(1.19) The bacterial strains used are attenuated, non-colonising strains so are incapable of causing human infection and are therefore harmless to humans.

The viral vector to be used will be pseudotyped with the envelope protein VSV-G from Vesicular Stomatitis Virus. So, if introduced into the body by injection, ingestion or through a wound, the virus could enter human cells and integrate into cellular DNA. Although the virus is replication incompetent (does not carry gag, pol or env genes), so it cannot make new progeny virus and establish a productive infection, its insertion into cellular DNA could result in a potentially oncogenic mutation.

The recipient cells are harmless to humans.

----------------------------------------------------------------------------------------------------------------------------------------------------------------

(1.20) The bacterial strains used are attenuated, non-colonising strains that cannot survive outside culture conditions and are therefore harmless to the environment.

The viral vectors and plasmid vectors are replication incompetent so therefore can not self-replicate and transfer to another host so are harmless to the environment.

The cells that will eventually receive and integrate the viral or plasmid DNA cannot survive in the outside environment as they are only viable under culture conditions and therefore are harmless to the environment.

**Host/vector system**

GMM/1: lines 1.12, 1.24

(1.12) Lentiviral vectors: Commercial TZV vector from Tranzyme and derivatives (including pGIPZ).

The plasmid vector to be used are based on well-established, standard laboratory cloning and expression vectors (pCDNA3.1, pClneo, pGEM, pCAβ, pCAβ-IRESGFP). These contain either CMV or beta-actin promoters which are active in mammalian cells. The plasmids are not mobilizable.

---------------------------------------------------------------------------------------------------------------------------------------------------------------

(1.24) The viral vector used is a lentiviral vector that contains the CMV (Pol II) promoter to drive expression of the hairpin cassette. The lentiviral vector does not contain the appropriate accessory elements to form a viral particle itself and therefore poses no harm to health and the environment. Packaging and envelope proteins are contained on two additional plasmids to the lentiviral expression vector and these plasmids must be introduced into the cell and expressed alongside the lentiviral vector for viable lentiviral particles to be produced.

The standard plasmid vectors are not replication competent in mammalian cells. They replicate in host bacteria, but do not express cDNAs in bacteria. Expression of cDNAs occurs only in mammalian cells, under promoters such as CMV, beta-actin or SV40. Plasmids cannot be transmitted from cell to cell and therefore do not represent harmful potential for the environment.
The RNAi hairpins are sequences that have been derived de novo and are not from an organism. They have been designed as small sequences with both a sense, antisense and loop sequence to form RNA hairpin when transcribed which will initiate a downstream cascade of events leading to knockdown of the target gene to which the hairpin was designed.

The cDNAs will be derived from the human or mouse genome and obtained as IMAGE clones or likewise. The accessory proteins are from the HIV-1 virus.

The hairpin sequences will be transcribed and the RNA will then form a hairpin structure. The hairpin structure will induce a normal cellular in vivo downstream sequence of processing events in response to foreign cellular single-stranded RNA intruder molecules that will result in the post-transcriptional down regulation of the gene to which the hairpin sequence is targeted.

The cDNAs will be expressed from viral promoters, or plasmid-derived promoters (e.g. CMV, SV40).

Although we cannot know the exact cDNAs to be used yet, we can expect that they will reflect genes involved in cell signalling and growth control and as such may be growth factors or proto-oncogenes.

If the inserted sequence were to be expressed in humans after accidental transfer the hairpin could lead to the down-regulation of a gene to which it targets cia RNAi interference. This could be a gene essential for growth regulation such as a tumour suppressor gene, therefore resulting in a potentially oncogenic change. This, however would not be severe as the virus is replication incompetent and therefore self-inactivating as none of the structural genes are actually present in the packaged viral genome so no new virus can be produced and no other cells can be infected. Physical insertion of the virus into the genome of the host cell could also potentially disrupt a tumour suppressor or oncogene, however the likelihood of this is very low.

Expression of cDNAs in human cells might induce a growth advantage on those cells. However, this is unlikely to cause significant, harmful effects as very few cells would be affected and the cDNAs used are not expected to have strong oncogenic potential.

VSV-G pseudotyped lentivirus can infect mammalian cells. Potentially the hairpin could be expressed in another mammalian species and lead to the down-regulation of a growth regulatory gene such as a tumour suppressor gene resulting in a potentially oncogenic mutation. This, however, is extremely unlikely as the hairpin is targeted to human genes and many hairpins are not homologous with the genes from other species. If the hairpin were to target and lead to the reduction of a gene via RNA interference it would not be severe as the virus is replication incompetent and therefore self-inactivating as none of the structural genes are actually present in the packaged viral genome so no new virus can be produced and no other cells can be infected.

If the cDNA-containing virus gained access to other animals, it could be expressed in another mammalian species and lead to the down-regulation of a growth regulatory gene such as a tumour suppressor gene resulting in a potentially oncogenic mutation. However, it is very unlikely that the cDNAs would gain access to another species and the viruses are non-replicative.

The envelope protein is VSV-G from the Vesticular Stomatitis Virus so, if introduced into the body by injection, ingestion or through a wound, the virus could potentially enter cells and integrate into cellular DNA. Although the virus is replication incompetent (does not carry gag, pol or env genes), so it cannot make new progeny virus and
establish a productive infections, its physical insertion into cellular DNA could result in a potentially oncogenic mutation. This would be a very unlikely event and if so only a very small number of cells and would not impact on the pathogenic outcome of an exogenous viral infection. The packaging viral components are from the HIV-1 virus. The full length HIV-1 virus is harmful to humans, however the packaging vector used does not contain the full length HIV-1 molecule. Many components of HIV-1, that are critical for HIV-1 infection but not required for viral packaging, have been removed so the virus is attenuated.

The de novo hairpin donor sequences could potentially be expressed in cells and lead to the knockdown of certain genes leading to the increase of oncogenic potential of the virus. Similarly the cDNAs may have weak oncogenic potential. This would, however, only affect a very small number of infected cells and as the virus is replication incompetent and cannot make new viral progeny, it would no impact on the pathogenic outcome of an exogenous viral infection.

Evaluation of foreseeable effects

GMM/1: lines 1.17, 1.18, 1.32

(1.17) The envelope protein is VSV-G from the Vesticular Stomatitis Virus so, if introduced into the body by injection, ingestion or through a wound, the virus could potentially enter cells and integrate into cellular DNA. Although the virus is replication incompetent (does not carry gag, pol or env genes), so it cannot make new progeny virus and establish a productive infection, its physical insertion into cellular DNA could result in a potentially oncogenic mutation. This would be a very unlikely event and if so only a very small number of cells and would not impact on the pathogenic outcome of an exogenous viral infection. Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GMM/1: line 1.29 or GMM/2: lines 2.13 (as applicable)

2.13 WASTE Management
Describe the waste management measures which you will apply to the activity. Include:
1. The treatment method,
2. Degree of kill,
3. Proposed process testing/monitoring measures to ensure this degree of kill will be achieved,
4. Ultimate form and packaging for removal from the department.

Note that for activity class 2 and 3 GMMs, the organisms must be inactivated by a validated method in the laboratory suite.

The wording is taken from HSE notification form CU2 section 12. This information must be supplied to the HSE when notifying a project.

1. 2.5% Trigene advance or Virkon (v/v) will be used to treat liquid viral waste (at least 18 hours) and also any spills and for disinfection of equipment and laboratory materials used. Work surfaces will be wiped down with 5% Trigene advance and 70% ethanol or IMS after use. Clorox will be used to treat liquid bacterial waste overnight.
2. 100%

3. Virkon and Trigen advance are certified by the PHLS to provide 100% viricidal kill under these conditions. Clorox provides 100% bacterial kill. Additionally Trigene, Clorox and Virkon will be used with their lifespan to ensure effectiveness. Autoclave runs are regularly validated by waste management staff.

4. Solid waste will be double-bagged in biological waste bags and then autoclaved 132°C for 15 mins then bagged in yellow biohazard bags and removed by UCL waste services

**Project Ref** 14/13.2

- **Date Ackn'd**: 29/04/2013
- **CU2 Project Title**: Differentiation and function of haematopoietic cells and lymphocytes
- **Class**: Non-GMM
- **Consent Granted**: Consent Granted

---

**Date Project Ceased**: 02/03/2022
**Project Additional Information**

**Purposes of the contained use**

In this project we aim to investigate the molecular regulation of T-cell and erythrocyte differentiation. In particular we will focus on the Hedgehog, Bone Morphogenetic Protein and Notch signalling pathways. We will ask how these signalling pathways influence lymphocyte, myeloid and erythroid differentiation, by over-expressing or knocking-down components of the pathway in lymphocytes, erythroblasts, myeloid cells and their progenitors in cell culture, and measuring impact on function, differentiation, survival and cell cycle progression.

**Recipient or parental organism**

Lentivirus eg. HIV-derived lentiviruses, prepared in 293 cells Human and mouse haematopoietic progenitor cells, lymphocytes, erythroblasts, thymic epithelial cells, and cell lines.

The recipient organisms are not harmful to humans and are not capable of surviving in the environment.

**Host/vector system**

HIV-derived lentiviruses, prepared in 293 cells: eg. pLentiLox3.7 (pPLL) encoding eGFP with IRES, packaged in 293 T cells, with packaging proteins on separate plasmids (pMDL, pRev, pENV (vSVG)). This system is described in Rubinson et al, Nat Genet. 2003.

In some instances we may also use commercially available lentiviral supernatants.

The lentiviral vectors used are multi-attenuated, meaning they are devoid of all potentially pathogenic encoded functions. In addition they are replication-defective which means that the vector cannot multiply on its own unless supplied by certain proteins in trans. It is self-inactivating which means that the viral promoter in the U3 region of the 5' LTR has been disabled by genetic manipulation. Only a very unlikely event of multiple recombinations during the process of generation of the viral vector can expose the person to a wild type HIV-1. The possibility of such an event is extremely low.

**Origin & function**

Human and mouse sequences

Lentiviruses - can infect human cells.

Puro and Neo - antibiotic resistance genes

The gene products of interest that we insert may modify the differentiation status, signalling capacity or cell cycle status of cells in which they are expressed. The fluorescent markers should have no functional impact on the cells in which they are expressed.
It is unlikely, but possible that knocking-down some of the genes of interest, or over-expressing others, might be oncogenic in human tissue, or contribute to oncogenic transformation if expressed in cells with other mutations.

The risk of transfer to species in the environment is negligible.

The lentiviruses are HIV-derived, but are replication-deficient, therefore represent a low risk.

The inserted genetic material has not been implicated in pathological characteristics of donor organism.

**Evaluation of foreseeable effects**

The lentiviruses are HIV-derived, but are replication-deficient, therefore represent a low risk.

The inserted genetic material has not been implicated in pathological characteristics of donor organism.

Only a very unlikely event of multiple recombinations during the process of generation of the viral vector can expose the person to a wild type virus. The probability of such an event is extremely low. The most hazardous GMM are the lentivector viruses and the most hazardous step is dealing with concentrated viral stocks before infecting the target cells.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All GMMs are inactivated for disposal using standard biosafety level 2 procedures. Briefly, liquid and solid wastes are treated with either PRESEPT effervescent disinfecting tablets (2.5g) Trigene, or 0.1% Virkon. Work surfaces are decontaminated on completion of work or at the end of the day and after any spill or splash of viable material with disinfectants that are effective against the agents of concern. Virkon and Trigene have been shown to achieve 100% GMO kill when used as directed. Klercide and 70% ethanol are routinely used which have been shown to be 100% effective in tissue-culture related decontamination. Waste will be double-bagged in biological waste bags, sealed, autoclaved and then removed by waste services. Autoclaving will be at 121 degrees centigrade/15 pounds per square inch/for 15 minutes. This range is used to kill all pathogens and spores strips of the Bacillus stearothermophilus are used as indicators of the process. Expected kill: 100%. Tissue culture medium containing viral supernatant will be treated with 0.1% Virkon for at least 10 minutes prior to sealing for autoclaving as described.

Work surfaces are decontaminated on completion of work or at the end of the day and after any spill or splash of viable material with disinfectants that are effective against the agents of concern.

All cultures, stocks, and other regulated wastes are decontaminated with detergent before disposal by an approved decontamination method such as autoclaving. Materials to be decontaminated outside of the immediate laboratory are placed in a durable, leakproof container and closed for transport from the laboratory. Materials to be disposed of off-site from the facility are detergent-treated and autoclaved prior to packaging in accordance with applicable local, state, and government regulations, before removal from the facility. Autoclaving will be at 121 degrees centigrade/15 pounds per square inch/for 15 minutes. This range is used to kill all pathogens and spores strips of the Bacillus stearothermophilus are used as indicators of the process. Expected kill: 100%
The UCL Genetic Modification Safety Committee has approved your experiment entitled Differentiation and function of haematopoietic cells and lymphocytes, as an Activity Class 2, Containment Level 2 project.

2022/03/02
Varicella-zoster virus (VZV) infection is manifested as a vesicular rash and its replication in skin is central to the natural history. We aim to:

1. Study in detail the effect of VZV replication on keratinocytes and epidermal differentiation
2. Investigate the effect of epidermal differentiation on the replication of VZV and other alpha herpesviruses e.g. HSV1
3. Identify residues in the live attenuated VZV vaccine responsible for reversion of the vaccine back to a virulent wildtype phenotype.

This will be achieved by

1. Silencing/overexpressing human proteins of interest using lentiviruses
2. Introducing reporter cassettes into a VZV BAC to follow viral replication and cloning individual viral Open Reading Frames (ORFs) into a viral vector system.
3. Introducing single base changes by site directed mutagenesis in genes that have been identified as attenuating by deep sequencing of the live attenuated Oka Varicella-zoster vaccine virus, the wild type virus from which it is derived and other clinically derived samples.

The effect of the above will then be assessed in keratinocyte monolayers and 3-D skin models.

Recipient or parental organism

Top10 F' containing fragments of VZV DNA from a subcloning vector
SW102 containing VZV BAC;
SW102 containing VZV BAC modified with galK or kanSacB
pLNCX2 containing VZV ORFs
Common disabled E Coli K12 or B derivatives

Transfection of the VZV BAC DNA extracted from the recipient organism into permissive cell-lines will result in the production of VZV. VZV and HSV1 infect humans but cause a mild disease and most humans are exposed during childhood. Reactivation of VZV results in the development of herpes-zoster (Shingles) and HSV-1 reactivation results in cold sores. Complications can arise from infection of pregnant women. All DNA work will be carried out using the Oka parental wildtype virus genome bacterial artificial chromosome (BAC) cultivated in non-pathogenic SW102 E.coli. The donated sequences from shuttle vectors pGALK or pKANSACB have a history of safe use.

Introduction of modified VZV sequences into the BAC, by expression of the lamda prophage, within the non-pathogenic SW102 E.coli is not expected to alter the pathogenicity of the SW102 strain.

SW102 and Top10f'strains of E.coli have been modified such that it will only grow under laboratory conditions.

Herpesvirus particles are capable of survival in the environment. However, in environmental tests evidence has been presented that after 30 min at room temperature infectious VZV particles survival ranged from 0.1 to 19% depending on the surface tested (Levin et al Journal of clinical microbiology, Vol. 19, No. 6p. 880-883)

Host/vector system

Derivatives of pBR322
Commercially available vector used to subclone fragments of the VZV genome that will be modified by site directed mutagenesis e.g. Topo vectors
pgalK- available shuttle vector used to direct mutagenesis of BAC
pKanSACB- available shuttle vector used to direct mutagenesis of BAC
Commercially available vectors e.g. pLNCX2 (Clontech) will be used to express individual VZV ORFs.
Lentivectors and gammaretroviral vectors pLNCX2 (Clontech), CMV intron (MLV packaging plasmid from Cosset lab), VSVg
Introduction of point mutations using a site-directed mutagenesis approach will utilise plasmids containing fragments of the VZV genome to be mutated. The fragments of VZV DNA will not be able to be expressed in humans as the vectors used will not contain eukaryotic promoters. These plasmids therefore pose a low risk to workers.

PCR products amplified from pgalK or pKANSCAB contain genes under the expression of prokaryotic promoters. The genes (galK or kanamycin/SACB fusion) in these intermediate products are only capable of being expressed by bacteria and therefore pose low risk to human workers.

Introduction of mutagenic sequences into the VZV genome will be carried out in bacterial strain SW102 This strain is derived from DY380 and contains a lambda prophage recombinering system(http://web.ncifcrf.gov/research/brb/recombineeringInformation.aspx). The SW102 strain has been modified such that the SW102 bacteria will only survive under laboratory growth conditions. These cells therefore pose a low risk to workers.

Varicella Zoster Virus, HIV, MMLV, VSV, HSV1, human

PCR products used in the mutagenesis of the BAC amplified from the shuttle vectors pgalK, pKanSACB or pTopo do not contain eukaryotic promoter sequences and therefore are not expected to have biological activity in human tissue. PCR products amplified from pgalK or pKanSACB and successfully introduced into the BAC are however expected to allow the SW102 bacteria to grow under restricted growth conditions e.g minimal media + galactose (pGalk) or in the presence of kanamycin (pKanSACB). In addition PCR products amplified from pKanSACB are expected to make the bacteria sensitive to the presence of sucrose in growth medium.

VZV recovered from the modified BAC will be expected to maintain biological activity in Mewo cells but it is expected that introduction of the mutations will result in attenuation of the virus in explant culture or keratinocyte cell-lines.

Function of the individual Viral ORFs are varied from viral transactivators to glycoproteins. Human genes cloned will be involved in the process of epidermal differentiation, either as part of the epidermal structure e.g. cytokeratins, signalling pathway e.g. NOTCH, wnt etc or enzymes e.g. kallikreins.

Expression of BAC virus DNA in humans could result in the synthesis of infectious virus particles. Approximately 90% of the population has significant immunity to VZV and the infectious dose required to successfully initiate infection is thought to be high. It is therefore likely that accidental transfer of the virus would be successfully contained by host cell immunity.

The human and individual viral ORF inserts may cause a local immune reaction (skin, draining lymph node), with redness and swelling.

Humans are the only species that VZV can infect.

In susceptible individuals Varicella Zoster virus (VZV) is the causative agent of the acute infection Varicella (Chicken-pox). Reactivation of VZV results in the development of herpes-zoster (Shingles). Complications due to VZV infections are rare but can arise in adults, particularly pregnant women and immunosuppressed individuals. HSV1 is the causative agent of genital herpes and cold sores, complications occur in rare events, can carry risks for pregnant women and foetus.

In this project, regions of VZV DNA will be amplified from the complete VZV genome using PCR and cloned into the commercially available pTOPO vector. These fragments of DNA by themselves will not be pathogenic to humans. The DNA fragments are also not expected to alter the pathogenicity of the Top10F' E.coli harbouring the vector.

The lentivectors and gammaretroviral vectors are deleted for all coding sequences and are replication defective. The other viral sequences encode envelope proteins which are not pathogenic. Top10 F are a non-pathogenic strain of E.coli.
In susceptible individuals Varicella Zoster virus (VZV) is the causative agent of the acute infection Varicella (Chicken-pox). Reactivation of VZV results in the development of herpes-zoster (Shingles). Complications due to VZV infections are rare but can arise in adults, particularly pregnant women and immunosuppressed individuals. The lentivectors and gammaretroviral vectors are deleted for all coding sequences and are replication defective. The other viral sequences encode envelope proteins which are not pathogenic. Top10 F are a non-pathogenic strain of E.coli.

The most hazardous step in the procedure is the subsequent production of relatively large quantities of infectious VZV particles following recovery of GM-virus from the BAC by transfection of DNA into the permissive cell-culture line. Human infection via inhalation is considered the most significant hazard to laboratory workers.

**Evaluation of foreseeable effects**

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Bacterial waste will be disinfected prior to disposal and solid waste autoclaved.

The treatment of waste this way will result in 100% kill of all micro-organisms used in this project.

Class II microbiological safety cabinets will be wiped down with trigene/distel (1:200) or absolute ethanol after work completed.

Liquid and solid waste will be treated with trigene/distel (1:200). Tissue culture plastics will be double bagged and autoclaved according to departmental guidelines, sharps e.g needles will be disposed of within a sharps bin and sent for incineration.

The treatment of waste by disinfection and incineration will be effective at killing 100% of VZV. In environmental tests VZV particles survival ranged from 0.1 to 19%, after 30 min at room temperature, depending on the surface tested (Levin et al Journal of clinical microbiology, Vol. 19, No. 6p. 880-883). VZV will not therefore survive disinfection, which will remove the virus envelope required for infection and incineration.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

The project was approved by the GMSC as AC2 following a number of minor amendments/clarifications.
The purpose of this project is to elucidate the precise molecular mechanisms how crosslinking of several members of TNF-R superfamily an IL-1R/TLR superfamily trigger various signalling pathways, i.e. activation of NF-κB, MAPKs or induction of cell death. In order to gain precise knowledge in the molecular mechanism employed by cells, we will use three basic approaches that will employ the use of replication-defective viral vectors. First, we will use retroviral MSCV based vectors to express proteins of interest containing immunoaffinity tag, enabling isolation of these proteins from cells. We will then use mass-spec to analyse the
molecular modification and protein composition of signalling complexes isolated from cells upon TNF-R superfamily or IL-1R/TLR superfamily stimulation. The advantage of using this approach is that we will be able to express our tagged protein at nearly physiological level and thus we will be able to study the physiological composition of signalling complexes triggered upon TNF-R superfamily an IL-1R/TLR superfamily stimulation.

Second, we will isolate mouse embryonic fibroblasts (MEFs) from mice deficient in the proteins of interest. The generation of knockout mice and isolation of MEFs cells does not involve viral vectors and thus is not described in this project risk assessment. The MEFs will be immortalised with large T antigen using lentiviral infection. This approach will enable us to study the signalling in the cells derived from various mouse strains.

Third, we will use lentiviral based vectors to introduce shRNA sequences that will target the mRNA of proteins of interest in cell lines. This will enable us to study the role of the proteins of interest in physiological settings.

This project requires production of viruses that can potentially infect human cells. However, all viruses used in this project will be replication-defective and therefore once the target cells are infected by virus, they will not produce new viral particles. Thus the critical part of this project is viral production and cell infection that must be carefully planned and monitored.

This project was previously performed under the licence from Imperial College London and transferred to UCL in February 2013.

Recipient or parental organism

Retroviral particles will be produced in Phoenix-Ampho (human cell lines) and Phoenix-Eco (mouse cell lines). Phoenix cells are based on the 293T cell line expressing gag-pol and envelope proteins.

Lentiviral particles will be produced in Hek293T.

Recipient human cell lines will be K562, U937, THP1, A549, HepG2 and Jurkat

Recipient mouse cells will be mouse embryonic fibroblasts

The produced viral particles are potentially pathogenic, as they can infect human tissues. However, the produced viral particles are replication defective and thus cannot propagate upon infection. Furthermore, viral particles are highly unstable and are quickly inactivated in cell culture. The most dangerous viral particles produced will be the lentiviral particles containing large-T sequence, that is potentially oncogenic.

The intended target cell lines are not pathogenic and are not able to survive outside the laboratory environment. Upon infection with replication-defective viruses, the target cell lines will not be able to create new viral particles. Some of the recipient cell lines used in this study are immortalized. Accidental infection or inhalation or exposure to wounds could enable these cells to enter the bloodstream or airway and lungs of the operator and this could subsequently lead to potential harmful effect. It is very unlikely that used cell lines will be able to survive in the recipient as these cells will be recognised and disposed of by the immune system.

Host/vector system

For retroviral infections we will use MSCV containing a multiple cloning site followed by IRES and EGFP sequence, enabling selection of cells that have been infected as GFP positive:

MSCV containing IRES-EGFP (Clontech)

For lentiviral infections we will use following constructs:

pMD2G (Tronolab) … Envelope Plasmid for Virus Production in Combination with psPAX2
psPAX2 (Tronolab) … Packaging Plasmid for Virus Production in Combination with pMD2G
pFU-large T vector (kindly provided by John Silke)
… vector containing the sequence of large T that will be transported to the target cell line
For lentiviral expression of shRNA the vector used will be pLKO.1 from Sigma, together with pMD2G and
psPAX2
Neither retroviral (MSCV) nor lentiviral (pFU) vectors containing the sequence of genes of interest
can be transcribed in prokaryotic cells. These vectors do not contain sequences coding accessory
proteins and thus could not form viral particles on their own and do not possess any danger to health or
environment.
In order to produce viral particles, the retroviral vectors must be transfected to Phoenix cell lines that
were previously stably transfected by other two different proteins encoding accessory proteins.
In order to produce lentiviral particles additional two vectors (pMD2G and psPAX2) must be
transfected to HEK293T alongside with pFU-large T or pLKO.1 vectors.

