties and safety measures as these become available. These will provide improved safety and thus reduced risk to users.

The transfer vector systems are derived from FIV or HIV and have been specifically engineered for biosafety by
separating the packaging signals and viral LTR’s on the expression plasmid from the viral structural and expression
genes (gag, pol and rev from FIV and the VSV-G gene from Vesicular Stomatitis Virus, or similar alternatives, in place
of FIV or HIV env) encoded on three or four separate plasmids, which remain in the packaging cell line, effectively
precluding the production of replication competent virus in the target cell or should the viral vector escape
containment. FIV vectors are included as they may be more efficient for some cell types. It does not imply any
different containment or risk considerations than HIV based vectors. The plasmids expressing these gene products
carry no packaging signals or LTRs and so cannot themselves be mobilised with the vector and have been
engineered not to contain any regions of homology to each other or to the viral vector, to prevent undesirable
recombination events which might result in replication competent virus being produced.
The viral vector and recombinant virus have a broad host range when pseudotyped with e.g. the VSV-G envelope
protein. The normal tropisms of HIV and FIV have been broadened to include multiple tissues from a broad range of
species. Pseudotyping with alternatives to VSV-G, for example measles virus derived glycoproteins, will produce
particles with more restricted tropisms.

Origin & function

 Either genomic or cDNA sequences originating in humans or other eukaryotes or shRNA sequences will be cloned
into the lentiviral vectors. These will include both entire gene sequences as well as partial gene sequences. As well
as “wild type” sequences, we will include sequences that are known to be mutated (either by deliberate genetic
manipulation or by use of cDNA derived from cell lines harbouring known mutations). In some instances clones will be
purchased from Open Biosystems. A few examples of the gene sequences to be used are outlined below:
shRNAs:
• TRB1 (pseudo-kinase)
• HDAC6 (histone deacetylase)
• S100A4 (calcium-binding protein)
• AKT3 (protein kinase)
• NF-κB (transcription factor)
cDNAs:
• MMP-14 (protease)
• ST14 (protease)
• PRSS23 (protease)
• NF-κB (transcription factor)
• PAR-2 (G protein coupled receptor)
• antigen receptors
• other immune genes (cytokines, costimulatory molecules)

These sequences will be inserted into replication deficient lentiviral vectors described above and expressed in the
cells above. The fluorescent protein of the lentivirus vector will enable us to visualise the sub-cellular localisation,
trafficking and cellular consequences of expression of these genes, facilitating our analysis of their function.

Evaluation of foreseeable effects

 The only viral sequences in the transfer vectors are the 3’ and 5’ long terminal repeats (LTR’s), # packaging signal
and the Rev response element (RRE) required for the production of viral particles. Deletion of accessory genes vpr,
vpu, vif and nef mean that the vector is unable to replicate once it has transduced the target cell. In addition third
generation lentivirus are deleted for the tat gene and carry a SIN deletion of the 3’ LTR ($U3) which results in “selfinactivation”
of the lentivirus following transduction of the target cell, precluding adventitious activation of the vector by
endogenous retroviruses and minimising the risk of recombination with ERVs. These vectors also contain a bacterial 
origin of replication and ampicillin resistance gene, an internal promoter such as CMV or SFFV promoter driving the 
gene of interest linked via an IRES element with a gene encoding a fluorescent protein for FACS-mediated sorting. 
Reversion to wild type virus is extremely unlikely given that several recombination events would be needed 
reconstitute an active viral genome, the viral genes are present on three different plasmids which have minimal 
sequence homology and the viruses are self-inactivating following insertion (i.e. the LTR’s are destroyed upon 
genome insertion). There is a long history of the safe use of these viral vectors.

Reversion to wild type is extremely unlikely given that several recombination events would be needed reconstitute an 
active viral genome, the viral genes are present on three different plasmids which have minimal sequence homology 
and the viruses are self-inactivating following insertion (i.e. the LTR’s are destroyed upon genome insertion). There is 
a long history of the safe use of these viral vectors.

**Containment**

While containment level 1 is sufficient to control risks associated with the GM work, in accordance with the ACGM 
Compendium of Guidance 2000, Part 2A, Annex VI, a parallel BioCOSHH assessment has considered hazards 
associate with possible adventitious agents when using mammalian cell culture. The BioCOSHH assessment 
concludes that containment level 2 should be used to control these hazards and consequently all work involving 
mammalian cell culture will be carried out under full containment level 2. This does not alter the assignment of the GM 
activity class. Established standard operating procedures (SOP1, attached) for work at containment level 2 will be 
employed.

**Controls**

In accordance with the SACGM Compendium of Guidance, GMM mammalian cells will be handled at containment 
level 2 and using microbiological safety cabinets (MSC) for operations likely to generate aerosols. All GM virus waste 
will be properly inactivated by autoclaving using established procedures (SOP2, attached). Spillages will be soaked 
with tissue paper, which will afterwards be autoclaved. Contaminated surfaces will be decontaminated with a 1-2% 
virkon solution (SOP2, attached). 
The use of sharps will be prohibited. Only plastic pipettes will be used in the tissue culture facilities. Furthermore, all 
contaminated materials and media including waste destined for subsequent incineration will be autoclaved (see 12). 
The generation of aerosols will be avoided or contained by use of MSC’s.

Given the uncertainty about the hazards of most potentially oncogenic sequences and the small quantities used 
(microlitre/microgram quantities), prevention of exposure or total enclosure is not “reasonably practicable”. Therefore 
the following measures are applied in the light of this GM risk assessment, will be used:

1) Good microbiological practice will be used at all times and strongly emphasised by senior staff. Designated 
workers will be trained in good microbiological practice before commencing any work with potentially oncogenic DNA 
sequences. They will be made fully aware of the potential hazards of such work and what to do in the event of 
accidental exposure.

2) Access to the laboratory where novel DNA fragments which could potentially be oncogenic is handled, will be 
limited to authorised personnel and designated workers on this project?

3) All experimental procedures involving naked DNA will be performed so as to minimise aerosol production. 
Procedures which are likely to generate aerosols such as the use of sonicators, vigorous shaking and mixing etc. will 
be avoided, or where necessary, will be carried out in closed containers or a class II MSC.

4) Procedures using lentiviral particles, packaging cell lines and exposed cells will only be carried out in the tissue 
culture suite. Normal procedure for handling biological material in the TC suite will be largely sufficient for handling the 
cells and particles. Specific items of relevance here include:
Safety cabinets are routinely disinfected prior to and following use.
Gloves and lab coats to be worn throughout.
Designated microbiological safety cabinets to be used.
No wild type virus will be used in same MSC.
Each packaging lentivirus will be monitored for their ability to produce infectious particles. Cell culture supernatants will be tested 3-5 days after infection for the presence of infectious particles by addition to 293T cells followed by monitoring the expression of encoded genes or their function (e.g. positivity for fluorescent protein by FACS).
All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment such as glassware (SOP3, attached).
Autoclaves will be validated by annual thermocouple mapping and each run will be monitored using TST (Time, Steam, and Temperature) test strips (Albert Browne Ltd., TST class 6 emulating indicator 121°C for 20 min).

Project Additional Information

**Purposes of the contained use**

The work performed in the fibrosis laboratory in ICM is concerned with different aspects of transcriptional regulation, cell and organ function as well as therapeutic modalities of the Nuclear factor kappaB (NF-kappaB) family of proteins and their regulators. This includes processes such as transcription and DNA replication, regulation of signalling cascades and appropriate functioning of various organs. NF-κB is a family of transcription factors that come in 5 different forms; namely p65 (RelA), RelB, c-Rel, p50/p105 (NF-κB1) and p52/p100 (NF-κB2). These proteins bind in different dimer combinations to gene promoters and regulate gene transcription. They are often bound in the cytoplasm by inhibitory proteins known as inhibitors of NF-κB or IκBs. There are seven IκB proteins namely IκBα, IκBβ, IκBγ, IκBε, Bcl-3 and the precursor proteins p100 and p105. NF-κB dimers are released from IκB proteins when the latter are phosphorylated by the actions of the Inhibitor of NF-κB Kinases (or IKKs). There are three IKKs namely IKKα (IKK1), IKKβ (IKK2) and NEMO (IKKγ). For a general review of the NF-κB pathway please see Hayden and Ghosh 2004, Genes and Development, 18, 2195-2224.

Growing evidence presented by multiple groups has culminated in the hypothesis that pathogenesis of disease in organs which are susceptible to fibrosis i.e. liver, skin, kidney and lung follows a common course; rounds of chronic inflammation/damage → organ fibrosis → increased susceptibility to develop cancer. This is known as the "inflammation-fibrosis-cancer axis". NF-kB family members can influence every step of this disease continuum, therefore we aim to understand the molecular events underpinning this axis in multiple organs which are susceptible to inflammatory and fibrotic disease, as common pathways are likely to exist, thus allowing us to identify generic drug targets.

We have previously reported that the absence of one of the NF-κB subunits, p50, in a mouse model results in increased inflammation and fibrosis (scarring) in the liver compared to controls in response to chemical injury. In addition these mice develop more liver tumours than controls. We have also shown that the absence of the c-Rel, a different NF-κB subunit, results in protection from the effects of liver injury on hepatic inflammation and fibrosis. However, in liver regeneration models these mice exhibit a reduced capacity to regenerate. The individual NF-κB subunits have discrete biological functions and these data highlight the importance of studying the exact role of each subunit and their post translational modifications in the pathogenesis of liver fibrosis, cancer and regeneration. In addition, the role of the
The role of this project is to investigate the exact gene targets and regulatory mechanisms of the different components of the NF-κB pathway mentioned above in the pathogenesis of liver disease. An important tool in allowing us to achieve this will be the use of adenoviral vectors to deliver wild type and functionally inactivated forms of the NF-κB subunits or their associated signaling proteins to the primary cells in vitro as well as liver of animals that will be used in models of liver fibrosis, regeneration and cancer (see associated GM 10/31.form for use of adenoviruses in animals).

### Recipient or parental organism

Adenovirus containing constructs expressing NF-κB proteins or mutants which have inhibitory or stimulatory functions will be given intravenously to both normal and genetically modified mice e.g. gene knockout or knock-in mice for members of the NF-kappaB family or their associated adapter molecules, or stimulating receptors including:

- Nfkb1 knockout mice
- TLR3 knockout mice.
- Mkk4 knockout mice.
- RelB knockout mice
- TLR4 knockout mice.
- Mekk1 knockout mice.
- c-rel knockout mice
- TLR9 knockout mice.
- TNF Receptor knockout mice.
- 3xNF-kappaB-luciferase reporter mice
- Myd88 knockout mice.
- IL-6 knockout mice.
- TpL2 knockout mice.
- ASK1 knockout mice
- IL-10 knockout mice.
- TLR2 knockout mice.
- Lys (TRIF-deficient mice) knockout mice.
- RelA+/- (Hets).
- Knockin of mNfkbp1 gene (S340A).

Or mouse cells: primary inflammatory and liver cell types which will be used for expression of the adenovirally encoded mutant/wt NF-kB subunits and their associated signalling or adapter molecules are:

1. Mouse/rat hepatocytes
2. Mouse/rat hepatic stellate cells
3. Mouse/rat endothelial cells
4. Mouse/rat myofibroblasts
5. Mouse/rat Bone marrow
6. Mouse/ rat fibroblasts
7. Mouse/rat Inflammatory cells
The Adenovirus being used; ad5-attenuated is replication deficient and will not lyse human cells. Adenovirus will either be obtained from a commercial supplier or collaborator. Additionally the adenovirus may be propagated in Vero/293 cells. Adenovirus will either be obtained from a commercial supplier or collaborator as described in GM 10/30 (virus vector and cell culture work).

The constructs used in this study will be expressing NF-kB Family proteins or mutants which have inhibitory or stimulatory functions. Although not all of these proteins are currently been expressed in adenovirus, many have been used in adenovirus or other systems such as baculovirus or Herpes Virus Saimiri without causing adverse effects or leading to immortalisation of cells, examples of which are described in GM 10/30 (virus vector and cell culture work).

The specific genetic material to be studied includes:

Human cDNAs for the various NF-κB family members (listed below) or mutant forms of these proteins or interacting/regulatory proteins (some may be conjugated with inert tags such as FLAS, green fluorescent protein (GFP) or haemagglutinin (HA) 9 amino acid epitope added for identification) will be inserted into adenovirus. The intention is to express these genes in mammalian cells and use various techniques to analyse their effect on gene expression, transcription factor function, the cell cycle and apoptosis. We also intent to express mutated versions of NF-kB transcription factors which may interfere with dimerisation and/or DNA binding.

The cDNAs encode for wild-type or mutant forms of:

1) RelA
6) IKKa
2) p50
7) IKKb
3) p52
8) NEMO
4) RelB
9) IkBa
5) C-Rel
10) Other kinases or phosphatases that may be shown in future studies to affect NF-kB signalling pathways.

We intend to express mutated forms of above proteins where mutations affect the ability of particular serine or threonine residues to be phosphorylated (i.e. mutation into alanine). We may also generate cDNAs where same serines or threonine have been mutated into aspartic or glutamic acid thus generating a constitutively active phosphomimic. It is impossible to predict what function these novel mutations may have on the cells transduced. The reason for this is the fact that phosphorylations of different subunits have different functions in different cells types. E.g. phosphorylation of S536 on RelA signals for termination of NF-kB activity in macrophages, whereas the same modification in hepatic stellate cells and hepatocytes has the opposite function.

Adenovirus will be given to mice by intravenous injection via the appropriate vessel e.g. tail vein or intra-hepatic or transduced cells may be administered via the appropriate route e.g. via the tail vein or intra-hepatic and then liver injury models or controls will be performed. We will then determine whether expression of these genes affects the injury process by assessing liver pathology using histochemical and biochemical techniques. We will measure downstream targets of our expressed proteins e.g. markers of inflammation, cell cycle and apoptosis by qRT-PCR.

These studies will allow us to discern the role of the individual NF-kB subunits and their post-translational modifications in the pathogenesis of liver disease and enable us to dissect out subtle regulatory pathways that would otherwise be impossible to study.

Evaluation of foreseeable effects

The Adenoviral vectors to be used are "attenuated" through deletion of the E1 region of the genome (containing E1A and E1B) and through insertions and deletions within the E3 gene that inactivate it. This has several affects on the virus. Firstly deletion of the E1A gene eliminates the potential for viral transformation of cells, since the E1A gene product is absolutely required for this process. It is also required for activation of all other early genes (E1B, E2, E3 and E4). The E1B gene product (also deleted) co-operates with E1A in transformation. The E2 region (E2A and E2B) contains DNA binding (E2A) and DNA polymerase (E2B) activities that are absolutely essential for viral replication. The E3 gene product helps in viral avoidance of the immune system by binding to the major histocompatability complex MHC polypeptides in the endoplasmic reticulum. However, this gene is also inactivated in this strain of adenovirus, resulting in the virus being highly susceptible to immune surveillance. The E4 gene product is required for formation of an active complex between the E1B gene product and the E4 gene product.

The above characteristics mean that the recombinant virus is totally unable to replicate in E1A- deficient cells of any organism. Under normal circumstances no human or
animal cells contain the E1A gene product, resulting in the inability of this virus to replicate in any naturally occurring organism in the external environment (human or non-human mammalian). The recombinant virus is also unable to recombine with a wild-type virus in a way that could generate a functional virus (recombination with a wild-type virus would, by the nature of the recombination event, remove the E1 region from the wild-type virus thereby inactivating its ability to replicate). Taken together, the above means that the recombinant virus is essentially unable to propagate in the external environment.

The inserts to be used in this study, based on the NF-kB pathway and associated proteins have not been reported to cause immortalisation or transformation in human cells. The effects of over-expressing some of the various NF-kB pathway gene products have not been previously characterised in terms of immortalisation or transformation, however. It is possible, therefore, that changing the expression of genes from this pathway could be harmful. The inhibition or activation of the NF-kB pathway could result in activation or inhibition of pathways that regulate the cell cycle and apoptosis, i.e. they could potentially be oncogenic. NF-kB also regulates inflammation and immune function. It is also possible that expression of these proteins could therefore produce adverse inflammatory effects and immune suppression. However, while the inserts would be expected to have biological activity the most likely effect if a human became infected could be a localised increase in inflammation. Although, as described above, these genes are known to play a role in cancer they have not been shown to be transforming in their own right in human cancer cells. In vivo: Viral particles capable of transducing a wide range of mammalian cells will be used in our experiments and these represent the hazardous material. However, because of its incompetence to replicate, short half-life and inefficient transduction rates, the risk of transmission outside the laboratory is effectively zero. Although there is only very low risk associated with an infected animal, this work still involves the use of an infectious agent that is able to infect human cells. Risks associated with working with infected mice could include might scratching/bite during handling or their waste products might be infectious. All researchers will wear gloves and laboratory coats, handling will be kept to a minimum and bedding will be incinerated to minimise risks. Additionally transfer of a replication deficient virus via a scratch or bite represents a very low risk. The biggest risk is a needle stick injury as a researcher might stab themselves or someone else with a syringe and inject harmful material. To control this risk animals will be restrained in appropriate restraining tubes, needles will not be re-sheathed but disposed of directly into sharps bins (for incineration) and only one person will give the injection to minimise the risk of a needle stick injury. All staff and students will undergo training in loading syringes and injecting virus and for the handling and disposal of needles. Personnel will also be instructed in the emergency procedures in the event of accidental contamination through needle stick injury or wounding.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

All handling and packaging of the virus will be carried out in CL2 labs in class 2 microbiology safety cabinets so as to minimise aerosol spread. Any transport of materials to the animal facilities will use clearly labelled leak proof, drop-tested containers. All GM virus or animals infected with GM virus will be stored and handled only inside Containment Level 2 animal room and laboratory suite (Room MB108) in the CBC animal facility. Isolators will be used for additional safety. The animal facility is isolated from the rest of the University and access is by card and keypad. Holding and procedures rooms are maintained at negative pressure relative to the surroundings. The PI and the research team will control the specific risks of the project.

1. All handling and packaging of the virus will be carried out in CL2 facilities in class 2 microbiology safety cabinets so as to minimise aerosol spread. Transport of infectious materials to the animal facilities will use clearly labelled leak - proof and drop – tested containers. All GM viruses or animals infected with GM virus will be stored and handled only inside Containment Level 2 animal room and laboratory suite (Room MB108) in the CBC animal facility. Isolators will be used for additional safety. The animal facility is isolated from the rest of the University and access is by card and keypad. Holding and procedures rooms are maintained at negative pressure relative to the surroundings. The PI and the research team will control the specific risks of the project.

2. Replication defective viral vectors are used to ensure proliferation occurs only in special packaging cell lines or in the presence of complimentary plasmids;

3. All in vitro work is conducted in CL2 facilities with CL2 operating procedures applied in full to prevent infection of the worker or release of virus into the external environment.

4. Good microbiological practice will be used at all times and strongly emphasised by senior staff. Designated workers will be trained in good microbiological practice and working at CL2 before commencing any work with potentially infective materials. They will be made fully aware of the potential hazards of such work and what to do in the event of accidental exposure.

Staff carrying out the techniques will wear PPE (lab coats, gloves, lab specs) at all times during work. Staff will also be encouraged and expected to attend the USO biological and GM safety training courses in order to keep up with the most appropriate procedures. All personnel dealing with the animals will be required to wear protective clothing including but not limited to lab coats, gloves and removable footwear. They will also be expected to have read and understood any risk assessments pertaining to this project and to have documented this.

5. The users will also use microbiological safety cabinets to prevent risk of exposure by inhalation route. All aspects of work will be contained in sealed tubes during
centrifuging, storage and transport. Any sharps will be discarded into the autoclave bins within the class II cabinets and sealed prior to removing. All cabinets will be disinfected using 1% Virkon to ensure no exposure by subsequent users.

6) Sharps use will be kept to a minimum, as needle stab injury is a possible risk. The use of sharps in CL2 facilities is strongly discouraged and all precautions will be taken to identify procedures or devices that might be used in these projects which could cause an injury and infection of the researchers. Where so identified safer alternative methods or equipment will be sought. Where the use of such items is essential staff / students will be appropriately trained in their handling and disposal; sharps will be discarded into bins within the class II cabinets and sealed prior to removing for autoclaving and incineration.

7) The CBC is a controlled access area and measures are in place to ensure animals are not removed from the department. The animals are maintained in closed cages in rooms with self-closing doors. Access is via at least 3 additional self-closing doors and an external access door controlled by a keypad and swipe card. The doors are all flush to the floor. The floor drains are screwed down to the floor and have very small drainage holes, much too small for a mouse. The mice are all checked daily and records are kept of the numbers in each cage. All virally infected animals will be killed, at the end of the experiment, with the carcass being incinerated.

8) Bedding may be contaminated with cells, virus or waste products, however, it is unlikely that these cells or virus would be viable and, as these have limited ability to survive outside the laboratory, the risk can be considered negligible however as a precaution all bedding materials will be incinerated after autoclaving.

9) Workers showing an allergic response to the animals are not required to come into contact with them. Consequently, there is a low risk to human health. All staff involved are regularly assessed for signs of allergy.

10) Additional control measure concerning waste materials derived from routine culture and preparation of cells for implant are details on the accompanying form GM risk assessment GM10-30.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

In vitro use: All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile.

In vivo use: All contaminated materials, including bedding, waste destined for incineration and animal carcasses, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Waste will be transported in leak proof containers. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored using TST (Time, Steam, and Temperature) test strips (Albert Browne Ltd., TST class 6 emulating indicator 121°C for 20 min). Autoclaved waste will then be incinerated following standard university procedures. Records will be kept for all inactivation and preventative procedures

Please enter comments on the GM safety committee on the risk assessment

The risk assessments associated with this project have been scrutinised and approved by the local genetic modification safety committee. The members of the committee were satisfied that all foreseeable risks associated with the GM hosts and vectors had been identified and that the risks to human health and the environment were minimised and controlled by the declared use of facilities, equipment and operating procedures for containment of the GM organisms.

02/03/2022
This risk assessment covers research projects at the Northern Institute for Cancer Research utilising the same or functionally very similar lentivirus vectors and mammalian host cells. In addition these projects share similar aims and use the same approaches. We are submitting a generic risk assessment for these projects after discussions with HSE inspector. The projects involve the assessing the biological function of candidate genes implicated in malignant progression which emerge from ongoing genomics projects characterising collections of primary tumour material. Some projects are screens to assess the functional relevance of various genes/proteins systematically in a more global fashion.

Typically the methodology will involve a gene highly over or under-expressed in a particular cell line and reversing the expression by either overexpressing the gene or expressing a shRNA to knock-down expression of the gene in question. Lentiviral particles will be generated on site containing either a cDNA or appropriate shRNA.
cDNA sequences of humans or mice origin and/or the appropriate shRNA sequences will be cloned into the lentiviral vectors. These may include partial or entire gene cDNAs or shRNAs may be used to create a pool of cells with several integrated constructs which will then undergo in vitro or in vivo selection to screen for constructs which either promote or inhibit leukemic cell proliferation or engraftment.

Recipient or parental organism

Packaging cell line 293T (and thereof derived cell lines) is derived from the well-characterised 293 cell line (Pear et al., PNAS 1993; 80; 8392; ATCC CRL-11268). This cell line stably and constitutively expresses a temperature-sensitive version of the SV40 large T antigen. This cell line will be used to produce lentiviral particles. These vectors alone are replication incompetent owing to their lack of envelope and gag-polymerase encoding sequences. Virus is therefore produced by co-infection of the 293T cell line with lentiviral vector along with one or more viral envelope encoding plasmids (e.g. VSV-G or constructs derived from the measles virus [MV] hemagglutinin and fusion protein genes [HΔ24 and FΔ30]) and a plasmid encoding the HIV or FIV gag-pol and the regulatory genes including rev, nef and vif. Plasmid DNA will be produced in standard K12 E-coli hosts but mammalian promoters would preclude expression of ORFs.

Mammalian cell lines and primary mammalian cells will be used for infection with the supernatant generated by the packaging cells. Cell lines such as MT2 or MT4 producing infectious particles will not be used for transduction. Most cell lines are derived from solid tumours or leukaemias. All cell lines have a long history of safe use and are commonly handled in UK labs at CL2 or CL1. All facilities at Newcastle University where these materials are handled are at CL2 standard. Use of new cell lines will be registered with the UBSO as a minor addition to the risk assessment summarising their properties and status. The mammalian cells and somatic stem cells are only able to survive if maintained in tissue culture in the laboratory, or if injected into inbred syngeneic or immunodeficient animals.

Host/vector system

The transfer vector systems are derived from FIV or HIV and have been specifically engineered for biosafety by separating the packaging signals and viral LTR's on the expression plasmid from the viral structural and expression genes (gag, pol and rev from FIV and the VSV-G gene from Vesicular Stomatitis Virus, or similar alternatives, in place of FIV or HIV env) encoded on three or four separate plasmids, which remain in the packaging cell line, effectively precluding the production of replication competent virus in the target cell or should the viral vector escape containment. FIV vectors are included as they may be more efficient for some cell types. It does not imply any different containment or risk considerations than HIV based vectors. The plasmids expressing these gene products carry no packaging signals or LTRs and so cannot themselves be mobilised with the vector and have been engineered not to contain any regions of homology to each other or to the viral vector, to prevent undesirable recombination events which might result in replication competent virus being produced.

The viral vector and recombinant virus have a broad host range when pseudotyped with e.g. the VSV-G envelope protein. The normal tropisms of HIV and FIV have been broadened to include multiple tissues from a broad range of species. Pseudotyping with alternatives to VSV-G, for example measles virus derived glycoproteins, will produce particles with more restricted tropisms.

Origin & function

cDNA sequences of humans or mice origin and/or the appropriate shRNA sequences will be cloned into the lentiviral vectors. These may include partial or entire gene sequences, or mutant forms of the gene sequences, under the control of constitutive promoters. In screening applications, many of the genes or targets of the shRNAs will have unknown function but may include known oncogenes or tumour suppressors. In the case of mutated genes, these will comprise of characterised sequences which have deliberately mutated by site directed mutagenesis. An example of a mutation that is constitutively activating might be a KRASv12 mutation which has been demonstrated to result in overactive ras signalling and therefore again should be considered to pose a greater hazard than the wildtype sequence. Other targets may include known proto-oncogenes/tumour suppressors such as RUNX1, ERG, GRIK2, PARK2, FOXO3, CRLF2, TP16, TP53 or TERT.