Origin & function

The sequences of genes that will be used in this study are derived from mRNA sequences expressed
in human and mouse tissues.
The sequences of shRNA will be obtained from Sigma together with the expression plasmids.
In this project we will be expressing gene sequences coding several proteins involved in signal
propagation upon TNF-R superfamily an IL-1R/TLR superfamily triggering:
FADD is adaptor linking certain members of TNF-R superfamily an IL-1R/TLR superfamily receptors
to downstream signalling pathway. It functions as an adaptor protein.
Caspase-8 is enzyme involved in initiation of apoptotic cell death upon certain types of stimulation.
RIP1, RIP3 are kinases that mediate activation of certain signalling pathways.
HOIP, HOIL-1, Sharpin are subunits of linear ubiquitin chain assembly complex, that is responsible
TRAIL-R1, TRAIL-R2 and CD95 are members of TNF-R superfamily.
The retroviruses produced in Phoenix-Ampho and lentiviruses are potentially able to infect human
cells. Both lentiviral and retroviral particles are not able to propagate upon infection, thus even after
accidental infection of human cells they will not be able to replicate and infect other cells in the body.
However, there is a risk that upon integration to human cells the viral delivered sequences would be
integrated in genome and this could somehow induce tumorigenic transformation of infected cells. Albeit
unlikely, this danger is common to all retroviruses and lentiviruses used in research and special
measures must be taken so such a situation would not happen.
The intended sequences encode proteins that are not known to be oncogenic, with the exception of
large T antigen that will be used for immortalisation of mouse embryonic fibroblasts.
Since the viruses upon infection are not able to propagate and the genes analysed are derived from
mouse and human genes, it is unlikely that expression of these sequences would cause any harm to
other species in environment. Furthermore, the virus particles are highly unstable outside the laboratory
environment.
The cell lines used for viral production are not pathogenic on their own and they are not able to
survive outside the laboratory environment. However, it should be noted that the cell lines used in this
study are immortalized. Accidental injection or inhalation or exposure to wounds could enable these cells
to enter the bloodstream or airway and lungs of the operator and this could subsequently lead to potential
harmful effect. It is very unlikely that used cell lines will be able to survive in the recipient as these cells
will be recognised and disposed of by the immune system.
Special care should be taken during the production of viral particles. As described in section 1.15 the retroviruses produced in Phoenix-Ampho and lentiviruses are potentially capable of infecting human cells. Thus direct exposure of operator to the viral containing supernatant or to the suspension of virus producing cells can lead to potential infection. This danger is even increased when the virus containing supernatant or virus producing cells would be injected in the bloodstream of operator by sharps or if exposed to open wounds or if inhaled. To minimise this danger, no sharps will be allowed and protective coat and gloves will be worn. All work will be carried in class II cabinet.

Evaluation of foreseeable effects

The cell lines used for viral production are not pathogenic on their own and they are not able to survive outside the laboratory environment. However, it should be noted that the cell lines used in this study are immortalized. Accidental injection or inhalation or exposure to wounds could enable these cells to enter the bloodstream or airway and lungs of the operator and this could subsequently lead to potential harmful effect. It is very unlikely that used cell lines will be able to survive in the recipient as these cells will be recognised and disposed of by the immune system.

Special care should be taken during the production of viral particles. As described in section 1.15 the retroviruses produced in Phoenix-Ampho and lentiviruses are potentially capable of infecting human cells. Thus direct exposure of operator to the viral containing supernatant or to the suspension of virus producing cells can lead to potential infection. This danger is even increased when the virus containing supernatant or virus producing cells would be injected in the bloodstream of operator by sharps or if exposed to open wounds or if inhaled. To minimise this danger, no sharps will be allowed and protective coat and gloves will be worn. All work will be carried in class II cabinet.

The most hazardous step is production of viral particles, that can potentially infect dividing (in case of retroviruses) or both dividing and non-dividing (in case of lentiviruses) human cells. Upon accidental infection of human cells the viruses can no longer divide and thus the cells will not propagate the infection further.

If an accidental infection of human manipulator would occur, two risks are emerging. First, just by introducing the viral sequence in human DNA can promote oncogenic mutation. Second, the expression of target sequences can lead to some modification of cells that can be oncogenic. All sequences used in this study are however non-oncogenic, with the notable exception of mouse large T antigen used for mouse embryonic fibroblast immortalisation.

Thus the most hazardous procedure employed in this project is the production of lentiviruses that will transduce large T antigen to target cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1. The treatment method
   All liquid waste will be incubated overnight in the presence of 5% Trigene advance. Any spills will treated with 5% Trigene advance. Work surfaces will be cleaned with 1% Trigene advance followed by 70% ethanol. Laboratory equipment will be decontaminated with 1% Trigene advance followed by 70% ethanol. All solid waste will autoclaved at 134 °C for 30 minutes.
2. Degree of kill
The degree of kill is expected to be 100%. According to our supplier of Trigene Advance (also manufactured under new commercial name Distel) StarLab this compound at 1% concentration is highly active virucidal agent. The killing of several viral strains, including HIV, has been tested by using EPA protocol and complete deactivation was observed.

3. Proposed process testing/monitoring measures to ensure this degree of kill will be achieved:
Trigene advance has been tested to provide complete killing of various viral strains. The functioning of autoclave is validated by waste management staff on regular basis by thermocouples.

4. Ultimate form and packaging for removal from the department:
Upon inactivation with 5% Trigene advance the liquid waste will be disposed in dedicated sink. The solid waste will be disposed in biological waste bags, autoclaved and disposed by UCL waste services.

Project Ref 14/13.5

- Date Ackn'd 25/07/2013
- CU2 Project Title Understanding the coordination of hepatitis C virus entry and humoral immune evasion
- Class 3
- Culture Vol Class 2 1-50 litres
- Culture Volume Class 3-4 <1 litre

Project Containment

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The UCL GMSC approved this as a Class 2 activity following a minor clarification regarding the use of personal protective equipment.
Previous studies indicate that the mechanism of HCV entry is intrinsically linked to virus particle antibody evasion. This study aims to clarify the interdependence between HCV entry and immune evasion.

HCV establishes a persistent infection in - 80% of cases, leading to hepatitis, cirrhosis and hepatocellular carcinoma. Chronically infected patients raise HCV-specific antibody responses capable of preventing virus interaction with target cells in vitro. However, HCV persists in the face of these apparent neutralising antibodies (nAbs), suggesting that HCV exhibits immune evasion strategies.

The entry of HCV into hepatocytes is a complex process that involves at least four cellular receptors. Like other viruses that use multiple entry factors (e.g. HIV and rotavirus), it is thought that HCV undergoes an ordered sequence of receptor interaction, with each step being accompanied by a conformational change in the virus particle. Such a programme of molecular events allows viruses to shield critical epitopes until the moment that they are required to allow, for instance, co-receptor interaction or membrane fusion. Consequently there is only a narrow window of opportunity in which antibody-mediated neutralisation can occur, allowing the virus to achieve entry to the face of humoral immune assault.

Patient derived HCV is hard to propagate in vitro, therefore studies will be performed with a panel of cell culture proficient infectious clones, referred to here as HCVcc. In this study we will use the HCVcc system to investigate how HCV entry mechanisms inform humoral immune evasion strategies and vice versa. Specifically, we will propagate HCVcc, allowing us to characterise certain properties of virus particles, such as entry mechanisms and sensitivity to neutralising antibodies. We will monitor viral evolution in cell culture and patient quasispecies diversity by sequencing, this will involve extraction of viral RNA, conversion to cDNA and potential onward cloning of these sequences. We will also purify virus particles for biochemical analysis, for instance, by density gradient centrifugation. Viral sequences encoding specific proteins may be sub-cloned to allow production of virus protein in isolation, however these will not pose any risk to human health.

All work with replicative virus will be carried out at containment level 3 (CL3)

Our ultimate goal is to understand the molecular events that allow coordinated HCV entry and nAb evasion. In doing this we hope to design therapies and vaccines to interfere with these mechanisms therefore accessing the untapped potential of patients own humoral immune response.
is possible to cure infected individuals with a combined regime of interferon and ribavirin, furthermore, a range of new anti-virals are dramatically improving treatment efficacy. Notably, the HCVcc infectious clone is a genotype 2 virus, and as such is particularly sensitive to interferon based treatment.

HCV is principally transmitted by percutaneous inoculation. In infected patients the primary routes of infection are needle sharing amongst intravenous drug users and blood transfusions. In a research setting, the primary risk comes from contaminated sharps or, potentially, eye-splash exposure. However, these risk are all but eliminated under CL3.

Host/vector system

HCV is an RNA virus, the HCVcc system comprises the viral genome encoded as DNA in a bacterial cloning vector (pGEM-T Easy) downstream of a T7 RNA polymerase promoter. The DNA clones are generated and maintained in standard disabled bacterial strains. Full-length infectious RNA genomes are transcribed from the promoter and then introduced in to human hepatoma cells by electroporation. The electroporated cells are then cultured under containent level 3 conditions to produce infectious virus particles that can be propagated further.

Origin & function

The original clones were derived from human patients specifically GenBank accession' AB237837.1 and derivatives thereof, originally describe in Lindenbacg, Science, 2005,309,p623-6. We will modify these sequences by introduction of specific mutations that modulate virus entry and immune evasion, and protein tags/fluorescent proteins that allow us to visualise and quantify viral infection. We may also introduce viral sequences derived from patient isolates to study how viruses evolve in their natural host. Viral sequences encoding specific proteins may be sub-cloned into other plasmids to allow production of virus proteins in isolation, however these will pose no risk to human health.

Evaluation of foreseeable effects

Cell culture infectious (HCVcc) is a class three virus capable of causing chronic hepatitis and progressive liver disease. However, it is transmitted exclusily be percutaneous inoculation and is not capable of transmission by air or ingestion. Replicative HCVcc particles and infected cells are handled and stored under containent level three (CL3), this all but eliminates the possibility of accidental inoculation. Notably, although aerosol droplets containing HCVcc may be generated by pipetting and/or vortexing, these will be contained within the microbiology safety cabinet (MSC) and are not a viable route of transmission.

The risks posed by genetically modified HCVcc essentially mirror that of wild type virus; these viruses will have the ability to establish chronic infection and progressive illness in exposed individuals.

We intend to make specific mutations in the viral genome and insert protein tags to visualise virus or monitor infection. We may also introduce sequences mutations in the viral genome and insert protein tags to visualise virus or monitor infection. We may also introduce sequences derived from patients quasispecies. There is a possibility that the specific mutations will increase viral fitness or pathogenesis, whereas it is highly unlikely that the insertion of protein tags will be advantageous to HCV. Importantly, it is extremely unlikely that the proposed modifications will render the virus transmissible by any novel route, for instance by airborne transmission. HCV is highly adapted to its biological niche and multiple. Complex adaptations would be required to alter its route of transmission, it is arguable whether these adaptations would ever be selected for in an experimental setting.

As with wild type virus, CL3 confers a very low risk of exposure.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containent for the Class of activity. (Measures & Justification)

We request that electroporation of human hepatoma cells with HCV RNA be performed at class 2 containent. Once electroporated the cells can be considered infected, however, the virus life cycle dictates that infectious virus particles will not be produced before 12 hours post electroporation (Tellinghuisen et al., 2008, PLoS Pathog 4(3):
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virus inactivation will be achieved by overnight incubation in 10% virkon, this will occur in a sealed vessel within a MSC. Contaminated solid waste will be treated in a separate vessel, also inside the MSC. All waste, including inactivated virus, contaminated solid waste and non-contaminated material will be sealed in bags and autoclaved, liquid waste and virkon baths will be solidified using verna gel prior to autoclaving. A standard autoclave destruct run will be used to inactivate waste (30 mins at 135°C). Inactivated and autoclaved materials will be disposed of as clinical waste.

It is impractical to assess the degree of kill regularly, additionally, the concentration of virkon in the inactivation solution will invalidate the standard infectious assay. However, HCV is a relatively instable enveloped virus and extremely sensitive to detergent. The initial virkon treatment will disrupt the virus envelope, thus inactivating the particle, subsequent autoclaving will denature all virus proteins. Based on World Health Organisation guidelines and experimental evidence (Song et al. Virology Journal 2010, 7:40), the above treatment is expected to inactivate all virus.

A record of the autoclave runs will be made, in the event of a failed run the waste will be autoclaved again. Given the level of redundancy in the waste disposal protocol, it is highly unlikely that virus inactivation will fail.

Project Ref 14/13.6
The ultimate goal of this project is to develop novel autologous cell therapy strategies for patients affected by different forms of muscular dystrophy. This project will be composed of several different aims, detailed below:

1. Genetic correction of patients' mesoangioblasts by transfer of a Human Artificial Chromosome, expressing dystrophin and several beneficial functions, followed by transplantation into dystrophic/immune deficient mice to test their ability to alleviate the dystrophic phenotype. For other forms where the mutated gene is not large, target selecting lentiviral vectors will be used.

2. Derivation of patients induced pluripotent stem cells (iPSC) from patients affected by muscular dystrophies such as Limb Girdle Muscular Dystrophy 2D, characterized by a strong reduction of pericytes from which mesoangioblasts are derived, or from patients at an advanced stage of disease, when skeletal muscle biopsies no longer yield cells able to proliferate in culture. iPSC cells will be derived from fibroblasts of these patients, expanded, genetically corrected and then differentiated to mesoangioblasts according to a protocol developed in the lab (Tedesco et al., 2012). These cells will be tested for their ability to alleviate the dystrophic phenotype as described in 1.

3. In vivo generation of additional, functional artificial muscles (Fuoco et al., 2012) by combining mesoangioblasts and special biomaterials and implanting the device sub-cutaneously. The artificial muscle receives vessels and nerves from the host and matures almost identically to the underlying normal muscle. This strategy may benefit localized forms of muscular dystrophy (e.g. Oculo-Pharingeal Muscular Dystrophy) or localized lesions of skeletal muscle due to trauma, surgical resections, senile or iatrogen lesion of sphincters.

**Recipient or parental organism**

Organism from which the sequence coe from: Human, Mouse, Dog

Vectors: Lentivirus, Retrovirus

**Host/vector system**
Lentivirus: 2nd and 3rd generation vector with virulence genes deleted

Cells: standard competent cells (XL10-Gold and XL1-Blue Agilent Technologies), Murine cells, Human cells, Canine cells

Origin & function

Origins and Functions of the genetic material involved:

Reprogramming factors (described below); reversible immortalization of cells lines (described below); cDNA of genes encoding for muscle proteins mutated in muscular dystrophies, for transcription factors regulating muscle development and regeneration.

The over expression of the four reprogramming factor (Oct4, Sox2, Klf4 and cMyc) reprogram the target somatic cells. The individual known functions and expected activity of each of the 4 reprogramming factors is described below:

Oct4: is a key transcription factor in pluripotency, its highly expressed during embryonic development and in embryonic stem cells. It acts co-operatively with Sox2 and Nanog to promote pluripotency and suppress differentiation.

Klf4: It’s known to bind putative regulatory elements of Oct4, Sox2, Nanog and other pluripotency associated genes. His overexpression is thought to upregulate Nanog and to repress p53.

C-Myc: is a transcription factor that plays roles in cell cycle progression, apoptosis and cellular transformation. The overexpression of cMyc in somatic cells is expected to promote reprogramin to a pluripotent state.

Regarding the immortalization factors, the simultaneous expression of Bmi-1 and hTert is expected to allow the cells to not enter into senescence.

Bmi-1: the expression of Bmi-1 promotes the cell cycle, it’s a negative regulator of p16 (inhibitor of the cell cycle). His co-expression with hTERT is expected to immortalize the target cells (human and canine mesangioblasts).

hTERT: it’s a catalytic subunit of the enzyme telomeras (RNA-dependent polymerase). Telomerase is a ribonucleoprotein polymerase that maintains telomere ends by addition of the telomere repeat TTAGGG. The enzyme consists of a protein component with reverse transcriptase activity, encoded by this gene, and an RNA component that serves as a template for the telomere repeat. Telomerase expression plays a role in cellular senescence, as it is normally repressed in postnatal somatic cells, resulting in progressive shortening of telomeres. Specifically TERT is normally repressed in postnatal somatic cells, resulting in progressive shortening of telomeres. Specifically TERT is responsible for catalyzing the addition of nucleotides in TTAGGG sequence to the ends of a chromosome's telomeres. This addition of repetitive DNA sequences prevents degradation of the chromosomal ends following multiple rounds of replication. hTERT is often up-regulated in cells that divide rapidly, including both embryonic stem cells and adult stem cells. It elongates the telomeres of stem cells which consequently increases the lifespan of the stem cells by allowing for indefinite division without shortening of telomeres. Therefore, it is responsible for the self-renewal properties of stem cells. High expression of hTERT is also often used as a landmark for pluripotency and multipotency state of embryonic and adult stem cells. Over-expression of hTERT was found to immortalize certain cell types as well as impart different interesting properties to different stem cells.

Evaluation of foreseeable effects

All our viruses are replication defective. The retroviral and lentiviral vectors used lack viral structural genes and require [ackaging cells to generate retro/lentivirus, therefore they are non-replicating.

The four reprogramming factors are standard practice in IPS cell research and no reports of safety issue have arisen where proper precautions have been taken. If there were an accidental transfer to humans the likelihood of the person developing IPS cells is negligible given that the efficiency of generating human IPS cells from target cells is only 0.02% under favourable culture conditions. Moreover, these retroviruses can only infect actively dividing cells, so is unlikely to be able to infect human cells readily.
The episomal plasmids cause no harm to humans as they are used as naked DNA plasmids. They will no be transfected into viral packaging cells to generate virus. Even if directly transmitted into a human by accidental transfer the plasmid DNA would be immediately degraded by DNA nucleases on the skin and by other host defences.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

2.5% (v/v) Virkon will be used to treat liquid waste (left overnight) and also used to decontaminate any spills and for disinfection of any reusable equipment and laboratory materials used. Liquid waste will subsequently be disposed in a tank for the biological liquid waste. Work surfaces will be wiped down with 70% ethanol. Virkon was certified by the PHLS to provide 100% GMO kill under these conditions by denaturing and inactivating cells proteins. Solid waste will be double bagged in biohazard bags and removed by UCL waste services validate all the autoclave cycles to ensure no risk to the environment.

Project Ref 14/14.1
The research that we have been carrying out is focused on skin diseases including rare genetic skin diseases Netherton syndrome (NS), recessive dystrophic Epidermolysis Bullosa (RDEB), keratitis-ichthyosis-deafness syndrome (KID), and a far more common disease, atopic dermatitis (eczema). We want, through the research, to understand the patho-mechanisms underlying these conditions and develop more specific treatments for these diseases.

For genetic skin diseases, we want to genetically modify patients' stem cells by delivering either wild type gene or siRNA to cells. Lentiviral vectors have been and will be used for the delivery tool as other methods such as non-viral delivery are not efficient enough, especially in primary skin cells (keratinocytes) and some other cell lines. We are also carrying out the research on eczema. Eczema is a multifactorial disease with the feature of impaired skin barrier function. The pathogenesis is complex and remains unclear. We want to use approaches of gain- and loss- of function of candidate genes to demonstrate the patho-mechanism of dysfunctional skin barrier in eczema. Lentiviral vectors will be used to deliver and express candidate genes or siRNAs into skin cells, and the biological interference of these genes involved in skin barrier formation and function will be studied.

As primary skin cells have a limit lifespan under in vitro culture condition, we need to immortalise primary cells with E6 and E7 genes from human papilloma virus type 16 (HPV16) to expand cells' lifespan. Like all papilloma viruses, HPV 16 establishes productive infections only in keratinocytes of the skin or mucous membranes. While the majority of the known types of HPV cause no symptoms in most people, HPV16 can - in a minority of cases - lead to cancers. Therefore, E6/E7 proteins are oncogenic. Vectors used in the project are non-replicating and the most of genes to be expressed by these vectors (listed in section 1.07) are non-pathogenic, non-oncogenic and non-hazardous, except from E6/E7.

The cDNAs listed below have been or will be cloned. These viruses are intended to be used for tissue culture studies in mammalian cell, in invitro organotypic culture and in vivo mouse-human chimaeric skin grafting model. These animals are normally studied for a period of up to six months.

The maximum culture volumes of any of the above handled on one occasion will be less than 210mls for lentivirus production (with each tissue culture flask containing no more than 20 ml of medium for virus production). The inactivation of lentivirus will be by PRESEPT tablets, Distel (formally Trigene) and 70% IMS for liquids and by autoclaving for solids and plastics.

Recipient or parental organism

E. coli disabled strains (e.g. DH5alpha, JM109, Stbl 3);
Mammalian cell lines (established or commercially available), mammalian primary cells including keratinocytes, fibroblasts and bone marrow stem cells;

Replication-deficient self-inactivating (SIN) lentiviral vectors which are based on third generation lentiviral vectors (i.e. pCCL SIN) or second generation vectors (i.e. pHIREN) with engineered safety features which are resembling third generation vectors in terms of safety.

Mooney murine leukemia virus (MoMuLV)- derived vectors (MSCV, Sfada/W, SRS11) lacking international non-proprietary names (INN), again representing a similar level of safety, when using inserts which are deemed harmless.

The following promoters will be used in the lentiviral vectors: Spleen focus forming virus (SFFV), CMV, EF1 alpha, PGK; tissue specific promoters including human involucin promoter, human actin promoter and human SPINK5 promoter.

Commercial TZV vector derivative pGIPZ (from UCL siRNA library) with various hairpin sequences.

The bacterial strains used are attenuated non-colonising strains, so they are incapable of causing human infection and are therefore harmless to humans.

The viral vector to be used will be pseudotyped with the envelope protein VSV-G from Vesticular Stomatitis Virus. If introduced into the body by injection, ingestion or through a wound, the virus could enter human cells and integrate into cellular DNA. Although the virus is replication incompetent so they cannot self-replicate and transfer to another host so are harmless to the environment.

The cell which will eventually receive and integrate the DNA cannot survive in the environment as they are only viable under culture conditions and therefore are harmless to the environment. The mice to be reconstituted with transduced bone-marrow or keratinocytes (skin cells) could conceivably escape into the environment but would be unable to transmit the viral construct to another organism and also not able to transmit in the germ line to an offspring.

Lentiviral Gag/pol expression vectors p8.9 and derivatives (HIV-1). Viral expression vector pMDG and derivatives (VSV-G)

ORIGINS AND FUNCTIONS OF THE GENETIC MATERIAL INVOLVED

Apart from HPV16 E6/E7 which are oncogenes (detailed description see 1.10), all other insert sequences listed above are human cDNA sequences, NONE of which fall into any harmful category, such as:
- oncogenes and proto-oncogenes,
- growth factors and GF receptors
- any other sequences coding for significant biological activity that might be harmful were these to be expressed in people accidentally exposed to the vector.

Sleeping beauty transposase (salmonoid) in present form deemed harmless.

siRNA hairpin sequences in either the commercial TZV vector from Tranzyme and derivatives (including pGIPZ), or in above SIN lentiviral vectors. These siRNA sequences are intended to target and down-regulate expression of the following human mRNAs only: SPINK5, KLKs, GAPDH, EGFP, PAR2. All of these siRNA target down-regulations, even if accidentally occurring after user exposure are not expected to cause any harm, due to a combination of the function of the targets, no expected harmful action of other molecules when presence of lower amounts of the target, and the expected relatively low amount of cells involved.

Host/vector system

Lentiviral Gag/pol expression vectors p8.9 and derivatives (HIV-1). Viral expression vector pMDG and derivatives (VSV-G)

ORIGINS:

Homo sapiens

ORIGIN AND FUNCTIONS OF THE GENETIC MATERIAL INVOLVED

Apart from HPV16 E6/E7 which are oncogenes (detailed description see 1.10), all other insert sequences listed above are human cDNA sequences, NONE of which fall into any harmful category, such as:
- oncogenes and proto-oncogenes,
- growth factors and GF receptors
- any other sequences coding for significant biological activity that might be harmful were these to be expressed in people accidentally exposed to the vector.

Sleeping beauty transposase (salmonoid) in present form deemed harmless.

siRNA hairpin sequences in either the commercial TZV vector from Tranzyme and derivatives (including pGIPZ), or in above SIN lentiviral vectors. These siRNA sequences are intended to target and down-regulate expression of the following human mRNAs only: SPINK5, KLKs, GAPDH, EGFP, PAR2. All of these siRNA target down-regulations, even if accidentally occurring after user exposure are not expected to cause any harm, due to a combination of the function of the targets, no expected harmful action of other molecules when presence of lower amounts of the target, and the expected relatively low amount of cells involved.
into any harmful category, such as:

- oncogenes and protooncogenes,
- growth factors and GF receptors
- any other sequences coding for significant biological activity that might be harmful were these to be expressed in people accidentially exposed to the vector.

Sleeping beauty transposase (salmonoid) in present form deemed harmless.

siRNA hairpin sequences in either the commercial TZV vector from Tranzyme and derivatives (including pGIPZ), or in above SIN lentiviral vectors. These siRNA sequences are intended to target and down-regulate expression of the following human mRNAs only: SPINK5, KLKs, GAPDH, EGFP, PAR2. All of these siRNA target down-regulations, even if accidentally occurring after user exposure are not expected to cause any harm, due to a combination of the function of the targets, no expected harmful action of other molecules when presence of lower amounts of the target, and the expected relatively low amount if cells involved.

WILL THE SEQUENCE CAUSE HARM IF EXPRESSED IN HUMANS AFTER ACCIDENTAL TRANSFER

If the inserted sequence were to be expressed in humans after accidental transfer cDNA sequences or the RNAi hairpin (described in section 1.10), they could lead to expression of de novo functional proteins or to the down-regulation of the gene to which it targets via RNAi interference, respectively. Such expression of the inserted cDNAs are, however, all deemed to be of little significance due to the non-harmful nature of the sequences used and the expected accidental exposure in cell numbers. Accidental targeting of RNAi in humans is not deemed to be of a harmful nature due to a combination of the function of the targets, no expected harmful action of other molecules when presence of lower amounts of the target, and the expected relatively low amount of cells involved. In addition, for both cDNA inserts and siRNA, the effect would also not be severe due to the fact that the virus is replication incompetent and self-inactivating as none of the structural genes are actually present in the packaged cell genome, so no new virus can be produced and no other cells can be infected. Physical insertion of the virus into the genome of the host cell could potentially disrupt a tumour suppressor or oncogene, however the likelihood of this is low and is drastically reduced by the lack of use of sharps when handling virus. Although E6 and E7 are oncogenes, accidentially occurring of inserted nucleic acid after user exposure are not expected to cause severe harm. The reasons are

i. The oncogenic activities of HPV E6/E7 genes have been documented extensively (Munger et al. Journal of Virology, 2004, p11451-11460). The expression of E6/E7 in primary human keratinocytes effectively facilitates their immortalization. However, HPV immortalized cells are nontumorigenic. They can undergo malignant progression only after extended growth in tissue culture or when additional oncogenes such as ras or fos are expressed. The development of cervical cancers in a transgenic mouse model in which E6/E7 is expressed in basal epithelial cells is also dependendt on long-term exposure to low doses of estrogen. Similarly, progression of HPPV-positive cervical lesions in human occurs at a low frequency and requires the acquisition of host cellular mutations. Therefore, it is unlikely that one will develop skin cancers after exposure E7/E7 to the skin in the lab. In fact, E6/E7 genes have been used to immortalise keratinocytes for more than 20 years in skin research, but there was no report that tumorous cells were grown in people carrying out the experiments.

ii. If the oncogenes were to be expressed in human after accidental transfer, E7/E6 could lead to a potentially oncogenic mutation. This, however, would not be severe as vectors used for our study is replication incompetent and can be produced and no other cells can be infected.

iii. Physical insertion of the genes into the genome of the host cells could potentially disrupt the tumour suppressors. However, as E6/E7 is only partial genes of HPV16, they won't be assembled /matured into virions without the expression of HPV16 late genes L1 and L2 in the transduced cells. So again, the infection would be limited and no new cells can be infected.

WILL THE SEQUENCES CAUSE HARM IF TRANSFERRED TO SPECIES IN THE ENVIRONMENT

No, risk of transfer to environmental species is negligible, and would not be expected to cause harm. VSV-G pseudotyped lentivirus can only infect mammalian cells. Potentially genes or the siRNA hairpin constructed in viruses could be expressed in another mammalian species and lead to gene over expression or the down-regulation of target genes. This is, however, extremely unlikely as the both transgene and hairpin is expressed/targeted to mammalian genome. If happened, it would not be severe as the virus is replication incompetent and self-inactivation. None of the structural genes are actually present in the packaged viral genome, so no new virus can be produced and no other cells can be infected.
IS THE DONOR ORGANISM PATHOGENIC?

The envelope proteins in viral vectors are VSV-G from the Vesticular Stomatitis virus. If introduced into the body by injection, ingestion or through a wound, the virus could potentially enter cells and integrate into cellular DNA. Although the virus is replication incompetent (does not carry gag, pol or env genes), so it cannot make new progeny virus and establish a productive infection, its physical insertion into cellular DNA could result in a potentially oncogenic mutation. However, this would be a very unlikely event and if so only a very small number of cells and would not impact on the pathogenic outcome of an exogenous viral infection. The packaging viral components are from the HIV-1 virus. The full length HIV-1 molecule. Many components of HIV-1 that are critical for HIV-1 infection but not required for viral packaging have been removed, so the virus is attenuated.

IF THE DONOR ORGANISM HAS PATHOLOGICAL OR HARMFUL CHARACTERISTICS, ARE THE DONATED SEQUENCES INPLICATED IN THEM?

The de novo cDNA inserts or hairpin donor sequences could potentially be expressed in cells and lead to the expression of a novel gene or knockdown of the expression of certain genes. However, the inserts/siRNA are all deemed harmless or of very low risk. In addition, this would only involve a very small number of cells and as the virus is replication incompetent and cannot make new viral progeny, it would not impact on the pathogenic outcome of an exogenous viral infection.

SUMMARISE THE POTENTIAL FOR HARM IN THIS PROJECT

Only a very unlikely multiple recombinations during the process of generation of the viral vector can expose the person to wild type HIV-1. The probability of such an event is extremely low. The most hazardous GMM are the lenti-vector viruses and the most hazardous step is the harvesting of the viral supernatant before infecting target cells. However, the most of the inserts used throughout this work is deemed to have harmful effects, except from the oncogenes E6 and E7.
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

I) The treatment method: Liquid and solid waste are treated with PRESEPT effervescent disinfectant tablets (2.5g/tablet in 2-5 litres). All plastic-ware used in tissue culture are autoclaved. Work surfaces are decontaminated on completion of work and/or at the end of the day and after any spill or splash of viable material with disinfectants that are effective against the agents of concern. Distel (formerly Trigene) and then 70% ethanol or IMS are used during tissue culture and virus preparation procedures to ensure high effective in tissue-culture related decontamination

II) Degree of kill: 100%

III) Proposed process testing/monitoring measures to ensure this degree of kill will be achieved: Both PRESEPT effervescent disinfecting tablets and Distel are certified by Public Health England (PHE) to provide 100% vircidal kill under these conditions. Additionally, PRESEPT and Distel will be used with its lifespan to ensure effectiveness. Autoclave runs are regularly validated by waste management staff twice a year.

IV) Ultimate form and packaging for removal from the department: Solid waste will be double -bagged in biological waste bags and then autoclaved at 132C for 15 mins, then bagged in yellow biohazard bags and removed by UCL waste services.

Project Ref 14/14.10

Date Ackn'd CU2 Project Title Class CultureVolClass2 CultureVolumeClass3-4

02/03/2022  Page 812 of 15326
Use of lentivirus vectors to deliver cDNAs and shRNAs to canine, mouse, human cell lines, mouse primary cells (MEFs) and whole mouse embryos (in vitro culture)

This project is concerned with determining the processes that control the development of neural tube. Defects in neural tube development can give rise to neural tube disorders accounting for 1 to 1000 birth defects. The overall aims of this project are to understand the molecular mechanisms underlying the developmental process of neural tube formation. We are particularly, but not exclusively, interested in targeting the genes, Grhl2 and Grhl3, encoding grainyhead-like protein transcription factors. The purpose of the project is to over-express and knock-down expression of these genes, both of which cause neural tube defects in mouse models. These aims will require lentiviral production to introduce cDNAs or shRNAs into the cells using viral delivery to test the function of grainyhead-like proteins in neural tube closure. Our specific goals are to reduce the expression of grainyhead-like proteins in cell lines in order to identify the downstream target genes and to overexpress these proteins to examine the functional effect on cell behaviour. This could lead to further development of chemical or RNA/DNA-based regulators of grainyhead-like proteins that could be used therapeutically to tackle neural tube disorders.

Recipient or parental organism

Cell lines: Human 293T cells, canine MDCK cells, murine IMCD3 cells, murine NIH-3T3s and other epithelial and endothelial lines Whole mouse embryo in vitro culture (Embryonic days 8.5 and 9.5) Primary murine cells: MEFs

Host/vector system

Lentiviral vectors: The vector is a replication-deficient self-inactivating (SIN) lentiviral vector based on second generation vectors (i.e. pHR'SIN) with engineered safety features resembling third generation vectors in terms of safety using the spleen focus forming virus (SFFV) promoter. The 3rd generation vectors express gag and pol from one packaging vector and rev from another. 3rd generation packaging systems do not express tat. pGIPZ, lentiviral Gag/pol expression vectors, viral envelope expression vector.
Grainyhead-like proteins 2 and 3 are transcription factors essential for neural tube development. cDNA encoding Grainyhead like proteins will be amplified by RT-PCR using RNA derived from tissue of a wild-type mouse.

The RNAi hairpins are sequences that have been derived de novo and are not from an organism. They have been designed as small sequences with both a sense, anti-sense and loop sequence to form a RNA hairpin when transcribed which will initiate a downstream cascade of events leading to knockdown of the target gene to which the hairpin was designed.

In order to fully characterise the function of grainyhead-like proteins we will also introduce cDNAs or shRNAs targeting grainyhead-like protein target genes (transcriptionally regulated by Grhl proteins) into cells. The genes to be knocked down/over-expressed will be decided on the basis of transcriptomic data from ongoing experiments in mice and from RNA sequencing profiling of Grhl expressing cell lines.

If the inserted sequence were to be expressed in humans after accidental transfer, the cDNA sequences or the RNAi hairpin could lead to the expression of de novo functional proteins or to the down-regulation of a gene which is targeted via RNAi interference (provided it is raised against human sequences or conserved murine sequences).

Grainyhead like 2 protein has been described to have oncogenic properties and could lead therefore to a potentially oncogenic change. However, the virus is replication incompetent and therefore self-inactivating. None of the structural genes are actually present in the packaged viral genome so no new virus can be produced and no other cells can be infected. Therefore, risk is considered minimal.

Physical insertion of the virus into the genome of the host cell could potentially disrupt a tumour suppressor or oncogene, however the likelihood of this is very low. Expression of cDNAs in human cells might induce a growth advantage on those cells. However, this is unlikely, to cause significant, harmful effects as very few cells would be affected and the cDNAs used are not expected to have strong oncogenic potential.

The bacterial strains used are attenuated, non-colonising strains so are incapable of causing human infection and therefore harmless to humans. The viral vector to be used will be pseudotyped with the envelope protein VSV-G from Vesicular Stomatitis Virus. If introduced into the body by injection or through a wound, the virus could enter human cells and integrate into cellular DNA. Although, the virus is replication incompetent (does not carry gag, pol or env genes) and cannot make new progeny virus or establish a productive infection, its insertion into cellular DNA could result in a potentially oncogenic mutation. The recipient cells are harmless to humans.

Possible effects in the environment: Potentially the hairpin could be expressed in another mammalian species and lead to down-regulation of a growth regulatory gene such as a tumour suppressor gene resulting in a potentially oncogenic mutation. This, however, is extremely unlikely as the hairpin is targeted to human or mouse genes and many hairpins are not homologous with the genes of other species. If the hairpin were to target and lead to the reduction of a gene via RNA interference it would not be severe as the virus is replication incompetent and therefore self-inactivating as none of the structural genes are actually resent in the packaged viral genome so no new virus can be produced and no other cells can be infected. If the cDNA-containing virus gain access to other animals, it could be expressed in another mammalian species and lead to the down-regulation of a growth regulatory gene such as a tumour suppressor gene resulting in a potentially oncogenic mutation. However, it is very unlikely that the cDNAs would gain access to another species and the viruses are non-replicative.

The bacterial strains used are attenuated non-colonising strains that cannot survive outside culture conditions and are therefore harmless to the environment. The viral vectors plasmid vectors are replication incompetent so therefore cannot self-replicate and transfer to another host so are harmless to the environment. The cells that will eventually receive and integrate the viral DNA cannot survive in the outside environment as they are only viable under culture condition and therefore are harmless to the environment.

The virus will be used in designated level 2 laboratories. Also, in order to prevent contamination of workers by virus no
glass or other sharps will be used with live virus (The lentivirus will be added to the rat serum which is the normal culturing medium for mouse embryos and the expression of the genes of interest will be evaluated after 24h or 48h of culture). Staff will be protected by a lab coat and gloves. Also, the safety cabinet in tissue culture room 203 level 2 ICH will be used as containment. No adverse effects have been described through the accidental exposure to lentiviral vectors. The risk of harm or exposure and harm human health is therefore very low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be double-bagged in biological waste bags, sealed with a biohazard tape and autoclaved at 132°C for 15min by trained staff (Ground floor at ICH room G17) then bagged in biohazard bags and removed by UCL waste services. 10% Distel or 2-5% Virkon (v/v) will be used to treat liquid waste (18 hours) and also used to decontaminate any spills and for disinfection of any reusable equipment and laboratory materials used. Liquid waste will subsequently poured down the sink after the treatment with Virkon. Virkon and Distel are certified by the PHLS to provide 100% virucidal and GMO kill under these conditions by denaturing and inactivating viral, bacterial and cellular proteins. Virkon and Distel will be used within their lifespan to ensure the required kill is achieved.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

The UCL GMSC agreed the classification of this work as Activity Class 2 pending some minor clarifications regarding disinfection and disposal of waste.

02/03/2022
The proposed project aims to investigate inflammatory and immune responses in mycobacterial infection using the zebrafish Mycobacterium marinum infection model. Mycobacteria are a group of pathogens, several of which are important causes of human disease, including M. tuberculosis: the causative agent of tuberculosis. Model systems for the study of tuberculosis include the zebrafish, and several important advances in understanding mycobacterial disease have now come from this model (Adams and several important advances in understanding mycobacterial disease have now come from this model (Adams 2011, Clay 2007, Davis 2009, Tobin 2010, Volkman 2010)). Infection will be established by microinjection of zebrafish embryos via previously validated routes including yolk sac injection at early stages or injection into the caudal vein at 24-36 hours post fertilisation (hpf) (Carvalho 2011, Benard 2012) of either fluorescently labelled or wild type M. marium. Up to a maximum of five days post fertilisation, zebrafish larvae will be harvested in RNA later, Qiazol or RLT buffer for gene expression studies, SDS reducing buffer for Western blotting or mounted for microscopy studies to acquire qualitative and quantitative information on bacterial load, and interaction with immune cells.

References

M. marinum is a non-tuberculous mycobacterium, and in humans is an opportunistic pathogen which occurs commonly in the environment, with no evidence of person to person spread. M. marinum has been described to cause tenosynovitis in the hand and wrist, associated with penetrating injuries in the presence of contaminated water, occasionally progressing to osteomyelitis. More commonly, M. marinum may cause skin and soft tissue infection following trauma in the presence of contaminated water, most commonly from fish fins, bites or unrelated trauma accompanied by exposure to contaminated water. In temperate climates, infection is commonly related to fishing, fish tank cleaning or in aquarium workers. Due to the lower temperature to which M. marinum is adapted, infection is usually confined to the skin and extremities. Infection begins as one or more nodules at the site of trauma. Spread to deeper tissues can occur. Treatment is with multiple antibiotics, as with other non-tuberculous mycobacteria (Piersimoni, 2008). Infections can be more severe and disseminated in the immunosuppressed, including those on anti-TNF therapies (Ramos, 2010). As noted above M. marinum does have the potential to cause disease in humans. The GMM would be less likely to cause disease given the burden of carrying the insert without any gain to pathogenicity. Any infection could be readily treated with antibiotics as mentioned above.

M. marinum is commonly found in environmental water, and so has the capacity to survive in the environment following inadvertent release. Currently, no environmental hazards have been associated with the organism. Mycobacteria will be separated from research aquaria. It has previously been shown that M. marinum does not grow in standard mammalian tissue culture media at 37 degrees celsius (Ramakrishnan, 1994).

References

evaluation of foreseeable effects

None of the fluorescent reporter expressing mycobacterium marinum are hazardous. The GMM would be less likely to cause disease in humans, given the burden of carrying the insert without any gain to pathogenicity. There are no environmental risks associated with the inserted genetic material.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All potentially infected solid waste, including M. marinum infected zebrafish larvae, will be chemically disinfected by using 5% Distel (final concentration) before being discarded into an approved autoclave bag. Before the bag is too full it will be closed with a cable tie and then placed in a second autoclave bag, also secured with a cable tie. Bags will be placed in a blue bin to await collection and transport to be autoclaved (The Sterilising Equipment Company). Waste will be autoclaved at 134 degrees Celsius, 20 minutes hold time, 3 bars pressure. Autoclaved waste is categorised as offensive and is double yellow tiger bagged and locked away until collected and incinerated by a UCL contractor (Grundons). Glass microinjection needles will be disinfected using 5% Distel (final concentration) before being disposed of in a sharps bin and then incinerated by a UCL contractor (Grundons). Waste autoclaves alarm and will fail the cycle if any of the above parameters are not met. The staff either re-run the cycle or transfer waste to a different autoclave to ensure decontamination. Each autoclave has a printer attached which records all cycle parameters at set intervals throughout the ~2 hour run. All potentially infected liquid waste will be chemically disinfected using 5% Distel (final concentration) for at least 12 hours before being discarded to drain. Distel disinfectants employ chlorine dioxide chemistry to provide highly effective and safe biocidal cover. Distel has been found to be biocidal with 30 seconds to 5 minutes against a range of mycobacterial species, including, M tuberculosis (Tristel Produc Brochure 2007).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The project was approved by the UCL GMSC (at their meeting on 11/12/2013) as AC2 pending clarification of a number of minor issues relating to the handling of infected fish larvae and risks to immunosuppressed staff

To test the hypothesis that nerve growth factor receptor trkA activation via the tumour suppressor p53-dependent repression of the trkA phosphatase SHP-1 expression, promotes differentiation, cell cycle arrest or apoptosis of neuroblastoma cells. Such an understanding of the functional consequences for the tumour cell of the interactions between these proteins will in the longer term, facilitate the design of novel therapies, that would promote targeted cell-cycle arrest, differentiation or cell death of neuroblastoma cells.

We will use known neuroblastoma cell lines to test the outcome of p53-dependent repression of SHP-1, in terms of trkA-phosphorylation and tumour cell proliferation, apoptosis, survival and differentiation.

To determine their role, SY5Y, IMR32, SK-NAS, SK-NBE, Lan-1 and Lan-5 cell lines will be used together with mouse-NIH3T3 and p53-/- murine fibroblasts cell lines. Tranfections with mammalian expression vectors encoding wild type or mutant trkA, p53 or SHP-1 as well as infections with wild type or mutant trkA, p53 and SHP-1 recombinant retroviruses will be undertaken. The role of SHP-1 in trkA-activation will be further assessed by knocking-down SHP-1 expression with mammalian vectors or retroviruses encoding SHP-1-siRNA.

Recipient or parental organism

A, cell lines:
SY5Y, IMR32, SK-NAS, SK-NBE, Lan-1, Lan-5, mouse-NIH3T3, p53-/- murine fibroblasts cell line, Phoenix cells, Platinum cells lines, GP2-293 cells and LinXE cells.

B, Bacterial E coli strains:
HB101, JM109, DH5alpha.

Associated risks and likeliness of occurrence

A, The recipient cells (cell lines) that will receive and integrate the DNA are harmless to humans. These cells cannot survive in the environment as they are only viable
under culture conditions and therefore are harmless to the environment.

B. The bacterial strains used are attenuated non-colonising strains so are incapable of causing human infection and are, therefore, harmless to humans. Also, these strains cannot survive outside culture conditions and are therefore harmless to the environment.

Host/vector system

A. Retroviral vectors

pBABE retroviral vectors contains sequence/elements derived from Moloney murine leukemia virus (MMLV) and IRES-marker genes. pBABE is described by Morgenstern J.P. and Land H. (Nuc. Acid Res. VOL. 18 NO.12 (1990) 3587 and is commercially available from Cell Biolabs Inc.

pLNCX retroviral vector contains sequences/elements from Moloney murine leukemia virus (MMLV) LTR and IRES-marker genes. pLNCX is described by Miller A.D. and Rosman G.J. (Biotechniques VOL.7 (1989) 980) and is commercially available from Clontech.

B. Transfection vectors

pLTR was obtained by cloning proviral Harvey murine sarcoma virus 5' LTR (enhancer, promoter and cap sites) and the SV40 polyadenylation site into a pBR322 backbone containing a EcoRI, XhoI, BglII multiple cloning site, pLTR has been described by Michalovitz d. ET AL., (Cell VOL 62 (1990)671).

pCMV was derived from BCNGneo - miL2 (containing the CMV promoter, splicing and polyadenylation sequences derived from the beta globin gene) of which the human beta globin sequences and the il2 sequences were excised. Also the HSV thymidine kinase gene was introduced to drive expression of the neomycin gene. pCMV has been described by Baker S.J. et al., (Science. VOL 249 (1990) 912).

pMEX was constructed by introducing the Moloney murine sarcoma virus LTR, the SV40 polyadenylation site and the multiple cloning sites of pBluescript into a pBR322 backbone. To this construct the SV40 promoter driving the expression of the neomycin resistance gene was also added. pMEX has been described by Oskam R. et al. (PNAS Vol 85 (1988) 2964).

C. Cloning vectors

pCR2.1 TOPO is a cloning vector with T overhangs, kanamycin and ampicillin resistance, and no mammalian promoter. pCR2.1TOPO is commercially available from Stratagene.

Associated risks and likeliness of occurrence

Modifications of the retrovirus vector (pBABE and pLNCX - retrovirus) have resulted in removal of gag, pol, and env genes from the virus. Thus, the retrovirus is replication incompetent and therefore self-inactivating as none of the structural genes are present in the packaged viral genome. Packaging and envelop proteins are contained in packaging cell lines (Phoenix cells, Platinum cell lines, GP2-293 cells and LinXE cells) and not the virus. The retrovirus is, therefore, attenuated and cannot replicate and form new viable virus.

Also, although the retrovirus is replication incompetent, if introduced into the body by injection, ingestion or through a wound could enter human cells and integrate into cellular DNA. The physical insertion into cellular DNA could result in a potentially oncogenic mutation. However, the likelihood of infection is very low and no adverse effects have ever been described through accidental exposure to retroviral vectors and if so in only a very small number of cells.

The retroviral vectors have been modified to be replication-defective vectors, thus, they have not yet known pathogenicity to humans and cannot transfer to another host and so are harmless. Also, the virus vectors are of no risk to the environment as viral particles are labile and do not survive on environmental surfaces outside the laboratory.
The transfection and cloning vectors do not cause harm to humans or the environment.

**Origin & function**

A, trkA sequences derived from human. These are sequences coding a receptor tyrosine kinase that when stimulated is involved in giving rise to cell signals that promote cell proliferation, differentiation or apoptosis.

B, p53 sequences derived from human and mouse. These sequences code for a tumour supressor gene that is involved maintaining the coding integrity of the cellular DNA and the regulation of the cell cycle.

C, SHP-1 derived sequences from human. These sequences code for the trkA tyrosine phosphatase that regulates trkA tyrosine phosphorylation and function.

**Associated risks and likelihood of occurrence.**

The donor sequences could potentially increase the oncogenic potential of the retrovirus, specifically, some vectors are likely to contain p53 sequences that could have oncogenic potential. However, it is unlikely that these vectors or retroviruses could infect humans. If infection was to occur, it would not be severe as it would only include a very small number of cells. No adverse effects have ever been described through accidental exposure to retroviral vectors and if so only very small number of cells would be infected, thus the overall risk is low. The retroviral vectors that do not encode such sequences with oncogenic potential are extremely unlikely to have pathogenic potential if accidentally injected.

Pooled viral preparations are likely to contain clones with oncogenic potential, however the relative infectious titres of these vectors within the population are too low to measure, making the vector preparation very safe. If a person were infected by infectious retroviral particles they are replication incompetent and therefore self-inactivating, thus there is no chance of transmission to another cell or person. It is extremely unlikely that an infection would occur and no adverse effects have ever been described through accidental exposure to retroviral vectors thus the overall risks are low.

**Evaluation of foreseeable effects**

The intended recipient organisms prior to modification

The bacterial strains to be used are non colonising and incapable of surviving in the environment or causing human infection. They pose no risk to users or the environment.

The cell lines used cannot survive outside the laboratory incubators and as such do not pose a threat to health or the environment.

None of the DNA retroviral vectors are harmful to health or the environment and do not supply a survival advantage to any microorganisms. The packaging viral components of the retroviruses are expressed by the packaging cell lines and have been removed from the retroviral vector.

None of the DNA transfection or cloning vector plasmids are harmful to health or to the environment and do not supply a survival advantage to any microorganisms.

The most hazardous GMM are the retroviral preparations. These could theoretically be hazardous as the retrovirus is amphotropic. If the virus enters the body by injection, ingestion or through a wound, it could enter cells and integrate itself into cellular DNA. However the risk is minimal and likelihood is very low. The virus is replication incompetent and a productive infection. The retroviral vectors have been modified to be replication-defective vectors as the viral particles do not contain all the necessary components. This is because the required components are expressed by the packaging cells (Phoenix cells, Platinum cells lines, GP2-293 cells and LinXE cells) and not the retroviral vector, thus, they have not known pathogenicity to humans and cannot transfer to another host and so are harmless. Also, infection would only be in a small number of cells and would not impact on the pathogenic outcome of an exogenous viral infection. Some of the inserted sequences are likely to have oncogenic potential as their insertion into cellular DNA could result in a potentially oncogenic mutation. However, the likelihood of this occuring is very low as an infection will not be severe and
would only happen in a small number of cells. Therefore the overall risks of the experiment are low. Also, pooled viral preparations are likely to contain clones with oncogenic potential but the relative infectious titres of these vectors within the population are too low to measure, making the pooled vector preparation very safe. Moreover, the viral particles are labile and do not survive on environmental surfaces outside the laboratory making infection unlikely.