The aim is to use either overexpression or knock-down of gene-expression to assess the potential contribution to tumourigenesis of each candidate identified from our genomics screens. Once a stably infected cell line is produced experiments performed will depend on the particular gene selected but will typically involve a panel of typical proliferation, apoptosis and/or invasion assays as well as collection of RNA/DNA/Protein for further profiling analysis and potentially in vivo engraftment.

Evaluation of foreseeable effects

02/03/2022
This risk assessment covers research examining Urinary tract infections (UTI) caused by uropathogenic Escherichia coli (UPEC) are one of the most prevalent microbial diseases in the UK. These infections are often self-limiting so a key public health challenge is to reduce antibiotic usage. The project will utilise an in vitro system to monitor phenotypic adaptation of UPEC during prolonged growth conditions. The objective is to increase our understanding of how recurrent infection occurs and identify feasible biomarkers for application in management strategies.

To achieve this, our experimental plan aims to establish continuous-cultures of laboratory and clinically derived UPECs in growth media supplemented with and without antibiotics. We will monitor phenotypic adaptation to this environment through bacterial growth rate, flagella and fimbriae expression, bacterial persistence and activation of host innate defence systems. This controlled modelling approach will enable us to plot the time course of phenotypic adaptation and so link phases of phenotypic adaptation UPEC to susceptibility to both innate and external bactericidal agents.

The genetic manipulations we will carry out in doing experiments to investigate these problems are all aimed at improving basic understanding of UPEC pathogenesis in a model growth system. We will apply a wide range of genetic modifications, including gene knock outs, insertion of reporter genes, such as LacZ and gfp (and its variants), insertion of regulated promoters and mutagenesis with transposons. Resistance genes will be used as selective markers for these constructions but these will comprise well tried and tested genes that do not constitute a threat to the evolution of resistant pathogens.

Strains to be used:
- Escherichia coli K-12
- Escherichia coli BL21
- Escherichia coli CFT073 - ACDP Class 2 approved
E. coli K-12 and BL21 strains: E. coli K-12 strains and derivatives (e.g. MG1655, W3110, C600 MC1000, JM109, DH5) are defined as disabled or non-colonising in the SACGM Compendium of Guidance (Part 2A, Annex 11, para 11) and is therefore equivalent to an ACDP hazard group 1 organism. E. coli BL21 and derivatives are described in SACGM Newsletter 30 (Nov. 2001, para 3) as being "broadly equivalent to K12 strains and that in most cases work which uses this host can be considered as a class 1 activity, but the cloning of a bacterial pathogenicity determinant into BL21 will need careful consideration and may in some cases warrant classification as class 2".

E. coli CFT073 and clinical isolates: Although CFT073 was originally a natural pathogenic UPEC isolate, it has been maintained and passaged in the laboratory for several decades. CFT073 will still be handled as a potential pathogen following the same protocols we will use to handle the known clinical isolates. Taking into consideration the mode of infection required for healthy individuals for UPEC to cause symptomatic infections, the hazard risks associated with CFT073 and the clinical isolates are still considered to be low.

Host/vector system

Vectors to be used:
- E. coli plasmid vectors such as pUC, pBR322, p15A, R1, F, RK2/RP4, RSF1010 and pSC101;
- E. coli bacteriophages P1, λ and M13

All vectors to be used are standard vectors with a long history of safe use in the laboratory, or derivatives thereof. These include non-mobilisable or mobilisation-defective E. coli K-12 vectors such as pUC, pACY184, pLG339, pBR332 and derivatives including, for example, the pET and similar expression vectors. We also use non-mobilisable derivatives of plasmids R1 and F. Moreover, the use of non-mobilisable or mobilisation defective vectors minimises the likelihood of transfer to other species. Some experiments will employ the non-self transmissible but mobilisable 'suicide' vectors e.g. pK18 mob. These vectors will be constructed in standard E. coli K-12 hosts that do not support the mobilisation of the plasmid. These suicide vectors are constructed to allow redundancy of target plasmid, i.e. in the very unlikely event of unintended mobilisation to a different strain or species these vectors would be unlikely to be able to replicate outside E. coli and so should not constitute any greater risk. Moreover, horizontal transfer genes between different E. coli strains already occurs in nature. However all these plasmid derivatives are essentially listed as Group 1 in the SACGM Compendium of Guidance 2000 (Part 2A Annex 11, 25, 26 and 35). Bacteriophage manipulations using P1, λ and M13 are confined to E. coli. Genetic manipulations involving generalised or specialised phage transduction would be used to move genetic markers from various backgrounds within a species (e.g. P1). The marker will usually involve the disruption or manipulation of specific genes involved in essential cellular processes, as such is unlikely to pose any increased hazard above the handling of the wild type strain, which would then be transduced to other genetic backgrounds.

Origin & function

The vectors will contain drug resistance markers already widely distributed in nature. Resistance markers (cat, bla, aphA, spc, tet, and hyg), reporter genes (such as lacZ, lux, gfp (and derivatives), etc.), epitope tags (such as FLAG, HA, c-myc, 6xHis, etc), artificial promoter constructions (e.g. PBAD). Genes will, in general, be derived from the host organism (e.g. genes directly involved in pathogenicity, introduced by either a plasmid replicon or inserted directly into the host genome.

Evaluation of foreseeable effects

Drug resistance markers used in these vectors are already widely distributed in nature. Strain construction will involve plasmid derivatives passing through E. coli K-12 for amplification prior to reintroduction into the host bacterium. It is therefore possible that these constructs could have biological effects on E. coli K-12 and UPEC, but it is difficult to envisage the hazard being significantly greater than the handling of the parent strains from which the DNA was isolated. In general the GMs proposed fall into two categories; firstly, gene disruptions where no functional gene product should be produced. These plasmids will then be used to generate chromosomal disruptions in the chromosomes of the host bacterium, so doing the plasmid replicon will either be destroyed, or will be non-cloned in plasmids in such a way as to be controlled by artificial promoters, e.g. pBAD, ppt and synthetic lac is not functional, or used as expression systems to allow the purification of the encoded gene product. Since the genes to be targeted are though to be associated directly with pathogenesis, it is highly unlikely that their manipulation and removal will benefit pathogenesis.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The work is category 2 it will be carried out under full containment level 2 (see Compendium of Guidance, Part 3) conditions this will include the use of microbiological safety cabinets where appropriate and full PPE compliance.

Furthermore a strict policy of hand washing on leaving the laboratory when handling E. coli/UPEC is in place. All contaminated materials, including waste destined for incineration and spent culture media, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Annual thermocouple mapping will validate autoclaves and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile.

Where this option of decontamination is not possible (e.g. small spills on benching or floor and minor contamination of microscopes or spectrophotometers) an alternate chemical decontamination method will be employed; i.e Peroxygen compounds - VIRKON at a concentrate of 1%.

Is an emergency plan required according to regulation 20?  N

Please enter comments on the GM safety committee on the risk assessment

Reviewer 1 - SB Institute for Genetic Medicine.
Following my review this looks like a very well written proposal and seems suitable to me to be approved as a Class 2 project under CL2 conditions.

Reviewer 2 - CM Institute for Ageing and Health
Following review attached are my thoughts*, very few comments as this seems a fairly comprehensive assessment. Only thing to do is update references to current SACGM. I agree with CL2 if this is looking at wild type E. coli.

* The attached document contained grammatical improvements not containment control improvements.

Reviewer 3 - AK Institute for Cellular & Molecular Biosciences. Please find attached below a Class 2 GM project from PA & JH on UPEC. It has been through the ICAMB GM committee and suggested revisions have been incorporated and we approve this project for submission.

### Project Additional Information

#### Purposes of the contained use

The principles and goals of Synthetic Biology are to design and employ useful DNA parts to construct, standardise, modify and re-structure nucleic acid sequences, genes and natural biological systems in order to understand and provide new solutions for public health, energy and environmental challenges. E. coli and Pseudomonas spp may serve as prokaryotic platforms for construction of biological logic and memory circuits for further facilitating synthetic biology studies. This notification is for routine cloning, manipulation and transcriptional expression of DNA sequences from other microorganisms (ACDP hazard group 1 and 2) into disabled E. coli or Pseudomonas spp, parental strains or isogenic mutants. To establish bacterial platforms the procedures involve (i) sub-cloning, DNA sequencing, site-directed mutagenesis or transposon random mutagenesis; (ii) construction or genomic insertion of fusions with harmless reporter genes such as lux, phoA, gfp, lacZ; (iii) construction of recombinant plasmids for subsequent transformation or mutagenesis of prokaryotic cells (e.g. Pseudomonas spp); (iv) construction of recombinant plasmids for the purpose of transcriptional expression of bacterial DNA sequences; (v) construction of biological logic and memory circuits in prokaryotic platforms.

### Recipient or parental organism

Two bacterial species are involved in this notification which are Escherichia coli and Pseudomonas spp. Disabled E. coli K12, B strains and their derivatives such as DH5a, S17-1, BL21 (DE3) as defined in the Compendium of Guidance will be used. They are considered as ACDP group 1 and not pathogenic. Recent research commissioned by the HSE (Chart et al. 2000), An investigation into the pathogenic properties of E. coli strains BLR, BL21, DH5a and EQ1 (J. Applied Microbiology, 89, p1048 – 1058) showed that BL21 is unlikely to be pathogenic, lacking any of the pathogenic mechanisms associated with E. coli strains involved in enteric infections. BL21 may be considered unlikely to colonise and establish a persistent infection in the gut of a healthy individual. The Pseudomonas spp. strains used in this notification have been isolated from a wide variety of sources including historical clinical environments that over the years became well-established laboratory strains. They include ACDP hazard groups 1 (P. fluorescens, P. putida, P. syringae) and ACDP hazard groups 2 (P. aeruginosa).
Pseudomonas aeruginosa is a Gram-negative bacterium commonly found in soil and ground water. It rarely affects healthy people and most community-acquired infections are associated with prolonged contact with contaminated water. Although P. aeruginosa is an opportunistic pathogen (i.e. more likely to infect patients who are already very sick as opposed to healthy individuals), it can cause a wide range of infections, particularly among immunocompromised people (HIV or cancer patients) and persons with severe burns, diabetes mellitus or cystic fibrosis. Serious Pseudomonas infections usually occur in people in the hospital and/or with weakened immune systems. Infections of the blood, pneumonia, and infections following surgery can lead to severe illness and death in these people. The most significant potential routes of exposure to Pseudomonas are from the direct contact with the bacteria, but other routes of exposure may take place depending on the strain and circumstances. The risks of infection are very low for healthy individuals and the infections could be efficiently eradicated by antibiotic therapy.

Host/vector system

Bacterial hosts used in this notification are mentioned as above.
A range of vectors as defined in the Compendium of Guidance will be used to introduce recombinant DNA sequences into E. coli. Non mobilisable: pACYC184, pUC series and their derivatives (pUC19, pUC57), or other vectors Bom-/(Nic-), Mob- and Tra-.
Mobilisable defective: Pinpoint, pBR322, pET30, pTrc99A or other vectors Bom+//(Nic+) but Mob- and Tra- which can efficiently be mobilised if they are co-resident with certain other plasmids.
Shuttle vectors: carrying simultaneously dual E. coli (R6K, ColE1 or p15A) and broad host range replicons (e.g. Pseudomonas) such as pVS1 derivatives (pME60xx series), pRO1600 derivatives (pUCpXx series, pFLP2, etc.) and ColE1 derivatives (e.g. pME3087, pME3088, pHKBS1, etc.).
Mobilisable Suicide vectors: these plasmids with R6K replication origin (e.g. pGP704, pRL27, pLM1, pKNG101, pDM4, etc.) can only replicate in E. coli supplying with pir gene (e.g. strain S17-1 λpir) and have narrow host range. These plasmids will only be used for construction of recombinant plasmids in E. coli for subsequent conjugative to defined bacterial strains such as Pseudomonas spp.
A range of suicide vectors that are unable to replicate in Pseudomonas spp. will be used for the construction of the mutations of Pseudomonas.
Non mobilisable: pACYC184, pUC19, pUC57, or other vectors Bom-/-(Nic-), Mob- and Tra-
Mobilisable defective: Pinpoint, pBR322, pET30, pTrc99A or other vectors Bom+/-(Nic+) but Mob- and Tra- which can efficiently be mobilised if they are co-resident with certain other plasmids.
Mobilisable Suicide vectors: these plasmids can only replicate in E. coli (e.g. strain S17-1 λpir) but not in Pseudomonas and are used to mobilize plasmids from E. coli into Pseudomonas including R6K derivatives (e.g. pGP704, pRL27, pLM1, pKNG101, pDM4, etc.). The suicide vectors may also contain transposons such as Tn5 (pUT-miniTn5 and derivatives) and Tn7 (pUC18R6KT-mini-Tn7T and derivatives), Tn917 (pTV series) or other of similar nature in order to create insertion mutants.
A range of vectors will be used to introduce recombinant genes and DNA parts into Pseudomonas spp once a functional replicon in these organisms has been incorporated into the vector when required.
Non mobilisable: pUCPxx derivatives (e.g. pUCP18), pBRR1 derivatives (e.g. pBBR1MCS-x series, pME6000, etc.) or other vectors Bom-/-(Nic-), Mob- and Tra-
Mobilisable defective: Pinpoint, pBR322, pET30, pTrc99A or other vectors Bom+/-(Nic+) but Mob- and Tra- which can efficiently be mobilised if they are co-resident with certain other plasmids.
Shuttle vectors: carrying simultaneously dual E. coli (R6K, ColE1 or p15A) and Pseudomonas or broad host range replicons such as pVS1 derivatives (pME60xx series), pRO1600 derivatives (pUCpXx series, pFLP2, etc.) and ColE1 derivatives (e.g. pME3087, pME3088, pHKBS1, etc.).
Mobilisable Suicide vectors: these plasmids can only replicate in E. coli (e.g. strain S17-1 λpir) but not in Pseudomonas and are used to mobilize plasmids from E. coli into Pseudomonas including R6K derivatives (e.g. pGP704, pRL27, pLM1, pKNG101, pDM4, etc.).

Origin & function

In order to fit the principles and goals of Synthetic Biology, genes and DNA parts from ACDP hazard group 1 and 2 organisms will be cloned into these vectors, and housed either in E. coli or in Pseudomonas spp. For example, the bacterial quorum sensing (QS) systems from other gram-negative bacteria (e.g. elastase, LasA protease rhamnolipids, type III flagellar-mediated swimming motility and pyocyanin in Pseudomonas aeruginosa) will be cloned into E. coli; the restriction-modification (RM) systems from E. coli will be cloned into P. aeruginosa or P. putida for methylation of the introduced plasmid for further studies; DNA partition (parAB) and DNA transportation systems from other bacterial organisms (e.g. Neisseria) will be introduced into bacterial hosts for DNA manipulation; transcriptional regulators (e.g. LazI, AraC and TetR) or promoters (e.g. cIa and cI434 from E. coli bacteriophages A and 434, respectively) from various ACDP hazard group 1 and 2 microorganisms will be cloned for constructing logic circuits or gene regulatory networks; computer-aided designed (CAD) DNA sequences without harmful biological functions will be cloned for constructing nucleic acid structures. The majority of genes and DNA parts for this project have been described in the standard biological parts website (http://parts.igem.org/DNA). Occasionally,
novel promoters, aptamers and regulators (such as novel quorum sensing (QS) genes (luxI/R) from other gram-negative bacteria) will also be cloned into E. coli. The vectors may contain fusions reporter genes such as lux, phoA, gfp, lacZ and antibiotic resistance markers (cat, bla, kan, spe, tet, erm) that are already in routine use in standard cloning vectors.

The vectors may contain transposons such as Tn5, Tn7, Tn917 or other of similar nature with strong transcriptional terminators in order to create random insertion mutants or targeted chromosomal fusions (e.g. mini-Tn7 with reporter genes insertion in the downstream of PA5548 of P. aeruginosa (Nature Method 2005, 2:443). The suicide vectors could also contain reporter genes such as lux, phoA, gfp, lacZ. For the chromosomal deletion/insertion mutants, only antibiotic markers (cat, kan, tet, erm) that are already in routine use in standard cloning vectors will be used.

**Evaluation of foreseeable effects**

Although the E. coli hosts are not known to be pathogenic and could be considered to be analogous to biological agents in hazard group 1, the introduction of genes such as QS systems, DNA partition systems, or transcriptional regulators from group 1 and 2 microorganisms into these strains could potentially make them pathogenic and so be classified as hazard group 2.

Pseudomonas species used in these experiments are hazard group 1 apart from P. aeruginosa which is hazard group 2. The well-characterised vectors that will be used in Pseudomonas spp. (i) are non-mobilisable (e.g. pUCPxx and pBBR1 series and their derivatives), mobilisation-defective (e.g. pBR322 and its derivatives), shuttle vectors between E. coli and Pseudomonas (e.g. pME60xx series) or mobilisable suicide vectors (R6K derivatives from E. coli to Pseudomonas); and (ii) contain only selective markers that are already in routine use in standard cloning vectors; and (iii) contain no recognisable harmful sequences. There will be no possibility of viral particles being produced in Pseudomonas and the likelihood of unintended transfection of eukaryotic cells and unintended transformation of other prokaryotic cells is extremely low. These vectors are unlikely to be maintained outside the laboratory in the absence of selective pressure. Therefore the level of risk of the recipient strains should not increase over an equivalent to hazard group 2. The introduced genes and standard DNA parts from ACDP hazard group 1 and 2 microorganisms such as RM systems, QS systems or DNA partition systems genes are unlikely to increase the level of risk of the resultant strains over an equivalent to hazard group 2. Genes such as reporters or routine used antibiotic resistance genes are under the control of their own promoter or native Pseudomonas promoters and their expression levels are not expected to be above native levels of expression therefore the level of expression of downstream targets are not expected to increase. It is difficult to envisage how the mutagenesis or chromosomal fusions could enhance the virulence of the Pseudomonas spp. which should not be above the equivalent to hazard group 2.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Only GM micro-organisms will be involved.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Decontamination and autoclaving will be carried out where required. All solid waste materials will be disposed of into the autoclave bags, yellow clinical waste bags or sharps bins as required. All used sharps will be placed immediately after use into a sharps bin. Sharps bins will be located on the bench where the sharps are used so that they can be disposed of directly after use. All bacterial contaminated waste including both solid and liquid forms will be autoclaved before disposal.

a) Decontamination.
1% Trigene will be used for disinfection. The surfaces of the working bench and the microbiological safety cabinet will be decontaminated with 1% Trigene after use. Laboratory benches will be swabbed with 1% Trigene after any activity.

b) Autoclaving.
All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile.

Spillages of any GMOs or any of their contaminated products will be localised by spillage kits and disinfected with 1% Trigene. In the event of any injection injury or other serious accidental exposure seek first aid or medical attention if required.

**Purposes of the contained use**

In this project interactions of cell wall-deficient bacteria with their murine and human hosts will be investigated and compared with those of their walled counterparts. Several mutations have previously been shown by our group to predispose Bacillus subtilis to grow in the absence of a cell wall, as so-called L-form bacteria. The mutations were identified in genes involved in synthesis of the cell wall, such as murA-F, polyisoprenoid synthetic pathway, such as ispA, as well as genes involved in the production of bacterial membrane, such as accDA. Interestingly, B. subtilis L-forms were able to divide independently of FtsZ, a protein conserved amongst bacteria and essential for division in rods. In this project mutations in genes involved in synthesis of bacterial cell wall and membrane, as well as those responsible for division will be introduced into bacterial species specified in section 7, to encourage their growth without the cell genes, such as lacZ, gus and gfp (as well as its many variants), insertion of regulated promoters, using non-clinically relevant antibiotic-resistance genes as selective markers. L-form bacteria obtained during the course of this project will be used to extend our knowledge about cell wall-deficient bacteria in general and to establish how the cell wall affects interactions with host cells in comparison to their rod-shaped or coccal counterparts. Effects on pathogen invasiveness and uptake, as well as host responses, such as cytokine production and intracellular signalling pathways, will be investigated using gentamycin protection assay, microscopy, FACs analysis, q-PCR, Western blotting, ELISA assays, protein arrays and DNA microarrays. Most of the work will involve murine macrophage-like cell lines RAW264.7 and J774 as well as human macrophage-like cells lines U937 and THP1. Epithelial cell lines such as HEK293 and HeLa might also be tested. In the later stages of the project isolated murine and human macrophages might be used as well as murine animal models. It is predicted that pathogenicity of L-forms will be severely compromised in comparison to their wall-sufficient counterparts, because the introduced mutations will affect essential cell processes such as generation of protective cell wall and division.

**Recipient or parental organism**

All of the organisms listed below are ACDP hazard group 2:

- Listeria monocytogenes strains EGD, EGDe, 10403S and derivatives
- Enterococcus faecalis V583 and derivatives
- Enterococcus faecium Aus0085 and derivatives
- Salmonella enterica serovar Typhimurium C5 and SL1344 and derivatives
- Staphylococcus aureus strains Wichita, MW2, Newman, COL and derivatives

**Host/vector system**

- E.coli/Listeria shuttle vectors: pMAD (allelic replacement vector), pPL2 (site specific Listeria integrative plasmid pMK-pMK4 (site-specific Listeria integrative plasmid) and their derivatives
- Staphylococcus aureus bacteriophage 80
- E. coli/Staphylococcs aureus and Enterococcus shuttle vectors pBR322 series, pDL277 (expression, cloning vectors), pMUTIN4 (lacZ fusion integrative vector), pSG series (N-terminal GFP fusion integrative vector), E. coli/Salmonella pBR322, pBAD series, pAT153, pGEX series (expression, cloning vectors)
- Salmonella pGP704 and pLac (gene disruption vectors)
- Salmonella P22HTint bacteriophage

**Origin & function**

- Resistance markers (such as cat, bla, kan, neo, spc, tet, ble, apr, and hyg), Reporter genes (such as lacZ, gus, gfp (and derivatives), etc.), Epitope tags (such as HA, c-myc, 6xHis, etc.), artificial promoter constructions (e.g. PxyL or PsPac). Genes will in general be derived from the host organism (e.g. genes directly involved in cell division, chromosome segregation, cell wall biosynthesis, metabolism), introduced either on a plasmid replicon or inserted directly into the host genome. Homologous genes from other bacteria might be introduced in some cases for convenience of manipulation.
The genes of interest predominantly encode proteins involved in essential cellular processes such as cell wall biosynthesis and division that we would like to understand better. Cell wall-defective mutants are likely to be resistant to antibiotics, which target cell wall components or their synthesis, such as most β-lactam antibiotics. However, their susceptibility to antibiotics that target other sites than the cell wall in order to reach their target (e.g., Gentamycin, daptomycin, metronidazole). Moreover, cell wall-defective mutants are also expected to be severely compromised in their ability to infect host and cause disease. Cell wall plays a critical role in protection of bacteria from the environment and the host immune system. Bacteria deprived of the cell wall have to be cultivated in a carefully designed osmoprotective internalin A (InlA) and ActA, T3SS1 and T3SS2 type III secretion systems of Salmonella spp. Secretion and correct folding of others, such as listeriolisin O (LLO) and phosphatidylinositol-specific phospholipase C (PI-PLC) or malfunction in cell wall-defective mutants, which are therefore unlikely to pose a significant threat. Mutants defective in other highly conserved metabolic functions such as division are very unlikely to become more pathogenic than the parent strain and in fact the opposite is more probable.

The threat that cell-wall defective bacteria may pose to environment is negligible, because these organisms die outside carefully designed osmoprotective medium.

All of the vectors to be used are standard vectors with a long history of safe use in the laboratory. These include non-mobilisable or mobilisation-defective Salmonella pBR322, pBAD series, pAT153, pGEX series. Streptococcal?Enterococcal pDL277, pSG series and pMUTIN4 and Listerial pMAD. The use of non-mobilisable or mobilisation defective vectors minimises the likelihood of transfer to other species.

The gene disruption vectors pGP704 and pLac are non-self transmissible but mobilisable in a host engineered to carry the bacteriophage lambda pir gene product. Listerial pPL2 and pLMK series also are non-self transmissible but mobilisable in a host that carry PSA phage.

Genetic manipulations involving generalised or specialised phage transduction would be used to move genetic markers from various genetic backgrounds within a species. (e.g. Staphylococcus aureus bacteriophage 80:: or salmonella-specific bacteriophage P22HTint). The marker will usually involve the disruption or manipulation of specific genes involved in essential cellular processes, as such is unlikely to pose any increased hazard above the handling of the wild type strain, which would then be transduced to other genetic backgrounds.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated materials, including waste destined for incineration and spent culture media, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Annual thermocouple mapping will validate autoclaves and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile. Where this option of decontamination is not possible (e.g. small spills on benching or floor and minor contamination of microscopes or spectrophotometers) an alternate chemical decontamination method will be employed (VIRCON and/or Distel) where necessary. When the work is completed hands will be sanitised with NovaClenz sanitiser (VWR)

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
The aim of our work is to functionally and structurally characterise Clostridial proteins involved in the virulence and pathogenicity mechanisms of this important human and animal pathogen. Our goal is to gain further insight into the mechanisms used to cause disease that can be exploited in the future to control or prevent infection.
Recipient or parental organism

Wild type and antibiotic sensitive variants of ACDP hazard group 2 Clostridial strains, mainly C. difficile but C. perfringens and C. sordellii may be included.

Disabled Escherichia coli K12 strains.

Host/vector system

1. Transfer into Clostridia of integrative transposons by conjugation from E. coli. In this case no vector will remain in the bacteria, with the exception of remnants of the transposon, which will be inactive.

2. Clostridia / Plasmid pMTL960. This plasmid replicates in both E. coli and Clostridia. It carries a chloramphenicol resistance gene which is active in both E. coli and Clostridia.

Origin & function

1. We intend to knock-out any gene, with particular focus on genes relation to sporulation, cell wall components and pilins. This procedure will not introduce foreign DNA into the recipient, other than an antibiotic resistance cassette and a transposon. The antibiotic resistances used will not be those used for therapy in infection, i.e. they will not encode vancomycin or metrinidazole resistance.

2. As we have to complement any mutation in a Clostridial strain, we will introduce on a plasmid, the wild type version of the gene into the mutant strain. As we intend to knock-out essentially any gene in the genome, we can summarise the intended functions of the genes as "normal cell metabolism" and "pathogenesis". For the purposes of plasmid introduction, the genes of interest are initially introduced in E. coli for conjugation with Clostridia.

3. We will also introduce a series of marker genes into the Clostridia, e.g. fluorescent protein, luciferase.

Note: no active toxin genes will be transferred into any Clostridia recipient.

Evaluation of foreseeable effects

1. Creation of mutants. As we intend to create mutants with decreased virulence, which we will determine using in vitro assays, e.g. cell culture techniques, we predict that the mutants will be less virulent than the wild-type strains. That also expands to the ability to survive in the environment. As an example, our collaborators have made knock-outs in a complex of 2 proteins we are also studying; in both cases, the resulting strains do not sporulate or have attenuated sporulation (personal communication). Similarly, knocking out the main S-layer protein results in cells that die and can't grow. We expect similar results as we look at other proteins involved in these processes. It is unlikely that any introduced genetic material could be transferred to related microorganisms. This is because the transposons which are inserted into the chromosome do not retain their ability to retarget another gene once inserted into the genome, i.e. they are rendered non-transposable.

2. Complementation of mutants. There is a very small chance that, by introduction of a gene into a strain defective in that gene, that the increased gene dosage will change the virulence of the strain. It is possible that some complemented mutants might have increased virulence, but we consider this unlikely. Clinical symptoms are directly associated with the production of toxins and although other components seem to vary between strains, no direct association with increased virulence has been established (see Hunt & Ballard, 2013, Micro Mol Biol Rev 77:567-581 for a review of virulence factors and variations between strains). There have been no reports to date that increasing the expression of essential cell wall proteins, pilis or genes involved in sporulation results in an increase virulence. The strains created will only survive in the laboratory under antibiotic selection. If such a strain was to infect a person or animal, the plasmid would be rapidly lost and the strain would not be any more virulent than the wild-type and, as explained above, is expected to be less pathogenic. Similarly, it is unlikely that the genes present on the plasmids could be transferred to another micro-organism, as the plasmids are easily lost once the antibiotic pressure is removed.

3. Introduction of marker genes. All marker genes used will be non-toxic and would not be expected to increase the virulence of the strain.
4. E. coli. The genes of interest will be included in E. coli for conjugation with Clostridia. This assessment excludes deliberate in-frame insertion of expressible DNA downstream of a prokaryotic promoter with the intention of expressing proteins (either alone or as fusion proteins) within E.coli. However, it is recognised that inserted DNA may contain sequences that have promoter activity in E. coli, but: (i) inserts are likely to be out-of-frame, or inverted with respect to the vector reading frame; (ii) codon usage will bias against high-level expression in E. coli. Moreover, the vectors to be introduced both in E.coli and Clostridia, will be low copy number so high-level expression is unlikely. The combination of the above factors greatly reduces the likelihood of biologically active proteins being produced in E.coli. Further, even if biologically active proteins are produced, as toxins are excluded from these experiments, consequences for human health are minimised.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Cultures will be inactivated by either chemically or by heat serialisation (autoclaving)
Autoclaving (used for all waste: solid and liquid culture waste, agar plates etc)
134oC 30 minutes
Each run is monitored by Departmental staff
Autoclave is tested annually by use of a 12 point thermocouple test
Chemical sterilisation (used for liquid cultures when autoclaving is not possible such as to clear accidental spills and disinfect working areas)
Addition of Virkon to a final concentration of 1%; leave overnight; dispose of waste down sink.
Validation – manufacturer’s data, best standard practice in clinical and laboratory settings.

Is an emergency plan required according to regulation 20? N

### Project Additional Information

**Purposes of the contained use**

This project will involve the creation of transgenic lines of the wheat pathogen *Zymoseptoria tritici* as well as other GMMs. The aim of the project is to investigate the molecular mechanisms that enable *Z. tritici* to infect its host. *Z. tritici* causes septoria tritici blotch disease that is characterised by necrotic blotches on wheat leaves. We are interested in how environmental signals are sensed and regulate the morphological changes of *Z. tritici* that are required for its virulence. *Z. tritici* is a dimorphic fungus that can exist in a yeast or filamentous form, with the latter being essential for host infection. Initially we will focus on the role of nutrients (particularly nitrogen and carbon) in the development of *Z. tritici*. The growth of *Z. tritici* on agar plates and in liquid media containing different nutrients will be analysed to determine those conditions that induce morphological change. Genes that are involved in nutrient sensing and morphological change will be identified through a combination of targeted and random mutagenesis by the introduction of a selectable marker into the *Z. tritici* genome using *Agrobacterium tumefaciens* mediated transformation. Epistatic analysis will identify any genetic interactions between the identified genes. Genes will be tagged with various epitopes (e.g. FLAG, GFP) to facilitate protein cellular localisation, detection via western blotting and isolation using immunoprecipitation techniques. Tagged and mutated genes will usually be expressed from their native promoters, occasionally from a constitutive promoter and will be integrated into the *Z. tritici* genome. The levels of mRNA originating from genes of interest will be analysed by standard methods (e.g. northern analysis). In some cases, the ability of *Z. tritici* genes to complement the homologous genes in the yeast *Saccharomyces cerevisiae* will be tested by expressing those genes in *S. cerevisiae* using standard yeast expression vectors. Several *Z. tritici* genes will be expressed in *E. coli* (BL21) for protein isolation purposes. *Z. tritici* mutants of interest will be analysed for their ability to infect wheat by collaborators at other institutions such as Dr. J R (Rothamsted Research), Dr. A C (Syngenta AG) and Dr. A S (Durham University). The growth of wheat and testing of transgenic lines of *Z. tritici* will be undertaken by collaborators in appropriate containment plant pathogen glasshouse or growthroom facilities and will not be tested in Newcastle (See section 10).
Zymoseptoria tritici strain IPO323, a modified Ku70 delta strain of IPO323 (Bowler et al., Mol. Plant Pathol. 2010 11: 691–704) and UK environmental isolates received from academic and commercial research labs (e.g. Rothamsted Research; Syngenta AG). These strains will be used to generate mutants that contain a gene disruption for functional studies. Note: Zymoseptoria tritici is the asexual state (anamorph) that was previously named Septoria tritici. Mycosphaerella graminicola is the sexual state (teleomorph).

Saccharomyces cerevisiae. This is the commonly used model yeast considered to be especially disabled and non-pathogenic (Compendium of Guidance 2000, Part A, Annex II).

Agrobacterium tumefaciens strains containing a disarmed Ti plasmid and therefore considered disabled [e.g. AGL-1, EHA105 (Hellens and Mullineaux, Trends Plant Sci. 2000 5: 446-451)] will be used to transform Z. tritici.

Recipient or parental organism

Non-mobilisable S. cerevisiae vectors: Examples that are routinely used include multicopy 2u vectors, low copy centromeric vectors and single copy integrating vectors (Compendium of Guidance 2000, Part A, Annex II).

Non-mobilisable or mobilisable defective E. coli vectors: Examples that are routinely used will include pBR322, pBluescript, the pUC vector series and the pET vector series (Compendium of Guidance 2000, Part A, Annex II).

Agrobacterium vectors: Mobilisable plasmids (e.g. pNOV2114, pCHYG) containing antibiotic resistance cassettes will be transformed into A. tumefaciens for transfer to Z. tritici strains according to the following reference (Motteram et al., Mol. Plant Microbe. Interact. 2009 22: 790–799).

Host/vector system

The genetic material that will be used in this project will originate from reference Z. tritici strain IPO323. Generally, Z. tritici genetic sequences will be amplified using PCR and then cloned into E. coli vectors so that they may be modified by mutation or gene tagging before being reintroduced into the Z. tritici genome. Reporter genes (such as lacZ) will be introduced into the Z. tritici genome to analyse gene regulation. Genomic and cDNA libraries will also be generated and used.

Origin & function

The pathogenicity of Z. tritici is a polygenic trait so that the expression of a single Z. tritici gene is not going to convert S. cerevisiae or E. coli into pathogenic organisms. In addition, Z. tritici genes will only be expressed using mobilisation defective plasmids (Compendium of Guidance 2000, Part A). The aim of this project is to dissect at the molecular level the mechanisms that link nutrient availability to the morphology and virulence of Z. tritici. Most, if not all, of the Z. tritici transformations that will be

Expression in Z. tritici.

Agrobacterium mediated transfer will be used to integrate targeted or random single copies of DNA cassettes into the Z. tritici genome. The transformation of Z. tritici using A. tumefaciens is an efficient way to generate genomic integrations and thereby disrupt gene function (Motteram et al., Mol. Plant Microbe. Interact. 2009 22: 790–79). Dominant markers containing genes that confer resistance to antibiotics such as hygromycin, neomycin and nourseothricin will be introduced to disrupt Z. tritici genes. The targeted inactivation of genes involved in nutrient acquisition or the control of morphology, are expected to reduce the fitness of Z. tritici. Mutants generated by random integration of antibiotic resistance markers will be screened for defects in nutrient acquisition or the control of morphology. The majority of these mutants will also be expected to reduce the fitness of Z. tritici with a consequent loss of virulence. In addition, mutated or tagged Z. tritici genes that are expressed from their native promoters will be reintroduced into the Z. tritici genome. It is predicted that mutated or tagged Z. tritici genes will have wild type or reduced activity. Furthermore, wild type Z. tritici genes expressed from their native promoters will be reintroduced into the Z. tritici genome to test the ability of these sequences to complement mutant strains. These genes will be expressed at wild type levels (to restore the wild type phenotype) which is highly unlikely to increase the virulence of Z. tritici over the wild type strains.

Expression of Z. tritici genes in S. cerevisiae and E. coli.

The pathogenicity of Z. tritici is a polygenic trait so that the expression of a single Z. tritici gene is not going to convert S. cerevisiae or E. coli into pathogenic organisms. In addition, Z. tritici genes will only be expressed using mobilisation defective plasmids (Compendium of Guidance 2000, Part A). The aim of this project is to dissect at the molecular level the mechanisms that link nutrient availability to the morphology and virulence of Z. tritici. Most, if not all, of the Z. tritici transformations that will be
undertaken will inactivate a specific gene target that have a negative influence on nutrient sensing and those virulence factors that respond to nutrient levels. Examples are genes that code for homologues of nitrogen sensing pathways in other fungi that regulate growth and morphology such as those in the protein kinase A (PKA) and mitogen-activated protein kinase (MAPK) pathways. Consequently, any mutations that alter nutrient sensing are likely to result in a reduction in the fitness of Z. tritici, which will likely reduce the ability of a mutant strain to survival within the environment. Furthermore, fungi that are maintained under laboratory conditions tend to exhibit reduced virulence (Franzot et al., 1998 Infect. Immun. 66: 89-97). The transfer of Z. tritici genes that will be expressed in E. coli is unlikely as these genes will be expressed from non-mobilisable or mobilisable defective plasmids. The transfer of chromosomally integrated tagged, mutated or disrupted genes within Z. tritici will only occur via sexual reproduction. It is conceivable that if laboratory strains were to escape into the environment that they could mate with environmental strains of Z. tritici. As described in section 3A.4, it is likely that all integrated variant alleles will either have no influence or reduce the fitness of Z. tritici. Therefore it is unlikely that the progeny of an environmental Z. tritici strain and a strain generated in the course of this work would be more virulent than a wild-type strain.

Human Risk
Z. tritici is a wheat pathogen that humans commonly come into contact with without causing disease. It is therefore highly unlikely that a variant strain of Z. tritici that is generated in the course of this work will pose a threat to healthy individuals. In addition, only disabled S. cerevisiae, and E. coli strains will be used (S. cerevisiae, E. coli K12 – Compendium of Guidance 2000, Part A, Annex II; E. coli BL21-ACGM Newsletter 30, Nov. 2001).

Environmental Risk
Z. tritici has been isolated from UK environmental sources and therefore laboratory strains would be predicted to survive within the same ecological niches as wild-type isolates. As described in section 3A.4, the generated strains will be most likely less fit than wild-type isolates. All E. coli and S. cerevisiae strains are highly disabled (S. cerevisiae, E. coli K12 – Compendium of Guidance 2000, Part A, Annex II; E. coli BL21-ACGM Newsletter 30, Nov. 2001).

All fungal work will be carried out at containment level 2. Infection by Z. tritici is initiated by the germination of spores on wheat. Spores are produced both asexually (pycnidiospores) and sexually (ascospores) by structures known as pycnidia and pseudothecia, respectively. These structures only form on wheat leaves and do not form when Z. tritici (anamorph) or M. graminicola (teleomorph) are cultured in liquid medium or on agar plates, growth conditions that will be used during the work at Newcastle. The virulence studies using wheat leaves will not be undertaken at Newcastle but by collaborators (see section 2.1) that have experience of these experiments and will be covered by their control measures. Z. tritici will be maintained as non-desiccated haploid fungi. Any procedures that may result in aerosols will be carried out using sealed containers or carried out in designated Class 2 safety cabinets. All materials contaminated with GMMs, including liquid waste, solid waste, glassware, plastic ware and sharps in CinBins will be autoclaved. Autoclaved sharps in CinBins and solid waste including agar plates will then be incinerated. Following sterilisation, liquid waste will discarded in the sink. Accidental spills of GMMs will be treated with Virkon (peroxycenic acid) (2%) overnight, wiped up and retreated with Virkon. Contaminated material will be autoclaved. Virkon (2%) will also be used for routine cleaning (1-2 hours contact time) of bench tops and laboratory equipment. All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment such as glassware. Autoclaves are validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile. In the event of spillage of a large culture (2 litres), all liquid will be absorbed using towels, which will then be autoclaved and then incinerated. The contaminated area will then be treated with Virkon (peroxycenic acid) (2%) overnight, wiped up and retreated with Virkon (2 hours). The Virkon contaminated towels will also be autoclaved and then incinerated.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A
Decontamination and autoclaving will be carried out where required. All solid waste materials will be disposed of into the autoclave bags, yellow clinical waste bags or sharps bins as required. All used sharps will be placed immediately after use into a sharps bin. Sharps bins will be located on the bench where the sharps are used so that they can be disposed of directly after use. All bacterial contaminated waste including both solid and liquid forms will be autoclaved before disposal. a) Decontamination. 1% Trigene will be used for disinfection. The surfaces of the working bench and the microbiological safety cabinet will be decontaminated with 1% Trigene after use. Laboratory benches will be swabbed with 1% Trigene after any activity. b) Autoclaving. All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile. Spillages of any GMOs or any of their contaminated products will be localised by spillage kits and disinfected with 1% Trigene. In the event of any injection injury or other serious accidental exposure seek first aid or medical attention if required.

The University Biological Safety Committee unanimously agreed that the risk assessment for the project "Identification of genes involved in the virulence of the wheat pathogen Zymoseptoria tritici using gene disruption and modification" submitted by Dr R was appropriate and adequate and represented a Class 2 Contained Use Activity with transgenic plant pathogens.

</tbody>
</table>
The purpose of this project is to generate induced pluripotent stem cells (iPSCs), which can then act as a model for prostate development and carcinogenesis. These cells will then be used both in vitro and in vivo by transplantation into immunodeficient mice to form prostate like glands.

Sendai viruses are included on ACDP Approved List of Biological Agents (see www.hse.gov.uk/pubns/misc208.pdf) and in the Health and Safety Executive (http://www.hse.gov.uk/biosafety/gmo/acgm/acgmcomp/part2.pdf) the use of these viral agents is categorised as Hazard Group 1 (microorganisms that are not hazardous to human health).

The CytoTune®-iPS 2.0 Reprogramming System uses vectors based on a modified, non-transmissible form of Sendai virus (SeV) to safely and effectively deliver and express key genetic factors necessary for reprogramming somatic cells into iPSCs (Oct4, Sox2, Klf4 and c-Myc). There are 3 vectors containing the transgenes: Klf4, Oct4, Sox2, and c-Myc. These genes are known to contribute to the maintenance of pluripotency and the regulation of cell growth and apoptosis. Abnormal expression of c-Myc is also to function as a known oncogene. These reprogram target cells into iPSCs.

SeV vectors used in this kit consist of viral proteins NP, P, M, F (activated), HN, and L, and the SeV genome RNA, from which the F gene is deleted. The F gene is responsible for binding of Sendai virus to cell membrane and budding of new viral particles. Because SeV infects cells by attaching itself to cell surface receptor sialic acid, present on the surface of many cell types of different species, the vectors are able to transduce a wide range of cells. However, they are no longer capable of producing infectious particles from infected cells, because the viral genome lacks the F-gene.

In addition, the presence of functional mutations such as temperature sensitivity in the amino acid sequence of several SeV proteins (SeV/TSΔF, SeV/TS12ΔF, and SeV/TS15ΔF) renders the vectors easily removable from transduced cells. The mutations are in the M, HN, P and L proteins whilst the F gene is completely deleted (see below):
SeV/TSΔF mutations:
M protein - G69E, T116A, A183S
HN - A262T, G264, K461G
P - L511F
L - N1197S, K1795E
F - Deleted
SeV/TS12ΔF:
P - D433A, R434A, K437A
F - Deleted
SeV/TS15ΔF:
P - D433A, R434A, K437A
L - L1361C, L1558I
F - Deleted

The presence of functional mutations causing temperature sensitivity in the amino acid sequence of several SeV proteins (SeV/TSΔF, SeV/TS12ΔF, and SeV/TS15ΔF) renders the vectors easily removable by incubating cells at 38–39°C for 5 days. Sendai virus is cleared from cells by a combination of dilution and RNA degradation by the host cell. It has been shown that Sendai virus vectors are naturally removed from iPS cells induced using the conventional method, by passaging and culturing using common methods (Fusaki N. et al. (2009) Proc Jpn Acad Ser B Phys Biol Sci 85(8): 348-362). Natural removal was also observed for iPS cells induced using Sendai virus vectors simultaneously carrying three reprogramming factors and temperature-sensitive Sendai virus vectors simultaneously carrying three reprogramming factors.

Multiple sites of essential genetic code (as described above) to generate a wild type SeV are missing, making the chance of spontaneous conversion vanishingly small. Exposure to wild type virus is possible in mouse studies, where the Sedai virus is a natural pathogen, appears to be still a perceivable, if not minuscule risk. Moreover, the use of temperature sensitive mutations, dilution and degradation of the virus product in expansion of cells thereafter, checking of measurable of virus by PCR before committing to murine work will be effectively remove this risk of reversion to wild-type.

SeV is a non-human pathogen and does not induce disease in humans. SeV is responsible for respiratory tract infection in mice, hamsters, guinea pigs and rats, with infection passing through both air and direct contact routes (Baker, DG. 1998. Clinical Microbiology Reviews. 11:231-266). The virus is easily killed by drying or disinfectants/detergents. One of the tests for the validation of legitimate iPSCs include xenograft formation but given the above limitations in SeV transmission, any residual virus particles are rapidly diluted out by cell proliferations and routine checking for SeV by PCR is used to confirm loss from cells.

The host cells will be human primary culture or cell lines and, once reprogrammed will undergo monitoring of the dilution and heat sensitive erradiation according to the above methods, formally documented with PCR confirmation that the cells are clear of transgenes. Only "cleared" cells will be maintained and taken forward for additional experiments.

Origin & function

The SeV vector system is intended to express the transgenes Klf4, Oct4, Sox2 and c-Myc in primary mammalian cells in order to generate iPSCs.

Evaluation of foreseeable effects

1. Deletion of the F gene means the vector cannot bud out from the infected cell to infect other cells. These cells are replication incompetent following the first round of infection, as described in the above section.

2. There are temperature sensitive mutations to disable replication of the virus and ultimate loss of virus delivered transgenes. As described above, the virus contains temperature inducible mutations and there is dilution of virus particles that removes the virus from the host cells, including removal of known oncogene c-Myc.

3. The viral vector would be able to transduce many tissues should it come in contact with them. The major hazard is therefore represented by the packaged virus prior to infection of the target cells and residual virus in the medium of infected cells. The two potential transmission routes are by external exposure (either skin lesions or mucous membranes; only in the case of very high titres and aerosol production) and by accidental injection/inoculation using sharps.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
NOTE: In accordance with the SACGM Compendium of Guidance 2000, Part 2A, Annex VI, a parallel BioCOSHH assessment has considered hazards associate with possible adventitious agents when using mammalian cell culture. The BioCOSHH assessment concludes that containment level 2 should be used to control these hazards and consequently all work involving mammalian cell culture will be carried out under full containment level 2. This does not alter the assignment of the GM activity class. Established code of practice (SOP) for work at containment level 2 will be employed.

GMM mammalian cells will be handled at containment level 2 and using microbiological safety cabinets. All GM virus waste will be properly inactivated by autoclaving. Spillages will be soaked with tissue paper, which will afterwards be autoclaved. Contaminated surfaces may be decontaminated with either a 1% virkon solution or 70% ethanol.

Only plastic pipettes will be used in the tissue culture facilities. Furthermore, all contaminated materials and media including waste destined for subsequent incineration will be autoclaved.

The use of sharps will be prohibited and all precautions will be taken to identify procedures or devices that might be used in these projects which could cause an injury to the researchers. Where so identified safe alternative methods or equipment will be sought.

The generation of aerosols will be avoided or contained.

Given the uncertainty about the hazards of most potentially oncogenic sequences and the small quantities used (microlitre/microgram quantities), prevention of exposure or total enclosure is not “reasonably practicable”. Therefore the following measures are applied in the light of this GM risk assessment, will be used:

(1) Good laboratory techniques will be strongly emphasised. Designated workers will be trained in good laboratory techniques before commencing work with potentially oncogenic DNA sequences. They will be made fully aware of the potential hazards of such work.

(2) Procedures using Sendai virus particles and exposed cells will only be carried out in the tissue culture suite. Normal procedure for handling biological material in the TC suite will be largely sufficient for handling the cells and particles. Specific items of relevance here include:

- Safety cabinets are routinely disinfected prior to and following use
- Gloves and lab coats to be worn throughout
- Designated microbiological safety cabinets to be used (class II)
- No wild type virus to be used

Staff competence will be checked during regular inspections of tissue culture facilities and during their project presentations involving sendai virus work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
1. This looks like a well-written form to me. It would be good to include a little more description of the primary cells and cell lines that will be used (Section 3A.1.1).
2. I am slightly unclear as to the final destination of the transduced cells. In Section 1 on the project, it states the purpose is "to generate induced pluripotent stem cells (iPSCs), which can then act as a model for prostate development and carcinogenesis." However, later on in Section 3B1.3 it says "Theoretically viable SeV may infect rodent cells. The chances of carrying viable virus from the hood, changing of lab clothes, lethal affects of drying, maintenance of a pathological titre to reach a rodent is vanishing." I'm not sure why this is mentioned unless the iPSCs mentioned earlier are to be introduced into rodents. If the iPSCs are to be introduced into rodents, then it needs to be described as this will no doubtably require sharps, as well as the consideration of infecting rodent cells in vivo.

The final risk assessment is approved by the committee for notification.

### Project Additional Information

02/03/2022
## Purposes of the contained use

Inflammation is a hallmark of many diseases including autoimmune/hyperimmune disorders, infection, cancer and a determining factor for the success of organ transplantation. Inflammation is a process orchestrated by multiple cell types and soluble factors including cytokines/growth factors and alters many fundamental cellular processes. Our research program focuses on understanding the role of amino acid metabolism in inflammation and its influence to adaptive immune responses. The GM program proposed in this application aim to: 1. understand critical molecular and cellular mechanisms during an inflammation process through modifying expression of genes of interest in relevant cell types (e.g. macrophages, fibroblast etc); 2. To establish experimental inflammatory disease models by establishing GM cells expressing nominal antigens in order to monitor adaptive immune responses or by manipulating gene expression in an adult mice to induce diseases such as cancer or prime immune response against a defined antigen;

The approaches include 1. ectopic expression of genes of interest or their mutant; 2. knocking down gene expression using siRNA; 3. establishing cell lines by immortalize primary cells with ectopic expression of oncogenes. 4. gene editing by introducing DNA modifiers such as Cre recombinase into cells or mice. 5. injecting viral vector carrying antigen genes into mice to prime immune response.

We propose to use replication deficient viral vectors including murine retroviral vectors, lentiviral vectors and adenoviral vectors in this program application.

## Recipient or parental organism

### Host:
1. Cells including established cell lines and primary cells from human, mouse and other mammalian origin
2. Mouse

### Host/vector system

| Vectors  | 1. Moloney murine leukemia virus (MMLV) based mouse retroviral vectors, GAG Pol Env deleted making the vector replication deficient. Using certain pseudotyping such as amphotropic ENV will increase the host range in comparison to original MMLV.  
2. HIV based lentiviral vector (pLenti-Trip) (obtained from Dr and original from pLenti Invitrogen), GAG Pol Env, vpr, vpu, vif, nef and tat gene are deleted and carry a deletion of the 3’ L TR (ΔU3) which results in “selfinactivation. Original pLenti with Plasmodin resistant gene were from Invitrogen and modified by Dr. To enhance nuclear import, a DNA fragment containing a central polypurine tract sequence and the central termination sequence, which together form a triple-stranded DNA flap (TRIP) was inserted in to pLenti vector before CMV promoter. Vector is replication deficient and insertion of TRIP fragment will facilitate integration. Using certain pseudotyping such as VSV glycoprotein will increase host range of lentiviral vector in comparison to original HIV.  
3. FLV based lentiviral vector (initially developed by Norian Lab in Stanford). GAG, Pol, Env deleted making the vector replication deficient. Using certain pseudotyping such as VSV glycoprotein will increase host range in comparison to original FLV  
4. Adenoviral vector left-hand ITR, E1a, and partial E1b sequence deleted making the vector replication deficient. |

### Origin & function

Protein coding sequences: DNA sequence coding proteins from human, mouse and other mammalian origins as well as bacteria and virus origin will be introduced to hosts to express the protein of interest or their mutants. Inserts can be classified as
1. Oncogenic, which will directly cause cells to immortalize or transformation;
2. Cell signal modifiers, which include cell surface receptors, intracellular kinases, kinase inhibiting proteins, secreted proteins such as cytokines and growth hormones such as interferons and inteferon receptors;
3. metabolic enzymes such as amino acid and lipid catabolism enzymes,
4. transcription factors and orphan receptors such as IRF3 and AHR;
5. cytoskeleton protein and nucleus scaffold protein such as modified GFP tagged actin;
6. cell basic machinaries such as molecular cheparones and mitochondria structure proteins;
7. genetic modifiers and protein modifiers such as Cre recombinase and biotin ligase (BirA);
8. viral antigens such as influenza A virus nucleoprotein, VSV glycoprotein etc;

Non-protein coding sequence: Inserts can be classified as
1. siRNA will be designed against genes of interest from human, mouse and other mammalian origin as well as viral origin to suppress the expression of genes of interest;
2. genetic modifiers such as a sequence designed for gene editing using crispr technology.