Precautions in place to minimize risks

Access to the Institute of Child Health, UCL, is secured by restricted access at all entrances and additionally to all laboratory areas. All work involving viruses will be performed in class 2 cabinets in containment level 2 laboratories specified particularly for retroviral GMM work. All DNA vectors containing viral proteins will be grown separately to avoid opportunity for recombination. To prevent contamination of workers by virus, when handling any GMM or GMM-derived DNA or virus, no glass or other sharps will be used in the rooms where the viruses are prepared and used and workers will be protected by a lab coat and nitrile gloves. Skin lesions will be covered with a bandage in addition to the protective wear. Specific guidelines will be in place to ensure all viral preparations are handled, labelled, stroed, transported and cleaned correctly. All those involved in the project will be made aware of the guidelines and the associated risks as well as anyone else who may use the laboratory. Persons involved on project from other Institutes will work under the supervision of a competent trained worker from this project. No-one visiting the laboratory that is not involved in this work will work on this project. All persons entering the facility will be made aware of the safety precautions upon entering the facility. All equipment used in the retroviral laboratory will be available in other general purpose laboratories for general use so it should not be necessary for others who are not involved in retroviral work to enter the laboratory.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

<td>E. After treatment, all solid waste will be double-bagged, autoclaved, placed in yellow biohazard safety bags and furhter treated by UCL waste services.</td>
</tr>
<tr>
<td>F. All retroviral supernatant will be stored in double containment and transferred within the laboratory within doubly sealed containers.</td>
</tr>
</tbody>
</table>

We expect 100% kill (routine laboratory practice for viral vectors). 2-5% Virkon (v/v) will be used to treat liquid waste (18 hours) and also used to decontaminate any spills and for disinfection of any reusable bottles or other equipment and laboratory materials used. Liquid waste will be subsequently poured down the sink after treatment with Virkon.

Work surfaces will be wiped down with 2-5% Virkon and 70% ethanol or IMS after use. Virkon is certified by the PHLS to provide 100% viricidal and GMO kill under these conditions by denaturating and inactivating viral and cellular proteins. Virkon will be used within its lifespan of 7 to 10 days to ensure required kill is achieved. Solid waste will be double bagged in biological waste bags, sealed and autoclaved at 132°C for 15 mins by trained staff then bagged in yellow biohazard bags and removed by UCL waste services. Autoclave runs are regularly validated by waste managemet staff.
The University Biological Safety Adviser, on behalf of the UCL GSMC agreed the classification of this project as AC2 following a number of minor clarifications/amendments from 3 UCL GM advisers.

### Project Additional Information

#### Purposes of the contained use

My Laboratory focuses on determining the mechanisms by which Vaccinia virus subjugates host cells proteins and cellular functions. This work relies heavily on the use of recombinant viruses for cell, molecular, biochemical and virology based experimentation.

#### Recipient or parental organism

Wild type and recombinant vaccinia viruses [strains western reserve (WR) and International health department strain J (IHDJ)] expressing EGFP, mCherry or containing viral structural proteins modified by EGFP, mCherry, HA, FLAG sequences, or a combination thereof.

#### Host/vector system

N/A

#### Origin & function

The GFP sequence was originally derived from Aequorae victoria, and modified to produce mCherry. HA is derived from influenza virus and FLAG is an artificially derived sequence.

#### Evaluation of foreseeable effects

The wild type viruses are the most virulent. The recombinant viruses will either express fluorescent proteins to mark stages of gene expression or package fluorescent structural proteins for visualization of virus particles. All of these insertions either have no impact on virus pathogenicity or limit the pathogenicity of the virus.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid materials (plastic dishes) potentially containing virus will be collected in autoclave bags contained within metal housing containers and autoclaved. Smaller plastic objects (tips used to handle virus or virus containing liquid) will be subjected to UV irradiation up to 12 hours for virus inactivation prior to autoclaving.

Liquid waste will be collected in aspiration bottles containing Trigene Advanced Virucidal solution prior to autoclaving.

For routine infection work pasture pipettes will be utilized for aspirating virus containing media into proper disposal containers. All aspiration will be followed by disinfection of pasture pipettes through aspiration of 70% ETOH which results in a degree of killing of 90% (Block S.S 2001; Disinfection, Sterilization and Preservation).

Vaccinia virus can be 100% inactivated upon autoclaving occurs within 15 min (Espy M.J. et al. 2002; Detection of vaccinia virus by LightCycler by PCR after autoclaving: implications for biosafety of bioterrorism agents).

Trigene: ATS labs study ‘Virucidal efficacy of a disinfectant for use on inanimate environmental surfaces’ March 2007. In addition we have routinely used trigene for vaccinia virus in activation for the last 8 years, prior testing indicated a EC50 of 1% Trigene in vaccinia stock solutions containing 1x10E9 units of infectious virus/milliliter.
The UCL Biological Safety Adviser, on behalf of the UCL GMSC agreed the project classification of AC2, following a number of minor amendments and clarifications.

Project Additional Information

Purposes of the contained use

Oxazol(in)e and thiazol(in)e heterocycles are present in a wide range of bioactive compounds, including antimicrobials, anti-malarial and anti-tumour agents. Oxazole/Thiazole-containing peptides are naturally produced by a wide range of bacterial and archael organisms through the post-translational modification of ribosomally-synthesised peptides.

Chemical synthesis of polyheterocycles is challenging, making the use of synthetic biology approaches a viable route towards the discovery and synthesis of bioactive compounds. The research program is currently focused on characterising the natural enzymes and the range of viable polyheterocycle products that can be synthesised. That will also include synthesis optimisation of known polyheterocycles such as plantazolicin (an antimicrobial) and telomestatin (a potent telomerase inhibitor), and potentially synthesis scaling up to provide alternative synthetic routes for this class of compounds.

In addition, starting from a library of poly heterocyclic compounds, the program will use directed evolution methodologies to identify novel antimicrobials, novel antitumour agents and novel metamaterials (e.g. UV absorbing peptide aptamers). Those directed evolution methodologies will include in vitro selection strategies as well as bacterial cell display strategies.

Because of the strong correlation between oxathiazoles and bioactive molecules and given the varied nature of activities reported, it is likely that the peptide library will contain a range of biological activities. In a worst case scenario, it is possible that some of the GMMS generated could be capable of synthesising (exporting or displaying) low concentrations of oxathiazole peptides toxic to humans.

Recipient or parental organism

Auxotrophic lab-adapted standard E. coli strains - NEB beta-10, NEB T7 express, DH5alpha.

Host/vector system

pBAD30, pMAL-c2, pET, pTWIN (NEB IMPACT system) - all are well-characterised inducible expression systems

Origin & function

We are focusing on oxathiazole synthase complexes from Bacillus amyloliquefaciens and Pyrococcus furiosus. The synthetase genes being used were commercially synthesised and codon-optimised for E. coli expression. The heterotrimeric synthetase complex catalyses the cyclodehydration of serines, threonines and cysteines in peptides containing specific leader sequences, followed by their dehydrogeneration. Oxathiazole synthetases (and their natural peptide substrates) have not been linked to bacterial pathogenesis in humans.

Some oxathiazole compounds, such as telomestatin and other anti-tumour agents, can affect human health. Because peptide precursor libraries will be synthesised it is possible that compounds that can affect human health will be generated.

The bacterial display systems being considered are already characterised gene fragments from E. coli (EspP) and Pseudomonas syringae (INP) that provide a suitable platform for protein expression on the bacterial surface. The proteins involved in the bacterial display system have not been implicated in pathogenesis. Potential toxicity from fused oxathiazole compounds may be limited by the fusion partner - compounds cannot diffuse into the environment and fusion partner may interfere with toxic function.

Evaluation of foreseeable effects

Synthetase genes will be overexpressed in the bacterial host and purified for in vitro assays. This is of negligible risk.
Peptide precursors will be overexpressed for selection and characterisation. In selection experiments, peptide precursors (alone or as fusion partners) will be co-expressed (using inducible expression) with synthetases to generate the polyheterocycle in vivo. This will result in GMMs expressing potentially bioactive molecules in mixed cultures. Selection experiments will not use more than $10^9$ bacterial cells at any one time.

For characterisation, precursor peptides are going to be expressed and purified prior to in vitro modification by purified synthetases (unless in vivo heterocycle synthesis is significantly more efficient).

Forseeable effects:
Because of the fiversity of the precursor peptide library, it is possible that variants hazardous to human health will be generated. The risk derives from the direct effect of the modified peptides and potentially by altering how the bacterial cell expressing the polyheterocycle variant interacts with human cells. The risks are minimised by using inducible systems and through the small experimental scale.

Effect of gene transfer:
Gene transfer would require concomitant transfer of the three synthetase genes and the peptide precursor (or its cell display version), which will be on separate plasmids.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste, including bacterial agar and plasticware (used in bacterial growth, selection, screening or purification), will be autoclaved before disposal by incineration. Autoclaving will be carried out at UCL, facilities following autoclave's manufacturer recommendations to obtain effectively 100% kill.

Liquid waste, including bacterial cultures and cleared cell lysates, will be chemically inactivated with Virkon (with concentrations above manufacturer's advice to obtain 100% kill) prior to being disposed down the sink.

Project Additional Information

Purposes of the contained use

Proposed activity for a new lab carrying out PI3-kinase research, to generate, introduce, express or knock-down in mammalian cell systems, genes which have a potential for cancer therapy.

Recipient or parental organism

Standard disabled bacteria strains derived from E. coli such as DH5alpha, DH10B, XL-1 and BJ183 for the 'AdEasy' system.

Animals: C57-B6, BALB/c, ICRF nude, and other murine strains as appropriate (see attached animal GM risk assessment).

Host/vector system

Varous well characterised non-pathogenic mammalian cell lines including HEK293, and various human and murine primary and carcinoma cell lines available from CRUK cell services, ATCC and Clonetics which are well characterised, non-pathogenic; pAdtrack and pAdEasy adenovirus expression systems: Ad5 and Ad2 wild type and deletion mutants, containing inserted transgenes;
pAd/BLOCK-iT Adenoviral RNAi Expression System, E1 region is deleted. The pAd/BLOCK-iT Adenoviral RNAi Expression System is a second generation system. It includes a number of safety features designed to enhance its biosafety. The entire E1 region is deleted. Viral replication only occurs in cells that Express E1. Adenovirus produced from the pAd/BLOCK-iT-DEST expression vector is replication-incompetent in any mammalian cells that do not express the E1a and E1b proteins. Adenovirus does not integrate into the host genome upon transduction. Because the virus is replication-incompetent, the presence of the viral genome is transient and will eventually be diluted out as cell division occurs;
Please refer to attached risk assessment for more details.

**Origin & function**

Replication defective viruses will contain the following types of genes:
Genes that can induce differential tumour cell suicide including tumour suppressor and apoptosis-inducing genes including PTEN, p53, p16 and members of the bcl-2/bax family; Dominant-negative mutants including mutants of signal transduction molecules such as PI3-kinase, RAS, AKT, MAPK or molecules that regulate their functions (such as the APPL1 adaptor protein); These would produce molecules that would promote tumour cell death but have no effect on normal cells.

Marker genes such as GFP, beta-Galactosidase and Luciferase will also be used as control vectors.

In all viruses used only one transgene will be expressed in one construct at any one time.

Constructs will be targeted to mammalian cells and models of disease.

**Evaluation of foreseeable effects**

Most gene products as described previously act within tumour cells to promote cell death. Replication defective viruses (E1A deleted) cannot replicate or produce virus from recombination events in normal cells as the genes would not be present to complement.

None of the genes expressed can complement for the defective nature of the viruses: inclusion of a gene such as p53 would actually restore wild type function of the cancer cell (rather than the virus) and make the virus unable to replicate.

Work with replication incompetent adenoviruses will take place within a Cat 2 environment where protected clothing is worn, and will be manipulated within a biological safety cabinet. In case of accidental spillage spills would be immediately inactivated with Distel disinfect and a breathing mask used to avoid inhalation. This will reduce the likelihood of exposure to an extremely low level.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Work with GM animals for this project will be carried out in the BSU facilities at UCL: Within these facilities, the mice will be housed in individually ventilated cages within a strictly contained environment, within a specialised unit staffed by experienced personnel. There is no opportunity for experimental mice to escape to the local environment; rooms where GM animals are housed are fitted with rodent barriers and also all external doors leading to the unit. Drains are fitted with mesh to prevent release of GM animals to the environment. The survival of GM animals in the environment is considered negligible as they are specifically bred laboratory strains with low fecundity.

Staff working within this facility will be given full training on handling GM animals and will work using the appropriate protective clothing. Adenoviral constructs will be administered to the mice via intra-tumoural injection and tail vein injection.

It is highly unlikely that any virus will be shed by the animals, and risk to human health is negligible - work within a Ct 2 facility should minimise exposure. Material exposed to GM animals ie:bedding, carcasses, cages (and anything else that lends itself to autoclaving) will be autoclaved to render it "no longer live GM" before being disposed of as clinical waste

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
The likelihood of release of GM organisms from the laboratory is low as all GM waste is decontaminated before incineration through UCL waste contractors. No viable GMOs are discarded.

1. Solid waste:
Contaminated glassware is disinfected first with 1% Distel (Trigene), before autoclaving (134°C, 20min, effectively 100% kill). Distel is a high level disinfectant. Plasticware that has come in contact with the organisms mentioned above is either autoclaved (134°C, 20 min, effectively 100% kill) then incinerated as clinical waste, or put into 1% Distel overnight, washed and then incinerated as clinical waste.

2. Liquid waste:
Tissue culture liquids: Liquid waste is diluted overnight in 1% Distel, after which the solution is disposed of down the sink.

Distel is used following manufacturer's instructions and will provide effective kill from overnight treatment;
Distel: Broad spectrum efficacy within short contact times - 30 seconds to 5 minutes;
Sporicidal, Mycobacterial, virucidal, fungicidal and bactericidal efficacy;
Performance validated within a wide range of peer-reviewed scientific publications;
Acknowledged and recommended by professional societies, public and private sector healthcare institutions

# Project Additional Information

## Purposes of the contained use

The development of gene delivery technology is a vital component as both a biological research tool and as a means of evaluating gene therapy protocols for future clinical use. Although there has been tremendous progress in developing viral vectors to deliver therapeutic genes into mammalian cells, more research is required to achieve the efficiency required for clinical use. Furthermore, the delivery of reporter genes to cells is a vital component of furthering our understanding of diseases in mouse models. Unfortunately, the use of cultured cells in vitro is not sufficient to model the complex issues at hand and so in vivo rodent models are required. The purpose of our work is to continue developing viral vectors for their eventual use in the clinic and to also use them to further understand disease.

A variety of disease-specific transgenes will be packaged into various different gene therapy delivery agents (vectors) which will then be tested for their efficacy in either normal outbred mice or the appropriate transgenic mouse model. The diseases studied include defects of the nervous system (e.g. Gaucher disease, Parkinson's disease, Infantile Neuroaxonal Dystrophy and Batten's disease). The gene therapy vectors will include adeno-associated viral (AAV) and lentiviral constructs.

In addition, gene transfer can be used to deliver luciferase under the control of signalling pathway-specific promoters. Therefore, the equivalent of luciferase-reporter mice can be generated easily and quickly without having to purchase and breed entire colonies. This technology is likely to significantly reduce the number of mice used to study disease pathways and we aim to explore the full potential of this technology ("photonic somatotransgenic biosensing") across numerous disciplines, by using various disease model systems.

This project involves the construction of various viral backbones and so we will be using many combination of promoter, transgene and viral backbone (e.g. retro/lentivirus, AAV). For example we may wish to construct an AAV backbone containing the human phospholipase A gene controlled by the neuron-specific synapsin promoter. Alternatively, we may wish to construct a lentiviral backbone containing the CLN3 gene controlled by the ubiquitous CMV promoter. To keep this application as broad as possible it is not possible to provide exhaustive lists of all constructs. However, as all constructs being dealt with here are non-toxic DNA sequences they all carry the same risks and have the same health and safety considerations.
The developed viral vectors carrying either therapeutic or reporter genes require to be administered to mice housed at the Biological Services Unit, UCL School of Pharmacy, University College London. These vectors will be injected into the mice by various routes of administration. It is the administration of these vectors to mice within the BSU at the UCL School of Pharmacy that is covered by this application.

Recipient or parental organism

Recombinant adeno-associated viruses (AAV):
All AAV vectors used here are replication-defective through deletion of the rep and cap genes and insertion of the recombinant gene expression cassette within the AAV inverted terminal repeats (ITRs). The AAV vectors are generated by co-transfection of the AAV vector (carrying the expression cassette) and a helper plasmid carrying the helper functions necessary for AAV packaging in trans. The cells are then infected with a plasmid containing the adenoviral serotype 5 genomic sequence to provide helper function for AAV replication. Upon a cytopathic effect in the cells, AAV particles are harvested and purified by HPLC.

Recombinant retroviruses (including lenti- and spuma-viruses):
Replication deficient retroviral particles are generated in cell lines following co-transfection of three different plasmids. These supply the self-inactivating transfer vector containing the insert gene and viral Long Terminal Repeats (LTR) (but lacking any expression of HIV genes); packaging and structural proteins, gag/pol; and envelope (env) in the multi-deleted packaging plasmid pCMVdeltaR8.74 and in the pMD.G2 plasmid (in the case of VSV-G). The env gene is taken from another virus (eg vesicular stomatitis virus G (VSV-G), baculovirus gp-64, filovirus glycoprotein or mouse leukaemia amphotropic/ecotropic envelopes) which result in lentiviral particles able to transduce a variety of cell types. The transfer vector also contains a poly-purine tract (cPPT) and the woodchuck hepatitis virus post-transcriptional regulatory element (WPRE) for increased efficiency of production. The vector produced is self-inactivating due to a deletion in the promoter/enhancer region of the 3' LTR, that gets copied onto the 5' LTR during transduction of the cell and prevents production of viral RNA. The only expression from the vectors is of the transgene cDNA, controlled by an internal promoter.

Host/vector system

Prokaryotic plasmids, eukaryotic expression vectors, replication-deficient self-inactivating (SIN) lentiviral vectors which are based on third generation lentiviral vectors (i.e. pCCLSIN) or second generation vectors (i.e. pHR'SIN) with engineered safety features which are resembling third generation vectors in terms of safety.

Origin & function

All inserted sequences are from either human, mouse, firefly or bacteria.

All gene products are either enzymes (e.g. glucocerebrosidase and phospholipase A), reporter genes (e.g. GFP and luciferase), transmembrane proteins e.g. CLN3 or NPC1) or siRNA hairpin sequences.

None of the sequences fall into any harmful category such as oncogenes and proto-oncogenes, growth factors and GF receptors, any other sequences coding for significant biological activity that might be harmful were these to be expressed in people accidentally exposed to the vector.

In the unlikely event that any of these inserted sequences were to be expressed in humans after accidental transfer, the cDNA sequences or the RNAi hairpins could lead to expression of functional proteins or to the down-regulation of the gene to which the RNAi hairpin targets via RNAi interference, respectively. Expression of the inserted cDNAs is deemed to hold little risk due to the non-harmful nature of the sequences used and the number of cells that would be affected by accidental exposure. Accidental targeting of RNAi in humans is not deemed to be harmful either due to a combination of the function of the targets, no expected harmful action of other molecules when presence of lower amounts of the target, and the expected relatively low amount of cells involved. In addition, for both types of sequence, the effect of accidental expression would not be severe due to the fact that all viruses used are replication deficient and so no new virus particles can be produced so no other cells can be infected. It is possible that physical insertion of the virus into the genome of the host cell could potentially disrupt a tumour suppressor or oncogene, however, the likelihood of this is extremely low.

The risk to the species in the environment is even lower since they would only be exposed to much smaller amounts of the sequences.
Evaluation of foreseeable effects

The mammalian donor organisms are not harmful however some of the donated sequences are from viruses (e.g. the envelope proteins VSV-G from Vesicular Stomatitis virus and gp 64 from baculovirus) some of which are infectious to humans.

The sequences used from viral donor organisms are either promoters/enhancers or envelope proteins so none of these are involved in the harmful characteristics of the original donor organism. Even if these viral sequences were introduced into the body by ingestion, through a wound or after spillage onto skin, the viral sequences would not enter human cells and would therefore not be expressed. The sequences used from mammalian or bacterial donor organisms are the transgenes or RNAi hairpin sequences, none of which are pathogenic.

The most hazardous GMM is lentivirus. The most hazardous step is injecting the lentiviral constructs into mice due to the use of sharps.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Good Laboratory practice will be used and all material that has been exposed to viral vector will be disposed of by trained service staff. All solid waste (e.g. tubes, syringes, plastics, gloves) will be placed into disposable bags and sharps (e.g. needles) will be placed into sharps bins for immediate autoclaving at 131 degree celsius for 30 mins. This will achieve 100% kill and destruction of any viral vector. Any liquid waste (very small volumes of viral vector, <1 ml) will also be autoclaved at 131 degrees celsius for 30 mins also achieving 100% kill and destruction of viral vector. All animal carcasses that have received viral vectors will be destroyed by incineration that will achieve 100% kill and destruction of vectors.

Examining the progression of neonatal bacterial meningitis (NBM) caused by Escherichia coli K1 using bioluminescent imaging techniques in a neonatal rat model

E. coli O18:K1 strain A192PP (rat passaged strain - Mushtaq et al., 2005) is a human pathogen. The parenteral strain (A192/DSM.No. 10719) was originally isolated from a sepsicaemia patient (Achtman et al., 1983). A192PP may therefore be able to colonise the human adult and neonatal gastrointestinal tract, although rat-passage makes this less likely. Neonates are at higher risk. Additionally, the E. coli A192PP GM strain will have acquired kanamycin resistance. Due to the risk presented to human health contained use is required.

pUTmini-Tn5.

The plasmid can only be maintained in lambda pir+ donor strains (donor strain to be used: E. coli S17-1 lambda pir). Plasmid can be transferred by conjugation from donor to recipient (A192PP) (pir negative strain) and acts as a suicide vector. The mini transposon is disarmed and so forms stable integrations within recipient
chromosome and cannot re-mobilise (Winson et al., 1998).
E. coli S17-1 lambda pir (donor): lambda-pir lysogen of S17-1 (thi pro hsdR3 hsdM. recA RP42-Tc: :Mu-Km: :Tn7(TpR SmR)) (Simon et al., 1983) - enables the donor strain to maintain the pUTmini-Tn5 plasmid.

**Origin & function**

**luxCDABE Km2.**
The entire lux operon (luxCDABE) from the nematode symbiont Photorhabdus luminescens ATCC29999 (Hb strain) (Winson et al., 1998) will be inserted into recipient (E. coli O18:K1 A192PP) chromosome. Along with a kanamycin resistance cassette (Km2).
The operon will provide the mechanics for bioluminescence emission from the recipient. Recipient strains will also become resistant to kanamycin (kanR) due to acquisition of mini-Tn5 luxCDABE Km2 (which will be used for selection purposes).

**Evaluation of foreseeable effects**

- As previously described, the E. coli A192PP strain will acquire bioluminescence (luxCDABE) and kanamycin resistance (Km2).
- **Hazards to human health**
  - E. coli A192PP GM strain (like the parental A192PP strain) may be able to colonise the human adult gastrointestinal (GI) tract if ingested, however rat passage of the parent strain (A192) makes this less likely.
  - E. coli A192PP GM strain (again like the parental strain) may be able to colonise the human neonatal GI tract, however risk of exposure of such individuals is considered low. However, if exposure occurred, the most hazardous outcome could be sepsis and meningitis. Again, as detailed above, rat passage of the parent strain (A192) makes this less likely. However, any individuals at risk/working with this GMM will be informed of possible danger to neonates before entering facilities. No vaccine is available, however antibiotics, including but not limited to betalactams, aminoglycosides, tetracyclines and chloramphenicol can be used, should prophylaxis be required.
  - E. coli A192PP GM strain will acquire kanamycin resistance. However other antibiotics, as stated above, can be used for prophylaxis.
  - The acquisition of foreign genetic material may increase, decrease or have no effect on the virulence of the strain. This will depend on where transposon insertion occurs (random event). However, due to the expected metabolic burden on the strain (caused by the presence of exogenous genetic material), a reduction or no change in virulence is expected to be observed.
  - The acquisition of bioluminescence is not expected to present any hazard to human health.
- **Hazards to the environment**
  - If colonisation of a host with the E. coli A192PP GM strain did occur, the organism could be shed into the environment in faeces/urine.
  - E. coli A192PP GM strain is unlikely to transfer the transposon to other bacterial strains in vitro, in vivo or in the environment, as the mini-Tn5 to be used is disarmed (transposase is present on the suicide vector, but lost during integration into host chromosome). This enables stable integration into the recipient chromosome (i.e. transposon is not self-transposable).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

UCL School of Pharmacy
- Solid waste (contaminated agar plates, rat carcasses, peri-anal swabs, plastics and sharps): autoclavable waste will be placed in two autoclave bags (double-bagging) and placed in blue boxes for collection by UCL School of Pharmacy support staff on a daily basis and be sterilised by autoclaving for a cycle of 120°C for 15 mins. Autoclaved waste will then be disposed of by support staff. Rat carcasses will be macerated/incinerated and disposed of by Biological Services Unit (BSU) support staff. Contaminated sharps (e.g. surgical scissors) will be sterilised by autoclaving. Other sharps (e.g. syringe needles) will be placed in supplied yellow sharps bins and disposed of by UCL support staff for incineration.
- Liquid waste (liquid bacterial cultures, blood, organs (homogenised): autoclavable waste will be placed in two autoclave bags (double-bagging) and placed in blue boxes or placed in buckets for collection by UCL School of Pharmacy support staff and treated as above.
- Personal protection equipment/clothing will be disposed of in accordance with UCL regulations.