MMLV based murine retroviral vectors will be used to transduce human and mouse cells including established cell lines and primary cell lines. Examples of inserts include oncogenes in order to facilitate cell immortalization, viral antigen in order to monitor immune response in mice, metabolic enzymes such as indoleamine 2,3-dioxygenase (100), siRNA for gene supression.

Lentiviral vectors will be used to transduce tumor cell lines (mouse or human) and to deliver genes into mice. Examples include viral antigen in order to monitor immune responses or metabolic enzymes such as 100

Adenoviral vectors will be used to deliver cre recombinase to cells or animal tissues. Cre recombinase will be used to delete genes flanked with two 10xP sites. Only non-oncogenic/non toxic inserts will be carried by adenoviral vectors.

**Evaluation of foreseeable effects**

Viral vectors

Modification of viral vector cause virus to be replication deficient thus suitable to be used as gene transfer vehicle. while introducing a pseudotyping other than its original ENV protein will increase the host range for retro and lentiviral vectors.

- MMLV based vectors - GAG, POL and ENV are deleted
- Lentiviral vectors - GAG, POL and ENV are deleted. Accessory genes vpr, bpu, vif and nef are also deleted so that the vector is unable to replicate. Deletion of the tat gene and deltaU3 deletion of the 3' L TR results in 'selfinactivation' of the lentivirus following transduction of the target cell.
- Adenoviral vector - left-hand ITR, E1a and partial E1 b sequences are deleted which limit the virus replication capacity.

The highest risk inserts are the oncogenic sequences - these are only inseted into the MMLV retroviral vector

Two potential risks to humans may arise from the hazards of working with the naked plasmid vector + insert DNA containing the potentially oncogenic or other hamful sequence and the supernatant containing the viral particles from the packaging cell line. However, the transfection efficiency even under optimal culture conditions is negligible, and therefore transfection of researcher's cells with naked DNA under accidental/non-optimal conditions would be effectively zero.

Cell lines/animal work

Introducing oncogenes will directly cause cell lines to immortalize or transform. If during an unlikely event these cells were inoculated into the human organism, then these cells are recognised as non-self and will be destroyed by the immune system. Other sequences will alter cellular proliferation or differentiation as part of basic cellular machinernary or responses to extracellular signals (eg, cell signaling modifiers and metabolic enzymes). Some may
play roles in disease progress or pathogenesis. E.g., overexpressing cytokine and transcription factor gene may lead to deregulation of inflammatory response and overexpressing of a tryptophan metabolite enzyme may promote tumorogenesis by creating a favorable immune suppressive microenvironment. The gene products will be biologically active when transfected into mammalian cells and probably expressed at a level higher than seen in the wild type cells. However, the recipient transfected cells will be either primary human or mouse cells or well-characterized stable eukaryotic cell lines in tissue culture that have a history of safe use and these hosts can be considered disabled hosts because the cells are unable to colonize the worker (i.e., not their own cells). Genetic modifiers such as Cre recombinase and sequences designed to edit genes using CRIP technology will change the host cell genetic composition permanently and the physiological effects is gene dependent. Viral vectors carrying Cre recombinase gene is expected to delete the DNA sequence between two 10xP sites in a cis form in host DNA.

Introduction of viral antigen into the cells will change the antigenicity of the cell when injected into an animal.

Containment and control measures for GMOs that are not microorganisms (e.g., GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile.

Animals that have been exposed to GM viral vectors are not autoclaved but are treated as ‘inactivated’ GM waste. They will be disposed of by placing in a yellow "CinBin", separately from other types of clinical waste and will be held in a cold store/freezer until the allocated waste company collects them. The "Cin Bin" provides a secure means of storage and transport of the waste, the plastic containers are robust and leakproof and the lids cannot be removed once they have been fixed on. The waste company Healthcare Environmental Group is a GM registered carrier and the waste will be destined for incineration which will provide the validated means of GM virus inactivation.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

02/03/2022
The GMSC advised that lentiviral/retroviral and adenoviral vectors should be separated into two separate risk assessments due to the different types or risks. This has been implemented and the two risk assessments are submitted with this notification.

Further details of training were required - this has been added and the information is in the submitted risk assessments.

### Purposes of the contained use

The projects involve assessing the biological function of candidate genes implicated in malignant progression and/or neurodegeneration which emerge from ongoing genomics projects characterising collections of primary tumour/brain material.

Lentiviral particles will be generated on site using either a cDNA or appropriate shRNA. cDNAs may occasionally contain a mutation where a dominant negative or constitutively active version of the gene is required. The purpose is to perturb the natural state of the gene in question and to assess the effects on cells. Downstream analysis may involve cell cycle analysis, proliferation, cytotoxicity, apoptosis or differentiation assays, and development of in vivo xenograft models. RNA, DNA and protein would typically be extracted from infected cells in each case to verify appropriate infection and to validate cDNA/shRNA expression. A lentiviral pool expressing various cDNAs or shRNAs may be used to create a pool of cells with several integrated constructs which will then undergo in vitro or in vivo selection to screen for constructs which either promote or inhibit cell proliferation or engraftment.

### Recipient or parental organism

Cell lines in culture: 293T Human embryonic kidney cell line (packaging cell line), adherent and suspension human and mammalian cell lines (including cancer cells) (such as HeLa, MEF, MRC7, SK-N-SH, DAOY, MON, KD, Molt-4, RPMI-8402, MN-60, Pre-B-697) immortalised normal cells and primary mammalian cells.

### Host/vector system

We will be mainly using third and subsequent generation lentivirus. They are replication incompetent and self inactivating (SIN). The systems separate the packaging signals and viral LTRs on the expression plasmid from the viral structural and expression genes (gag, pol and rev from FIV or HIV and viral envelope glycoproteins such as the VSV-G gene from Vesicular Stomatitis Virus, in place of HIV or FIV env). The viral structural and expression genes and the envelope glycoprotein genes are separated on at least two additional plasmids.

### Origin & function

cDNA sequences of human or mouse origin and/or the appropriate shRNA sequences will be cloned into the lentiviral vectors. These may include partial or entire gene sequences, or mutant forms of the gene sequences, under the control of constitutive promoters. Many of the genes or targets of the shRNAs will have unknown function but may include known oncogenes or tumour suppressors. As an example, we will use mutant B-RAF and N-Ras constructs to generate primary human fibroblasts with oncogene-induced senescence phenotype.

The aim is to use either overexpression or knock-down of gene-expression to assess the potential contribution to tumourigenesis of each candidate identified from our genomics screens. Once a stably infected cell line is produced, experiments performed will depend on the particular gene selected but will typically involve a panel of typical proliferation, apoptosis and/or invasion assays as well as collection of RNA/DNA/Protein for further profiling analysis and potentially in vivo engraftment.

### Evaluation of foreseeable effects

Known oncogenes such as mutant B-RAF or N-Ras or shRNAs that will silence known tumour suppressor genes may be inserted into primary cells and cell lines. There is therefore a theoretical possibility that they could render the cells neoplastic. If during an unlikely event these cells were inoculated into the human organism, then these cells are recognised as non-self and will be identified by the immune system. Inserted gene products will be both genomic, cDNA sequences or small interfering double stranded RNA sequences originating in humans or rodents, including those which could be implicated in tumour progression, i.e. oncogenic and tumour suppressor DNA sequences. Specific functions will vary depending on the particular experiment, but will include functions that are known to contribute to the maintenance of pluripotency and/or differentiation and the regulation of cell growth and apoptosis. The gene products will be biologically active when transfected into mammalian cells and probably expressed at a level higher than seen in the wild type cells. However, the recipient transfected cells will be either non-self primary human or mouse cells or well characterised stable eukaryotic cell lines in tissue culture that have a history of safe use and these hosts can be considered disabled hosts because the cells are unable to colonise the worker (i.e. not their own cells).
Two potential risks to humans may arise from the hazards of working with the naked plasmid vector and insert DNA containing the potentially oncogenic DNA and the supernatant containing the viral particles from the packaging cell line. However, the transfection efficiency even under optimal culture conditions is negligible, and therefore transfection of researcher’s cells with naked DNA under accidental/non-optimal conditions would be effectively zero. The potential oncogenes will only be sufficiently oncogenic to induce tumourigenicity in immortalised cell lines or in pre-malignant cells or give a growth advantage to cells in culture without inducing tumourigenicity. Tumourigenesis is a multistage process requiring the interaction of many mutated genes which also lessens the risk from delivery of a single oncogene or tumour suppressor gene to a target tissue. The principle route of transmission that could lead to transduction of laboratory workers by packaged viral particles is inoculation. Therefore, use of sharps will be prohibited. Other possible routes of transmission such as inhalation, ingestion and eye splashes are less likely to lead to tumourigenesis because of the required very high titres, which will not be achieved under the given experimental conditions. Consequently, the risk of tumourigenesis is negligible.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Spillages will be soaked with tissue paper, which will afterwards be autoclaved. Contaminated surfaces may be decontaminated with trigene solution. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMSC suggested that for all experiments using the transduced material, lack of infectious particle production is confirmed by the addition of cell culture supernatant to 293T cells. Additional information on the monitoring and validation of autoclaves was added. The GMSC committee agreed on the assignement of this work to activity class 2.

We aim to utilise a commercially available ‘immortalisation’ kit that utilises Lentiviral vectors to transfect Simian Virus 40 (SV40) T antigen to induce immortalization. We have previously successfully transfected these cells with Lentiviral agents. SV40 T antigen has been shown to be the simplest and most reliable agent for the immortalization of many different cell types, and its mechanism of action is relatively well understood.

We will culture these cells according to well-defined tissue culture protocols. The cells will be transferred to an appropriate well plate and transfected with Lentiviral vectors (incubated overnight), following manufacturers protocols. The next day we will remove the viral supernatant and add the appropriate volume of complete growth medium to the cells and incubate. After 72 hours incubation we will subculture the cells. After 10-15 days we will screen for positive transgene expression (i.e. Western blotting, RT-PCR).

Recipient or parental organism

Primary human airway (subglottic sub site) epithelial cells cultured in submerged culture at passage 0 - 2. Taken from theatre patients via brushings.

Host/vector system
Ready to use Lentiviral particles will be purchased from abm inc. USA. Particles are produced by abm inc using a standard protocol meeting BioSafety Level 2 requirements https://www.abmgood.com/SV40-Cell-Immortalization.html#documents

Immortalisation is induced using simian virus 40 (SV40) T antigen (pLenti SV40-T)
The virus is replication incompetent. The following features ensure replication incompetence –
An enhancer deletion in the U3 region of 3ΔLTR ensures self-inactivation of the lentiviral vector following transduction and integration into the target cell’s genomic DNA. The number of lentiviral genes necessary for packaging, replication and transduction is limited to three (Gag/Pol/Rev), and their expression is derived from different plasmids, all lacking packaging signals. These plasmids share no significant homology to the expression vector, thus preventing the generation of replication-competent virus by recombination events. None of the Gag, Pol, or Rev genes will be incorporated into in the packaged viral genome, thus making the mature virus replication-incompetent.

Origin & function

This Lentiviral vector is derived from abm inc. as a pre made virus for immortalisation utilising simian virus 40 (SV40) T antigen. This gene is expressed under the control of the CMV promoter.

Evaluation of foreseeable effects

We envisage that the Lentiviral vector will infect the primary epithelial cells and transfect Simian Virus 40 (SV40) T antigen to induce immortalization of the cells. It is expected that this will be achieved by inactivating the tumor suppressor genes (p53, Rb, and others) that can induce a replicative senescent state in cells. Recent studies have also shown that SV40 T antigen can induce Telomerase activity in the infected cells.

The major hazard is presented by the packaged virus prior to infection of the target cells and residual virus in the medium of transfected cells. The lentiviral system is pseudoviral in nature; its coat proteins are derived from the vesicular stomatitis virus (VSV). The VSV G coat-protein confers significant stability and increased pleiotropy. Thus it is possible that infection may occur should the lentivirus come into contact with broken skin (such as needle-stick injury) or mucous membranes. Inhalation is also a potential source of exposure. However, the risk of harm to the worker is virtually zero. Contact with mucosal membranes, skin and inhalation will be prevented utilising standard class two containment protocols. Needle stick injury is a potential source of harm, however no needles are to be used at any point in the use of this agent. In addition the virus is replication incompetent so infection would be localised

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Containment level 2 behaviour and activities will be used to control for any associated hazards related to this work. We have dedicated human cell culture facilities within our laboratories. Standard operating procedures for work at containment level 2 will be employed.

Infection of mammalian cells will be undertaken in dedicated cell isolation and culture facility within Prof Pearson’s laboratory (room M1.086). Standard operating procedures for work at containment level 2 will be employed including class 2 microbiological safety cabinets. Notifications will be placed in the work area to inform staff that viral work may occur in this area. When virus is being used signs will be placed on hoods, doors and incubators indicating this and will be used only for these samples until full decontamination is undertaken as described below.

We already have protocols in place and risk assessments for epithelial cell culture.

Work will be carried out in a dedicated microbiological safety cabinet within a dedicated room, and only trained authorized personnel will be allowed to work with lentiviral particles.

The following measures will be applied:
1. Good microbiological practice will be used at all times and strongly emphasised by senior staff.
2. Personal protection equipment will be used all the time while performing lentivirus-involving experiments. These include Howie-style lab coat and gloves.
3. All experimental procedures will be performed so as to minimise aerosol production. Procedures which are likely to generate aerosols such as the use of sonicators, vigorous shaking and mixing etc. will be avoided, or where necessary, will be carried out in closed containers or the microbiological safety cabinet.
4. Procedures using lentiviral particles, packaging cell lines and exposed cells will only be carried out in room M1.086. Normal procedure for handling biological material will be largely sufficient for handling the cells and particles.
5. The safety cabinet is routinely disinfected prior to and following use.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile.

Two main virucidal disinfecting agent will be used: 1% (v/v) Trigene Advance for routine surfaces and tools disinfection (e.g. safety cabinet surface, centrifuge rotor, pipette), and for disinfection of liquid waste (e.g. spent medium) and for submersion of other disposable waste (pipette tips, conical tubes, and other culture ware). Trigene is a best available virucidal disinfectant. This includes killing numerous types of viruses including HIV virus, and thus lentivirus.

Solid waste (e.g. cultureware, pipette tips, used gloves) will be stored in appropriate yellow bins before autoclaving. Once autoclaved, bins bags will be disposed of by incineration via the yellow clinical waste route.

Liquid waste (e.g. cultures in flasks or spent media) will be sterilised in the culture flasks in designated waste buckets by addition of Trigene to a concentration of at least 1% (w/v) for overnight disinfection. Trigene-disinfected solutions will be disposed of as inactivated waste via the designated drain in the tissue culture room.

Culture flasks will be disposed of (following removal, appropriate disinfection and disposal of culture medium) by addition of Trigene solution inside the flasks and firmly closing the flask lids. These flasks will be left overnight by the sink on the disinfection bench. After leaving overnight, solutions will be discarded as inactivated waste while flasks will be placed in the designated yellow bins for autoclaving before disposal via clinical waste route.

Non-diposable contaminated items (e.g. centrifuge buckets etc.) will be disinfected by complete submersion in Trigene solution overnight. Items will then be rinsed in water and dried.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

Requested that the evaluation of risk in section 3A.2.3 should be upgraded from 'effectively zero' as this does not reflect insert being oncogenic.

For 3A5 the Phrase "In addition the virus is replication deficient so the contamination would be localised." Should be changed to "In addition the virus is replication incompetent so the contamination would be localised."

Recommended that centrifuge buckets are decontaminated with Trigene rather than Virkon as Virkon can corrode and changing disinfectants for different jobs may be confusing.

Changes implemented and the GMSC agreed the classification as activity class 2.

Project Ref 540/16.6

Screening for compounds that suppress the loss of mitochondrial dynamics in response to human cell infection with Listeria listeriolysin

Project Additional Information

Purposes of the contained use
To identify the molecular pathway that causes the loss of mitochondrial dynamics as cells become infected with listeriolysin. The intention is to use this information to determine novel targets to protect cells against listeria infection

Recipient or parental organism
The host organism is Listeria monocytogenes EGDe (BUG1600). For the production of the constitutive cGFP expression in strain BUG2539, the plasmid pAD1 was chromosomally integrated and selected by resistance to chloramphenicol. This resulted in constitutive expression of cGFP from the pHYPER promoter. Production of the strain is characterised in Balestrino et al. App Env Micro 2010, 76, 3225-6.

Host/vector system
No vectors will be used and no genetic manipulation will be performed. This application is solely to use strains of Listeria that have been previously modified.

Origin & function
The two strains of Listeria monocytogenes (background EGO) both constitutively express soluble Green Fluorescent
Protein which is necessary to visualize and measure the bacterial number in close proximity to human Hela or U20S cells grown on either 96 or 384 well plates. One is a standard strain constitutively expressing gfp. The second is a negative control for expression of the ILO toxin, which has been engineered with a deletion in the Hly gene encoding ILO. These two cell lines will be used in a large screen to identify components that promote the loss of mitochondrial dynamics on infection as follows: human cells will be transfected with a druggable targets siRNA library approx. 3 days prior to infection with the Listeria bacteria with an approx. multiplicity of infection of 50. After 1 hr of infection, cells will be treated with 5 nM tetramethylrhodamine methyl ester, a compound that concentrates in the mitochondrion as a function of the membrane potential. Images will be captured post-incubation and the effect on fission calculated by determining mitochondrial aspect ratio (a measure of mitochondrial fragmentation).

**Evaluation of foreseeable effects**

The gram-positive bacterium Listeria monocytogenes is a ubiquitous, intracellular pathogen which has been implicated within the past decade as the causative organism in several outbreaks of foodborne disease. Listeriosis, with a mortality rate of about 24%, is found mainly among pregnant women, their fetuses, and immunocompromised persons, with symptoms of abortion, neonatal death, septicemia, and meningitis. The organism has a multifactorial virulence system, with the thiol-activated hemolysin, listeriolysin 0, being identified as playing a crucial role in the organism's ability to multiply within host phagocytic cells and to spread from cell to cell. The organism occurs widely in food, with the highest incidences being found in meat, poultry, and seafood products. Only standard strains of Listeria monocytogenes will be used.

Infectious Dose: Given the widespread distribution of Listeria in foods, ingestion of the bacteria is likely to be a common event. However in general the incidence of listeriosis is low from 2 to 8 sporadic cases per million in Europe and US. The minimum dose required to cause clinical infection in humans seems to be significantly higher than in other food borne pathogens. The approximate infective dose of Listeria monocytogenes has been estimated to be 10 to 100 million colony forming units in healthy hosts, and only 0.1 to 10 million colony forming units in individuals at high risk of infection [Farber, J. M., Ross, W. H., & Harwig, J. (1996). Health risk assessment of Listeria monocytogenes in Canada. International Journal of Food Microbiology, 30(1-2), 145-156].

Listeria monocytogenes is classified as a Hazard Group 2 (HG2) pathogen. It is difficult to envisage how constitutive expression of the chromosomally encoded GFP could increase the virulence of the Listeria monocytogenes host strain beyond that of the parent HG2 strain, in the event of accidental exposure to humans. Indeed one of the strains to be used has been attenuated by the deletion of the hly gene encoding listeriolysin 0 which as stated already is a major virulence factor. Hence the hazards of accidental human exposure to this GM strain will be significantly reduced compared to those of the parent.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Disinfection and autoclaving will be carried out where required. All waste materials will be disposed of into yellow clinical waste bins or sharps bins as required . All used sharps will be placed immediately after use into a sharps bin. Sharps bins will be located on the bench where the sharps are used so that they can be disposed of directly after use. All infected waste will be autoclaved before collection by external waste disposal contractor

a) Disinfection.
1% Virkon/Trigene will be used for disinfection. The surfaces of the microbiological safety cabinet will be disinfected with 1% Virkon/Trigene after use. Laboratory benches will be swabbed with 1% Virkon/Trigene after any activity.
b) Autoclaving.
All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored using TST (Time, Steam, and Temperature) and test strips (Albert Browne Ltd., TST class 6 emulating indicator 121°C for 20 min). In addition the TST strips are kept for record inspection.
L. monocytogenes can be inactivated by ozone, high pressure (500MPa), and high temperatures (at least 70°C for 2 minutes).

CU2 Project Title Transduction of mammalian cells using lentiviral vectors

Class 2

CultureVolClass2 < 1 Litre

Class VolumeClass3-4

Consent Granted
This risk assessment aims to cover all research projects at the Institute of Genetic Medicine utilising the same or functionally very similar lentivirus vectors and mammalian host cells. The projects involve assessing the biological function of candidate genes implicated in multiple cellular functions/Scientific areas. Some projects are screens to assess the functional relevance of various genes/proteins systematically in a more global fashion. Typically, the methodology will involve a gene highly over or under-expressed in a particular cell line and reversing the expression by either overexpressing the gene or expressing a shRNA/CRISPR to knock-down/knock-out expression of the gene in question, respectively. Lentiviral particles will be generated on site containing either a cDNA or appropriate shRNA/CRISPR. cDNAs may occasionally contain a mutation where a dominant negative or constitutively active version of the gene is required. Cells will be infected by titrated lentivirus particles followed by antibiotic selection or sorting by FACS. The purpose is to perturb the natural state of the gene in question and to assess the effects on cells. Downstream analysis may involve cell cycle analysis, proliferation, cytotoxicity, apoptosis or differentiation assays, and development of in vivo xenograft models. RNA, DNA and protein would typically be extracted from infected cells in each case to verify appropriate infection and to validate cDNA/shRNA/CRISPR expression. A lentiviral pool expressing various cDNAs or shRNAs/CRISPRs may be used to create a pool of cells with several integrated constructs which will then undergo in vitro or in vivo selection to screen for constructs with particular relevant functions (i.e., genetic screens) (e.g. of cell functions tested: differentiation, proliferation, tumorigenic potential, etc).

Recipient or parental organism

293 Human embryonic kidney cells (packaging cell line; Pear et al, PNAS 1993; 90:8392), adherent and suspension human and mammalian cell lines (including cancer cells such as Ishikawa, HEC-1A, AN3CA, HCC-38, MFE-296, MFE-319, EFO27, MCF7, DAOY, MON, KD), immortalised normal cells (e.g., MCF-10A, 184B5) and primary mammalian epithelial cells (e.g., mouse embryonic fibroblasts -MEFs-).

Lentiviral constructs will be expanded using E. coli K12 derived bacterial host strains (e.g. DH5). 293T packaging cells will be used to create lentiviral particles by transfection. Packaging cell line 293T (and thereof derived cell lines) is derived from the well-characterised 293 cell line (Pear et al., PNAS 1993; 80; 8392; ATCC CRL-11268). This cell line stably and constitutively expresses a temperature-sensitive version of the SV40 large T antigen. This cell line will be used to produce lentiviral vectors. These vectors alone are replication incompetent owing to their lack of cell and gag-polymerase encoding sequences. Virus is therefore produced by co-infection of the 293T cell line with lentiviral vector along with one or more viral envelope encoding plasmids (e.g. VSV-G or constructs derived from the measles virus [MV] hemagglutinin and fusion protein genes [HΔ24 and FΔ30]) and a plasmid encoding the HIV or FIV gag-pol and the regulatory genes including rev, nef and vif. Mammalian cell lines and primary mammalian cells will be used for infection with the supernatant generated by the packaging cells. Most commercial cell lines that will be used are derived from solid tumours or leukaemias, have a long history of safe use and are commonly handled in UK labs at CL2 or CL1. All facilities at Newcastle University where these materials are handled are at CL2 standard. The mammalian cells and somatic stem cells are only able to survive if maintained in tissue culture in the laboratory, or if injected into inbred syngeneic or immunodeficient animals.

Host/vector system

The transfer vector systems are derived from FIV or HIV and have been specifically engineered for biosafety by separating the packaging signals and viral LTR's on the
expression plasmids from the viral structural and expression genes (gag, pol and rev from FIV and the VSV-G gene from Vesicular Stomatitis Virus, or similar alternatives, in place of FIV or HIV env) encoded on three or four separate plasmids, which remain in the packaging cell line, effectively precluding the production of replication competent virus in the target cell or should the viral vector escape containment. FIV vectors are included as they may be more efficient for some cell types. It does not imply any different containment or risk considerations than HIV based vectors. The plasmids expressing these gene products carry no packaging signals or LTRs and so cannot themselves be mobilised with the vector and have been engineered not to contain any regions of homology to each other or to the viral vector, to prevent undesirable recombination events which might result in replication competent virus being produced.

The viral vector and recombinant virus have a broad host range when pseudotyped with e.g. the VSV-G envelope protein. The normal tropisms of HIV and FIV have been broadened to include multiple tissues from a broad range of species. Pseudotyping with alternatives to VSV-G, for example measles virus derived glycoproteins, will produce particles with more restricted tropisms.

### Origin & function

The factors we will introduce into the cell lines are non-coding shRNAs, non-coding RNAs (e.g., microRNAs), CRISPRs and coding cDNAs originating in humans or rodents. The use of shRNAs/CRISPRs will generate single cells with stable gene expression knockdown/knockout. On the contrary, cDNA constructs will be used to generate single cells with stable expression of any particular gene. Gene knockdown/knockout performance will depend upon shRNA/CRISPR target specific and efficient recognition.

cDNA sequences of humans or mice origin and/or the appropriate shRNA/CRISPR sequences will be cloned into the lentiviral vectors. These may include partial or entire gene sequences, or mutant forms of the gene sequences, under the control of constitutive promoters. In screening applications, many of the genes or targets of the shRNAs will have unknown function but may include known oncogenes or tumour suppressors. In the case of mutated genes, these will comprise of characterised sequences which have deliberately mutated by site directed mutagenesis. An example of a mutation that is constitutively activating might be a KRASv12 mutation which has been demonstrated to result in overactive ras signalling and therefore again should be considered to pose a greater hazard than the wildtype sequence. Other targets may include known proto-oncogenes/tumour suppressors such as RUNX1, ERG, GRIK2, PARK2, FOXO3, CRLF2, TP16, TP53 or TERT.

The aim is to use either overexpression or knock-down/knock-out of gene-expression to assess the potential contribution to cellular processes (e.g., tumourigenesis, differentiation, etc) of each candidate identified from our genomics screens. Once a stably infected cell line is produced experiments performed will depend on the particular gene selected but will typically involve a panel of typical proliferation, differentiation, apoptosis and/or invasion assays as well as collection of RNA/DNA/Protein for further profiling analysis and potentially in vivo engraftment.

### Evaluation of foreseeable effects

The only viral sequences in the transfer vectors are the 3' and 5' long terminal repeats (LTR's), the packaging signal and the Rev response element (RRE) required for the production of viral particles. Deletion of accessory genes vpr, vpu, vif and nef mean that the vector is unable to replicate once it has transduced the target cell. In addition third generation lentivirus are deleted for the tat gene and carry a SIN deletion of the 3’ LTR (U3) which results in “self-inactivation” of the lentivirus following transduction of the target cell, precluding adventitious activation of the vector by endogenous retroviruses and minimising the risk of recombination with ERVs. These vectors also contain a bacterial origin of replication and ampicillin resistance gene, an internal promoter such as CMV or SFFV promoter driving the gene of interest linked via an IRES element with a gene encoding a fluorescent protein for FACS-mediated sorting.

In particular global screens may affect any gene expressed in the test system. Consequently, known oncogenes or shRNAs that will silence known tumour suppressor genes may be inserted into primary cells and cell lines. There is therefore at this stage a theoretical possibility that they could render the cells neoplastic. If during an unlikely event these cells were inoculated into the human organism, then these cells are recognised as non-self and will be destroyed by the immune system. Inserted gene products will be both genomic, cDNA sequences or small interfering double stranded RNA sequences originating in humans or rodents, including those which could be implicated in tumour progression, i.e. oncogenic and tumour suppressor DNA sequences. Specific functions will vary depending on the particular experiment, but will include functions that are known to contribute to the maintenance of pluripotency and / or differentiation and the regulation of cell growth and apoptosis. The gene products will be biologically active when transfected into mammalian cells and probably expressed at a level higher than seen in the wild type cells. However, the recipient transfected cells will be either primary human or mouse cells or well characterised stable eukaryotic cell lines in tissue culture that have a history of safe use and these hosts can be considered disabled hosts because the cells are unable to colonise the worker (i.e. not their own cells).
Two potential risks to humans may arise: 1) the hazards of working with the naked plasmid vector + insert DNA containing potentially oncogenic DNA or shRNA/CRISPR against any tumour suppressor and 2) the supernatant containing the viral particles from the packaging cell line.

1) The amount of DNA is relatively low and it is envisaged that the risk of naked DNA entering the human body is relatively low. Linearized cloned DNA is usually introduced into the cells using different transfection techniques, however the transfection efficiency even under optimal culture conditions is not high, therefore transfection of researcher’s cells with naked DNA under accidental/non-optimal conditions would be rather low.

2) The viral vector would be able to transduce many tissues should it come in contact with them. The major hazard is therefore represented by the packaged virus prior to infection of the target cells and residual virus in the medium of transfected cells. The two potential transmission routes are by external exposure (either naked skin or mucous membranes) and needle-stick injury. Some of the genes that will be studied are novel and potentially could have oncogenic effects or interfere with the ability of the cells to survive in culture. If those genes were to be transfected directly into living human tissue any detrimental effects that they might cause are uncertain. However, the genes will only be transfected into cell lines or primary cells which have no ability to survive outside tissue culture environment. Even in the event of needle stick injuries or aerosol exposure, these cells (which will exist in very low numbers) will be destroyed by the human immune system.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMO waste materials including all tissue culture fluid etc generated in this project MUST be autoclaved. No other inactivation or waste disposal routes will be used. Spillages must be cleaned up with disinfectant but the tissues and other waste materials must then all be autoclaved.

All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored using TST (Time, Steam, and Temperature) test strips (Albert Browne Ltd., TST class 6 emulating indicator 121°C for 20 min).

Please enter comments on the GM safety committee on the risk assessment

Upon the advice of the committee Dr Llobet-Navas has extended the scope of his original risk assessment to allow this notification to cover other appropriate lentiviral activities that may take place in the future in the Institute for Genetic Medicine.

The committee advised that, although the risk assessment covers 2nd generation lentivirus vector systems or better, 3rd generation (or safer) vectors should be used in preference to 2nd generation where possible.

Purposes of the contained use

This risk assessment covers research projects in our lab utilising lentivirus vectors and mammalian host cells. The projects involve assessing the biological function of candidate genes implicated in neuronal function or brain tumour progression. Genetic modification will occur in vitro and in vivo.

Lentiviral particles will be generated on site containing either a cDNA or appropriate shRNA. cDNAs may occasionally contain a mutation where a dominant negative or constitutively active version of the gene is required. The purpose is to perturb the natural state of the gene in question and to assess the effects on cells. Downstream analysis may involve cell cycle analysis, proliferation, cytotoxicity, apoptosis or differentiation or neuronal function assays, and development of in vivo xenograft models. RNA, DNA and protein would typically be extracted from infected cells in each case to verify appropriate infection and to validate cDNA/shRNA expression. A lentiviral pool expressing various
cDNAs or shRNAs may be used to create a pool of cells with several integrated constructs which will then undergo in vitro or in vivo selection to screen for constructs which effectively modify cellular function.

Controlling Abnormal Network Dynamics using Optogenetics (CANDO) is a major multi-site cross-disciplinary project to develop a cortical implant for optogenetic neural control. The goal of this project is a first-in-human trial in patients with focal epilepsy. This seven-year, £10M award from the Wellcome Trust and EPSRC involves collaboration between 13 research groups based in Newcastle, Imperial College and University College, London. The role of my lab in this collaboration is to design and produce molecular biological tools to support neurophysiology research, particularly lentiviral vectors for gene delivery. Optogenetics is a powerful tool to understand and experimentally manipulate neural activity. Ectopic expression of channelrhodopsin (ChR2) allows light-evoked stimulation of neurons in the adult mammalian brain. The channelrhodopsin gene will be subcloned under a cell-specific or ubiquitous promoter and tagged with a reporter such as green fluorescent protein (GFP).

Research by our group and others has demonstrated that tumour cells derive their energy from fatty acid sources as well as carbohydrates. Our research focuses on either upregulating or downregulating cellular signalling factors and factors involved in fatty acid bioenergetics with relevance to brain tumours. This work aims to increase understanding of tumour cell biology and identify potential new drug candidates. In view of this goal, our research involves creating and inserting shRNA for genetic knockdown experiments and also overexpression constructs for evaluating the contribution of particular gene products in fatty acid metabolism and signalling. This project aims to modify brain-derived cells to evaluate or modify their oncogenic capacity. The aim is to use either overexpression or knock-down of gene-expression to assess the potential contribution to tumourigenesis of multiple candidate genes. Once a stably infected cell line is produced, experiments performed will depend on the particular gene selected but will typically involve a panel of typical proliferation, apoptosis and/or invasion assays as well as collection of RNA/DNA/Protein for further profiling analysis and potentially in vivo engraftment.

The third-generation self-inactivating lentivirus we intend to produce in the course of this project was developed in the Trono and Baltimore labs to eliminate replication competence while maintaining the ability of the vector to infect both dividing and non-dividing cells. The lentiviral vectors employed do not present risk of homologous recombination (SACGM 2.11.14).

The transfer vector systems are derived from FIV or HIV and have been specifically engineered for biosafety by separating the packaging signals and viral LTR’s on the expression plasmid from the viral structural and expression genes (gag, pol and rev from FIV and the VSV-G gene from Vesicular Stomatitis Virus, or similar alternatives, in place of FIV or HIV env) encoded on four separate plasmids, which remain in the packaging cell line, effectively precluding the production of replication competent virus in the target cell or should the viral vector escape containment.

The viral vector and recombinant virus have a broad host range when pseudotyped with e.g. the VSV-G envelope protein. The normal tropism of HIV has been broadened to include multiple tissues from a broad range of species. Pseudotyping with alternatives to VSV-G, for example measles virus derived glycoproteins, will produce particles with more restricted tropisms.

The viral vector is disabled. >2/3 of all genes are deleted, including all genes involved in viral replication and genes encoding the original viral coat proteins. The vector is a third-generation self-inactivating (SIN) design. This design produces a disabled, replication-incompetent lentiviral vector that lacks the genes encoding for the original packaging proteins, structural proteins, reverse transcriptase and integrase, and additional virulence factors present in HIV-1. Deletion of accessory genes vpr, vpu, vif and nef mean that the vector is unable to replicate once it has transduced the target cell. In addition third generation lentiviruses are deleted for the tat gene and carry a SIN deletion of the 3’ LTR (the U3 region) which results in “self-inactivation” of the lentivirus following transduction of the target cell, precluding adventitious activation of the vector by endogenous retroviruses and minimising the risk of recombination with ERVs. Finally, a pseudotyped envelope (e.g. vesicular stomatitis glycoprotein) has been substituted for the original HIV-1 envelope protein.

Packaging cell line 293T (and thereof derived cell lines) is derived from the well-characterised 293 cell line (Pear et al., PNAS 1993; 80; 8392; ATCC CRL-11268). This cell line stably and constitutively expresses a temperature-sensitive version of the SV40 large T antigen. This cell line will be used to produce lentiviral particles. These vectors alone are replication incompetent owing to their lack of envelope and gag-polymerase encoding sequences, as well as their self-inactivating nature. Plasmid DNA will be produced in standard competent E.coli hosts (e.g. Stbl3, Stbl2, DH5 alpha, etc).
Virus will be added to cells in vitro to create stably-transduced cultures. The viruses are third-generation, self-inactivating constructs and are not replication competent.
Virus will also be injected directly into the brains of adult mice. Mice are themselves containment systems, since they are non-permissive hosts for this virus.
Mammalian cell lines and primary mammalian cells will be used for infection with the concentrated or unconcentrated supernatant generated by the packaging cells. Cell lines such as MT2 or MT4 producing infectious particles will not be used for transduction. Most cell lines are derived from normal brain tissue or solid tumours.

Host/vector system

Replication-incompetent self-inactivating lentivirus will be produced by transfection of HEK293T cells with plasmids such as pMDLg/pRRE (Addgene #12251) and pRSV-REV (Addgene #12253), which encode viral packaging proteins; pMD2.G (Addgene #12259), which encodes the pseudotyped VSVg coat protein, or pMD.RVG.CVS24.N2c (Addgene #19712), which encodes the pseudotyped rabies glycoprotein coating; and pEMCV-IRES-GFP (Addgene #12254) or similar third-generation lentivirus plasmid, which allows for the expression of the gene of interest and a reporter tag for identification of infected cells. Each plasmid will be transfected along with three viral production genes (for example, pMDG, pRSV-REV and pMDLg/pRRE) into HEK293T cells by calcium chloride coprecipitation. HEK293T will assemble the third-generation lentiviral vector and release it into the media.
The plasmids used for transfection of HEK293T cells are commercially available and have been modified to increase the safety and efficiency of viral production. The lentiviral constructs we use originated from the labs of Didier Trono and David Baltimore, and represent some of the safest and easiest-to-use vectors available for the delivery of genes into mammalian tissue [1-3]. The resultant lentiviruses are replication-deficient, and are used in many labs around the world at this time for in vivo applications [3-4]. Furthermore, they are designed to be extracellularly unlikely to become replication competent, with >2/3 of the viral genome deleted from the final packaged vector (including the abolition of gag/pol and wild-type envelope genes). These viruses also have self-inactivating properties to prevent integrated genes from being repackaged, in the event a subsequent infection ever occurs.
References

Origin & function
cDNA sequences of human or mouse origin and/or the appropriate shRNA sequences will be cloned into the lentiviral vectors. These may include partial or entire gene sequences, or mutant forms of the gene sequences, under the control of constitutive or cell-specific promoters. Many of the genes or targets of shRNA will have unknown function but may include known oncogenes or tumour suppressors.
For the first project, we aim to use optogenetics to evoke neural activity. Optogenetics is a powerful tool to understand and experimentally manipulate neural activity. The genes of interest to be inserted into the vector will therefore include opsins for the purpose of optogenetic stimulation of mammalian neurons. Ectopic expression of channelrhodopsin (ChR2) and its variants allow light-evoked stimulation of neurons in vitro and in the adult mammalian brain.
Although this is not an exhaustive list, inserts in the vector plasmid construct may include genes such as:
ChR2 (H134R) channelrhodopsin with standard peak activation and decay kinetics
ChR2 (L132C) CATCH construct for eliciting calcium currents
ChR2 (E123A) ChETA construct for faster closure kinetics
ChR2 (I170V) ChIEF construct for faster closure kinetics
ChR2 (T159C) TC mutant for a bigger photocurrent
ChR2 (C128T) Step-Function Opsin for bistable on-off control
Chronos – a sensitive blue-light-activated excitatory opsin
Chrimson – a sensitive red-light-activated excitatory opsin
eNpHR3.0 – chloride pump which inhibits neuronal activity with peak excitation at 590nm and fast decay time
ACR2 – chloride channel which inhibits neuronal activity with peak excitation at 470nm
ArchT – proton pump which inhibits neuronal activity with peak excitation at 590nm

For the second project, we aim to increase or decrease mitochondrial activity and metabolic gene expression by manipulating expression of pro-metabolic transcription factors such as PGC1α, transporters such as CPT1α, and enzymes such as acyl CoA dehydrogenases. The goal of this manoeuvre is to explore the intrinsic metabolic limitations on energy-intensive cellular activities such as firing action potentials (in the case of neurons) or cell cycle progression (in the case of tumour cells). In addition, we will explore the role of metabolism on cellular activities by using shRNA delivered to cells in vitro. The shRNA constructs will be cloned into a third-generation lentiviral vector plasmid and the resulting viral particles will be delivered to cells.

Although this is not an exhaustive list, inserts in the vector plasmid construct may include genes such as:

- PGC1α – enhances the metabolic capacity of cells dependent upon oxidative respiration
- PPARG – acts as a transcription factor to regulate pro-metabolic gene expression
- CPT1α – acts as a transporter of acyl-carnitines across the mitochondrial membrane for beta-oxidation
- Medium-Chain acyl CoA dehydrogenase – acts as an enzyme to break down fatty acids for energy
- shRNA targeting any of the above genes, for example

For the third project, we aim is to use either overexpression or knock-down of gene expression to oncogenically transform mammalian cells, particularly to assess the contribution of metabolic changes to malignant behaviour and to assess the effects of oncogenic transformation on cellular metabolic strategy. Once a stably infected cell line is produced, experiments performed will depend on the particular gene selected but will typically involve a panel of typical proliferation, apoptosis and/or invasion assays as well as collection of RNA/DNA/Protein for further profiling analysis and potentially in vivo engraftment.

Although this is not an exhaustive list, inserts in the vector plasmid construct may include genes such as:

- H-Ras – an oncogene
- EGFR – a growth factor receptor
- p53 – a tumour suppressor
- shRNA against any of the above genes, for example
- HPV exons 6 and 7 – encodes gene products that disrupt tumour suppressor signalling

Promoters used in the vector plasmid construct for both projects may include ubiquitous promoters (such as CMV, EF1, etc) or cell-specific promoter regions (such as hThy1, hSyn1, CamKII, PV, GFAP, etc).

Fluorescent reporter proteins based on green fluorescent protein (GFP from Aequorea victoria), and similar safe, non-toxic fluorescent proteins from other organisms (e.g. Discoma spp. mCherry (Shaner et al. Nature Biotechnology 2004) will be used. Transfection with GFP and other fluorescent reporter proteins are considered safe as there has been widespread use of these proteins both in vitro and in vivo with no deleterious effects.

Evaluation of foreseeable effects

There are potential routes of transmission by which the viral vector or its products could be delivered, and these risks can be controlled with appropriate measures. The viral vector would be able to transduce many types of tissues should it come in contact with them. The major hazard is therefore represented by the packaged virus prior to infection of the target cells and residual virus in the medium of infected cells. The two potential transmission routes are by external exposure (either skin lesions or mucous membranes; only in the case of very high titres and aerosol production) and by accidental injection/inoculation using sharps. If genes were to be transduced directly into living human tissue the detrimental effects that they could cause are uncertain but unlikely on their own to transform affected cells. Given that virus is replication incompetent and will only infect at low efficiency in sub optimal conditions any potential harm would be extremely limited. These risks will be further minimised by measures described below.

All those involved with this project will be trained in biological safety, GM safety and will have been advised by the PI and the project license holder on the detailed risk assessment for the use of sharps that has been prepared for this work. To minimize risk, blunt needles are used for injection and virus delivery is conducted by a controlled microinjection unit so there is no direct contact with the syringe or needle during injection.

The inserted genes include reporters such as enhanced green fluorescent protein (eGFP), which allows for identification of infected cells, and opsins such as channelrhodopsin, which allows for optical stimulation of neuronal activity. In addition, known oncogenes or shRNAs that will silence known tumour suppressor genes may be inserted into primary cells and cell lines. There is therefore a theoretical possibility that they could render the cells neoplastic. If during an unlikely event these cells were inoculated into the human organism, then these cells are recognised as non-self and will be identified by the immune system. Inserted gene products will be both genomic, cDNA sequences or small interfering double stranded RNA sequences originating in humans or rodents, including those which could be implicated in tumour progression, i.e. oncogenic and tumour suppressor DNA sequences. Specific functions will vary depending on the particular experiment, but will include functions that are known to
Contribute to the maintenance of pluripotency and/or differentiation and the regulation of cell growth and apoptosis. The gene products will be biologically active when transfected into mammalian cells and probably expressed at a level higher than seen in the wild type cells. However, the recipient transfected cells will be either primary human or mouse cells or well characterised stable eukaryotic cell lines in tissue culture that have a history of safe use and these hosts can be considered disabled hosts because the cells are unable to colonise the worker (i.e. not their own cells).

Two potential risks to humans may arise from the hazards of working with the naked plasmid vector + insert containing the potentially oncogenic DNA and the supernatant containing the viral particles from the packaging cells. However, the transduction efficiency even under optimal culture conditions is negligible, and therefore transfection of researcher's cells with naked DNA under accidental/non-optimal conditions would be effectively zero.

The individual potential oncogenes will only be sufficiently oncogenic to give a growth advantage to cells in culture without inducing tumourigenesis. Tumourigenesis is a multistage process requiring the interaction of many mutated genes which also lessens the risk from delivery of a single oncogene or tumour suppressor gene to a target tissue. The principle route of transmission that could lead to transduction of laboratory workers by packaged viral particles is inoculation. Therefore, blunt needles and pipet tips will be used. Other possible routes of transmission such as inhalation, ingestion and eye splashes are less likely to lead to tumourigenesis because of the required very high titres, which will not be achieved under the given experimental conditions. Consequently, the risk of tumourigenesis is negligible.

The self-inactivating lentivirus vector systems to be used are such that they have been extensively modified and are regarded as being stable, as are the inserted sequences. The lentiviral vector system to be used is considered to be “Third Generation” as defined by the SACGM Compendium of Guidance 2.11.9 as the accessory genes (vif, vpr, vpu, and nef) have been deleted along with the tat gene. The risk of dissemination of the described vector is extremely low due to it being replication incompetent and self-inactivating (SIN) (SACGM Compendium of Guidance, Part 2.11). The virus will be injected into mice or rats, which are non-permissive hosts for this vector. The extensive modification of the viral vector also prevents homologous recombination with other related viruses. All cultures are maintained under sterile conditions and it is unlikely that any hazardous sequences if they were present could be transferred to related organisms. The restricted location of the virus within the CNS of injected animals and the non-permissibility of rodents as hosts makes it unlikely that experimental animals would be able to transfer genetic material to other animals. Whilst it is possible for the virus to infect other organisms, this is considered unlikely (SACGM Compendium of Guidance, Part 2 “Risk assessment of genetically modified microorganisms (other than those associated with plants)”. Viral particles capable of transducing a wide range of mammalian cells will be produced by the packaging cell line and these represent the hazardous material. However, because of its incompetence to replicate and inefficient transduction rates, the risk of transmission outside the laboratory is effectively zero.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

IN VITRO WORK:
In accordance with the SACGM Compendium of Guidance, GMM mammalian cells will be handled at Containment Level 2 and using microbiological safety cabinets. All GM virus waste will be properly inactivated by autoclaving. Spillages will be soaked with tissue paper, which will afterwards be autoclaved. Contaminated surfaces may be decontaminated with either a 1% virkon solution or 70% Ethanol.

IN VIVO WORK:
Viral infection of animals will be performed under sterile conditions within a surgical suite equating to Containment Level 2, in order to control hazards associated with possibly adventitious agents and to avoid contamination. Used bedding and other materials from animal cages will be autoclaved for sterilization before leaving the CBC to be incinerated. Please see related documents (GM Risk Assessment Forms 2 and 5, relevant Home Office licenses) for more detail on how these procedures will be carried out.

Hypodermic needles will be used and therefore suitable training and precautions will be taken to minimise the potential for self inoculation. Viral vectors will be injected using blunt needles, therefore minimising the risk of accidental injury. A detailed risk assessment has been prepared and all staff will be required to demonstrate proficiency in all procedures before surgical work with viral vectors is allowed to commence.
GENERAL:
Used blunt needles, pipette tips, serological pipettes will be collected in a “CinBin” type container inside the biosafety cabinet and placed within the plenum of the MSC immediately after use. The container and its contents will be autoclaved prior to disposal by the clinical waste route. Blunt needles will in fact be used for injection but will be handled as if sharps. Biohazard boxes will be used as a secondary containment system to transport all materials to the autoclave.
All waste that is possibly contaminated with virus will be inactivated by incubation with a final concentration of at least 1% Trigene for 30 minutes and all of this waste will be collected in dedicated bags and these transferred to an autoclave using closed containers and will be inactivated by autoclaving at 121°C for 20 min. This procedure will ensure 100% killing efficiency. All autoclaved waste will be incinerated using the yellow bag route as clinical waste using an approved contractor.

INACTIVATION OF GMOs:
Dead animals are collected and treated as clinical waste and are disposed of by incineration following autoclaving.
Animals will be perfused with para formaldehyde (PFA) for experimental purposes and it is therefore inappropriate to autoclave this material. Although the PFA is expected to kill any residual GM virus present in the animal, it is not possible to accurately validate whether inactivation of GM virus has been effective. For this reason any PFA-perfused carcasses will be disposed of as GM waste. This waste will be collected by SCRL who are a GM registered carrier and who are aware of the arrangements and will be disposed of by incineration. All associated documentation for waste disposal will clearly state that this is GM waste. Waste will be securely stored and transported in yellow ‘Cin bin’ containers which have securely fastened lids.
Other waste that is possibly contaminated with virus will be inactivated by incubation with a final concentration of at least 1% Trigene for 30 minutes and all of this waste will be collected in dedicated bags and these transferred to an autoclave using closed containers and will be inactivated by autoclaving at 121°C for 20 min. This procedure will ensure 100% killing efficiency.
Temperature and time during each autoclave run will be monitored using indicator strips (TST control integrator, class 6 emulating indicator 121ºC for 20 min, Albert Browne Ltd, UK). The autoclave will be serviced and tested on an annual basis using an independent thermocouple mapping test.

Please enter comments on the GM safety committee on the risk assessment
The committee requested that:
Details of attendance on Biosafety and GM safety training courses were stated.
A definition of 'third generation' vector was included e.g. at least 3'SIN deletion and no gag, pol, env and regulatory genes
There is less rigidity in the list of inserts to allow flexibility of the risk assessment allowing other similar inserts to be included.
It was clear that blunt needles are to be used for all vectors, not just those containing the oncogenic sequences.
These were all addressed and included in the attached final documentation.

### Project Additional Information

**Purposes of the contained use**

Six wastewater treatment bioreactors have been established to monitor the dissemination of an antibiotic resistance plasmid throughout the reactors from a strain of E. coli to be seeded into the incoming wastewater stream. To distinguish antibiotic resistance genes that occur naturally in the wastewater, the seeded strain will carry a copy of plasmid RP4 into which the gene encoding the green fluorescent protein (GFP) has been cloned (Musovic et al., AEM, 76, 4813-4818 (2010) & EM Rpt 6, 125-130 (2014)). It will be transferred by conjugation to a wild type E. coli strain isolated from wastewater as the seed organism to investigate the fate of broad host range IncP-1 plasmid during wastewater treatment. The work will be performed in tandem with an on-going bioreactor experiment to study the dynamic of antibiotic resistance genes (ARGs) associated with mobile genetic elements (MGEs) during treatment processes. pRP4 encodes resistance genes for ampicillin, tetracycline and kanamycin. Mass balance of gfp-labelled pRP4- Plac::gfp plasmid will be quantified using flow cytometry (Medical School Flow Cytometry Core Facility) to monitor the conjugal transfer kinetics of the plasmid and the harboured ARGs between commensal bacterial. The experiment will involve the seeding of E. coli donor strain into six wastewater treatment bioreactors to track the transmission of the RP4 plasmid over a time series within the operating treatment cycle. Additionally, the prevalence of the antibiotic resistances encoded by pRP4 will be monitored by plate counts. The frequencies of the target resistances and the GFP signal will provide the required data from horizontal transfer in the bacterial cell population of the individual reactors.