Imperial College London
- Waste at Imperial College will be disposed of in accordance with local rules and regulations.
- During imaging procedures, urine/faeces are expected to be shed by neonatal rats - disposable animal beds will be used (with an additional layer of clingfilm will be placed underneath the imaging platform). This waste will be removed after imaging, bags sealed, returned to containment, autoclaved and disposed of in accordance with local Imperial College rules and regulations.
- CBS personal protection equipment/clothing will also be disposed of in accordance with Imperial College regulations.

**Project Ref** 14/15.1

**Date Ackn’d** 25/03/2015

**CU2 Project Title** Ranavirus host range and virulence - identifying the genetic mechanisms facilitating host range and virulence of viral pathogen that threatens European amphibian biodiversity

**Class** Class 2

**Culture Vol** < 1 Litre

**Consent Granted**

**Historical Significant Changes**

**Historical Date of Additional Info**

**Non-GMM**

**Historical Significant Changes**

**Recipient or parental organism**

Ranaviruses are an important amphibian pathogen; outbreaks in Europe have involved two lineages of virus (FV3-like and CMTV-like; Teacher et al. 2010, Price et al. 2014) which are both highly virulent but appear to have differing host ranges. We have identified a list of variable loci between the two lineages, which we consider non-essential since they represent genes where presence/absence varies across the virus phylogeny. The aim of knock outs is to explore this variation among ranaviruses at the genome level (novel and truncated genes) and how this may contribute to patterns of virulence and host range that we have observed in the wild. We will be replacing genes of interest with a marker cassette by recombination and will be following an established protocol (Chen et al., 2011).

Wild-type ranavirus strains - No members of this virus genus (or family) vector are known to infect mammals and they cannot grow in cell culture at temperatures above approx. 30C. Neither the wild type viruses nor the GMMs are therefore considered a threat to human health. Virus is cultured in a fish cell line (EPC). Wild type ranaviruses may pose an important risk to amphibian hosts and may also affect reptiles and fish. Amphibian ranavirus infections are notifiable to the OIE. We expect all/most KOs to generate viable GMMs due to our rationale for selecting genes for KO (mentioned above), and consider that standard aseptic procedures used routinely in culturing these viruses will ensure the likelihood of revertants is very low. Revertants have not been observed previously when the same protocols were followed elsewhere.
Host/vector system

Origin & function

Puromycin (antibiotic) resistance marker forms part of the inserted cassette in addition to green fluorescent protein (GFP, not considered hazardous to health). The inserted material will serve to purify and identify the GMM. There are no known direct hazards associated with the inserted material. Puromycin is an antibiotic used in laboratory cell culture and does not have medicinal uses meaning that any theoretical impact of release into the environment should be small. There is a possibility that the inserted cassette could be disseminated and maintained in the outside environment however the inserted genetic material is innocuous and the risk of dissemination is very small and can be limited further through standard containment protocols. Ranaviruses may persist for weeks or months in water and soil (Nazir et al., 2012) but they are obligate parasites of poikilothermic vertebrates that elicit infections in a dose-dependent fashion. Virus inactivation with routinely used disinfectants (bleach, virkon) is highly effective (Bryan et al., 2009) and autoclaving of waste provides a second layer of containment. The importance of adhering thoroughly to aseptic procedures to prevent contamination of virus cultures with xenobiotics and/or other ranavirus isolates being cultured simultaneously serves as a prerequisite barrier to dissemination of virus to the outside environment.

Evaluation of foreseeable effects

Neither the GMMs nor the process of generating them are considered a risk to human health. Ranaviruses can pose a severe risk to poikilothermic vertebrates (especially amphibians) but the innocuous nature of the inserted genetic material, the routine containment and disinfection protocols and the nature of the pathogen as an obligate parasite which is inactivated in the environment through time together identify this GM procedure as low risk.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Gloves and plastic consumables will be subjected to autoclaving (two 20min cycles at 120 celcius) prior to incineration, animal waste will be bagged securely and incinerated. Unused cultures will be treated with 5% Virkon solution and autoclaving (Two cycles of 20 mins at 120C).

**Project Ref** 14/15.2

- **Date Ackn'd**: 01/04/2015
- **CU2 Project Title**: Growth and transformation of Mycobacterium tuberculosis, Mycobacterium bovis (HG3 agents), Mycobacterium marinum, Mycobacterium bovis BCG
- **Class**: Class 3
- **Culture Volume Class 2**: < 1 Litre
- **Class Culture Volume Class 3-4**: < 1 Litre
- **Non-GMM**: Yes
- **Consent Granted**: Yes
- **Project notified under transitional arrangements**: N

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

Investigating the expression, turnover and role of regulatory RNA in Mycobacterium tuberculosis, Mycobacterium bovis, Mycobacterium marinum, Mycobacterium bovis BCG. Infection of cell lines or primary cells with either of the pathogens listed to investigate the effects that the modifications may have on pathogenesis. In addition we will investigate the possibility of using C. elegans as a host for M. marinum.

**Recipient or parental organism**
The most likely consequence of the planned modifications in all the species is a loss of bacterial fitness due to the imbalance in gene regulation. The vector inserts drive the expression of various mycobacterial RNAs or proteins as well as anti-bacterial resistance markers against hygromycin or kanamycin, commonly used laboratory antibiotics which would not be used as a treatment and so no hazard arises from this. Regulatory RNA and cell wall remodelling enzymes could in theory modify the host so it became slightly more tolerant to stress, but it is more likely to results in decreased fitness of the host cell and reduced tolerance to stress and antibiotics. GFP, beta-gal and the myc-tag have not been reported to have any effect on human health.

Host/vector system
Shuttle vectors able to replicate in Escherichia coli for cloning purposes and for expression or deletion of mycobacterial genes. Vectors are derivatives of pMV261, pMV361, pGOAL17. These vectors do not carry any risk by themselves.

Origin & function
The inserted genetic material is all derived from mycobacterial genes mostly those involved in regulatory RNA expression and genes involved in RNA metabolism in addition to reporter genes such as GFP and lacZ. The insertions are made to investigate the expression patterns and functions of regulatory RNAs.

Evaluation of foreseeable effects
The GMMs would be less likely to cause disease in humans or animals than their parental strains, given the burden of carrying the insert or gene deletion as there is no gain to pathogenicity.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Solid waste is sterilised in 5% Distel for at least 15 minutes after which it is autoclaved as well as incinerated. Agar plates are autoclaved and incinerated. Liquid waste is inactivated by adding Distel to a final concentration of 10% for at least 15 minutes before disposal.
Distel (formerly Trigene Advance): Contact time to kill Mycobacterium tuberculosis (TB) 30 seconds mixed at 1:20; 5 minutes mixed at 1:50. Distel has been found to be biocidal with 30 seconds to 5 minutes against a range of mycobacterial species, including M. tuberculosis.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The UCL GMSC agreed the classification of the work as Activity Class 2 and 3, subject to additional detail being provided, in particular on environmental risks. They agreed notification as a connected programme of work.

### Project Additional Information

**Purposes of the contained use**

This project will involve the production, storage, use and distribution of lentiviral and non-lentiviral vector based genome engineering tools, including CRISPR and TALE technologies. Vectors will be distributed as either bacteria, DNA and/or lentivirus to members within the UCL Cancer Institute at University College London for use in various...
projects. This will include lentiviral production from lentiviral vectors expressing genome engineering tools including CRISPR and TALEs, and subsequent use of this lentivirus in cell based screening functional assays. Additionally, large numbers of lentiviruses containing CRISPR guide sequences will be pooled in bacterial, DNA and viral formats to transduce cells in screens to subsequently undertake functional assays. Pooled DNA/virus will be distributed to people within the Institute and wider UCL for screening in various other projects.

Recipient or parental organism

| Cell lines: canine-MDCK, DK, D17, C2F; feline- AH927, CRFK, Mya1; Human-HeLa, TE671 , HT1080, 293T, HEL, HFFF, BJ1, Jurkat, CEM, supT1, C8166, A549, LECs, tMSCs; Mouse- MDTF, NIH3T3; Avian- QT36; MarsupialSC300; Bat Tb1lu; non-human primate- FRhK4, LLCMK2, CV1, VERO, Pindak, SMLF; bovine- MDBK, IMR31; Porcine- PK15, SKL, CPK, STIOWA; Mink- mv-1-lu; Rabbit- SIRC,eREP, ratHSN, RAT2, 9L, NRK. Primary Human and Mouse cells: Derived from various human and mouse tissues including embryonic stem cells, peripheral blood derived lymphocytes and macrophages. Bacterial E coli strains- HB101, XL 1-blue, Top10, PrimePlus, JM109, BL21, DH5alpha, SURE, KS1000, DE3, Lucigen Endura cells. Associated risks and likeliness of occurrence: The recipient cells (cell lines and primary cells) that will eventually receive and integrate the DNA are harmless to humans. They are also unable to survive outside culture conditions and are therefore harmless to the environment. The bacterial strains used are attenuated non-colonising strains that are harmless to humans and cannot survive outside culture conditions and are therefore harmless to the environment. |

Host/vector system

Lentiviral vectors:
Various 2nd and 3rd generation lentiviral expression plasmids including pLKO.1 and derivatives.
Lentiviral packaging vectors:
2nd and 3rd Lentiviral accessory and packaging vectors including Gag/pol expression vectors p8.9, psPAX2 and derivatives (accessory packaging vectors derived from HIV-1) and viral envelope expression vectors including pMDG and derivatives (expresses VSV-G from Vesticular Stomatitis Virus).
Non-viral expression plasmid vectors:
Various non-viral DNA plasmid vectors containing various mutations/genes either to expressed from the cell without integration or regions inserted into the recipient genome by homology dependent repair pathways. This includes PiggyBac vectors from Transposagen which are non-viral/non integrating expression vectors. PiggyBac vectors include two components expressed together in a cell 1) vector containing a cassettes of various genes that will be inserted into the genome at transposon sites 2) Vector expressing transposase that will mediate the integration of the expression cassette in 1 at transposon sites.
Details on Lentiviral system and vectors:
Lentiviral vectors are made by transfecting 3 plasmids into a packaging cell line such as HEK293T cells. The 3 plasmids used are contained within or will be transformed into E.Coli (see above) for propagation. The 3 plasmids are 1) a packaging plasmid expressing the required accessory proteins for viable viral particle production 2) an envelope plasmid, expressing the envelope protein for the viral particle and 3) the lentiviral vector carrying the cassette with the inserted sequence of interest. Once all 3 vectors are in the cell, each component from the 3 vectors will be expressed. The co-expression of the components from the various vectors will allow the formation of viral particles which will be released from the cells. By separating the components onto 3 independent plasmids, that do not have enough
homology to recombine, the viral packaging elements are not packaged into the virus themselves making the vector disabled and incapable of self-replication. This system therefore is incapable of producing replication competent virus making it very safe. In this particular project, the lentiviral expression vectors are packaged into VSV-G pseudotyped viral vectors made from gag-pol and VSV-G expression vectors that have been transfected into human cells.

Associated Risks and likelihood of occurrence:
Non-viral expression vectors including PiggyBac vectors many randomly integrate into the host cell genome but are non-viral and cannot establish an infection. They will not be able to enter cells of non-laboratory cells without specialised cell entry reagents and are therefore very safe.
The lentiviral vectors can infect human cells or any other mammalian cell as they are pseudotyped with the envelope protein VSV-G from the vesicular stomatitis virus and therefore if introduced into the body by injection, ingestion or through a wound, the virus could potentially enter cells and integrate its genome into cellular DNA. Physical insertion of the virus into the genome of the host cell could potentially disrupt a tumour suppressor or oncogene leading to an oncogenic mutation, however the likelihood of this is very low and has only occurred in a clinical setting following prolonged infection with high titre lentiviral vectors encoding growth promoting molecules and selection in vivo for cells with altered growth potential. Additionally, it would not be as severe as the virus is replication incompetent (does not carry gag, pol or env genes) so it cannot make new progeny virus and establish a productive infection. Also, it would only be a small number of cells and therefore would not impact on the pathogenic outcome of an exogenous viral infection. Additionally, the likelihood of infection is very low. No adverse effects have ever been described through accidental exposure to retroviral vectors. The viral particles are labile and do not survive on environmental surfaces outside the laboratory.
The packaging viral components are from the HIV-1. The full length HIV-1 virus is harmful to humans, however the packaging vectors used do not contain the full length HIV-1 molecule. Many components of this virus that are critical for HIV-1 infection have been removed with only those required for viral packaging remain. It is therefore attenuated and cannot replicate and form new viable virus.

Origin & function

The sequences contained within the lentiviral or non-viral expression vectors include:

Health and Safety

Guide RNAs: A component in the Clustered Regularly Interspaced Short Palindromic Repeats (CRISPR) Type II system - a RNA-Guided Endonuclease technology used for genome engineering. The guide RNA is a combination of the bacterial crRNA and tracrRNA molecules. The guideRNA encompasses various small de novo derived 17-20bp sense and antisense sequences that are homologous with a genomic DNA region of interest, which are designed to target anywhere within the Human or Mouse genome. This sequence defines the targeting specificity of the guide RNA where it will bind the DNA, triggering the (CRISPR associated) Cas9 endonuclease to make a double stranded break in the genomic DNA at this site. This triggers a DNA repair mechanism response which in turn results in genome modifications.

CRISPR associated 9 (Cas9) endonuclease: A component in the Clustered Regularly Interspaced Short Palindromic Repeats (CRISPR) Type II system- a RNA-Guided Endonuclease technology used for genome engineering. Cas9 is recruited to the genomic location by the bound guideRNA and cuts the DNA at this location. We will also use mutant versions of Cas9 that cannot cut the DNA but will be linked to various other effector molecules such as transcriptional activators/repressors which result in epigenetic modulation of DNA expression at this location.

Transcription activator-like effectors (TALEs): TALEs are modular proteins that can be designed to specifically bind to a desired region of genomic DNA. These TALE molecules can be linked to nucleases which will result in cutting of the DNA at the genomic location where the TALE binds, trigerring a DNA repair mechanism response and genome
editing, or linked to various other effector molecules such as transcriptional activators/repressors which result in epigenetic modulation of DNA expression at this location.

Other donor sequences:
Contain regions of homology with the genomic DNA of the system of interest alongside additional sequence with desired mutations, additional genes, fluorescence markers or antibiotic resistance genes that will be incorporated into the genomic DNA by DNA repair mechanisms when the TALE or Cas9 molecules have cut the DNA. The sequences contained within the PiggyBac expression vectors include:
Additional genes, fluorescence markers or antibiotic resistance genes, that will be incorporated into the genomic DNA at transposon sites when expressed alongside transposase from a separate non-viral/non-integrating plasmid.

Evaluation of foreseeable effects

Risks and likelihood of risks:
Health and Safety
Executive
The bacterial strains to be used are non colonising and incapable of surviving in the environment or causing human infection. They pose no risk to users or the environment.

None of the DNA viral vector plasmids are harmful to health or to the environment and do not supply a survival advantage to any microorganisms. The packaging viral components are from the HIV-1 virus. HIV-1 is harmful to humans, however, the packaging vector does not contain the full length HIV-1 molecule. Many components of HIV-1 that are critical for HIV-1 infection have been removed from the packaging vector. Only those essential for viral packaging remain.
The most dangerous GMM is the lentiviral preparations and the most dangerous step is the collection, concentration and use of this lentivirus, however this risk is minimal. Lentiviral vectors can infect human cells and therefore if introduced into the body by injection, ingestion or through a wound, the virus could potentially enter cells and integrate its genome into cellular DNA. If the inserted sequence were to be expressed in humans after accidental transfer, Cas9rr AL could cut and induce genome engineering changes in the host genome that may result in mutations that have oncogenic potential or mutations that have a severe effect on cell survival or normal function. Pooled viral libraries will also be used that contain many different guideRNAssrrALEs in the one pool, and some of the guideRNAssrr ALEs in these pools will result in mutations that have oncogenic potential or mutations that have a severe effect on cell survival or normal function. Additionally, physical insertion of the virus into the genome of the host cell could potentially disrupt a tumour suppressor or oncogene. However, the likelihood of infection very low as . all work will be performed in containment level 2 facilities. If a person were infected by infectious lentiviral particles they are replication incompetent (does not carry gag, pol or env genes) so they cannot make new progeny virus and establish a productive infection, so there is no chance of transmission to another cell or person. Also, it would only be a small number of cells and so would not impact on the pathogenic outcome of an exogenous viral infection. It is extremely unlikely that an infection would occur and no adverse effects have ever been described through accidental exposure to retroviral vectors therefore the overall risks of our experiment are low. Additionally the viral particles are labile and do not survive on environmental surfaces outside the laboratory making infection unlikely. Non-viral expression vectors including PiggyBac vectors many randomly integrate into the host cell genome but are non-viral and cannot establish an infection. They will not be able to enter cells of non-laboratory cells without specialised cell entry reagents and are therefore very safe. The cell lines used cannot survive outside the laboratory incubators and as such pose no threat to health or the environment.
Precautions in place to minimize risks
The entire of the Cancer Institute is a containment level 2 facility which is secured by restricted access at all entrances and additionally to all laboratory areas. All work involving viruses will be performed in class 2 cabinets in containment level 2 laboratories specified particularly for retroviral GMM work. All DNA
plasmids containing viral proteins will be grown separately to avoid opportunity for recombination. To prevent contamination of workers by virus, when handling any GMM or GMM-derived DNA or virus, no glass or other sharps will be used in the rooms where the viruses are prepared and used and workers will be protected by a lab coat and nitrile gloves. Skin lesions will be covered with a bandage in addition to the protective wear described above. Specific guidelines will be in place to ensure all viral preparations are handled, labelled, stored, transported and cleaned up correctly. All those involved in the project will be made aware of the guidelines and the associated risks as well as anyone else who may use the laboratory. Persons involved on project from other Institutes will work under the supervision of a competent trained worker from this project. No-one visiting the laboratory that is not involved in this work will work on this project. All persons entering the facility will be made aware of the safety precautions upon entering the facility. All equipment used in the retroviral laboratory will be available in other general purpose laboratories for general use so it should not be necessary for others who are not involved in retroviral work to enter the laboratory.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

10% Distel or Virkon (v/v) will be used to disinfection any solid waste including plastic flasks and tubes or other equipment and laboratory and liquid waste (16 hours) and also used to decontaminate any spills. Liquid waste is subseously poured down the sink after treatment. Work surfaces will be wiped down with 10% Distel and 70% ethanol after use.Virkon and Distel are certified by the PHLS to provide 100% viricidal and GMO kill under these conditions by denaturing and inactivating viral and cellular proteins. Distel and Virkon will be used with their lifespan to ensure required kill is achieved. Solid waste will be double-bagged in biological waste bags, sealed and autoclaved 132c for 15mins by trained staff then bagged in yellow biohazard bags and removed by UCL waste services. Autoclave runs are regularly validated by waste management staff

* Work with non-viral expression vectors including PiggyBac vectors will not require the treatment outlined above due to the safety of these reagents (non-viral). Solid waste will not be disinfected and will be double bagged in yellow biohazard bags and removed by UCL waste services for incineration only.

Is an emergency plan required according to regulation 20? N

The UCL GMSC approved this project as a Class 2 activity at their meeting on 12/12/14.
### Project Additional Information

**Purposes of the contained use**
Generate and use human and rat olfactory ensheathing cell lines conditionally immortalised using viral vectors.

**Recipient or parental organism**
Primary rat and human primary cells from the nervous system transduced with viral vectors.

**Host/vector system**
JS4, a recA-derivative of E.coli MC1 061, a disabled K12 strain. Non-mobilisable.

PA371, a second generation mouse amphotropic producer cell line that was used to derive the high titre producer for the U19tsA58 T antigen. Non-mobilisable.

TEFL YA and RD cells - both are derivatives of TE671 cells, third generation human packaging cell lines for production of stable, high titre defective helper-free amphotropic retroviruses that have a murine or feline envelope. Nonmobilisable.

Phoenix amphi cells are non-mobilisable derivatives of HEK293, used for production of high titre transient amphotropic virus stocks. Phoenix amphi were originally developed by Gary Nolan but obtained from ATCC. Free of adventitious agents.

pZipNeoSV(X)1, pBabeNeo/Hygro/Puromycin, pBabeNeo/HygroZeo, pBabe-puro-MyCER, pLNCX, pLNCX2, pLHCX, pLPcX, pWZLPuro, pWZLBlastF, pTMP, pUC57, pWZLPuro/BlastF, pRetroSuper

Origin & function

The proteins produced from the immortalizing genes are biologically active in humans and have the potential to extend the proliferative life span. SV40 T antigen, the catalytic subunit of human telomerase, HPV E7 and E6 proteins, Polyoma virus T antigens, Adenovirus E1 A, p53GSE, c-MycER are all immortalizing genes and have the potential to extend the proliferative life span of normal somatic cells. However, The c-MycER and ras-ER are oncogenes only active in the presence of tamoxifen, and tsSV40 U19tsA58 is biologically active only whilst cells grow in permissive conditions (33°C), and when growth in non-permissive conditions, there is an irreversible lost of immortality. VEGF-A 121, VEGF-A 165, VEGF-A 165/PIGF-2123-144, bFGF/PIGF-2123-144, PDGF-AA/PIGF-2123-144, IGF-1/PIGF-2123-144, GST-PIGF-2, GST-PIGF-2123-144 and NT3/PIGF-2123-144 encode for growth factors with or without a promiscuous domain (PIGF-2123-144) that binds with high affinity to extracellular matrix.

SV40 large T antigen and mutants there of obtained from Y. Gluzman, P. Sharp, P. Tegtmeyer, A. Smith, J. Pipas, T. Roberts and constructed by P. Jat.

Human catalytic subunit of telomerase from R. Weinberg.

c-MycER from Littlewood.

Human Papilloma virus 16/18 E7 and E6 gene from D. Shalloway.

Polyoma virus T antigens and mutants there of from B. Griffin, W. Eckhart and M. Fried.

Adenovirus E1 A and mutants there of from S. Lowe. P53 GSE fragment from A. Gudkov.

Full length ORF for cellular genes from ATCC and Gene Service.

Activated ras fused to estrogen receptor from J. Gil.

pmiR-Vec expressing micro RNAs from Gene Service.

VEGF-A121, VEGF-A165, VEGF-A165/PIGF-2123-144, bFGF/PIGF-2123-144, PDGF-AA/PIGF-2123-144, IGF-1/PIGF-2123-144, GST-PIGF-2, GST-PIGF-2123-144 and NT3/PIGF-2123-144 from M. Martino.

Evaluation of foreseeable effects

The transduced genes either singly or in combination can immortalise human cells. Therefore the viruses containing these genes could immortalise the operator's cells if they were exposed by inoculation.

Safety procedures ae in place that make the possibility of self infection remote. In addition, because the viruses are defective and helper free, they should not be able to spread themselves beyond the site of inoculation. The cultures of human cells transduced with the viruses should not produce infectious virus, because the viruses are defective and helper free. In addition, such fells should be rejected by the immune system following inoculation.

Most of the genes alone are unable to cause tumours but can cause tumours in conjunction with other genes. SV40 T antigen is an exception because it can act as an oncogene but at a low frequency and most likely in concert with cellular mutations. Ras does not cause tumours alone- other mutational events are required.

The vector itself could cause harm if it is integrated in the vicinity of an oncogene and induces its expression or if it is
inserted within a tumour suppressor so that its expression was lost. Integrated proviruses are capable of being mobilized by super-infection with helper viruses. The likelihood is low since the human cells that we will use are not producing helper viruses and we will segregate the transduced cells from other primary cultures, in particular mouse lymphoma cells or hybridomas that frequently produce helper viruses. Transduced cell lines for production of retroviruses will be monitored to ensure that the integrated proviruses have not been mobilized.

The most likely route for accidental release of the GMMs to the environment is through the air either by spillage or aerosolisation of high titre viral stocks- this will be avoided. Transmission is also possible through spillage of virus into drains. No virus contaminated liquid waste will be discarded into drains unless it has been decontaminated using sufficient chloros for >10,000 ppm and left for >24 hours. Neither the E. coli, the packaging cells, the amphotropic viruses or the transduced human cells will survive alone within the environment. The most likely route for accidental release of the GMMs to the environment is through the air either by spillage or aerosolisation of high titre viral stocksthis will be avoided.

The recombinant genes do not cause harm but the vectors encode antibiotic resistance markers that could be transferred if the insert was mobilized. The retroviral vectors encode resistance to G418, hygromycin, puromycin, ampicillin, blasticidin and zeocin and thus the GMMs will be resistant to the appropriate drug.

The cell lines PA317 (derivative of NIH3T3), TEFLYA and RD (derivative of TE671), and Phoenix ampho (derivative of HEK293) cells have a history of safe usage within the laboratory and are free of adventitious agents.

Primary rat and human somatic cells have the potential to be infected with adventitious agents.

The retroviral vectors have a history of safe use of over 15 years.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste such as dishes and flasks will be decontaminated with chloros (>10,000 ppm), or by autoclaving and then incineration. E. coli solid waste (agar plates, tips and pipettes) are autoclaved followed by incineration. Solid waste from tissue culture such as tubes, dishes, flasks and pipettes are autoclaved followed by incineration. After autoclaving or chemical disinfection, waste is put into yellow clinical waste bags or containers, collected centrally and transported by an approved waste route for incineration.

E. coli liquid waste is inactivated by treatment with 1 % Virkon for > 10 minutes. Liquid tissue culture medium is collected into containers containing sufficient chloros for > 10,000 ppm and left for >24 hours. After autoclaving or chemical disinfection, waste is put into yellow clinical waste bags or containers, collected centrally and transported by an approved waste route for incineration.