**Recipient or parental organism**

An E.coli strain isolated from domestic wastewater will be used as the seed organism to host the GFP-tagged pRP4 plasmid. The identity of the E. coli was confirmed by the Microbiology Department at the Freeman Hospital and is susceptible to 17 clinical antibiotics including major classes of beta-lactams antibiotics (e.g. Aztreonam,
Meropenam, Ertapenam), trimethoprim, ciprofloxacin, etc. A serotype test has also been carried out and has confirmed that the strain is not of the O157 serotype and therefore not shiga toxigenic.

Host/vector system

Plasmid RP4::Plac::gfp (Musovic et al., 2010) has a molecular size 56.4 kb, and encodes resistance against the antibiotics ampicillin, tetracycline and kanamycin. The used of the native pRP4 (ie without the gfp gene) is not subject to GM regulations or other restrictions.

Origin & function

The gfp gene has been introduced onto pRP4 to facilitate the monitoring of the transfer of the antibiotic resistance genes associated with pRP4 within the population of cells within the bioreactor. The gfp gene, obtained originally from Aequorea victoria, is widely used as a visual and quantifiable reporter gene and is not associated with any toxicity. Its role here is to monitor transfer to other cells in the bioreactor population. Plasmid RP4, subgroup alpha (Thomas, 1981) and tagged with a mini Tn5 insertion of a gfpmut3b gene, is derived from Pseudomonas putida KT2440 (Barth et al., 2015). The complete nucleotide sequence pRP4 has been published (Pansegrau et al., 1994). The plasmid will be obtained from Dr Musovic, Technical University of Denmark. The gfp gene will be expressed from the Plac promoter at a medium level of expression. Plate mating assays will be used to transfer the gfp-labelled plasmid to the indigenous E. coli. The resulting transconjugant will be used as the donor strain for the subsequent seeding experiments to track the fate and migration of the plasmid and the associated resistance genes to other indigenous bacteria found in wastewater treatment system. This is a natural process that occurs in wastewater treatment processes. The gfp-labelled pRP4 plasmid will not be subjected to any further modifications.

Evaluation of foreseeable effects

pRP4 is a well-characterised resistance plasmid belonging to the IncP-1 group, which is a promiscuous conjugal plasmid with the ability transfer and replicate in broad range of hosts especially to Gram-negative bacteria. The ability of the pRP4 to replicate and to be maintained in the recipient organisms poses a potential environmental and health risk if released. However, the work will be restricted to Containment Level 2 laboratories in both the Baddiley-Clark and Cassie Buildings. RP4 vector will be introduced in a closed bioreactor systems under contained use and all remnant materials, including the reactor outflow, will be inactivated by autoclaving. The only exception will be small (millilitre volumes) samples taken for FACS and DNA extraction, which will be inactivated during processing. The primary hazard is the potential of the commensal E. coli isolated from domestic wastewater being a pathogenic strain (ACDP Hazard Group 2), which may be carried through the biotreatment processes (activated sludge, secondary treatment biofilms and final effluent) but at much lower concentrations, equivalent to ACDP Hazard Group 2 (Compendium of Guidance). Prof David Graham has an internationally recognised reputation for running bioreactors using wastewater input streams, and the only variation in the proposed experiments is the presence of the gfp gene. As a result there will be no increase in the risk to human health. Ms Jong also has more than two year of experience running wastewater bioreactors. Therefore, under the proposed contained use, the recombinant organism is unlikely to represent an increased risk to human health. Level of risk is predicted to be low/medium.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored using TST (Time, Steam, and Temperature) test strips (Albert Browne Ltd., TST class 6 emulating indicator 121°C for 20 min). Contaminated materials used in laboratory during the experiment and waste will be disposed of via and appropriate route e.g. sharps in sharps bins, bulk materials in autoclaves. All outflow from bioreactors will be inactivated by means of autoclaving. A limited number of samples will be used for analytical studies (PCR, FACS etc), and these will be inactivated during processing and autoclaved after use.

02/03/2022
The only comment was "My only issue with the risk assessment is that it does not mention the possibility of the strain being HG3. Since it is an unknown strain, it would be useful to have some kind of assurance that it is not verocytotoxigenic (ie HG3). They may already know this from the identification that was done at the Freeman, but it would be worth stating it explicitly in the risk assessment." The confirmation that the strain was tested at the Freeman Hospital Microbiology Department to confirm it was not verocytotoxigenic was added to the GMM risk assessment form as requested.

**Historical Date of Additional Info**: 02/03/2022
Lentiviral particles will be generated on site containing either a cDNA or an appropriate shRNA. cDNAs may occasionally contain a mutation where a dominant negative or constitutively active version of the gene is required. The purpose is to perturb the natural state of the gene in question and to assess the effects on cells. Downstream analysis may involve cell cycle analysis, proliferation, cytotoxicity, apoptosis or differentiation assays. Stable cell lines will be obtained by antibiotic selection based on resistance genes encoded by the plasmids. Localization and protein-protein interactions will be determined by immunofluorescence microscopy and immunoprecipitation and/or western blotting respectively. RNA, DNA and protein would typically be extracted from infected cells in each case to verify appropriate infection and to validate cDNA/shRNA expression. A lentiviral pool expressing various cDNAs or shRNAs may be used to create a pool of cells with several integrated constructs which will then undergo in vitro or in vivo selection to screen for constructs which either promote or inhibit cell proliferation.

Established human cell lines: including HeLa, U2OS, HEK293, hTERT-RPE-1, MDA-MB231, Daudi, K562, Jurkat, MCF-7, U937, THP-1, Ramos, PC3,
Established mouse cell lines: NIH-3T3
Established hamster cell line: CHO

We will be using second and subsequent generation lentivirus and retrovirus. They are replication incompetent and self-inactivating (SIN). The systems separate the packaging signals and viral LTRs on the expression plasmid from the viral structural and expression genes (gag, pol and rev from FIV or HIV and viral envelope glycoproteins such as the VSV-G gene from Vesicular Stomatitis Virus, in place of HIV or FIV env). The viral structural and expression genes and the envelope glycoprotein genes are separated on at least two additional plasmids.

cDNA sequences of humans or mice origin and/or the appropriate shRNA sequences will be cloned into the lentiviral vectors. These may include partial or entire gene sequences, or mutant forms of the gene sequences, under the control of constitutive promoters. Many of the genes or targets of the shRNAs will have unknown function but may include known oncogenes or tumour suppressors, such as cDNAs encoding human or mouse genes, and mutants thereof: Haspin, Aurora B, MCAK, Pik1, Aurora A, Aurora C, Sgo1, Sgo2, TESO/RCC2, Rad5, WDR5, Hec1, Dsn1, Kn1, PP1, PP2A, RepoMan, INCENP, Survivin, Borealin, Histone H3, H4, H2A, H2B, H2AZ, H2AX, CENP-A, CENP-B, CENP-E, Rad21, Scc2, SMC1, SMC2, SMC3, SMC4, SA1, SA2, FLJ35779, ZNF198, astrin, Chk1, DikZIP, PRC1, Mklp2, Mklp1, KIf4, Bub1, BubR1, Mad1, Mad2, CTCF, TAF3, TAF5, DIDO3, BHC80, ING2/4, BPTF, EGFP; CRISPR Cas9 targeting factors and shRNAs for these genes.

The aim is to use either overexpression or knock-down of gene-expression to assess the potential contribution to cell cycle progression of each candidate identified from our genomics and proteomics screens. Once a stably infected cell line is produced experiments performed will depend on the particular gene selected but will typically involve a panel of typical proliferation, apoptosis cell biology assays as well as collection of RNA/DNA/Protein for further profiling analysis.
unable to produce infectious virus once it integrates into the host chromosome. Deletion of accessory genes vpr, vpu, vif and nef mean that the vector is unable to replicate once it has transduced the target cell. In addition third generation lentivirus are deleted for the tat gene and carry a SIN deletion of the 3’ LTR (deltaU3) which results in “self-inactivation” of the lentivirus following transduction of the target cell, precluding adventitious activation of the vector by endogenous retroviruses and minimising the risk of recombination with ERVs.

The origin of the virus the mechanism of attenuation, and its stability in both the parent viral vector and the recombinant vector:

The transfer vector systems are derived from FIV or HIV and have been specifically engineered for biosafety by separating the packaging signals and viral LTR’s on the expression plasmid from the viral structural and expression genes (gag, pol and rev from FIV and the VSV-G gene from Vesicular Stomatitis Virus, or similar alternatives, in place of FIV or HIV env) encoded on three or four separate plasmids, which remain in the packaging cell line, effectively precluding the production of replication competent virus in the target cell or should the viral vector escape containment. FIV vectors are included as they may be more efficient for some cell types. It does not imply any different containment or risk considerations than HIV based vectors. The plasmids expressing these gene products carry no packaging signals or LTRs and so cannot themselves be mobilised with the vector and have been engineered not to contain any regions of homology to each other or to the viral vector, to prevent undesirable recombination events which might result in replication competent virus being produced.

The viral vector and recombinant virus have a broad host range when pseudotyped with e.g. the VSV-G envelope protein. The normal tropisms of HIV and FIV have been broadened to include multiple tissues from a broad range of species. Pseudotyping with alternatives to VSV-G, for example measles virus derived glycoproteins, will produce particles with more restricted tropisms.

The probability of reversion to wild type is negligible. No single plasmid contains all the components necessary to produce viral particles. 2nd and 3rd generation viral plasmids will be used which means that 3 or 4 separate plasmids are required to produce virus. Reversion to wild type is extremely unlikely given that several recombination events would be needed reconstitute an active viral genome, the viral genes are present on three different plasmids which have minimal sequence homology and the viruses are self-inactivating following insertion (i.e. the LTR’s are destroyed upon genome insertion).

All potential routes of transmission of the virus known, eg those that may occur during a laboratory accident. The viral vector would be able to transduce many tissues should it come in contact with them. The major hazard is therefore represented by the packaged virus prior to infection of the target cells and residual virus in the medium of infected cells. The two potential transmission routes are by external exposure (either skin lesions or mucous membranes; only in the case of very high titres and aerosol production) and by accidental injection/inoculation using sharps.

The viral vector can infect humans or human cells in vitro. However, the severity of harm would be minor given that infection of human tissue if achieved would be with non-replicable virus and low-efficiency. Likelihood of harm Low given lab procedures for avoiding contamination, in particular no sharps, etc. The virus is generally weak and does not survive long outside of buffered solutions. Infection requires optimal conditions and the use of additives in cell culture. Immune-competent mice show sterilising immunity with wild-type virus infection; humans would also show such sterilising immunity. Risk is generally speaking no greater than that of handling human tissue or bodily fluids i.e. relatively safe given that proper precautions are taken to avoid infection during specialised training.

The GM virus would have the ability to infect human tissues should it come in contact with them. The major hazard is therefore represented by the packaged virus prior to infection of the target cells and residual virus in the medium of transfected cells. The main potential transmission routes are by external exposure to high titres (either skin lesions or mucous membranes). Some of the genes that will be studied could have oncogenic effects. If those genes were to be transfected directly into living human tissue the detrimental effects that they could cause are uncertain but unlikely on their own to transform affected cells. Given that virus is replication incompetent and will only infect at low efficiency in sub optimal conditions any potential harm would be extremely limited.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile.

Spillages will be soaked with tissue paper, which will afterwards be autoclaved. Contaminated surfaces may be decontaminated with either a 1% virkon solution or 70%
The GM safety committee agreed the classification of the risk assessment as activity class 2. The ability to use 3rd generation vectors was explored.

Human Clinical Applications

Project Ref 540/18.2

Immortalisation of mammalian cell cultures

Date Ackn'd 19/09/2018

Date Project Ceased

Consent Granted Not Applicable

Project notified under transitional arrangements N
Purposes of the contained use

To expand the life span of rare patient cell lines by releasing them from dependence on the growth factors normally necessary for their proliferation.

Recipient or parental organism

Host organism - Primary fibroblasts, PA317 and HEK293 cells

E.coli will be used to produce and propagate the viral vectors and associated production of plasmids which encode replication factors for viral production in HEK293 cells and PA317 cells. However, the viral vectors are not active in prokaryote, are not replicative as a double stranded DNA molecule and do not contain prokaryotic promoters adjacent to the inserted genes. Plasmid expression in prokaryotes is therefore limited to plasmid replication factors and antibiotic resistance, as found in standard molecular biology techniques and so this part of the process poses no risk above standard molecular cloning.

The target cells which will be infected with the virus are primary fibroblast cultures. These cells will be infected at moderate titre and it is anticipated that the viral vectors will have a biological effect, but will not replicate under these conditions due to the absence of essential replication factors. The effect of the virus is not anticipated to induce changes in these cells which will increase their pathogenicity, toxicity or infectivity. Once transduced excess virus will be removed and destroyed. The major risk is posed by the high titre virus, both before transduction and immediately following transduction where a significant quantity of infective virus particles is present. Following measurements of biological activity, cells will be disposed of via a standard route (see disposal SoP in appendix 2).

Human embryonic kidney cell line 293FT (HEK293) is a cell line optimised for viral transfection and serves as the standard cell line for viral production and packaging. Plasmids supplying the replication and packaging functions which have been deleted from the wild-type virus, or are normally provided by co-infecting adenovirus, will be transfected into the cells with the replication defective viral genome. The HEK293 cells are not anticipated to become more pathogenic or toxic through the process of viral production.

The major risk is posed by the high titre virus produced by the cells. These cells are widely used in this application and have a long history of safe use. Following viral production HEK293 cells will be disposed via a standard route consistent with CL2 containment PA317 cell line was derived from TK- NIH/3T3 cells by cotransfection with packaging construct DNA (pPAM3) carried in pBR322 and the herpes simplex virus thymidine kinase (TK) gene carried in pBR322. Introduction of retroviral vectors into these cells, by infection or by transfection, results in production of retrovirus virions with an amphotropic host range that are capable of infecting cells of many mammalian species. Virions produced by this line have been used successfully to transfer genes into humans. The PA317 cells are not anticipated to become more pathogenic or toxic through the process of viral production. The major risk is posed by the high titre virus produced by the cells. Following viral production PA317 cells will be disposed via a standard route consistent with class II containment.

Host/vector system

Vector system

The retroviral vector pLXSN has been widely used and has a history of safe use. The vector is detailed below:

pLXSN contains elements derived from Moloney murine leukemia virus (MoMuLV) and Moloney murine sarcoma virus.
MoMuSV), and is designed for retroviral gene delivery and expression (Miller & Rosman (1989) Biotechniques; 7(9): 980-990). Upon transfection into a packaging cell line, pLXSN can transiently express, or integrate and stably express, a transcript containing 4′+ (the extended viral packaging signal), the gene of interest and a selectable marker. The 5′ viral L TR in this vector contains promoter/enhancer sequences that control expression of the gene of interest in the multiple cloning site. The SV40 early promoter (PSV40e) controls expression of the neomycin resistance gene (Neor), which allows antibiotic selection in eukaryotic cells. pLXSN also includes the Col E1 origin of replication and E. coli AmpR gene for propagation and antibiotic selection in bacteria, although we do not plan to propagate the viral vector in E.coli.

pLXSN is deleted (relative to the wildtype retrovirus) for the gag, pol and env genes. This means that whilst the packaged viral particles are infectious, they remain unable to replicate outside the highly specific and engineered conditions of the packaging cell line.

**Origin & function**

The E6E7 region of human papilloma virus 16 (HPV16) has previously been isolated and cloned into pLXSN (Halbert et al. (1991) JVirol65: 473-478). This region of the HPV16 genome has been shown to be sufficient to transform cells in culture when expressed from this vector. The intention is to infect cells with a high titre virus and select those which take up large amounts of the virus, and so become resistant to G418 (the vector also expresses the Neor gene). Those cells which survive extended selection in G418 are generally transformed by their concomitant extended exposure to the E6E7 genes.

**Evaluation of foreseeable effects**

The viral vector would be able to transduce many tissues should it come in contact with them. The major hazard is therefore represented by the packaged virus prior to infection of the target cells and residual virus in the medium of transfected cells. The two potential transmission routes are by external exposure (either naked skin or mucous membranes) and needle-stick injury. Both are made extremely unlikely by the standard procedures employed in the CL2 tissue culture facility. Hypodermic needles or other sharp objects are not permitted in the viral handling laboratory or the MSC (see appendix 2), making needle stick injury very unlikely. Whilst pipette tips are used in the tissue culture facility, these are routinely filter tips, making contamination of the pipette barrels very unlikely. Standard use of surgical gloves and laboratory coats make external exposure to virus unlikely. However, there is a risk of contamination of the arms of the laboratory coat by an aerosol generated within the MSC. This necessitates the use of disposable covers for the laboratory coats whilst handling the packaged viral vector. External exposure by virus is unlikely to cause transfer of the viral vector since it is not expected to penetrate the epidermal layers of the skin. Direct exposure of virus to mucous membranes is difficult to envisage since all material must be sterilised using 1% Virkon prior to removal from the MSC, precluding the generation of aerosols containing viral particles in the vicinity of laboratory workers. Virally transduced genes will only be transfected into cell lines or primary cells which have no ability to survive outside tissue culture environment. Even in extreme events of needle stick injuries, these cells (which will exist in very low numbers) will be destroyed by the human immune system. Small numbers of cells that might exist in aerosols during the cell destruction also pose minimal risk of direct entry into the human body. These cells will be handled at CL2 and with all the measures described in Section 4 and appendix 1 and 2, the risk to human health will be minimised.

The following potential adverse consequences have been identified:

1. Random integration of virus into the genome. Although there is a risk of activating neighbouring oncogenes, this is unlikely since the viral vectors are both transcriptionally inert (other than the inserted sequences) and modified to reduce the frequency of integration.

2. Expression of E6/E7 genes. Retrovirus is unlikely to infect non-dividing cells, even at low efficiency. The risk that
E6/E7 will be expressed in these cells is therefore very low, even following exposure to high titre virus, itself an unlikely event. Furthermore, this would be a transient expression which in a non-replicative virus is unlikely to result in transformation of the cell. In vitro, cells must be transduced at high titre and placed under selective pressure with G418 in order to achieve transformation. It is unlikely that exposure to small quantities of virus will have harmful consequences.

The viral vectors are non-replicative, and any exposure would be to very small quantities of virus. The severity of these adverse events is likely to be both transient and treatable. The likelihood of harm is therefore negligible and the severity of harm is minor, a level of risk of effectively zero.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

In accordance with ACGM and ACDP requirements virus lysates and infected mammalian cells will be handled at containment level 2 and using microbiological safety cabinets. These, like any micro-organism, are extremely sensitive to rapid and complete inactivation by the disinfectants specified below which will be used in accordance with the manufacturer's instructions. Only plastic pipettes will be used in the tissue culture facilities, sharps must be excluded, the generation of aerosols prevented and all waste must be inactivated as below before disposal. Furthermore, the following measures, contained in the Compendium, Part 3A, Annex I paragraph 10, applied in the light of this GM risk assessment, will be used.

1. Good laboratory techniques will be strongly emphasised. Designated workers will be trained in good laboratory techniques before commencing work with viruses. They will be made fully aware of the potential hazards of such work.
2. Access to the laboratory where viruses are handled, will be limited to authorised personnel and designated workers.
3. Gloves will be worn at all times. Where users are handling high titre viral stocks, packaging cell lines or newly infected cell cultures (which will have a high viral titre in the medium) disposable plastic oversleeves are to be worn in the hood and disposed of as for gloves.
4. Sharps will be avoided, as stab injury is a possible means of inoculation of virions. Hypodermic needles, glassware, scalpels, scissors, sharp-edged metal/plastic boxes and microscope slides/coverslips are not permitted within the designated virus room or MSC. See appendices 1-3 for details and SoP.
5. The generation of aerosols will be avoided. All experimental procedures involving virions will be performed so as to minimise aerosol production. Procedures which are likely to generate aerosols such as the use of sonicators, vigorous shaking and mixing etc. will be avoided, or performed within the MSC.
6. Procedures using the viral particles, packaging cell lines and exposed cells will only be carried out in the designated tissue culture suite. Normal procedure for handling biological material in the TC suite will be largely sufficient for handling the cells and particles (see appendices 1 and 2 for details and SoP).
7. All liquid waste to be treated with 2-3% Virkon (see appendix 2).
8. Safety cabinets are routinely disinfected prior to and following use using 70% ethanol. These should also be routinely swabbed down with 1% Virkon as well as exposed to UV radiation.
9. Solid waste to be treated with 1% Virkon, collected into an autoclave bag within the MSC and autoclaved prior to disposal.
10. Gloves and designated lab coats to be worn throughout. Gloves to be disposed as solid waste and lab coats sterilised (autoclaved) before going to the laundry.
11. Designated microbiological safety cabinets to be used for all viral work.
12. Individual culture medium bottles for each cell line.
13. No wild type virus to be used in these facilities.
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated waste, including sharps bins, disposable plastics, laboratory glassware, or other contaminated materials will be autoclaved at 121°C for at least 30min to inactivate GMMs (100% kill) prior to disposal or cleaning and recycling. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous recording of the temperature/time profile. Culture media from cells will be treated with 2-3% Virkon for a minimum of 3 hours before disposal via drain.

Date Project Ceased

Project notified under transitional arrangements N
This risk assessment covers research projects in our lab utilising bacteria specifically Staphylococcus aureus, Staphylococcus epidermidis for the purpose of facilitating molecular biology procedures such as (i) sub-cloning, DNA sequencing, or site-directed mutagenesis; (ii) construction of chromosomal mutants; (iii) construction of fusions with harmless reporter genes such as GFP or tags such as HA and His; (iv) construction of chromosomal insertions with antibiotic resistance cassettes (v) construction of recombinant plasmids for subsequent purpose of over-producing proteins in Staphylococcus strains.

The genetically modified strains will be cultured in small to medium quantities for the isolation and analysis. This will involve solid and liquid culture of the strains, centrifugation, extraction of RNA, DNA and protein, microscopy, gel electrophoresis, western blotting, mass spectrometry and immunological studies.

Recipient or parental organism

We will use a number of strains of Staphylococcus aureus and Staphylococcus epidermidis including those that are MRSA.

Staphylococci are non-spore forming, facultative anaerobic, gram-positive bacteria from the group of cocci which occur naturally in humans and animals. Out of the 30 species which make up the genus Staphylococcus, the so-called "coagulase-positive" staphylococci have the highest pathogenic potency. The most important representative of the coagulase-positive staphylococci is Staphylococcus (Staph.) aureus. As staphylococci occur naturally on the skin and in the mucosa of animals and humans (particularly in the nasal area), food is mainly contaminated by secondary contamination through people. Meat and meat products offer favourable growth conditions for staphylococci. Other typical foods involved in staphylococcal intoxications are milk and dairy products, egg-containing preparations, salads, creams, cake fillings, ice-cream and pastry goods. Because of the heat stability of the enterotoxins, which are also resistant to the decomposition enzymes to be found in the gastrointestinal tract, the staphylococci can be destroyed through sufficient heat treatment but not the toxins possibly contained in the food.

PATHOGENICITY: Opportunistic pathogen, normal flora; produces a variety of syndromes with a range of clinical manifestations; clinically different in general community, newborns, menstruating women, and hospitalized patients; food intoxication is characterized by abrupt/violent onset, severe nausea, cramps, vomiting, and diarrhea using lasting 1-2days; animal bites can result in localized infections; may cause surface or deep/system infections in both community and hospital settings; surface infections include impetigo, folliculitis, abscesses, boils, infected lacerations; deep infections include endocarditis, meningitis, septic arthritis, pneumonia, osteomyelitis; systemic infection may cause fever, headache malaise, myalgia; newborns are susceptible to scalded skin syndrome (SSS) caused by exfoliative toxins; may be colonized during delivery resulting in sepsis meningitis; toxic shock syndrome is an acute multi-system illness caused by TSST-1 a super antigen; characterized by sudden onset, high fever, vomiting, profuse watery diarrhea, myalgia, hypotension erythematous rash

EPIDEMIOLOGY: Occurs worldwide; particularly in areas where personal hygiene is suboptimal; in hospitals by development of antibiotic-resistant strains

HOST RANGE: Humans; to a lesser extent, warm-blooded animals

INFECTION DOSE: Virulence of strains varies greatly

MODE OF TRANSMISSION: Contact with nasal carriers (30-40% of population); from draining lesions or purulent discharges; spread person-to-person; ingestion of food containing staphylococcal enterotoxin (food may be contaminated by food handlers hands); from mother to neonate during delivery

INCUBATION PERIOD: Variable and indefinite, commonly 4-10 days; disease may not occur until several months after colonization; interval between eating food and onset of symptoms is usually 2-4 hours (30 min to 8 hours)

COMMUNICABILITY: As long as purulent lesions continue to drain or carrier state persists; auto-infection may continue for the period of nasal colonization or duration of active lesions

RESERVOIR: Human; patients with indwelling catheters or IVs act as reservoirs for nosocomial infections; food borne - occasionally cows with infected udders
ZOONOSIS: Yes - direct or indirect contact with infected animals
VECTORs: None
DRUG SUSCEPTIBILITY: Many strains are multi-resistant to antibiotics and are of increasing importance; methicillin resistant (MRSA) strains have caused major outbreaks world-wide; Vancomycin resistant (VRSA) are being increasingly isolated; sensitivity must be determined for each strain.
Staphylococcus aureus only rarely causes a severe or life threatening disease in a laboratory situation. In particular people who are immunocompromised need to take care and a separate risk assessment may need to be conducted.
Staphylococcus epidermidis belongs to the group of coagulase negative Staphylococci that occurs naturally on the skin of animals and humans. S. epidermidis can however become an opportunistic pathogen if the skin barrier is breached and the bacterium enters the bloodstream. Occurs worldwide; particularly in areas where personal hygiene is suboptimal; associated with noscomial infections; in hospitals by development of antibiotic-resistant strains. Staphylococcus epidermidis only rarely causes a severe or life threatening disease in a laboratory situation.
S. aureus and S. epidermidis are both hazard group 2 biological agents.

Host/vector system

pRAB11, pIMAY, pORI. None of these vectors are mobilisable and only vectors that are either non-mobilisable or mobilisation-defective in bacteria as defined in the Compendium of Guidance will be used.

Origin & function

Genomic sequences will originate from Staphylococcus aureus or Staphylococcus epidermidis. Specific modifications and intended functions will vary depending on the particular experiment, but in all cases they will be restricted to facilitating routine molecular biology procedures such as those provided as examples in section 6.

Evaluation of foreseeable effects

The vectors that will be used, will be well-characterised vectors and that contain only selective markers that are already in routine use in standard cloning vectors. Level of risk effectively zero

The genes of interest inserted into S. aureus or S. epidermidis will be native to the genome of strains and will not present any additional hazard to human health. The antibiotic resistance cassettes used in our experiments will confer resistance to erythromycin and/or chloramphenicol, gentamicin, kanamycin and apramycin. These antibiotics are used to combat a range of bacterial infections in humans. Neither are recommended as a first choice in the treatment of Staphylococcal infections in humans. However, the Erm genes responsible for erythromycin resistance also mediate inducible resistance to clindamycin, which is used in the management of Staphylococcal infections, particularly those of the skin/skin structure. Clindamycin resistant strains are already circulating in the environment and other effective antibiotics are available. Level of risk Medium

It is unlikely that the genetic modification will alter significantly the fundamental properties of the parental micro-organism such as pathogenicity, infectivity, virulence, survivability or host range. Deletion of genes coding for secretion systems and toxins may be expected to reduce virulence as described in:

Anti-bacterial toxins will be overproduced in Staphylococcal strains. These toxins do not target humans or animals but specifically inhibit the growth of other Staphylococci so the modified strains are not expected to be more pathogenic. They may, however potentially outcompete other Staphylococcal strains present in the microbiota. Level of risk Medium

Transfer of genetic material may occur between related microorganisms. However, as stated above, the genes of interest inserted into S. aureus/S. epidermidis will be native to the genome of S. aureus or S. epidermidis (we will not cross-introduce genes). Antibiotic resistant strains are already circulating in the environment. Level of risk Medium

The genetically modified micro-organisms are likely to cause similar effects on human health (and the environment) as the wild type parent. Therefore, the containment measures for the parental micro-organisms (ie Containment Level 2) will be required to reduce the risks to research and
support staff and to the broader environment to an acceptable level. It is extremely unlikely that the genetic modification will alter significantly the fundamental properties of the parental micro-organism such as pathogenicity, infectivity, virulence, survivability, host range and/or response to prophylaxis/treatment. Therefore, additional Containment Level 3 control measures such as sealability for fumigation, HEPA filters on extract air and autoclave within laboratory suite are not merited for the level of risk i.e. not reasonably practicable. Level of risk Medium

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The work is small scale, for research purposes only. The work will be carried out in a laboratory which has been designated as containment 2 compliant and access to the laboratory (CBCB 3.34 and 3.30) and storage area (CBCB 1.09) is limited to personnel who require an authorised swipe-card for entry to the building at all times and the laboratories outside of normal working hours. All personnel will wear suitable PPE (e.g. Howie lab coats and gloves). Effective disinfectants will be made available at all times, namely 70% ethanol and 1% Virkon solutions used following manufacturer’s instructions. Virkon disinfectant contains oxone, potassium peroxomonosulphate, sodium dodecylbenzenesulfonate, sulphamic acid; and inorganic buffers. It is typically used for cleaning up hazardous spills, disinfecting surfaces and soaking equipment. Virkon will be used to decontaminate equipment and work surfaces at completion of work, at the end of the day, and following spills of viable materials. If a spill occurs, cover the spill with paper towels and soak the towels with a 1% Virkon disinfectant. Allow the material to soak for approximately 1 hour before discarding materials in biohazard bag for autoclaving. Bench tops are impervious to water and resistant to solvents, acids, alkalis, and chemicals used for surface decontamination. Skin should be decontaminated immediately when contamination suspected. Procedures will be carried out in such a way as to keep aerosol production to a minimum, for example centrifugation will take place in sealed centrifuge buckets, but there is no requirement for specific measures to control aerosol dissemination.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile.

# Project Additional Information

## Purposes of the contained use

The primary aim of this project is to investigate gene regulation and cell-cell sensing mechanisms in Pseudomonas spp. using molecular genetic tools. In addition, Pseudomonas spp. will be used as prokaryotic models for studying population behaviours such as biofilm formation using targeted mutagenesis by suicide plasmids, random mutagenesis by transposons (using λpir dependent vectors in a disabled Escherichia coli strain as DNA donor) or by labelling cells with fluorescent reporter genes carried on plasmids. The project will involve the construction and analysis of isogenic mutants and chromosomal fusions with reporter genes, such as lux, phoA, gfp, lacZ etc., and cloning of genes and DNA sequences for genetic complementation of mutants or expression of proteins in Pseudomonas spp belonging to other ACDP hazard group 1 and 2 species.

## Recipient or parental organism

The Pseudomonas spp strains used in these experiments have been isolated from a wide variety of sources including historical clinical environments that over the years became well-established laboratory strains. They include ACDP hazard groups 1 (P. fluorescens, P. putida, P. syringae) and ACDP hazard groups 2 (P. aeruginosa). Pseudomonas spp are Gram-negative bacteria commonly found in soil and ground water. It rarely affects healthy people and most community-acquired infections are associated with prolonged contact with contaminated water. Although P. aeruginosa is an opportunistic pathogen (i.e. more likely to infect those patients who are already very sick as opposed to healthy patients), it can cause a wide range of infections, particularly among immunocompromised people (HIV or cancer patients), neonates and...
persons with severe burns, diabetes mellitus or cystic fibrosis. Serious Pseudomonas infections usually occur in people in hospitals and/or with weakened immune systems. Infections of the blood, pneumonia, and infections following surgery can lead to severe illness and death in these people. The most significant potential routes of exposure to Pseudomonas are from direct contact with the bacteria, but other routes of exposure may take place depending on the strain and circumstances. The risks of infection are very low for healthy individuals and infections can be efficiently eradicated by antibiotic therapy.

Host/vector system

A range of vectors will be used to introduce recombinant genes and DNA sequences into Pseudomonas spp once a functional replicon in these organisms has been incorporated into the vector when required.

Non mobilisable: pUCPxx derivatives (e.g. pUCP18) or other vectors Bom-/(Nic-) Mob- and Tra-.

Shuttle vectors: carrying simultaneously dual E. coli (R6K, CoIE1 or p15A) and Pseudomonas or broad host range replicons such as pVS1 derivatives (pME60xx series), pRO1600 derivatives (pUCPxx series, pFLP2, etc.).

Mobilisable Suicide vectors: these plasmids can only replicate in E. coli (e.g. strain S17-1 λpir) but not in Pseudomonas and are used to mobilize plasmids from E. coli into Pseudomonas including R6K derivatives (e.g. pGP704, pRL27, pLM1, pKN501, pDM4, etc.) and CoIE1 derivatives (e.g. pME3087, pME3088, etc.) in order to create chromosomal insertions. The suicide vectors may also contain transposons such as Tn5 (pUT-miniTn5 and derivatives) and Tn7 (pUC18R6KT-mini-Tn7T and derivatives), Tn917 (pTV series) or other of similar nature in order to create insertion mutants. The likelihood of horizontal gene transfers from non-mobilisable is negligible. The likelihood of horizontal gene transfer from the shuttle or mobilisable suicide vectors to non-intended microorganisms outside the laboratory is likely a hazard. However, these vectors are unlikely to be maintained outside the laboratory due to the absence of antibiotic selective pressure or replication-required elements. At worst, the level of risk of the recipient strains should not increase over an equivalent to hazard group 2.

Origin & function

Only genes and DNA sequences from ACDP hazard group 1 and 2 organisms will be cloned into these vectors and housed in Pseudomonas spp ACDP hazard groups 1 and 2 organisms. For example, the quorum sensing systems from other ACDP hazard group 1 and 2 organisms (including Pseudomonas spp) will be cloned into P. aeruginosa or P. putida for mutant complementation or gene function study; DNA partition (parAB) and DNA transportation systems from other bacterial organisms (E. coli) will be introduced into Pseudomonas for DNA manipulation; regulatory genes and their responding promoters such as lacI, ampR, tetR or their homologs from other ACDP hazard group 1 and 2 organisms will be cloned for studying gene regulatory networks. The vectors may contain antibiotic resistance markers (cat, kan, tet, erm) that are already in routine use in standard cloning vectors. The vectors may contain transposons such as Tn5, Tn7, Tn917 or other of similar nature with strong transcriptional terminators in order to create random insertion mutants or targeted chromosomal fusions (e.g. mini-Tn7 with reporter genes insertion in the downstream of PA5548 of P. aeruginosa (Nature Methods 2005, 2:443)). The suicide vectors could also contain reporter genes such as lux, phoA, gfp, lacZ. For the chromosomal deletion/insertion mutants, only antibiotic markers (cat, kan, tet, erm) that are already in routine use in standard cloning vectors will be used. Once a stably genome modified bacterial strain is produced, experiments will depend on the particularly selected genes but will typically involve a panel of phenotype proliferation, biological assays as well as collection of DNA/RNA/Protein for further profiling analysis. The majority of genes and DNA sequences have been described in literatures or in the standard biological parts website (http://parts.igem.org/DNA). Occasionally, novel promoters, aptamers and regulators (such as quorum sensing (QS) genes from other gram-negative bacteria) will also be cloned into Pseudomonas spp.

Evaluation of foreseeable effects

The mutations (such as in-frame deletions, transposon/antibiotic markers insertions) will disable the functions of study genes such as quorum sensing (QS) communication pathways and the reporter fusions are used to study expression activity from native promoters. These are unlikely to increase the level of risk of the resultant strains over an equivalent to hazard group 2. The introduced genes and standard DNA sequences from ACDP hazard group 1 and 2 microorganisms such as isogenic or homologous QS systems or DNA partition systems genes are unlikely to increase the level of risk of the resultant strains over an equivalent to hazard group 2. These genes have no harmful biological activity to produce extra toxins, cytokines or allergens other than native biological elements. Genes such as luxI/R homologs or reporters are under the control of their own promoter or native Pseudomonas promoters and their expression levels are not expected to be above native levels of expression therefore the level of expression of downstream targets are not expected to change. Use of well-characterised vectors for mutagenesis and introduction of genes are unlikely to increase the level of risk of the resultant strains over an equivalent to harzard group 2. It is difficult to envisage how the use of vectors, mutagenesis, chromosomal fusions, or introduced genes described above could enhance the virulence of the Pseudomonas spp. which would not be above hazard group 2.
Only GM micro-organisms will be involved.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Decontamination and autoclaving will be carried out. All waste materials will be disposed of into the autoclave bags for autoclaving or yellow clinical waste bags for professional removal. All bacterial contaminated waste including solid agar plate and liquid broth will be autoclaved before disposal.

a) Decontamination.
Chemgene disinfectant will be routinely used for disinfection. The surfaces of the laboratory bench and the microbiological safety cabinet will be decontaminated with Chemgene after use. Spillages of any GMMs or any of their contaminated products will be disinfected with Chemgene.

b) Autoclaving.
All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. The cycle parameters of 121°C 15psi for 15min will be used. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile.

Risk assessment has been peer reviewed by Newcastle University GMSC and activity class 2 classification agreed. Minor comments received asking for clarification of assessment of inherent environmental risks prior to selection of containment and control measures. This has been addressed by the Principal Investigator

Project Ref  540/20.2
### Project Additional Information

**Purposes of the contained use**

The project specifically aims at identifying novel immune mechanisms to fight bacterial infections and specific bacterial survival strategies.

**Recipient or parental organism**

Salmonella typhimurium and Listeria monocytogenes

**Host/vector system**

Only non-mobilisable or mobilisation-defective low copy vectors will be utilised to produce small amount of proteins. These vectors encode determinants of resistance to ampicillin, chloramphenicol or kanamycin, selective markers that are in routine use. They contain no recognisable harmful sequences. This vector system was previously shown to have no effect on the level of risk to the host.

**Origin & function**

The inserted sequences will be derived from PCR amplification of either genomic DNA or plasmid DNA. Fluorescent proteins will be used as a marker for infected cells and it will in no way contribute to the infection process. Gene manipulation would not confer any survival or reproductive advantage over the wild-type

**Evaluation of foreseeable effects**

The expression of heterologous proteins is not anticipated to alter any pathogenic traits of the host. In general, chromosomal gene manipulation of Salmonella and Listeria will be aimed at inactivating virulence pathways, hence decreasing the ability to infect and not conferring any survival advantage compared to the wild-type. There is a potential risk that genetic alteration of certain genes, such as transcriptional regulators, may result in increased expression of pathogenic traits. The virulence phenotype of bacterial pathogens is usually dependent on the complex regulation and interactions of multiple genes and virulence factors. The risk associated with this scenario will be minimized by evaluating the target regulatory gene roles and its impact on pathogenesis (for instance bioinformatically or by comparison with published data) prior to deletion of the gene. Additionally, Hazard Group 2 control measures already in place would be sufficient to contain the organism. When GM strains will be used for infections, mice will be regularly checked for symptoms (e.g. body temperature, fur, behaviour) to avoid any unnecessary pain.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste materials will be disposed of into autoclave bags, yellow clinical waste bags or sharps bins as required. All pathogen infected waste will be autoclaved before disposal. Food, water and bedding that have been in contact with any animal during the infection trial will be placed in autoclavable bags and sterilized via the standard autoclaving route. Cages used for housing animals will also be sterilized by autoclaving. Deceased, infected animals will be placed in autoclavable bags, frozen and will subsequently be incinerated off site using standard procedures implemented at Newcastle University. All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored using TST (Time, Steam, and Temperature) test strips (Albert Browne Ltd., TST class 6 emulating indicator 121°C for 20 min).

Risk assessment has been peer reviewed by Newcastle University GMSC and activity class 2 classification agreed. GMSC queried use of 70% ethanol and suggested a propriatry one that has been adequately tested on the microorganisms used. Updated to Trigene/Chemgene where appropriate.

#### Purposes of the contained use

This risk assessment covers research projects in our lab utilising bacteria specifically Mycobacterium abscessus for the purpose of facilitating molecular biology procedures such as (i) sub-cloning, DNA sequencing, or site-directed mutagenesis; (ii) construction of chromosomal mutants; (iii) construction of fusions with harmless reporter genes such as GFP or tags such as HA and His; (iv) construction of chromosomal insertions with antibiotic resistance cassettes and their subsequent removal to leave unmarked deletions (v) construction of recombinant plasmids for subsequent purpose of complementing deletion mutants with a wild-type or mutated copy of the gene. The genetically modified strains will be cultured in small to medium quantities for the isolation and analysis. This will involve solid and liquid culture of the strains, centrifugation, extraction of RNA, DNA and protein, microscopy, gel electrophoresis, western blotting, mass spectrometry and immunological studies.

#### Recipient or parental organism

<table>
<thead>
<tr>
<th>Recipient or parental organism</th>
<th>Purpose of the contained use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mycobacteria are non-sporeforming, non-motile, aerobic, Gram-positive, rod-shaped bacilli belonging to the family Mycobacteriaceae. There are over 170 recognised species within the Mycobacterium genus, the majority being environmental organisms isolated from water and soil sources and all sharing the characteristic complex cell wall organisation. The most well-known species is Mycobacterium tuberculosis associated with the human disease TB and has the highest pathogenic potential of the genus. M. abscessus is rapidly-growing non-tuberculosis mycobacteria (NTM), that are particularly associated with the opportunistic infection of vulnerable individuals with respiratory pathologies, e.g. cystic fibrosis and bronchiectasis. M. abscessus is an airborne pathogen but can also cause skin and soft tissue infections. People with open wounds may be at risk for infection by M. abscessus. Rarely, individuals with underlying respiratory conditions or impaired immune systems are at risk of lung infection. PATHOGENICITY: Opportunistic pathogen, environmental organism; able to survive initial innate immune response through resistance towards phagocytosis by host macrophages. Infection of respiratory tissue leads to localized inflammation and granuloma formation by recruited immune cells. Persistence by M. abscessus leads to localized tissue destruction by inflammatory pathways. Tissue necrosis leads to reductions in respiratory capacities of the individual – breathing difficulties, persistent coughing, etc. M. abscessus can also cause skin and soft tissue infections, presenting as cutaneous nodules, pustules and abscesses. M. abscessus can also rarely cause meningitis and cerebral abscesses. EPIDEMIOLOGY: Occurs worldwide, especially prevalent in East Asia however incidence is increasing globally; resistant to wide range of antibiotic classes. HOST RANGE: Primarily humans, can potentially extend to some animals. INFECTIOUS DOSE: Virulence of strains varies greatly. MODE OF TRANSMISSION: Exact mechanism yet to be established; contaminated water sources known to be significant risk factor (i.e. contaminated shower heads).</td>
<td></td>
</tr>
</tbody>
</table>

**Project Additional Information**
either through biofilm formation or aerosolization. Fomites (dust particles) have been implicated in person-to-person transmission between high risk individuals.

**INCUBATION PERIOD:** Ranges from 1-15 days (mean = 5.5 days).

**COMMUNICABILITY:** As long as persistence continues in the infected individual’s respiratory tissues granuloma will remain, and person may be considered infectious and transmissible between vulnerable persons.

**RESERVOIR:** Environmental sources, colonisation of medical devices or surfaces through biofilm formation.

**ZOONOSIS:** Unknown

**VECTORS:** Unknown

**DRUG SUSCEPTIBILITY:** Cell wall physiology and antibiotic resistance genes makes therapeutic treatment via antimicrobials difficult. M. abscessus is thought to be resistant to the following antimicrobials – amoxicillin-clavulanic acid, cefepime, ceftriaxone, ciprofloxacin, doxycycline, imipenem, minocycline, moxifloxacin, tobramycin and trimethoprim-sulfamethoxazole.

Most effective antimicrobials M. abscessus are thought to be the following, clarithromycin, amikacin, cefoxitin and linezolid.

M. abscessus only rarely causes a severe or life threatening disease in a laboratory situation. In particular people who are immunocompromised need to take care and a separate risk assessment may need to be conducted.

M. abscessus is not listed in the HSE approved list of biological agents, however we are self classifying it as HG2 based on the description above. It was previously classified as the same species as M. chelonae. See https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3322061/; M. chelonae is included in the list as HG2.

M. abscessus is also classified as HG2 in the PHE culture collection: see https://www.phe-culturecollections.org.uk/products/bacteria/detail.jsp?refid=NCTC+10882&collection=nctc

**Host/vector system**

pORBIT, pMIND, pMV261. The vectors that will be used, will be well-characterised vectors and that contain only selective markers such as hygromycin and kanamycin that are already in routine use in standard cloning vectors. Only vectors that are non-mobilisable or mobilisation-defective in bacteria as defined in the Compendium of Guidance will be used.

**Origin & function**

The genes of interest inserted into M. abscessus will be native to the genome of strains and will not present any additional hazard to human health. The antibiotic resistance cassettes used in our experiments will confer resistance to hygromycin, kanamycin and/or chloramphenicol. These antibiotics are not recommended as a first choice in the treatment of M. abscessus infections in humans. Multi-drug resistant M. abscessus strains are circulating in the environment and other effective antibiotics are available.

Genes will be expressed from vectors at close to native (chromosomal) level, native promoter sequences will be used and is therefore unlikely that the cloned genes will confer any additional advantage for host colonisation. The toxins we will work on that use the ESX-4 T7SS are proteins that are strongly predicted to target other bacteria and not the host (e.g. cell wall hydrolases) and are therefore unlikely to present any additional risk to human health. GFP is non-toxic and has a long history of safe use – no hazards identified.

**Evaluation of foreseeable effects**

The vectors that will be used, will be well-characterised vectors and that contain only selective markers that are already in routine use in standard cloning vectors. Level of risk effectively zero

The genes of interest inserted into M. abscessus will be native to the genome of strains and will not present any additional hazard to human health. The antibiotic resistance cassettes used in our experiments will confer resistance to chloramphenicol, gentamicin and kanamycin. These antibiotics are used to combat a range of bacterial infections in humans. None are recommended as a first choice in the treatment of M. abscessus infections in humans. Level of risk Low

It is unlikely that the genetic modification will alter significantly the fundamental properties of the parental micro-organism such as pathogenicity, infectivity, virulence, survivability or host range. Deletion of genes coding for secretion systems and toxins may be expected to reduce virulence as described in:

Use of non-mobilisable or mobilisation-defective vectors in the mycobacterial hosts that very limited ability to survive outside the laboratory greatly reduces the likelihood of transfer to related microorganisms. There would be no advantage if a gene encoding an individual component of the T7SS were transferred to a related microorganism because at least six gene products are required to form a functional T7SS (we will not make any constructs that include all of these genes together). If a T7SS toxin were transferred to a related organism it would require that organism to have a T7SS that is sufficiently closely related to M. abscessus that it could recognise and secrete that toxin. This is unlikely because the T7SSs where examined are very specific and where examined are not able to report ‘foreign’ T7 substrates (e.g. Species-specific secretion of ESX-5 type VII substrates is determined by the linker 2 of EccC5. Bunduc CM, Ummels R, Bitter W, Houben ENG. Mol Microbiol. 2020 Jul;114(1):66-76; Identification of a substrate domain that determines system specificity in mycobacterial type VII secretion systems. Phan TH, Ummels R, Bitter W, Houben EN. Sci Rep. 2017 Feb 16;7:42704; EssC is a specificity determinant for Staphylococcus aureus type VII secretion. Jäger F, Kneuper H, Palmer T. Microbiology. 2018 May;164(5):816-820). Level of risk Low

The genetically modified micro-organisms are likely to cause similar effects on human health (and the environment) as the wild type parent. Therefore, the containment measures for the parental micro-organisms (ie Containment Level 2) will be required to reduce the risks to research and support staff and to the broader environment to an acceptable level. It is extremely unlikely that the genetic modification will alter significantly the fundamental properties of the parental micro-organism such as pathogenicity, infectivity, virulence, survivability, host range and/or response to prophylaxis/treatment. Therefore, additional Containment Level 3 control measures such as sealability for fumigation, HEPA filters on extract air and autoclave within laboratory suite are not merited for the level of risk i.e. not reasonably practicable. Level of risk Medium

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The work is small scale, for research purposes only. The work will be carried out in a laboratory which has been designated as containment 2 compliant and access to the laboratory and storage area (Catherine Cookson Building, Floor 2 laboratory 2023 and room 2016B) is limited to personnel who require an authorised swipe-card for entry to the building at all times and the laboratories outside of normal working hours.

All work will be conducted in a class 2 microbiology safety cabinet. All personnel will wear suitable PPE (e.g. Howie lab coats and gloves). A 1:10 dilution of the Distel disinfectant will be made available at all times and used following manufacturer's instructions. Distel will be used to decontaminate equipment and work surfaces at completion of work, at the end of the day, and following spills of viable materials. If a spill occurs, cover the spill with paper towels and soak the towels with a 1:10 dilution of Distel disinfectant. Allow the material to soak for approximately 1 hour before discarding materials in biohazard bag for autoclaving. Skin should be decontaminated immediately when contamination suspected.

Cold Storage (-80ºC, -20ºC and 4ºC) will be in restricted areas and will be suitably labelled (with strain, date and owner) containers.

All flasks and plates will be appropriately labelled (with strain, date and owner) and stored in a dedicated fridge in the CL2 laboratory (room 2023). All flasks and plates will be placed in a secondary container during storage time in the fridge to prevent accidental spill.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All materials used are to be regarded as potentially contaminated and disposed of accordingly to ensure 100% killing. Liquid waste is autoclaving and disposal of via sink disposal routes. Minimum 126ºC degrees for 45 minutes, 10 minutes free-steam. All waste materials will be disposed of into the autoclave bags, or sharps bins as required. Solid waste in autoclave bags and sharps bins are autoclaved before disposal.

a) Disinfection.

Distel laboratory disinfectant will be used for disinfection (https://www.lab-shop.co.uk/downloads/datasheets/382752_TM308%20-%20Specification.pdf). The surfaces of the microbiological safety cabinet will be disinfected with 70 Distel laboratory disinfectant at a 1:10 dilution after use. Laboratory benches will be swabbed with a 1:10 dilution of Distel laboratory disinfectant after any activity.

b) Autoclaving

All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored using TST (Time, Steam, and Temperature) test strips.
The GMSC asked for clarification about the restriction of storage areas and recommended secondary containment for storage of samples. Regarding disinfection the GMSC queried the use of two different disinfectants and recommended Distel used at 1:10 dilution as this is the manufacturer's recommendation. These points have been addressed in the risk assessment and procedures.

Page 8255 of 15326
This project intends to utilise the well characterised ability of Pseudomonas aeruginosa to form a biofilm mode of growth to establish whether bacterial biofilms could be used as a method to transfer proteins for gene therapy usage.

Pseudomonas aeruginosa has been shown to preferentially assume a biofilm mode of growth, embedding itself in a gelatinous organic polymer matrix composed primarily of alginate. There is a lack of understanding of the in situ regulation of biofilm matrix polymer formation nor whether the genetic promoters of the biofilm could be utilised to express non-biofilm genes in a formed biofilm. This project intends to address both aspects.

The contained use activity is required as part of this study involving vectors constructed at the Paterson Institute encoding the algC or the algD gene that encodes the enzyme phosphomannomutase or GDP-mannose dehydrogenase respectively that are both critical enzymes in the formation of the biofilm under the genetic control of the tetracycline response element or their natural promoters driving a non biofilm gene.