Is an emergency plan required according to regulation 20? N

Project Ref 14/15.5

Date Ackn'd: 27/05/2015
CU2 Project Title: Recombinant vaccinia virus purification by monolith chromatography

Class: Class 2
CultureVol: 1-50 Litres

Date Project Ceased: 
Non-GMM: Consent Granted

Tick if notifying a connected programme of work: N

Historical Significant Changes
Historical Date of Additional Info
Significant Change ID
Date of Significant Change

Project Additional Information

Purposes of the contained use
Recombinant vaccinia virus (VVL15RFP) is used as feed material for monolith chromatography studies. We want to
characterise the virus binding capacity to ion exchange monolith column and the elution by various salt to find out the virus recovery and ury levels. Cell culture and virus production, cell harvest and disruption, virus recovery are needed to generate the feed material.

Recipient or parental organism

vaccinia virus lister strain

Host/vector system

Vaccinia Virus Lister strain with thymidine kinase (TK) gene deletion and red fluorescent protein (RFP) gene insertion, VVL15 RFP

Origin & function

The origin of VVL15RFP is the wild type Lister strain vaccinia virus. It was designed so VVL15RFP is incapable of normal replication and need helper functions provided in trans in the packaging cell line to generate the virus particles. Wild-type vaccinia viruses have a natural tropism for tumours. Given the remarkable efficiency of vaccinia virus in inducing tissue destruction, genetic modifications of the virus (VVL15RFP) have been designed to create oncolytic vectors that specifically infect and replicate in tumour cells and attenuate in normal cells/tissues. The construct is a deletion mutant with regions of the viral genes that are critical for efficient viral replication in normal cells but dispensable in tumour cells. VVL15RFP with the thymidine kinase gene deletion further diminish virus replication in normal cells.

The red fluorescent protein gene sequence is from the choral Discosoma striata and has been inserted for assay purposes.

VVL15RFP was constructed by Dr. Yaohe Wang's research group in Institute of Cancer, Barts and The London School of Medicine and Dentistry, Queen Mary University of London. We will not perform any further modification of VVL15 RFP.

Evaluation of foreseeable effects

Attenuated VVL15TK-RFP is unlikely to cause an infection in humans. The wide type virus is only known to cause mild flu like symptoms. The TK-gene deletion in VVL15 RFP demonstrably reduces the virus' ability to infect nonimmortal cells and as such it can be regarded as conditionally replicative. Therefore the VVL15RFP virus attenuated by deletion of Thymidine kinase gene diminishes virus replication in normal cells. Even in the event of a complete breakdown of all containment procedures in the laboratory, the risk to human health would be extremely low.

The use of biological safety cabinets, lab coats and gloves, disinfection and autoclaving of waste will reduce the likelihood of exposure to an extremely low level. The laboratory will have restricted access to only a small number of well trained and experienced staff and postgraduates.

Vaccinia virus is unable to survive outside of a highly controlled laboratory environment, and is not able to pass on genetic information to a host in the event of an infection. This is because it can only selectively replicate in the cytoplasm of a host cell, and so doesn't incorporate it's DNA into the nucleus during infection.

In the event of accidental spillage in the laboratory, which is a containment level 2 facility, it would be disinfected with Virkon leading to the rapid destruction of live material thus eliminating the risk of genetic transfer to the environment. Even in the event of a complete breakdown of all containment procedures in the laboratory, the risk to the environment would be extremely low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Liquid waste and cellular material will be treated with Virkon. 1% Virkon is shown by the manufacturer to provide effective disinfection of 100% kill within 10 minutes. https://www.anachem.co.uk/catalogue/product/itemNo/290012

Waste Disposal of contaminated Solid Waste:
Place all plasticware that comes in contact with biological material in a flask containing 5% Virkon for 60 minutes then drain Virkon liquid down sink (with tap running). The plasticware or equipment will be autoclaved. The disposable plasticware will be transferred to a red bin for incineration.

Waste Disposal of contaminated Liquid Waste:
Pour all liquids containing biological material into a vessel containing 5% Virkon for 60 minutes then drain Virkon liquid down sink (with tap running) and transfer plasticware to a red bin for incineration.

Is an emergency plan required according to regulation 20? [N]

Project Ref 14/16.1
The purpose of this work is to identify cellular components important for infection by different viruses. These cellular components can also be used as molecular targets for the development of broad-spectrum antiviral drugs.

The only GMO is a GFP expressing Semliki Forest virus. The other viruses used (Semliki Forest virus, Sindbis virus, Vaccinia virus, Herpes Simplex 1 virus, and Yellow Fever Vaccine strain 17D) are wild type or attenuated viruses.

The GFP sequence was originally derived from Aequora victoria.

The recombinant virus expresses GFP for visualisation and quantification of infectivity. This modification either has no impact on virus infectivity, or it is likely to limit the infectivity of the virus.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All work will be conducted in compliance with the local rules for work in the containment level 2 Laboratory. Waste will be sealed in autoclavable bags inside a metal container before removing from the virus lab for autoclaving in Room G12 (LMCB). Liquid waste will be treated with Distel (5%) for at least 12 hours before disposal in the laboratory sink. Distel, formerly Trigene Advance: ATS labs study titled "Virucidal efficacy of a disinfectant for use on inanimate environmental surfaces", March 2007. This study concluded that TriGene advance (at 1:100) demonstrated complete inactivation of HIV type 1 at 30 min exposure time at RT.

Date Project 02/03/2022
### Purposes of the contained use

Investigating the effect on the life traits (lifespan, development, reproduction) of the model organism *C. elegans* when grown in the presence of the human gut microbes *Enterococcus faecalis*, *Pseudomonas aeruginosa*, *Klebsiella oxytoca* and *Enterobacter cloacae*.

### Recipient or parental organism

All the bacteria to be used are opportunistic pathogens. Although they have been mainly associated with severe disease in the immunocompromised, they can cause infection in healthy humans, albeit with less serious symptoms/consequences. The most likely consequence of the planned modifications in all the species is a loss of bacterial fitness due to the imbalance in gene regulation. The inserts drive the expression of anti-bacterial resistance genes against Spectinomycin. Spectinomycin is only used in the treatment of Gonorrhoea so very little hazard results from this. The inserts are not directly hazardous nor the genes they express. The GMM would be less likely to cause disease as a consequence of the cost of maintaining and replicating the insert. In addition, the insert does not add to the pathogenicity of the bacterial strain. Infections could be treated with a cocktail of antibiotics.

### Host/vector system

Shuttle vectors able to replicate in *Escherichia coli* for cloning purposes and for expression or deletion of *E. faecalis* genes. These vectors do not carry any risk by themselves. Transfer of genes is very unlikely to occur as these strains are not able to mate and therefore not capable of transmitting directly this genetic insert. If it were to occur, antibiotic treatment of the recipient strain would still be efficacious as for the wild-type strain.

### Origin & function

The inserted genetic material is all derived from *E. faecalis* genes mostly those involved in nucleotide metabolism.

### Evaluation of foreseeable effects

The GMMs would be less likely to cause disease in humans or animals than their parental strains, given the burden of carrying the insert or gene deletion as there is no gain to pathogenicity

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All potentially infected solid waste will be discarded in an approved autoclave bag. Before the bag is too full it will be closed with a cable tie and then placed in a second autoclave bag, also secured with a cable tie. Bags will be autoclaved in the autoclave in room SB23 and removed from the autoclave in the anteroom. Waste will be autoclaved at 134°C for 20 minutes, 3 bars pressure. Autoclaved material will be put in the appropriate bins. Autoclaved waste is categorised as offensive and is double yellow tiger bagged and locked away until collected and incinerated by a UCL contractor (Grundons). All infected liquid will be chemically disinfected with Virkon 1% for a minimum period of 24 hours before being discarded in the drain.

Virkon has a wide spectrum of activity against viruses, some fungi, and bacteria. Efficacy against Enterococcus faecium (a very close species to E. faecalis), Enterobacter, Klebsiella pneumoniae (a very close species to K. oxytoca) and P. aeruginosa has been demonstrated (http://virkon.nl/images/VirkonS_effectiviteit_bacteriën_dec2012.PDF) at concentrations of 1% or lower.

Please enter comments on the GM safety committee on the risk assessment

The UCL GMSC agreed the classification of the work as Activity Class 2, subject to additional detail being provided regarding the infectious nature of the agents.

Project Ref 14/16.3
Expression of non-toxic and non-pathogenic, but potentially oncogenic sequences, as well as non-oncogenic sequences, in animal cells in culture, using plasmids/retroviral/lentiviral expression vector to include the creation of amphotropic pseudotyped virus able to infect mammalian cells (human fibroblasts and/or human iPS cells). Plasmids/retroviral/lentiviral expression vector and cells infected with plasmids/retroviral/lentiviral expression vector may be injected into mouse/rat.

Replication-defective virus that expresses 4 transcription factors (Oct3/4, Sox2, c-Myc, and Klf4) in 293T cells and then infect human fibroblasts to generate human iPS cells will be produced.

Recipient or parental organism

Mouse/Rat work:
The bacterial strains used to produce the plasmid vectors are attenuated non-colonising strains that are harmless to humans and cannot survive outside culture conditions, and are therefore harmless to the environment.
The vectors packaged in Phoenix-ECO are replication-defective, non primate, non infectious and non-pathogenic to humans. There should be no risk to humans from it carrying transgenes, including potential oncogenes.

Human work:
HEK293 is a well characterised cell line derived from human embryonic kidney cells grown in tissue culture.
The recipient cells that will eventually receive and integrate the DNA are harmless to humans. They are also unable to survive outside culture conditions, and are therefore harmless to the environment.
The lentiviral vectors used will all be well characterised, with a history of safe use, and are inherently safe. The lentiviral particles could in theory be a risk to human health as they can infect human cells. However, all vectors will be self-inactivating & replication-incompetent, that is, each lentiviral vector particle infects and gives genomic modification of one cell, and that cell will not (and indeed cannot) subsequently produce and release further viral particles.
However in the unlikely event that the virus enters the body by injection, ingestion or through a wound, it could enter cells and integrate into cellular DNA. Its integration could result in a potentially oncogenic alteration, especially if the inserted sequence codes for an oncogene, activates oncogenes, or represses a tumour suppressor gene.

**Host/vector system**

| pCDNA,    |
| pBird,    |
| FUW,      |
| pEFGFP,   |
| pTdTom,   |
| pLKO.1    |

**Origin & function**

Moloney murine leukemia virus; HIV lentivirus

**Evaluation of foreseeable effects**

The lentiviral particles cannot survive outside of closed controlled cell culture conditions and are rapidly inactivated by dehydration or other environmental insults. They require close contact with contaminated fluids or percutaneous inoculation for transmission. The virus could, in principle, in the unlikely event of it being introduced to the cells of a worker, give genomic modification of cells of the worker.  
Some of the inserted sequences would produce transcription factors that could be oncogenic.  
The survival or retroviral vectors in the environment is poor, due to their fragile envelope. None of the cell lines or primary cells would be expected to remain viable outside the controlled culture conditions.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Lentiviral supernatants will only be handled whilst exposed in class 2 cabinets. They will be clearly labelled and stored in double containment and transferred within the laboratory in doubly sealed containers.  
Sharps will be used for mouse/rats injections. The vector or the cells transduced with the vector will be injected into the mouse/rats tissue. Safer sharps will be used if possible; all sharps will be disposed of after use into an appropriate sharps bin. In addition, all staff carrying the procedure will be training (with competency records kept) which should further limit the chances of sharp injuries.  
However no-sharps policy will be in place for all the human cells work.  
For the transport, the vials containing virus will be placed in a rack which will be in a “Tupperware-type” container with snap lock lid or a screw cap bottle sealed with parafilm, with some absorbent tissue at the bottom of the rack (and a made-up solution of Virkon and spare tissue would have to be brought with during transport in order to clean up a possible spillage promptly)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All solid Biohazard and GM waste at the WIBR is double bagged in autoclave bags, autoclaved on site at a minimum of 134deg C with a hold time of 20 minutes followed by offsite incineration. The autoclave runs are monitored for temperature and hold time automatically, with a print-out confirming a successful cycle. Sharps are incinerated off
Culture medium: 1% final concentration of Virkon treatment for 24h. Liquid waste will be inactivated with a final concentration of 1% Virkon for 24 hours. (Dupont specification says it has been independently proven that 1% solution kills bacteria within 5 minutes and parvovirus within 10 minutes.) Surfaces are cleaned with a solution of 1% Virkon or Trigene Advance 1:10 spray. Chlorasept tablets are also used on some occasions at a minimum of one 2.5gm tablet per litre of solution, again left for a minimum of 20 minutes.

The University Biological Safety Adviser approved this on behalf of the UCL GMSC subject to some minor amendments.
### Purposes of the contained use

Our model of infection employs adult pregnant mice to study ascending vaginal infection caused by *Escherichia coli* K1. We aim to use this model of infection combined with a genetically modified bioluminescent strain of *E. coli* O18:K1 (A192PP) to track the course of the infection using an IVIS bioluminescence imager. Strain A192 (DSM. No. 10719) (Achtman, et al., 1983) was used to generate this strain. A bioluminescent derivative of *E. coli* A192PP will be generated by introduction of the luxCDABE operon from the nematode symbiont *Photorhabdus luminescens*. The luxCDABE operon will be supplied through mini-Tn5 mutagenesis using the construct pUTm.

### Recipient or parental organism

ACDP hazard group: 2

### Host/vector system

**pUTmini-Tn5**
- Plasmid can only be maintained in lambda pir+ donor strains (e.g. *E. coli* S17-1 lambda pir).
- Plasmid can be transferred by conjugation to other bacterial strains (pir-) and acts as a suicide vector.
- Transposon is disarmed, so forms stable integrations within recipient chromosome and cannot re-mobilise. (Winson, et al., 1998) The mini-Tn5 is also transcriptionally isolated: a in frame stop codon (TAG) was introduced 18 codons upstream of the luxC ATG.

### Origin & function

The inserted transposon is the luxCDABE: lux operon from the nematode symbiont *Photorhabdus luminescens* ATCC29999 (Hb strain) (Winson, et al., 1998). With kanamycin resistance cassette (Km2). The operon will provide the mechanics for bioluminescence emission from the recipient strain. Recipient strains will become resistant to kanamycin (kanR) by acquisition of mini-Tn5 luxCDABE Km2.

### Evaluation of foreseeable effects

*E. coli* A192PP GM strain (like the parental A192PP strain) may be able to colonise the human gastrointestinal (GI) tract if ingested, however rat passage of the parent strain (A192) makes this less likely. As a strain of a bacterium becomes more adapted to a different species, that strain will become less adapted to the original host, thus decreasing in virulence with respect to the original host. (Koskiniemi S., Gibbons H.S., Sandegren L., Anwar N., Ouellette G., Broomall S., Karavis M., McGregor P., Liem A., Fochler E., McNew L., Rosenzweig C.N., Rhen M.,
E.coli A192PP GM strain may be able to colonise human neonates, however risk of exposure of such individuals is considered extremely low. However, if exposure occurred, the most hazardous outcome could be sepsis and meningitis. Again, as detailed above, rat passage of the parent strain (A192) makes this less likely.

E. coli A192PP GM strain will acquire kanamycin resistance. However other antibiotics, including but not limited to beta-lactams, aminoglycosides, tetracyclines and chloramphenicol can be used, should prophylaxis be required.

E. coli A192PP GM strain is unlikely to transfer the transposon to other bacterial strains in vitro, in vivo or in the environment, as the mini-Tn5 to be used is disarmed (loss of transposase during insertion - is present on the suicide vector). This enables stable integration into the recipient chromosome.

The acquisition of foreign genetic material may increase, decrease, or have no effect on virulence of the strain. This may depend on where the transposon insertion occurs (random event). However, due to the expected metabolic burden on the strain (caused by the presence of exogenous genetic material), a reduction or no change in virulence is expected to be observed, rather than an increase.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

- Animal housing at Central BSU Animal Facility has individually ventilated cages (IVCs).
- Appropriate personal protective equipment (PPE) will be worn at all times for work with animals; including P2 face masks, disposable gloves, overalls, shoe covers and mob caps.
- Infection of pregnant mice will be done on the bench top in B08 to enable mice to be anaesthised during bacterial instillation. However, only the trained operator will be in room B08 when any work with this bacteria is undertaken.
- Infected mice will be housed in individual IVC cages and will not be touched by BSU staff after infection with this bacteria.
- Imaging of mice colonised with E. coli A192PP (GM strain) will take place at Central BSU, UCL. Imaging procedures will then be done using the IVIS, located in room B08 within the CBS. B08 is a restricted access area (card access only, within the facility). Mice will remain in their IVCs for as long as possible before imaging occurs. During imaging, shedding of urine/faeces from colonised mice will be controlled using a disposable black card placed on the imaging platform (to act as a barrier). This card, as well as eppendorfs containing bacteria, will be disposed of by doublebagging prior to removal from BSU and transported for autoclaving.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

We wish to seek derogation in respect of having an autoclave in one of the locations of the work; 86-96 Chenes Mews. Currently only Class 1 GM activities are carried out in this location with liquid waste being disinfected before disposal and solid waste sent direct for incineration to an incinerator notified to HSE as being able to handle waste from Class 1 and Class 2 activities.

Any liquid waste form the proposed Class 2 activity will also be treated with disinfectant overnight (see below). Given that the amount of solid waste anticipated is minimal (no more than 2 autoclave bags/week), and the short term nature of the proposed activity (~6 months), it is proposed that solid Class 2 waste will transported to an adjacent building for autoclaving. Full details are given RA001530 (sent also with this notification) but, in summary, waste will be double bagged (2 autoclave bags closed with coloured cable ties to identify source of waste) and then placed in a small domestic size lidded wheelie bin and the lid fastened. The risk of spillage is therefore negligible during transport.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
The imaging platform will then be treated with 70% ethanol at the end of each procedure. Personal protective equipment/clothing will be worn at all times during imaging. Other facilities within the room include hand washing facilities, sharps disposal bins and general waste bins (orange bins).

General microbiology and processing of infected tissues within G13 at Chenies Mews will be done within a Class 2 safety cabinets.

- Bacterial culturing in Lab 103 will be done on a single use basis and the shaking incubator will be clearly labelled with a warning sign for other users of the lab.
- Sharps will be treated before use using 70 % (v/v) ethanol and disposed of after use in supplied sharps-bins for incineration. Surgical scissors and other surgical instruments (e.g. tweezers) will be autoclaved after use (a designated set of surgical instruments will be used for these experiments). All staff receive training in use of sharps as part of their HO PLH training.
- Solid (eg agar place and contaminated plastics) waste will be autoclaved, waste will be collected by UCL IFWH staff and will be sterilised by autoclaving for a cycle of 131oC for 30 mins. Transport of waste to the autoclave is covered by a separate risk assessment (RA001530) - also included with this notification.
- Liquid waste (eg bacterial cultures, blood from mice) will be treated with Presept (4 tabs/litre; final concentration of 2g/l or 4000ppm/l) overnight before disposal to drain.

Mice carcasses will be incinerated and disposed of by BSU support staff.

- Contaminated sharps will be placed in sharps bins and will be incinerated. Surgical scissors and other surgical instruments will be autoclaved after use.

---

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The University Biological Safety Adviser approved this as a Class 2 activity (after minor amendments/clarifications regarding waste handling) on behalf of the UCL GMSC.

---

Assessment of ingestion of GFP Pseudomonas by drinking water on the development of arthritis

Purposes of the contained use
To be able to track which parts of the gut that ingested bacteria migrate to.

Recipient or parental organism
Pseudomonas aeruginosa is classified as HG2 agent. Pseudomonas lives in soil and water and is normally only harmful in immunodeficient individuals.
The bacterium is a normal skin commensal however it can cause infection in severely immunodeficient individuals, and this is majorly the cases seen (linked to hospitalization). In hospitals, the bacteria can spread through medical equipment, cleaning solutions, and other equipment. For example, pseudomonas is one of the main causes of pneumonia in patients who are on breathing machines. Burn victims and people with puncture wounds may get dangerous pseudomonas infections of the blood, bone, or urinary tract. The bacteria can also get into the body through IV needles or catheters.
Healthy people can develop mild illnesses with Pseudomonas aeruginosa, especially after exposure to water. Ear infections, especially in children, and more generalized skin rashes may occur after exposure to inadequately chlorinated hot tubs or swimming pools. Eye infections have occasionally been reported in persons using extended-wear contact lenses.

Host/vector system
pUCP18?MCSgfpmut3:
Vector size: 5.492kb
Vector type: plasmid
Marker: bla (ampR)
Features:
GFPmut3: fluorescent maker under the control of Plac promoter
Origin of replication: ori from pRO1600
Unique restriction sites: BamHI, EcoRI, EcoRV, SmaI, XhoI
Double restriction sites: HindIII, PstI, SalI, XbaI

Origin & function

Green fluorescent protein GFPmut3: this gene is expressed under the control of the Plac promoter. This construct has been designed for Gram-negative bacteria fluorescence labelling.
GFPmut3.1 is a variant of the Aequorea victoria green fluorescent protein (GFP). This variant gives very bright green fluorescence when expressed in bacteria because it contains the GFPmut3b mutations (Ser-65 to Gly and Ser-72 to Ala) that increase the efficiency of protein folding and chromophore formation at 37°C (1). The GFPmut3.1 fluorophore has an excitation maximum at 501 nm, an emission maximum at 511 nm, and is minimally excited by UV light. The GFPmut3.1 gene also contains a Ser-2 to Arg substitution which creates an Sph I site at the initiating ATG codon.

Evaluation of foreseeable effects

This clone was derived from ATCC 10145TM and contains a multicopy vector encoding the green fluorescent protein GFPmut3. This gene is expressed under the control of the Plac promoter. This construct has been designed for Gram-negative bacteria fluorescence labelling. Ampicillin resistance gene (bla) encoded on a plasmid. Confers resistance to 300 mg/mL ampicillin. NB: this is not the antibiotic of choice for treatment of infection - most infections are susceptible to third-generation cephalosporins (ceftazidime), carbapenems (imipenem and meropenem), aminoglycosides (gentamicin and tobramycin) and colistin.
The wild type is a HG2 agent and there is no evidence to suggest the GFP modification has made the organism less fit/less pathogenic.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste produced in the Rayne Building will be autoclaved. Autoclave cycle is 121°C for 30mins, to kill any residual bacteria; after autoclaving, waste is disposed as offensive waste (in an off-site domestic waste incinerator). For disposal of liquid waste, Virkon will be added to a concentration of at least 1% and left overnight before disposal down the sink. Mice will be incinerated as infectious healthcare waste. Virkon has a wide spectrum of activity against viruses, some fungi, and bacteria. Efficacy against P. aeruginosa has been demonstrated (http://virkon.nl/images/VirkonS_effectiviteit_bacterien_dec2012.PDF) at concentrations of 1% or lower.
This project was approved as a Class 2 activity by the UCL UBSA on behalf of the GMSC after clarification and additional detail given in relation to the controls used for in vivo work.

Please enter comments on the GM safety committee on the risk assessment

Project Ref 14/17.1

Date Ackn'd 23/08/2017

CU2 Project Title Muscle cell Immortalization

Date Project Ceased

Class CultureVol

Class 2 1-50 Litres

Non-GMM Consent Granted

Project notified under transitional arrangements N

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID
### Purposes of the contained use

The aim is to immortalize muscle cells isolated from human muscle biopsies. Indeed, limitation of the proliferative capacity of satellite cells by cellular senescence restricts the development of in vitro models to study disease processes and to develop therapeutic strategies. This project aims to use a retroviral construct carrying the telomerase catalytic unit hTERT and the cyclin-dependent kinase 4 Cdk4 to overcome these limitations.

### Recipient or parental organism

A retroviral vector will be used to transduce human myoblasts.

### Host/vector system

A retroviral construct carrying both the human telomerase catalytic unit hTERT and the murine cyclin-dependent kinase 4 Cdk4. A resistance gene (hygromycin, neocyn, blasticidin etc) is also present.

### Origin & function

- murine Cdk4 overcomes the p16-mediated stress response
- hTERT maintains telomere ends by addition of the telomere repeat TTAGGG
- a resistance gene (puromycin, hygromycin etc) will be also used to select the transduced cells.

### Evaluation of foreseeable effects

hTERT is normally repressed in postnatal somatic cells. Deregulation of telomerase expression in somatic cells may be involved in oncogenesis.

We are using an amphotrophic envelop which can target a broad range of mammalian cells. The virus we produce is a non replicative retrovirus because gag-pol are cloned on a different plasmid. In theory, we cannot exclude any human infection. However, it is probably not likely to occur because all the experiments will be carried out in a Class II safety cabinet, with the appropriate equipments and without any sharp instruments.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All experiments will be carried out in Class II safety cabinets, viral supernatants will be centrifuged in sealed buckets in order to avoid/reduce aerosol., with the appropriate equipments and without any sharp instruments.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

- Solid waste is double-bagged in biological waste bags, sealed and removed to be autoclaved by waste services.
- Any material that contain or have come into contact with viral particles will be decontaminated by soaking in the virkon 1% for 1 hour.
- Liquid waste is treated with 1% Virkon. After decontamination, liquid waste is disposed of via the sink.
Virkon has been shown to achieve 100% GMO kill when used as directed. Journal of Hospital Infection 46 (3): 203-209

This project was approved as a Class 2 activity by the UCL UBSA on behalf of the GMSC after clarification and additional detail given regarding control measures.

Consent Granted Not Applicable

Project notified under transitional arrangements N

Tick if notifying a connected programme of work N

Historical Significant Changes
Genome-editing technologies will be used to manipulate the sequence of the cell genome with the aim to achieve a therapeutic effect.

Commercial E.coli disabled strains commonly used for the propagation of recombinant DNA. These will not express any of the CRISPR-Cas9 system proteins and are therefore unaffected.

The lentiviral vectors used are multi-attenuated meaning they are devoid of all potentially pathogenic virus encoded functions. In addition, they are replication-defective which means that the vector cannot multiply on its own unless supplied with certain proteins in trans. CRISPR-Cas9 system does not encode any protein that could promote replication.

The recipient mammalian cell lines are not considered harmful to immuno-competent humans.

Various 2nd and 3rd generation HIV based lentiviral expression plasmids.

The lentiviral vectors carry a deletion in the 3'LTR that does not affect generation of the viral genome in producer cells but results in "self-inactivation" of the lentivirus after transduction of the target cell. Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing packageable viral genome. A constitutive Rous sarcoma virus (RSV) promoter has been placed upstream of the 5'LTR in the expression vector to offset the requirement for Tat in the efficient production of viral RNA. Only 3 HIV-1 genes are used in the system (gag, pol and rev). Expression of the gag and pol genes has been rendered Rev-dependent by virtue of the HIV-1 revresponse-element (RRE) in the gag/pol mRNA transcript. The Rev protein itself is expressed from a separate plasmid. Addition of the RRE prevents gag and pol expression in the absence of Rev. The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 envelope protein. Genes encoding components required for packaging are on separate plasmids, which do not contain regions of homology to each other to prevent undesirable recombination events, which could contribute to the generation of replication-competent virus. None of these 'packaging plasmids' that allow expression in trans of proteins required to produce viral progeny (i.e. gag, pol, rev,
env) in the 293T producer cell line contain LTRs or the psi packaging sequence. Thus none of the HIV-1 structural genes are actually present in the packaged viral genome and, thus, are never expressed in the transduced target cell. The lentiviral particles are replication incompetent and only carry the sequences of interest.

Non-viral expression plasmid vectors.

Origin & function

The sequences contained within the lentiviral or non-viral expression vectors include:
- artificially synthesized short guide RNAs targeting various genes within human genome,
- Streptococcus pyogenes Cas9 encoding a nuclease that introduces double stranded breaks in the targeted DNA sequence,
- commercially available antibiotic (e.g. puromycin) resistance gene or a fluorescence tag (e.g. GFP) to allow for monitoring of transduction/transfection of the cells
- The lentiviral plasmids also contain WPRE.

Evaluation of foreseeable effects

In mammalian cells, spCas9 has nuclease activity which can lead to loss-of-function mutation of the gene targeted by the short guide RNA. There is a risk that some of these sequences target oncogenes or tumor suppressors or genes with general effect on the host immune system. None of the inserted sequences is expected to confer changes that will confer pathogenicity, immunogenicity, different tissue tropism nor ability to transmit to other hosts.

Gene transfer could possibly occur through accidental exposure to viral particles, via a cut or similar break in the skin. Therefore sharps will not be used in preparations containing viral particles or transfected packaging cells. If an accidental exposure were to occur, such viral particles would conceivably have hazardous effects if they infected a stem cell; reducing the chances of such exposure by not using sharps for viral particle preparations will significantly reduce the risk to human health. As has been stated already, all vectors are replication defective and so productive or replicative infections are not possible. It should be reiterated that these lentiviruses are extremely unstable even in tissue culture conditions.

The modified viruses should not pose a risk to the environment. The viruses are unstable, inactivated by detergent, UV light and ethanol, and would not survive outside the laboratory environment. The recipient cells cannot survive in the environment as they are only viable under culture conditions and as such pose no threat to health or environment.

Gene editing is not expected to provide mammalian cells with the capability to survive in the environment as they are only viable under culture conditions and the inserted sequence will not provide this ability.

The most dangerous GMM: packaged lentivirus. The most dangerous step is the harvesting and concentration of packaged virions.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste (culture plates, pipette tips, glass conical flasks) are sprayed with 5% Distel, autoclaved and then disposed of through the clinical waste management system. Autoclave cycles are validated using thermocouple; automatic fail if cycle is not completed.

Distel:
Broad spectrum efficacy within short contact times - 30 seconds to 5 minutes; Sporicidal, mycobactericidal, virucidal, fungicidal and bactericidal efficacy; Performance validated within a wide range of peer-reviewed scientific publications; Acknowledged and recommended by professional societies, public and private sector healthcare institutions http://medi-mark.co.uk/media-centre/article/users-of-trigene-advance Media waste is disposed down the sink with excess water after overnight treatment with 1:10 volume of 100% bleach. Bleach: WT CHLOR from CHELA - Sodium hypochlorite solution. http://www.chela.co.uk/shop/food/wt-chlor/ Using 12.5% hypochlorite (industrial strength bleach) in a 1:10 dilution (one part industrial strength bleach and nine parts water) yields 12,500 ppm or a 1.25% hypochlorite solution, for use within 30 days. One study reported that 25 different viruses were inactivated in 10 minutes with 200 ppm available chlorine. Klein M, DeForest A. The inactivation of viruses by germicides. Chem. Specialists Manuf. Assoc. Proc. 1963;49:116-8. Several studies have demonstrated the effectiveness of diluted hypochlorite and other disinfectants to inactivate HIV. Sattar SA, Springthorpe VS. Survival and disinfectant inactivation of the human immunodeficiency virus: a critical review. Rev. Infect. Dis. 1991;13:430-47.

Project Ref 14/18.2
The purpose of this work is to generate induced pluripotent stem (iPS) cells from mouse and human cells by employing viral and non-viral vectors coding for reprogramming genes. iPS cell technology has the potential to transform regenerative medicine especially in the areas of stem cell transplantation and patient-specific gene therapy. Briefly, mammalian cells will be treated with reprogramming factors to become embryonic stem (ES) cell like cells which are known as iPS cells. Once generated, these cells can be expanded at will maintaining their undifferentiated pluripotent state and can be subjected to differentiation pathways eventually leading to the formation of terminally differentiated somatic cells. To the best of our knowledge based on currently available scientific literature there is no suitable alternative to the use of the reprogramming vectors for the purpose of iPS cell generation. Upon successful execution, the iPS cells generated from this project will help us to study various genetic defects either from murine disease models or from human patient samples and would be crucial in our therapeutic approaches.

### Host/vector system

1. Lentiviral Gag/pol expression vectors p 8.9 and derivatives (HIV-1).
2. Viral envelope expression vector pMDG and derivatives (VSV-G).
3. A modified, non-transmissible form of Sendai virus (SeV) (ready made and commercially available)
4. A non-viral, non-integrating, self-replicating RNA-based reprogramming vector (ready made and commercially available)
Origin & function

The sequences contained within the lentiviral or non-viral expression vectors include:
1. cDNA sequences of reprogramming transcription factors: Oct-4, Klf4, Sox2, Glis1 and c-Myc
2. Additional sequences that have been added include eGFP reporter gene, luciferase gene, the mutated Woodchuck Posttranscriptional Regulatory Element (WPRE - truncated and with mutated X-protein non-functional start codon in lenti-viral vectors), Internal Ribosomal Entry Sites (IRES elements), F2A self cleaving peptide sequences, puromycin resistance gene

Activity

Evaluation of foreseeable effects

There is a risk that some of these sequences target oncogenes or tumor suppressors or genes with general effect on the host immune system. None of the inserted sequences is expected to confer changes that will confer pathogenicity, immunogenicity, different tissue tropism nor ability to transmit to other hosts.

Gene transfer could possibly occur through accidental exposure to viral particles, via a cut or similar break in the skin. Therefore sharps will not be used in preparations containing viral particles or transfected packaging cells. If an accidental exposure were to occur, such viral particles would conceivably have hazardous effects if they infected a stem cell; reducing the chances of such exposure by not using sharps for viral particle preparations will significantly reduce the risk to human health. All vectors used are replication defective and so productive or replicative infections are not possible.

Sendai virus is not pathogenic to humans. It is non-transmissible and has the fusion protein (F) deleted, rendering the virus incapable of producing infectious particles from infected cells. RNA-based vectors are non-viral, non-integrating and are extremely unstable at ambient temperatures and, therefore, do not present any risk to humans.

The most hazardous GMM are the lentivector viruses and the most hazardous step is the harvesting and concentrating the viral supernatant. Only a very unlikely event of multiple recombinations during the process of generation of the viral vector can expose the person to a wild type HIV-1. The probability of such an event is extremely low.

The modified viruses should not pose a risk to the environment. The viruses are unstable, inactivated by detergent, UV light and ethanol, and would not survive outside the laboratory environment. The recipient cells cannot survive in the environment as they are only viable under culture conditions and as such pose no threat to health or environment.

Reprogramming is not expected to provide mammalian cells with the capability to survive in the environment as they are only viable under culture conditions and the inserted sequence will not provide this ability. Accidental exposure of the lentiviral vector itself is not expected to result in transduction of cells in vivo. Successful transduction of cells requires specific culture condition in vitro to achieve gene modification. The target cells for transduction are keratinocytes, fibroblasts and other human cell lines which require specific culture conditions for survival. Therefore, the risk of engraftment of transduced cells is considered negligible. Even if an accidental exposure to the genetically modified cells was to occur, healthy immunocompetent individuals would be expected to promptly reject the allogeneic cells. The risk of transfer to environmental species is negligible, and would not be expected to cause harm as VSV-G pseudotyped lentivirus can only infect mammalian cells. Furthermore, the virus is replication incompetent and self-inactivating with none of the structural genes present in the packaged viral genome, so no new virus can be produced and no other cells can be infected.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**CU2 Project Title**

Lentiviral Vectors Production and transduction of cell lines and primary cells using Class 2 lentiviral vectors

**Class** Class 2

**Culture Volume** < 1 Litre

**Non-GMM Consent Granted**

---

**Historical Significant Changes**

**Historical Date of Additional Info**

**Withdrawn** N

**Tick if notifying a connected programme of work** N

---

**Project Additional Information**

**Purposes of the contained use**

Lentiviral vectors encoding for human oncogenes related to hematopoietic malignancies (e.g. BCR-ABL fusion gene, IDHR132K) will be applied to model malignant transformation in cell lines and primary human and murine cells.

**Recipient or parental organism**

- List recipient organism(s) to be used:
  - Cell lines: including Human-TF-1, K562, HEK293T, Jurkat, HEL 1.
  - Primary Human cells: Derived from human Bone Marrow Mononuclear cells isolated from Normal Donors (provided by Lonza) or Leukemia Patients obtained through the Cancer Institute (UCLH).
  - Primary Murine Cells: Obtained from Bone Marrow of wild type mice.

**Host/vector system**

The bacterial strains used are attenuated non-colonising strains so are incapable of causing human infection and therefore are harmless to humans.

Lentiviral vectors: Various 3rd generation lentiviral expression plasmids including pLKO.1 and derivatives. Lentiviral packaging vectors: 3rd Lentiviral accessory and packaging vectors including Gag/pol expression vectors p8.9, psPAX2 and derivatives (accessory packaging vectors derived from HIV-1) and viral envelope expression vectors including pMDG and derivatives (expresses VSV-G from Vesticular Stomatitis Virus).
The lentivirus is pseudotyped with VSV-G envelope so can infect human cells, however the viral vectors are not capable of self-replication as the viral particles do not contain all the necessary components and required components have been split over independent plasmids that do not have enough homology to recombine.

Origin & function

The integrating constructs will include the expression of the following genes:
- Markers of transduction: GFP, OFP, Venus, truncated NGFR.

Health and Safety

Executive
- Activators/repressors of gene expression belonging to the Tet OFF or Tet ON inducible system, ITta lrtTA
- Oncogenes: BCR-ABL (p210), IDH1 mutated - Various short Hairpin RNAs to knock down gene functions,

The lentiviral vectors can infect human cells or any other mammalian cell as they are pseudotyped with the envelope protein VSV-G from the vesicular stomatitis virus and therefore if introduced into the body by injection, ingestion or through a wound, the virus could potentially enter cells and integrate its genome into cellular DNA. Physical insertion of the virus into the genome of the host cell could potentially integrate a oncogene leading to an oncogenic hit, however the likelihood of this is very low and has never occurred in a research setting. Additionally, it would not be severe as the virus is replication incompetent (does not carry gag, pol or env genes) so it cannot make new progeny virus and establish a productive infection. Also, it would only be a small number of cells and therefore would not impact on the pathogenic outcome of an exogenous viral infection. Additionally, the likelihood of infection is very low. The viral particles are labile and do not survive on environmental surfaces outside the laboratory. The packaging viral components are from the HIV-1. The full length HIV-1 virus is harmful to humans, however the packaging vector used does not contain the full length HIV-1 molecule. Many components of this virus that are critical for HIV-1 infection have been removed with only those required for viral packaging remain. It is therefore attenuated and cannot replicate and form new viable virus. The cell that will eventually receive and integrate the DNA cannot survive in the environment as they are only viable under culture conditions and therefore are harmless to human health.

Evaluation of foreseeable effects

Lentiviral particles: The lentivirus is pseudotyped with VSV-G envelope so can infect human cells, however the viral vectors are not capable of self-replication as the viral particles do not contain all the necessary components and required components have been split over independent plasmids that do not have enough homology to recombine. Lentiviral Vector Production: LVs will be produced by transient co-transfection of a permissive cell line (HEK293T) with a combination of packaging and transfer vector constructs. The supernatant from this cells will be collected and subjected to concentration (through ultracentrifugation). After concentration the expected titers of the vector prep will be of 10^7-10^8 Transducing unit/ml. All work involving infectious virus will be performed in containment level 2 facilities in class 2 cabinets. To prevent contamination of workers by virus, no glass or other sharps will be used. Skin lesions will be covered with a bandage in addition to the protective wear described above. The risk of harm is therefore extremely low.

Some of the constructs that will be generated will contain genes that may result in oncogenic potential (e.g. BCR-ABL fusion gene or the mutated form of IDH (IDH1 R132, IDH2 R172). As described above, however, the virus cannot recombine and the likelihood of infection is extremely low as all work will be performed in containment level 2 facilities with all the personal protection described above. Additionally, no adverse affects have ever been described through the accidental exposure to retroviral vectors. Therefore the overall risks of our experiment are low. BCR-ABL fusion gene gives rise to a constitutively activated Tyrosine Kinase, which is able to drive uncontrolled proliferation and cell survival, resulting in leukemic transformation. Importantly, since it has been first characterized, BCR-ABL fusion...
protein has been extensively studied. Experimental work with mouse models and human cells have proved that BCRABL fusion gene can only act as a leukemia driver if the mutation is acquired in rare Hematopoietic Stem Cells residing in the bone marrow (HSCs), but not in more committed progenitors or differentiated cells. IDH1/fDH2 genes encode for isocitrate dehydrogenase. Mutations in these genes have been associated to oncogenic potential in gliomas and in hematologic malignancies. Mutated IDH acquire the ability to convert alpha-KG to 2-hydroxyglutarate (2-HG), which is now considered as an "oncometabolite". IDH1 R132H knock-in mice have a normal life span, similarly do not develop any malignancy.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Work involving viral supernatant will be performed in class 2 safety cabinets and grown within a closed incubator. Centrifugation of samples will be carried out in sealed rotors. After multiple passages and at least 14 days in culture, stably transduced cells may be moved to a standard culture room. Use of sharps is not permitted. If viral supernatent is transported outside of the laboratory, leak proof inner container surrounded by enough absorbent material to absorb the contents if broken and then contained within a second sealed contained.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

NA

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disposable tissue culture plasticware & cells used for viral production at the end of the procedure: The solid waste will be double-bagged in autoclave waste bags and autoclaved at 121 c for 15mins by trained staff then bagged in tiger bags.

Excess viral supernatant. Media recovered from GMM cells: 10% Distel or Virkon (v/v) will be used to treat liquid waste (16 hours) and also used to decontaminate any spills. Liquid waste is subsequently poured down the sink after treatment. Work surfaces will be wiped down with 10% Distel and 70% ethanol after use. Virkon and Distel are certified by the PHLS to provide 100% viricidal and GMO kill under these conditions by denaturating and inactivating viral and cellular proteins. Distel and Virkon will be used with their lifespan to ensure required kill is achieved.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Project Containment
This project aims to use replication defective lentiviruses to generate stable cell lines in which gene expression has been silenced or genes have been ectopically expressed. We use replication defective lentiviruses to generate cell lines from human and rodent cells which are poorly infected by amphotropic and ecotropic retroviruses. Lentiviruses are much more efficient at infecting non-dividing or poorly dividing cells.

The lentiviral silencing constructs are from the Open Biosystems human and mouse lentiviral shRNAmir libraries maintained and distributed by the UCL RNAi consortium. Both shRNAmir libraries consists of over 100,000 constructs in the pGIPZ lentiviral vector. Each construct, contains 22bp sense and antisense sequences that are homologous to a gene of interest to which the hairpin has been designed to target embedded, within a mir-30 sequence. When transcribed in vivo, these sequences give rise to short hairpin shRNAs which result in posttranscriptional down-regulation of gene expression by RNA interference. Lentiviral DNA constructs are packaged as lentiviruses using HIV accessory proteins for production of viral particles and the VSV-G envelope protein from
### Vesicular Stomatitis Virus

Lentiviral expression constructs encoding cellular full length or mutant genes are prepared and packaged as above. Lentiviral vectors and full length ORFs are obtained from DNA repositories and/or commercial suppliers. All ORFs are sequence verified.

### Host/vector system

- Lentiviral pGIPZ vector, lenti miRE silencing vectors and other commercially available lentiviral silencing vectors.
- Lentiviral expression vectors pReceiver, pLEX301, pLEX304, pLEX-MCS and pLenti6.2/V5-DEST and other commercially available lentiviral expression vectors. These vectors are all non-mobilisable or mobilisation defective.
- Most lentiviral vectors have deletions in the 3' LTR (SIN-LTR) such that deleted LTRs are generated upon viral replication so that they cannot be mobilised by exogenous virus. Moreover, no replication competent endogenous retroviruses have been detected in the human genome.

### Origin & function

- Genes whose expression will be manipulated are: PRNP, Tau, APP, TDP43, a-synuclein, STX6, GAL3ST1, PDIA4, CXC4R, CHODL, AIM2, FKBP5, ANK1, SLC26A4, PAPSS2, CHGA, IQGAP2, ITGA8, FN1, FST, RGS4, LIN52, BMYB, FOXM1, RELA, CEBP, LARP6, NR3C2, ZNF511, CEBPG, CBF, PRMT3, HMGB1, TFAM, DEK, HMGB2, SMD11, NUF1P1, PRRX1, TEAD4, YEATS4.
- RNAi hairpins for silencing gene expression are sequences that have been synthesized de novo and are not from an organism. They have been designed to target specific genes and comprise both sense and anti-sense as well as a loop sequence.
- Full length ORFs for ectopic expression of cellular genes: are from ATCC, Gene Service or other DNA repositories.
- Full length ORFs for transcription factors: obtained from DNASU plasmid repository, In vitrogen (Thermo Fisher) and Japanese ORF collection.
- The accessory proteins for lentiviral packaging are derived from HIV-1 virus and the VSV-G envelope protein is from Vesicular Stomatitis Virus. Both were provided by UCL Cancer Institute and originate from the laboratory of R. Weiss and G. Towers.
DIRECT EFFECTS
Both the gene silencing and ectopic expression are aimed at investigating the role of the various genes in either growth promotion or neurodegeneration. The viral vectors also encode resistance to a variety of antibiotics to allow for selection of stably transduced cells. None of the shRNAs or the cellular genes are pathogenic but are likely to be biologically active and alter the behaviour of the cells in which they are expressed; this is the aim. They are unlikely to be toxic because if they are, we will not obtain any stably expressing cells. Also unlikely to be allergens or act as hormones/ cytokines.

INDIRECT EFFECTS
The viral vectors have the potential to cause harm by insertional mutagenesis if the virus was to inadvertently infect a cell and integrate in a location that leads to activation of genes or suppression of genes involved in tumour formation or lead to production of a biologically active substance eg. hormone, cytokine.

EFFECT OF GENE TRANSFER
The major effect of silencing and/or overexpression of these genes will either be in promoting growth (tumour formation) or activating neurodegeneration pathways. Lentiviruses are capable of infecting non-dividing cells.

SUMMARY OF RISK TO HUMAN HEALTH
There are two types of risk to human health from these viruses: the shRNAs and genes that are involved in growth promotion have the potential to infect human somatic cells and promote growth, one of the prerequisites for tumour formation. However tumour formation is a multifactorial event. The shRNAs and genes involved in neurodegeneration could potentially infect and promote neurodegeneration, if these viruses were able to infect the appropriate human cell type. The other risk is from insertional mutagenesis, which could promote tumour formation or expression of a biologically active substance eg. hormone, cytokine.

Inadvertent infection by needle stick injury is the most likely route of infection. They will be minimized by not using sharps and needles.

SUMMARY OF RISK TO THE ENVIRONMENT
In the unlikely event of a containment failure, leading to an accidental release of the lentivirus into an environment, these viruses could lead to promotion of tumour formation and activation of neurodegeneration pathways if an animal was accidentally infected. Inadvertent infection by needle stick injury is the most likely route of infection. They will be minimized by not using sharps and needles.

Neither bacteria, human or mouse cells, lentiviruses or transduced cells will survive alone within the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

SOLID WASTE
E. coli solid waste (agar plates, tips and pipettes) are autoclaved followed by incineration. Solid waste from tissue culture such as dishes, tubes and flasks are chemically disinfected followed by incineration. Tissue culture pipettes are autoclaved followed by incineration.

Chemical disinfection is by 1% virkon or > 10,000ppm sodium hypochlorite for >1 hour, preferably overnight followed...
by incineration.

**LIQUID WASTE**

E. coli liquid waste is inactivated by treatment with 1% Virkon for >10 minutes.

Liquid tissue culture medium is collected into containers containing sufficient sodium hypochlorite for >10,000ppm and left for 24 hours.

Lentivirus supernatants are inactivated by treatment with sufficient sodium hypochlorite for >10,000ppm and left for 24 hours.

### Project Additional Information

#### Purposes of the contained use

This is a new research project. The ATIMP is a cryopreserved formulation of autologous CD34+ haematopoietic stem cells transduced ex vivo with the SIN lentiviral vector pCCL_CD11 b-coSGSH-WPRE vector encoding for the codon optimised human N-sulphoglucoasamine sulphohydrolase (SGSH) gene. To create the aforementioned ATIMP product, autologous CD34+ cells HSCs from MPSIIIA patients will be genetically modified using the CLCD11 b.co.SGSG vector; a self inactivating (SIV) lentiviral vector expressing the SGSH gene codon optimised for human use and regulated by hCD11 b. These transduced cells will then be cryopreserved until such time of infusion back to the patients. The cryopreserved formulation will be thawed at the patient's bedside and infused directly without further manipulation.

#### Recipient or parental organism

Autologous Hematopoietics Stem Cells (HSCs) from MPSIIIA patients or healthy donors. No producer cell line will be handled for this project as the vector is manufactured by an external company.

#### Host/vector system

The LV is packaged using four separate plasmids, a plasmid expressing the required viral proteins (gag and pol), a plasmid expressing Rev and a plasmid expressing the glycoprotein VSV-G envelope, combined with a genome plasmid comprising a SIN transfer vector carrying a major deletion in the 3’ L TR region. The system is engineered in such a way that minimal homology regions are present between packaging and transfer vectors, thus minimizing the likelihood of homologous recombination events and the generation of replication competent lentiviruses (RCL). The packaging construct is deleted of all HIV accessory proteins (vpu, vpr, nef, vif) and Tat. The packaging plasmids used are: pMDLg (6.6 ug per 75 cm2), pRSV/Rev (3.3 ug per 75 cm2) and VSV-G glycoprotein expression plasmid pMD.G (4.62 ug per 75 cm2). The transfer vector encodes a codon optimised human SGSH gene cDNA and sequences necessary for expression, encapsidation, reverse transcription and integration of the viral genome. In order to minimize the risk of RCL generation, the 3’ L TR of the transfer vector has been deleted in the U3 region. A WPRE sequence with mutations eliminating expression of the WPRE X protein is incorporated in the vector to enhance transgene expression. The vector is produced as cell-free LV supernatant from the 293T cell line and has an envelope pseudotype from VSV.

#### Origin & function

SGSH cDNA Wpre* (mutated)
The host organism (HSCs) do not represent any risk for the human health and safety as prior to collection, the donors are tested for an extended microbiology and virology panel. Moreover, cells are manipulated at all times inside the isolator and direct contact between the operators and the cells is not expected. Regarding the CD11 b.co.SGSG lentiviral vector, the risk of pathogenicity or toxicity in human cells is negligible. Cases of insertional mutagenesis have been reported in a small number of patients treated with gene therapy for immunodeficient diseases utilising retroviral vectors. However, the risk of accidental inoculation with lentiviral vector and the development of insertional mutagenesis is considered negligible for the following reasons: 1. The risk of insertional mutagenesis is considered to be lower with lentiviral vectors than retroviral vectors. 2. The current vector has been designed with the view to reducing the risks of insertional mutagenesis. 3. Only HIV negative patients will be used as donors for this project so the possibility of recombination with the Wild-type virus is negligible. For all the above reasons, the risks to human health and safety is considered negligible.