In the first experiments we must determine the activity our algC or algD promoter that has been inserted into our non-mobilisable vector. This can only be done in the wild-type strain (PAO1) as we require all the genetic components required for biofilm formation to be intact. Furthermore PAO1 is genetically identical to the delta strains of
P. aeruginosa (PAO1 algC and PAO1 algD) that is also being used in this study. It is hypothesised that when the transformed wild-type P. aeruginosa is grown under conditions that will allow the formation of the biofilm that expression of a non biofilm reporter gene such as B-galactosidase or green fluorescent protein will increase as this will be placed downstream of our algC or algD promoter.

We will then compare this data to that acquired by the transformation of the PAO1 alg C and the PAO1 algD (avirulent defined mutants) with the algC or algD gene under the control of the tetracycline promoter where it is hypothesised that addition of tetracycline to the medium will allow the induction of a biofilm. The final stage of this project will then look at whether the algC or algD promoter can be utilised to drive expression of non-biofilm genes within this tetracycline induced biofilm.

Recipient or parental organism

Pseudomonas aeruginosa strain PA01. The most widely used laboratory stain with complete physical and genetic maps being available and the genome sequenced. The original strain was isolated from a wound in 1955 by B Holloway described in detail in 1969 in Bacteriology Review. The environmental bacterium is a gram negative prototrophic bacteria that like many is an opportunistic human pathogen that causes bacteraemia in burn victims, urinary tract infections in catheterised patients and is the predominant cause of morbidity and mortality in cystic fibrosis patients.

Host/vector system

All vectors are based on non mobilisable vector systems. They will either be pUC, pGEM, pBluescript, pSP (Promega), pPROTet (Clonetech) based vectors.

Origin & function

E. coli - galactosidase gene or Aquea Victoria green fluorescent protein (GFP) under the control of the O, aerygubisa algC or algD promoter that normally promotes the expression of phosphomannomulase or GDP mannose dehydrogenase respectively in the wild type organism.

Evaluation of foreseeable effects

The algC and algD promoters regulate the formation of the P. aerugosa biofilm and so therefore it is foreseen that when the bacteria is grown under conditions to form a biofilm the algC and algD promoters will drive expression of the downstream B-galactosidase for GFP gene.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Animals will not be used in these experiments.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applied for.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, agar plates, cell pellets) are rendered inactive by either autoclaving or disinfection using 1% Virkon and are subsequently incinerated along with clinical waste.

Liquid waste [culture & medium - volumes <51] is disinfected using Virkon at either 2% or 3% for a minimum contact time of 1 hour prior to disposal to sewers.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
Please enter comments on the GM safety committee on the risk assessment

The committee have reviewed the amendments to the risk assessment 02/614 to include the use of Pseudomonas aeruginosa strain PA01 as a host and agree with its conclusions.

Date of Significant Change

Project Additional Information

Purposes of the contained use

To evaluate the effects of activation or inhibition of expression of the Notch and Wnt signalling pathways in mammalian cell lines and mammalian cell lines. Notch and Wnt signalling pathways are highly conserved cell-fate determination pathways, and play a central role, at the cellular level, regulating morphology, proliferation, motility and cell fate. Abnormalities in the components of these pathways are associated with a number of developmental disorders and cancer. Modulating the expression
of the pathways will help to understand the intricacies of the signalling system and understand the effects on cell development and cancer induction. If any of these translated sequences were over expressed, after self inoculation, in a target cell it could possibly result in transformation of that cell. Although this has not been proven, there is a risk factor associated with the production of vectors expressing such sequences.

**Recipient or parental organism**

Adenovirus serotype Ad5-Adenoviridae are classified as ACDP hazard group 2

Lentivirus - Human Immunodeficiency virus (HIV-1) is classified as ACDP hazard group 3

Retrovirus - MuLV based

**Host/vector system**

</tr>
</tbody>
</table>

**Origin & function**

| Reporter genes, including GFP, dsRed, Luciferase, will be used to assess modulation of the notch and wnt pathways in vivo. |
| Genetic material of human, murine, rat and Xenopus origin will elucidate the relative contributions of wnt and notch signalling on the differentiation of mesenchymal stem cells to chondrogenic, dipogenic or osteogenic lineages. |
| Due to the nature of the inserted genetic material (i.e oncogenic) containment level 2 controls and procedures will be employed in this project. |

**Evaluation of foreseeable effects**

The Adenoviral, Retroviral and Lentiviral based vectors are replication incompetent. Thus whilst they pose an infection risk to humans and other species, they are unable to initiate further rounds of replication/infection cycles.

If self-inoculation occurs with adenoviral constructs the chances of seroconversion are minimal due to double deletion of genetic material from replication deficient plasmid. The most likely course of events is that a localised immune response will clear the inoculated pathogen without any chances of further contamination. The retroviral and lentiviral vectors contain no viral genes so are essentially "gutless" shells. The chances of seroconversion are again minimal especially as the retrovirus is a murine pathogen.

The heterologous genes do not encode viral specific proteins, nor do they interfere with the known activities of the virus and as such are unlikely to have an effect upon the basic nature of the recombinant adenovirus and lenti or retrovirus. However since they are oncogenic the appropriate containment level to be used is CL2.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not Applicable
No animals will be used in this project

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid Waste materials (e.g. gloves, plastic ware, agar plates, cell pellets) are rendered inactive by autoclaving and are subsequently incinerated along with clinical waste. Surfaces are disinfected with 1% Virkon solution.

Plastic ware that can be effectively disinfected is treated with 1% Virkon solution for a minimum of 1 hour prior to incineration.

Glassware is treated with 1% Virkon for a minimum of 1 hour prior to cleaning.

Liquid waste (culture & medium - volumes < 5l) is disinfected by the addition of Virkon to give a 1% using Virkon at either 2% or 3% for buffered solutions (i.e. culture media). A minimum contact time of 1 hour is allowed prior to disposal to sewers.

Validation

Autoclaving

The discard autoclave is subject to regular three monthly service and annual validation. Records of service and validation are kept on site.

Disinfectant

For the modified bacteria, Lentivirus/retrovirus/adenovirus, Virkon is routinely used according to the manufactureres (Antek) guidelines. Antek report a 4 log kill for retrovirus at a dilution of 1:2000 i.e. 0.05% after 30 minutes. Our protocols require 2% & 1% Virkon which is excess of the validation concentration.

For bacterial systems we have carried out in-house tests and have shown that Virkon will provide effective kill at a concentration of 1% after 10 minutes contact time. We routinely allow a minimum contact time of 1 hour to ensure complete inactivation.

Project Additional Information

Purposes of the contained use

shRNA technology will be used to reduce the expression of genes of interest in primary murine haemopoietic cells and murine and human haemopoietic cell lines. Lentiviral vectors will be used to deliver the sequences of interest. Targets will be identified through proteomic assessment of proteins involved in stem cell biology and oncogenic transformation of haemopoietic cell lines. An example of such a target is the protein FMIP which is involved in M-CSF signalling.

Recipient or parental organism

Lentivirus parental organism - Human Immunodeficiency virus 1 (HIV-1) is classified as ACDP hazard group 3.

Host/vector system

Bacterial host - Escherichia coli k-12 derivatives (e.g. DH5-alpha).
Plasmid vector - pSuper and Bluescript (Strategene) or similar based vectors which are Bom-, Mob- and Tra-
Viral vectors - Recombinant Lentiviral vectors pseudotyped with VSV-G envelopes will be used in 293T cells.

Origin & function

Origins - genes of interest will arise from studies in primary murine haemopoietic cells and murine and human haemopoietic cell lines.

Genes of interest will be identified using proteomic analysis of stem cell differentiation and the process of transformation by leukaemic oncogenes. Protein profiles will be obtained by Mass Spec analysis of differentiating cells and the consequences of leukaemic oncogene expression on the proteome will be assessed. This will enable the identification of proteins that change during these processes. shRNAi will then be designed to target these genes.

An example of such a target is the protein FMIP which is involved in M-CSF signalling.

It is not intended to target known tumour suppressor genes or genes that could be inferred as such.

The project will be reviewed on a six or twelve month basis, in this regard: the exact frequency being dependent on the progress of this work.

Evaluation of foreseeable effects

The recombinant viral vectors are highly disabled vectors based on the HIV lentivirus. These self inactivating vectors have had regulatory and accessory genes deleted ensuring that viral particles produced in the packaging cells are replication incompetent. Thus whilst they pose an infection risk to humans and other species, they are unable to initiate further rounds of replication/infection cycles. The chances of seroconversion are minimal.

Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability it is thought there is NO significant increase of the likelihood of transfection via airborne routes of exposure. Besides the control measures identified are appropriate to guard against the associated risks.

The target genes do not encode viral specific proteins, nor do they interfere with the known activities of the virus and as such are unlikely to have any effect upon the basic nature of the recombinant lentivirus.

However since they are oncogenic by ACGM definition the appropriate containment level to be used is CL2.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

No animals will be used in this project.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, agar plates, cell pellets are rendered inactive by autoclaving and are subsequently incinerated along with clinical waste. Surfaces are disinfected with 1% Virkon solution.

The GMSC assessed the project as GM Class2.
The following points were highlighted

The recovery of viral particles/DNA by ultracentrifugation should not involve the use of sharps.

The project needs to be reviewed on a 6 or 12 monthly basis, depending on the progress of the work, in the context of reviewing any genes of interest which may be of uncertain function, in case this affects the risk assessment in any way (e.g. unknown tumour suppressor genes)

It was confirmed that the expression of shRNA may block normal self renewal and differentiation. It may also lead to the induction of cell death.

Project Ref 141/06.3

Date Ackn'd 25/05/2017
cu2 project title Expression of Rho GTPases using Retroviral Vectors

Date Project Ceased

Class 2

CultureVolClass2 < 1 litre

Non-GMM

Consent Granted Not Applicable

02/03/2022
Retroviral vector systems will be used to transfect well-studied cell lines either transiently or to establish stable cell lines. The project hopes to elucidate further, the role of Rho GTPases in tumourgenesis.

pLZRS- is derived from the Moloney murine leukaemia virus (MMLV); the env pol sequences being replaced by the LacZ gene; which in turn was replaced with a multiple cloning site, followed by an internal ribosomal entry sequence (IRES) and either neomycin or zeocin resistance gene.

Host/vector system

Bacterial host- Escherichia coli K-12 derivatives (e.g. Dalpha; TOPO 10)
Cell line host - Phoenix Retrovirus producer cells: eco and amphotrophic versions

Origin & function

Genes of interest will be generated by PCR from available plasmids or cDNA libraries. They will be of mammalian origin, including human. Examples include RAS, Raf, Asef.

From a functional perspective RAS is a "worst case scenario" being a known oncogene. Other oncogenes will also be used.

Evaluation of foreseeable effects

The vectors used are disabled vectors based on the Moloney murine leukaemia virus. They are used in conjunction with eco or amphotrophic versions of the Phoenix cell line. The systems used are designed such that viral particles produced in the packaging cell lines are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication. The chances of seroconversion is minimal.

The amphotrophic cell line will produce virus capable of infecting human cells: but not capable of replication. The ecotropic cell line produces virus which are capable of infecting murine cells only: and not capable of initiating further rounds of replication.

It is thought there is no significant increase in the likelihood of transfection via airborne routes of exposure. Besides the control measures identified are appropriate to guard against the associated risks.

The target genes do not encode viral specific proteins, nor do they interfere with the known activities of the virus and as such are unlikely to have any effect upon the basic nature of the recombinant virus.

However since some of the target genes are oncogenic the appropriate containment level to be used is CL2.

We have identified a number of genes that are overexpressed in childhood leukaemias. One of these, a cathepsin, appears to be involved in B-cell differentiation and may be involved in cell adhesion and/or migration. We propose to study this by (i) transducing human leukaemic cell lines with lentiviral vectors (either expression or RNAi) (ii) transducing human haematopoietic cells obtained from cord blood. We hope to show that overexpression of the protein leads to an invasive phenotype in leukaemic cell lines and altered development in HSC's.

Recipient or parental organism

Lentivirus parental organism - Human immunodeficiency virus-1 (HIV-1) is classified as ACDP hazard group 3.

Host/vector system

Bacterial host - BL21 (DE3)pLysS
Plasmid vector - Bluescript plasmids (Stratagene)
Viral vectors - A minimum of a 3-plasmid system will be used. A SIN-lentivector with a pseudotyped VSV-G capsule will be derived using 293T packaging cells.

Origin & function

Origins - gene of interest - The cathepsin, asparaginyl endopeptidase (AEP). This is expressed at various levels during the normal maturation of a lymphoblast and is not oncogenic. The cDNA has been cloned from a human cDNA pool and will be expressed in both its active and inactive forms and shRNA will be synthesised prior to insertion.
The recombinant viral vectors are highly disabled vectors based on the HIV-1 lentivirus. These self-inactivating vectors have had regulatory and accessory genes deleted ensuring viral particles produced in the packaging cells are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication / infection cycles. The probability of seroconversion is minimal. The VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability. It is thought that there is NO significant increase in the likelihood of transfection via the airborne route of exposure. The control measures utilised are appropriate to guard against this eventuality and associated risks. The target gene does not encode viral specific protein, nor does it interfere with known activities of the virus and so is unlikely to have any effect upon the basic nature of the recombinant lentivirus.

Evaluation of foreseeable effects

No animals will be used in this project at this site.

The GMSC assessed the project as GM Class 2.

It was noted that there is considerable experience of using such lentiviral vector systems are already in the Institute. The project needs to be reviewed within 12 months, depending on the progress of the work, to ensure that the risk assessment remains valid.

Responsibility as defined in legislation lies with the Head of of research group. They have managerial control and responsibility for ensuring suitable and sufficient risk assessments are undertaken and that work is conducted in accordance with Institute Codes of Practice, which have been drawn up to ensure compliance with HSE guidance.

Project Additional Information
We wish to investigate the roles of non-cancer cells within tumour. It is already known that these non-carcinoma cells promote tumour growth. We intend to culture the non-cancer cells and modify expression levels of particular candidate genes using lentiviral siRNA and retroviral cDNA expression vectors. This technology will help us elucidate molecular mechanisms by which the non-carcinoma cells promote tumour growth.

Recipient or parental organism

Lentivirus parental organism- Human Immunodeficiency virus-i (HIV-1) is classified as ACDP hazard group 3 Moloney Murine Sarcoma virus (MMSV) parental organism - hazard group 1. Causal agent of sarcoma in mice and rats.

Host/vector system

Bacterial host- E. Coli- XL1O Gold, Stbl3, and DH5 alpha.

VECTORS: PLKO1 siRNA lentiviral vector; pWPI lentiviral cDNA expression vector; pHAGE-CMV-eGFP lentiviral expression vector; PBabe retroviral cDNA expression vectors (puromycin, Zeomycin); pWZL Blast retroviral cDNA expression vector. Retroviral expression vectors MSCV IRES GFP; pLV-tetR1KRAB-red; iDuetl 01 (tetEF. GFP. PGK. hygro) - MI NON-mobilisable. Viral vectors/Host systems- SEE ADDITIONAL SHEET.

Origin & function

Genes of interest are: Human SDF-1/CXCL12 cDNA; human CXCR4 cDNA; human CXCR7 cDNA; humanTGF-beta cDNA; human EphB2 cDNA; human p16INK4A cDNA. The first 4 genes and their gene products play a role in tumour progression and proliferation. EphB2 and p16INK4A play a role in the regulation of cell positioning and proliferation. More detailed functional information for the above are given in appendix 2 of the risk assessment.

Evaluation of foreseeable effects

The recombinant lentiviral vector utilised is a highly disabled vector based on HIV. It is a self-inactivating vector which has had regulatory and accessory genes deleted ensuring that viral particles produced in the packaging cells (HEK 293T) are replication incompetent. Thus whilst they pose an infection risk; in that they can integrate into the chromosome, they are unable to pop-out and initiate further rounds of replication/infection cycles. The probability of seroconversion is thought to be minimal. Whilst the VSG envelope extends the cellular tropism and confers greater environmental survivability, it is thought that there is no increase in the likelihood of transfection via the airborne route of exposure. Besides, the control measures utilised for this work are appropriate to guard against the associated risks. It is worthy of note that the HIV specific envelope protein that targets CD4 T cells is exchanged for the ubiquitous VSV-g (Vesicular stomatis virus C protein), which makes it more visible to the immune system.

The target genes do not encode viral specific proteins, nor are they likely to interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the recombinant lentivirus. Likewise the recombinant Moloney reirovirus used (MMSV) is similarly disabled and is replication incompetent. MMSV is thought to be fragile and has poor environmental survivability capabilities. Again workplace precautions and controls will minimise the likelihood of risk to human health and the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

CU2 Project Title Knockdown of genes in normal haematopoietic and leukemic stem cells.

Class 2

CultureVolClass2 < 1 Litre  
CultureVolumeClass3-4

Non-GMM  
Consent Granted Not Applicable

Project notified under transitional arrangements  
N
Purposes of the contained use

Microarray experiments previously performed have identified a number of candidate genes that may be critical regulators of normal haematopoietic and/or leukemia stem cells (LSC5). This project seeks to evaluate the role of these genes in these cell types in murine and human model systems using genetic knockdown experiments. Briefly, murine or human bone marrow cells will be transduced using lentiviral vectors containing shRNAs and cells will then be functionally evaluated using a combination of in vitro and in vivo techniques, the latter involving transplantation of cells in to mice. Three lentiviral vector systems will be used: (i) pLB, which provides constitutive expression of shRNAs from a Pol III promoter, (ii) pSicoR, which provides constitutive expression of shRNAs from a Pol lII promoter with the option of irreversible Cre-mediated conditional inactivation of knockdown, and (iii) pSL1K, which provides the option of inducible knockdown from a tetracycline-responsive promoter.

Recipient or parental organism

Lentiviral parental organism- Human Immunodeficiency virus-i (HIV-i) is classified as ACDP hazard group 3

Host/vector system

Bacterla host:
Ecoli Stbl 3 (for generating lentiviral system plasmid)
Ecoli DH5 alpha (for all other plasmids)
Lentiviral vector systems:
pLB- see appendix 1 risk assessment
pSicoR- see append ix 1 risk assessment pSLIK-see appendix 3 risk assessment
used with 293 FT cells

Origin & function

Origins- genes of interest- Human
Microarray experiments have identified the genes of interest as candidates for regulation of normal haematopoietic and/or leukaemia stem cells (LSC5).
These include:
Bbx- an HMG-box transcription factor of unknown function
Bmprl- a TGFb family receptor
Transcription factors- Myb; E2f6; Mycn
Cell cycle regulatory proteins Cdkl, 2 and 6
RNA binding protein- Igf2bp3
Chromatin regulatory proteins- Arid2; Cbx 5; Hmgb3; Smarc2 and 5
Evaluation of foreseeable effects

The recombinant viral vector vectors are highly disabled vectors based on the HIV lentivirus. They are self inactivating vectors, which have had regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal (Details of the origins and deletions within the lentiviral constructs are given in appendix 1 and 3 of the risk assessment).

Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is thought there is NO significant increase in the likelihood of transfection via the airborne route of exposure. Control measures utilised are appropriate to guard against the associated risks.

The target genes do not encode viral specific protein, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the recombinant lentivirus.

Knock-down of some of the target genes which are cell cycle inhibitors or tumour suppressors may accentuate oncogenesis. Whilst knock-down of others, which are potential oncogenes, may inhibit oncogenesis.

Whilst the VSV-G envelope confers greater stability and environmental survivability, control measures employed will minimise risks to the environment. These control measures include rendering all solid or liquid waste inactive within the building (either by autoclaving or use of Virkon); work carried out in containment 2 laboratories or Home office inspected animal facilities; work within Class2 microbiological safety cabinets, routine disinfection of work surfaces; all staff are suitably trained in GM work and employing the necessary risk control measures.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Whilst no transgenic mice are generated in this project; transduced cells will be transplanted in to C571 BL6 mice by intravenous injection. This procedure will be carried out by specifically trained staff only.

The Biological Resource unit (BRU) houses all mice in sealed individually ventilated cages. All handling is within cabinets. The rooms are secured with sealed drains and close sealed doors. There are no open ducts within the room. Corridors are sealed with electronically locking flush fitting doors. All corridor risers are sealed. The unit is inspected regularly by Home Office inspectors to ensure that it meets the required standards.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located within the same building. Subsequently the solid waste enters the yellow bag clinical waste route and goes for incineration. The autoclave is performance validated by 12-point thermocouple tests on an annual basis. Records are kept on site.

Virkon is routinely used as per the manufacturer’s recommendations:Solid surfaces are disinfected with 1% Virkon solution. Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning. Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers (as per manufacturer’s recommendation).

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

02/03/2022
A query as to the risk to workers from any free virus whilst administering transduced cells to mice was raised. This is answered in appendix 8 of the risk assessment. The need to refer workers to the Institute GM Code of Practice and the local Virus room Code of Practice was raised. This was subsequently inserted in to section 7 vi and section 9.2 of the risk assessment. The GMSC agreed that it was a GM Class 2 project.

Historical Significant Changes

Transferred from GM141

Project Additional Information
### Purposes of the contained use

The project aims to investigate the biology of human leukaemia stem cells (LSCs) using a xenogeneic murine model system. Briefly, leukaemia is experimentally initiated in mice by infecting primary human bone marrow cells with retroviruses which carry oncogenes that are associated with human leukaemia. The transduced bone marrow cells are then transplanted into irradiated recipient immune deficient mice.

### Recipient or parental organism

Murine Stem Cell Virus (MSCV) viral vector system was derived from the Murine Embryonic Stem Cell Virus (MESV) and the LN retroviral vectors (first described in Hawley et al., (1992) Journal of Experimental Medicine 176:1149). The vectors achieve stable, high-level gene expression in hematopoietic and embryonic stem cells through a specifically designed 5’ long terminal repeat (LTR). This LW is from the murine stem cell PCMV virus, and it differs from the M0MuLV LTR used in other retroviral vectors by several point mutations and a deletion. These changes enhance transcriptional activation and prevent transcriptional suppression in embryonic stem and embryonal carcinoma cells. As a result, the LTR drives high-level constitutive expression of a target gene in stem cells.

### Host/vector system

- **Bacterial host:**
  - E.coli DH5 alpha (for amplifying plasmid stocks)

- **Viral vector system:**
  - MSCV used with Phoenix A and Phoenix GP cells

### Origin & function

- **Origins- genes of interest- Human**
- **Function of genes of interest- oncogenes associated with human leukaemia**
  - A full list of these genes is given in appendix 2 of the risk assessment

### Evaluation of foreseeable effects

The recombinant viral vectors are disabled vectors. They have had regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication! infection cycles. The probability of seroconversion is minimal (Details of the origins and deletions within the MSCV constructs are given in appendix 1 of the risk assessment).

Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is thought there is NO significant increase in the likelihood of transfection via the airborne route of exposure. Control measures utilised are appropriate to guard against the associated risks.

The target genes do not encode viral specific protein, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the virus.

Whilst the VSV-G envelope confers greater stability and environmental survivability, control measures employed will minimise risks to the environment. These control measures include rendering all solid or liquid waste inactive within the building (either by autoclaving or use of Virkon); work carried out in containment 2 laboratories or Home office inspected animal facilities; work within Class2 microbiological safety cabinets, routine disinfection of work surfaces; all staff are suitably trained in GM work and employing the necessary risk control measures.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Transduced cells will be transplanted into immune deficient mice by intravenous injection. This procedure will be carried out by specifically trained staff only.

The Biological Resource unit (BRU) houses all mice in sealed individually ventilated cages. All handling is within cabinets. The rooms are secured with sealed drains and close sealed doors. There are no open ducts within the room. Corridors are sealed with electronically locking flush filling doors. All corridor risers are sealed. The unit is inspected regularly by Home Office inspectors to ensure that it meets the required standards.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located within the same building. Subsequently the solid waste enters the yellow bag clinical waste route and goes for incineration. The autoclave is performance validated by 12-point thermocouple tests on an annual basis. Records are kept on site.

Virkon is routinely used as per the manufacturer’s recommendations: Solid surfaces are disinfected with 1% Virkon solution. Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning.

Liquid waste (culture and medium) is disinfected by the addition of Viricon to give a 1% final working concentration. 2% or 3% solutions of Viricon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers (as per manufacturer’s recommendation).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

A query as to the risk to workers from any free virus whilst administering transduced cells to mice was raised. This is answered in appendix 5 of the risk assessment.

The need to refer workers to the Institute GM Code of Practice and the local Virus room Code of Practice was raised. This was subsequently inserted in to appendix 6 of the risk assessment.

The GMSC agreed that it was a GM Class 2 project.

Project Ref 141/08.3
Recombinant Lentiviruses will be used to express genes involved in stress signalling pathways in primary mouse cells and mammalian cell lines. The gene products may be involved in signal transduction eg p38MAPK and JNK, or downstream target genes eg the dusp family of dual-specificity phosphatases. We will not use Lentiviruses to express genes that we could reasonably predict to have potentially harmful effects in humans eg oncogenes and pro-inflammatory cytokines.

The transduced primary mouse cells will be transplanted into mice and investigated in in vitro systems. Mouse, mouse primary cells and mammalian cell line responses to environmental stresses (e.g. chemotherapeutic agents) will be evaluated.

Recipient or parental organism

Lentiviral parental organism- Human Immunodeficiency virus-I (HIV-1) is classified as ACDP hazard groups

Host/vector system

Lentiviral vector System:
- pCMV-VSVG
- pMDL9/RRE
- pRSV-REV
- pRRL

Host : HEK 293 cells

Origin & function

cDNA5 encoding:
- p38 MAPKalpha, JNK1, JNK2, ERK1, ERK2
duspi, dusp4, dusp8, duspl0
- pten
These genes are signal transduction components, either kinases or phosphatises.
The origins of these genes are murine and human

Evaluation of foreseeable effects

The recombinant viral vector vectors are highly disabled vectors based on the -(IV lentivirus. They are self inactivating vectors, which have had regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication? infection cycles. The probability of ser000nversion is minimal

Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is thought there is NO significant increase in the likelihood of transfection via the airborne route of exposure. Control measures utilised are appropriate to guard against the associated risks.
The target genes do not encode viral specific protein, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the recombinant lentivirus.

The GMSC agreed that this was a GM Class2 project. They asked that the COSHI-I assessment be completed for the use of cell lines in this body of work. This has been done and is enclosed.