The inserted genetic material is not known to have any harmful effects. Its expression will be restricted to cells of the CD11 b lineage. The inserted genetic material is a physiological human. Therefore, it is not expected to alter the properties of the host organism apart from restoring the function of this gene when used to transduce autologous cells from MPSIIIA patients who have a faulty copy of this gene. The insert cannot be disseminated in the outer environment as the vector is non-replicative.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste disposed of following organisation's waste disposal policy. It is placed into dedicated plastic bins with lids, collected by central collection service and incinerated. All sharps are placed in puncture-proof containers and disposed of through the central collection service for infectious waste. Liquid waste is disinfected using Haz-tab (effervescent chlorine tablets) overnight before being disposed of down the sink.

Is an emergency plan required according to regulation 20?

Approved by the GM safety committee as a class 2 activity, due to the use of sharps in the experimental procedure.
This is a new research project intended to manufacture an advance therapy medicinal product (ATMP) for the treatment of X-linked severe combined immunodeficiency (X-SCID). The ATMP is a cryopreserved formulation of autologous CD34+ haematopoietic stem cells transduce ex vivo with the SIN lentiviral vector pCCL_EF1_IL2RGco_WPRE4 vector (G2SCID) encoding for the codon optimised human IL2RG gene. To create the aforementioned IMP product, autologous CD34+ cells HSCs from X-SCID patients will be genetically modified using a G2SCID vector; a self-inactivating (SIV) lentiviral vector expressing the IL2RG gene codon optimised for human use and regulated by EF1a. These transduced cells will then be cryopreserved until such time of infusion back to the
patients. The cryopreserved formulation will be thawed at the patient's bedside and infused directly without any further manipulation.

Recipient or parental organism

Autologous Hematopoietics Stem Cells (HSCs) from X-SCID patients or healthy donors. No producer cell line will be handled for this project as the vector is manufactured by an external company.

Host/vector system

G2SCID lentiviral vector: The G2SCID lentiviral vector is an integrative, 3rd generation replication-defective, self-inactivating (SIN) human immunodeficiency virus (HIV)-derived LV vector, with a mutated Woodchuck hepatitis virus Posttranscriptional Regulatory Element (WPRE) sequence. It directs IL-2 receptor gamma expression from a codon-optimized form of the IL2RG gene to all hematopoietic and lymphoid lineages. A LV vector derived from HIV-1 has been chosen because it is genetically stable, permanently integrates into the genome of transduced cells, and provides long-term gene expression in vitro and in vivo. The transduction of hematopoietic stem cells (HSC) with such LV can be achieved after limited pre-activation of the cells in short-term cultures with cytokines, in conditions that are compatible with the preservation of the self-renewing capacities of these cells.

The modifications introduced into the organisation of the parental HIV1 genome are described below:

-- Replication defective: The HIV-1 genome is split into 4 constructs consisting of 3 packaging plasmids and one transfer plasmid, which are co-transfected for the production of an infectious particle. The packaging of the particle is therefore conditional on the Rev and gag-pol genes, which are expressed in trans on separate plasmids. The minimal homology between the various cassettes for packaging and gene transfer minimizes the likelihood of homologous recombination events and the generation of replication-competent HIV particles (RCL).

-- SIN: A 400 base pair deletion was introduced in the 3'L TR to remove major transcription factor binding sites. Reverse transcription, which generates both U3 regions from the 3' of the viral genome, transfers the deletion to the 5'L TR of the pro-viral DNA. The integrated provirus therefore contains the therapeutic transgene flanked by two transcriptionally inactive L TRs with U3 deletions.

-- Mutated WPRE: This element is used to enhance the transgene expression in vivo and to increase viral titers during the manufacturing process. It has however been incriminated as the cause of hepatocellular carcinomas observed in mice treated with an equine LV vector. Although such concern has not been evidenced in mice treated with HIV-derived lentiviral vectors with the same WPRE, a mutated WPRE, so-called PRE4, is used in G2SCID in order to prevent any issues.

-- VSV-G envelope: VSV-G has been chosen because it has a broad tropism, and in particular the ability to target HSC.

Origin & function

IL2RG cDNA Wpre* (mutated). The intended function of the genetic material is to correct the genetic mutation present in the SCID-X1 patient HSCs and restore immune system function.

Evaluation of foreseeable effects

The host organism (HSCs) do not represent any risk for the human health and safety as prior to collection, the donors are tested for an extended microbiology and virology panel. Moreover, cells are manipulated at all times inside the isolator and not direct contact between the operators and the cells is expected.

Regarding the G2SCID lentiviral vector, the risk of pathogenicity or toxicity in human cells is negligible. Cases of insertional mutagenesis have been reported in a small number of patients treated with gene therapy for immunodeficient...
diseases utilising retroviral vectors. However, the risk of accidental inoculation with lentiviral vector and the
development of insertional mutagenesis is considered negligible for the following reasons:
1. The risk of insertional mutagenesis is considered to be lower with lentiviral vectors than retroviral vectors.
2. The current vector has been designed with the view to reducing the risks of insertional mutagenesis
3. Only HIV negative patients will be used as donors for this project so the possibility of recombination with the wild-
type virus is negligible.
For all the above reason, the risks to human health and safety is considered negligible.
The inserted genetic material is not known to have any known harmful effects. Although the protein is part of cytokine
receptors, its expression in the membrane of the cells will be regulated by the endogenous expression of the other
proteins that form part of this receptors:

02/03/2022
Use of adeno-associated viruses (AAV) or lentiviruses to study neurodegenerative diseases.

This risk assessment is in preparation for studies that will address the role of axonal transport in animal models of different neurological disorders. Axonal transport is frequently impaired in different neurological diseases, both directly by mutations in genes encoding motor proteins or indirectly by abnormal activity of regulatory pathways. However, the precise mechanisms underlying these defects in neurological diseases remain to be clarified.

Our studies aim to elucidate these gaps in our understanding of axonal transport and will allow the development of novel, targeted approaches to restore axonal transport during the onset and progression of disease in specific animal models of neurodegeneration.

This Risk Assessment covers the administration of recombinant adeno-associated virus (rAAV) or lentiviral vectors expressing non-oncogenic and non-pathogenic constructs to wild-type mice or rats and to animal models of neurological diseases to understand disease mechanisms and assess potential therapeutic efficacy of treatments.

Recipient or parental organism

Recipient organisms are mice or rats. Viral vectors will be injected intravenously, intramuscularly,
intraperitoneally, intra-cranially or intra-thecally.

**Host/vector system**

Non-replicating viral vectors:
1. Recombinant adeno-associated viruses (rAAV) or
2. Lentiviral vectors (2nd or 3rd generation).

Vectors will be obtained from collaborators, from commercial sources, or produced by our laboratory.

**Genetic & function**

Genetic material will include:

1) full-length or engineered versions of genes encoding proteins that are transported in axons (e.g. Mito-YFR to monitor mitochondrial transport) or neurotrophic factors to test effects on disease progression (e.g. brain-derived neurotrophic factor (BDNF));
2) shRNA or siRNA expression constructs to decrease expression of genes to test their involvement in disease progression;
3) reporter genes, (e.g. GFP) to be used as controls to monitor distribution of the rAAV vectors or to identify specific populations of cells;
4) genetically encoded antibodies for detection of specific proteins in vivo.

All the genetic material used is non-oncogenic, non-pathogenic and does not encode toxic proteins. Different promoters will be used to drive expression of transgenes including constitutively expressed promoters (e.g. CMV), inducible promoters (e.g. tetON or tetOFF systems), and tissue-specific promoters (e.g. driving expression in muscles (e.g. MCK) or neurons (e.g. CamKII)).

**Origin & function**

All vectors used in this proposal have been rendered replication-deficient.

The genome of engineered rAAV contains no pathogenic genes. Inverted terminal repeats (ITR) are present making viral self-replication impossible. rAAV are not permanently integrated into the host genome, rather they form stable episomes for transgene expression. Likewise, 2nd and 3rd generation lentiviral vectors are engineered not to self-replicate and the genome does not contain pathogenic genes. 2nd and 3rd generation lentiviral vectors are safe and not pathogenic for humans.

None of the genetic material inserted is a known oncogene or encodes for toxins. Insertion of the genetic sequences listed above will not affect the pathogenicity or transmission ability of the rAAVs or lentiviruses.

Since none of the vectors used are replication-competent, infected animals cannot transmit the virus or transgene. Both rAAV and lentiviruses are not able to replicate in the absence of helper viruses (which are not used here) or other helper functions. Treated animals will be kept in Individually Ventilated Cages.

**Evaluation of foreseeable effects**

All vectors used in this proposal have been rendered replication-deficient. The genome of engineered rAAV contains no pathogenic genes. Inverted terminal repeats (ITR) are present making viral self-replication impossible. rAAV are not permanently integrated into the host genome, rather they form stable episomes for transgene expression. None of the genetic material inserted is a known oncogene or encodes for toxins. Insertion of the genetic sequences listed above will not affect the pathogenicity or transmission ability of the rAAVs or lentiviruses.

Since none of the vectors used are replication-competent, infected animals cannot transmit the virus or transgene. Both rAAV and lentiviruses are not able to replicate in the absence of helper viruses (which are not used here) or other helper functions. Treated animals will be kept in Individually Ventilated Cages.

Only personnel highly trained in the use of ‘sharps’ under aseptic conditions will perform these procedures. Treated animals will be kept in Individually Ventilated Cages. The only risk arises from the use of sharps during the procedure of injection of the viral vectors into the animals. Only personnel highly trained in the use of ‘sharps’ under aseptic conditions will perform these procedures in specific surgery units provided with Laminar Flow Cabinets.

When possible, injections will be performed in anesthetized animals to facilitate handling. When possible, remotely-operated injectors will be used.
GM animals produced by injection of viral vectors will be housed in Individually Ventilated Cages in a dedicated unit of the Cruciform Building or of the Institute of Neurology. In case of necessity of transport, the animals will be maintained in double containment vessels. A separate risk assessment (RA024493/1) covers this activity.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste which has been in contact with the viral vector such as virus containing tubes, disposable equipment for surgery will be disposed of by soaking in a 2% Virkon solution for 1-12 hour and then subjected to autoclaving. Autoclaving (132 degrees celsius, 15 minutes holding time) will give 100% kill at this temperature and time.

Solid sharp waste will be disposed of in the appropriate sharp bin container and ultimately autoclaved.

Liquid waste which has been in contact with the viral vector will be disposed of by adding a 2% Virkon solution for 1-12 hour and then subjected to autoclaving. Autoclaving (132 degrees celsius, 15 minutes holding time) will give 100% kill at this temperature and time.

Carcasses of GM animals will be disposed of via incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GM safety committee were satisfied with the identified hazards, control measures and overall risk assessment.

Tile activity was approved as activity class 2.

This research project intends to manufacture an advance therapy medicinal product (ATMP) for the treatment of Adenosine deaminase (ADA) deficient severe combined immunodeficiency (ADA-SCID). The ATMP is a cryopreserved formulation of autologous CD34+ hematopoietic stem cells transduced ex vivo with EFS lentiviral vector encoding for the human ADA gene (OTL-101). To create the aforementioned product, autologous CD34+ HSCs from ADA-SCID patients will be genetically modified using an OTL-101 vector. These transduced cells will then be cryopreserved until such time of infusion back to the patients. The cryopreserved formulation will be thawed at the patient's bedside and infused directly without any further manipulation.

Recipient or parental organism

Autologous Hematopoietic Stem Cells (HSCs) from ADA-SCID patients or healthy donors. No producer cell line will be handled for this project as the vector is manufactured by an external company.

Host/vector system

The EFS-ADA Lentivirus (LV) used in the manufacture of OTL-101 is an ADA cDNA encoding LV containing the enhance'ri'promoter from the human EF1 a gene. The vector lacks viral coding sequences that may give rise to the formation of replication-competent lentivirus or immunogenic peptides and is also devoid of all LV enhancer-promoter sequences that are known to be involved in insertional mutagenesis by retroviruses and derived vectors. The EF1 a enhancer/promoter used is shortened by deletion of the first intron of EF1 a, which possesses strong enhancer activity and has potential to trans-activate adjacent cellular genes upon insertion. The EF1 a as promoter has
been shown to directly, high level transcription of reporter genes in murine hematopoietic cells and to have significantly reduced trans-activation potential compared with retroviral LTR (Zychlinski et al., 2008). In its plasmid DNA configuration, the EFS-ADA LV contains the following vector modules:

The pCCL SIN LV is derived from HIV-1 (Dull et al., 1998). All open-reading frames of HIV-1 genes have been deleted from the vector, leaving only 2007 bp (20.65% of HIV-1 genome) consisting of: the SIN long terminal repeats (LTRs), the packaging sequences, the revresponsive element (rRE) and the central polypurine tract (cPPT).

The 400 bp SIN deletion from the LTRs removes the promoter and enhancer (from -418 to -18 relative to the U3/R border), leaving only 53 bp with the attachment sequences for chromosomal integration and the polyadenylation signal.

A short promoter fragment (239 bp) from the human EF1 α gene, lacking intronic or enhancer sequences, drives transcription of q normal human ADA cDNA.

The transcriptionally disabled WPRE is downstream. The WPRE sequence used here is devoid of the hepadnaviral X-protein open reading frame and contains a point mutation that destroys the largest residual open reading frame of this element (Schambach et al., 2006). The same WPRE sequence has previously been used without evidence of side effects in a Pha-e I clinical trial in HIV-infected patients receiving autologous T cells transduced with an anti-HIV gamma-retroviral LTR vector containing this element (van Lunzen et al., 2007).

EFS-ADA LV → pCCL-c-EFS→hADA-WPRE. The intended function of the genetic material is to correct the genetic mutation present in the ADA-SCID patient HSCs and restore immune system function.

Evaluation of foreseeable effects

The host organism (HSCs). Do not represent any risk for the human health and safety as prior to collection, the donors’ informed consent was obtained. The genetic material is inserted into the donor cells by recombinant lentivirus particles. The packaging system used in the production of recombinant virus particles is a retroviral packaging system based on the HIV-1 packaging system (Dull et al., 1998). The vector is produced in human cell lines and the virus particles are harvested from the supernatant of the infected cells. The vector is non-replicative and does not integrate into the human genome.

A short promoter fragment (239 bp) from the human EF1 α gene, lacking intronic or enhancer sequences, drives transcription of the normal human ADA cDNA.

The transcriptionally disabled WPRE is downstream. The WPRE sequence used here is devoid of the hepadnaviral X-protein open reading frame and contains a point mutation that destroys the largest residual open reading frame of this element (Schambach et al., 2006). The same WPRE sequence has previously been used without evidence of side effects in a Phase I clinical trial in HIV-infected patients receiving autologous T cells transduced with an anti-HIV gamma-retroviral LTR vector containing this element (van Lunzen et al., 2007).

EFS-ADA LV → pCCL-c-EFS→hADA-WPRE. The intended function of the genetic material is to correct the genetic mutation present in the ADA-SCID patient HSCs and restore immune system function.

Origin & function

EFS-ADA LV ~ pCCL-c-EFS→hADA-WPRE. The intended function of the genetic material is to correct the genetic mutation present in the ADA-SCID patient HSCs and restore immune system function.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste disposed of according to the GOSH Pathology waste disposal policy. It is placed into dedicated plastic bins with lids and collected by the GOSH central collection service for infectious waste and incinerated. All sharps are placed in puncture-proof containers and disposed of through the central collection service for contaminated/infectious waste. Liquid waste is disinfected using Haz-tab (effective chlorine tablets) overnight before being disposed of down the sink.

If the intended waste disposal methods above are disrupted, there is an autoclave located in the building which can be used as a backup.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

Approved by the GM safety committee as a class 2 activity due to the use of sharps in the experimental procedure.

Project Ref 14/19.5

Date Ackn’d 31/05/2019

CU2 Project Title Investigation of streptococcal virulence factors using molecular microbiology and cell

Class 2

Culture Vol Class 2 < 1 Litre

Culture Volume Class 3-4
We seek to elucidate the role(s) of virulence factors in streptococcal pathogenesis using molecular microbiology and cell biology techniques, applied to infection models. This includes using molecular cloning techniques to generate bacterial mutants. We primarily seek to inactivate genes that encode putative virulence factors to induce a loss of gene function and loss of phenotype. Genetic complementation will also be performed to ensure that loss of phenotypes is not due to off-site mutations elsewhere in the chromosome. Streptococcus pneumoniae (pneumococcus), Streptococcus mitis and Streptococcus agalactiae (GBS) are most commonly found as colonizers of the human nasopharynx, mouth, and gut/vaginal tract, respectively, without causing disease. S. pneumoniae and S. agalactiae are also recognized as pathogens that can cause disease such as pneumonia, bacteraemia and meningitis in vulnerable populations such as the very young, the very old and immunocompromised persons. S. mitis is rarely pathogenic but may cause endocarditis and disease in the immunocompromised. S. mitis may also act as a reservoir for antimicrobial resistance and virulence genes for S. pneumoniae.

Given their pathogenic potential, we seek to identify and/or elucidate the mechanism of virulence factors encoded by streptococcal species. Our primary focus is on S. pneumoniae and S. agalactiae. To start, we plan to investigate the role of streptococcal cell surface proteins, toxins and known virulence factors (Ply and LytA for pneumococcus, HvgA for GBS) in establishing association with and transmigration through epithelial and endothelial barriers in vitro. The specific virulence factors that we study will evolve with time based on experimental results and new information in the literature.

Recipient or parental organism

1) Streptococcus pneumoniae is a hazard group 2 microorganism that is most commonly found as a nonpathogenic colonizer of the human nasopharynx, but may cause invasive and non-invasive disease in vulnerable populations such as young children and the elderly.
2) Streptococcus agalactiae is also a hazard group 2 microorganism that is most commonly found as a nonpathogenic colonizer of the human gastrointestinal tract and vaginal tract. It may also cause non-invasive and invasive diseases in vulnerable populations such as infants, elderly and pregnant people.
3) Streptococcus mitis is a nonpathogenic colonizer of the human oral cavity and only rarely causes disease under...
exceptional situations (pre-existing conditions, trauma).

4) Lactococcus lactis is a nonpathogenic species (hazard group 1) commonly used in the production of cheese and other dairy products, which in very rare and exceptional situations can cause endocarditis. L. lactis may be used to express streptococcal proteins to study the function of a gene product in isolation.

5) Escherichia coli is typically a colonizer of the human gastrointestinal tract that does not cause disease; however some strains are particularly virulent and causes enteric disease or urinary tract infections. The particular strains of E. coli we plan to use are lab-adapted, commercially available nonpathogenic strains used for molecular cloning and protein expression. E. coli strains will be used to replicate and store plasmids, and may be used to express proteins for protein purification.

Exposure to all the recipient microorganisms described above, whether WT or GMM, is not known to consistently result in carriage or disease even in vulnerable populations. With the exception of L. lactis, all other bacterial species are most commonly found as non-pathogenic symbionts of humans.

Host/vector system

Multiple suicide and replicative plasmids for molecular cloning, and expression of bacterial gene products. These plasmids are not inherently hazardous and do not alter the pathogenesis of the recipient cells. The plasmids usually contain an origin of replication, one or more antibiotic resistance marker for screening and selection, a multiple cloning site, and in a subset of plasmids a regulatory gene and promoter/operator sequence.

Origin & function

1) Genes from streptococcal species, in particular from S. pneumoniae and S. aga/aetiae, in their native, chimeric or inactivated forms to study the consequences of inactivating, altering or re-introducing the gene and gene product to the fitness and pathogenesis of the bacteria.

2) Commonly used antibiotic resistance markers (aph3, cat, tetM) for selection/screening of plasmids and to inactivate streptococcal genes by allelic replacement or gene insertion.

3) Reporter genes (gfp, mCherry, /aeZ, etc) for downstream functional assays, such as quantification of gene expression via beta-galactosidase assay or determination of protein localization through microscopy and/or subcellular fractionation.

4) Short peptide tags (His6, FLAG3, SUMO, HA etc) for tagging gene products and downstream tracking and functional assays, such as quantification of protein expression via Western blot or determination of protein localization through microscopy and/or subcellular fractionation.

Evaluation of foreseeable effects

Constructed GMMs are unlikely to be more hazardous than wild type (WT) strains. In most cases, we seek to attenuate the recipient micro-organism by mutating one or more genes, leading to a loss-of-function mutation, and to restore WT phenotype by complementation of the mutated gene in the GMM. Such mutations, or reversion to WT genotype, are highly unlikely to make the GMM more hazardous than WT bacteria. Tagging the genes with small peptide tag or placing a reporter gene, under the control of a native streptococcal gene are also highly unlikely to increase the hazardousness of the GMV/l. There may be a small fitness defect for the bacterium with gene and protein mgs. Whenever possible, mutations will be introduced by stable, double crossover homologous recombination into the chromosome to prevent unintended reversion to wild type. Antibiotic selection will be maintained to prevent loss of plasmids by the GMMs.

There is a very small chance that overexpression of certain virulence factors, or heterologous expression of the virulence factors in a non-pathogenic species will increase the virulence of the GMM. However, such virulence factors are also typically surface exposed and may be recognized by the immune response, and thus there is also a small
chance that the same mutation will reduce the pathogenesis of the GMM by stimulating more efficient immune
I clearance in an infected host. To isolate a single gene product to study, or to make large scale bacterial
culturing safer, we may heterologously express gene products in a less pathogenic species (L. /aetis or lab adapted
strains of E. co/i). This may have a small risk at making the recipient organism more pathogenic.(i.e. better able to
bind to epithelial tissue, more resistant to immune killing). Nevertheless, this is a common molecular biology
technique. As a precaution all GMMs will be handled according to containment level 2 conditions to prevent exposure
and contamination.
It is hypothetically possible that any escaped GMM could encounter other isolates of its same species in the
environment or host organism (such as humans) and share antibiotic resistance genes. To minimize risks, proper
containment and handling procedure of WT and GMMs will be carried out in accordance to containment level 2
guidelines. Additionally, we will not introduce any antibiotic resistance cassettes that confer resistance against
antibiotics most commonly used in therapy (ceftriaxone for pneumococcus, penicillin/amoxicillin for G8S).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

We do not plan to construct or use aflY GM animals and plants.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be placed in double-bagged clear autoclave bags. These bags will be sealed when 3/4 full
and autoclaved prior to other forms of disposal. Autoclaving will be done at 121°C, for 20 minutes or 126°C for 15
minutes at 100kfa, by specialized autoclave facility staff according to institutional guidelines. Printout report from the
autoclave's in-built temperature and pressure monitoring system as well as colour change on autoclave tape will be
used to validate the autoclaving process. Microbiology contaminated solid waste dispose in specialized yellow
"biological hazard" cardboard boxes will be incinerated. Liquid waste will be incubated with Virkon at a minimum final "
cQncentration of 1% overnight (>18 hoUrs) to kill the bacteria, followed by disposal in the sink with excess flowing "
water. . . .
Virkon is a commercially available disinfecting agents. Virkon is used according to manufacturer's instruction, which is
a minimum concentration of 1 % to disinfect bacterial cultures and surfaces .. Virkon is effective for killing streptococcus
~nd E. coli when used at the recommended concentratioD, amount and time
(http://wwW.fishersci.co.ukwebfiles/ukiweb-docs/SLSGD05.PDF).

The committee had no amendments to make and approved the activity as class 2.
Project Additional Information

Purposes of the contained use

The lab is focused on understanding the molecular mechanisms underlying neural stem cell function in normal and disease states. In particular the lab investigates the role of micro environmental niches which impinge on the function of neural stem cells. Using genetically modified mouse lines we can specifically label and follow the activation of neural stem cells in the sub-ventricular zone (SVZ), one of the two neurogenic niches, in the adult brain. We can induce injury in these mice and investigate the activation of astrocytes and neural stem cells mimicking the response of neural cells to a brain insult. We are also focused on understanding the progression of glioblastoma in the mouse brain, recapitulating the human disease in a model system in order to dissect out the molecular basis of induction,
migration and progression of the disease. By introducing lentiviral particles or piggybac plasmids encoding cell specific promoters driving known mutations associated with glioblastoma and tagged with fluorescent proteins directly into mouse brains we can mimic tumour progression in vivo. Thus, using a combination of genetically modified mice and introduction of tumor-inducing viral or plasmid particles we can identify crucial pathways associated with the different stages of the disease which may be drug-targetable in the future. Using the same mouse models eg p53fl/fl and Cdkn2a fl/fl we acutely isolate mouse neural stem cells and astrocytes and, in vitro methods determine the interactions of neural stem cells with their associated niches. Use of lentiviral produced cre recombinase enables deletion of specific tumour suppressor genes which have previously been associated with the progression of glioblastomas. We also isolate cells from our in vivo viral-induced tumours and use single cell sequencing techniques to determine differences in bulk tumour cells and those at the invading margins at the level of the transcriptome.

Recipient or parental organism

Especially disabled E. Coli K12 or B derivatives (e.g. DH1, DH5, HB1 01, JM1 01, JM 105, JM1 09, TG2, SUREtm, XL 1-Blue, Stbl3, BMH 71-18 mutS and ES1301 mutS or derivatives)
Mammalian tissue culture cells: 293T cells will be used to produce replication-incompetent virus. The auxiliary proteins and the VSV-g envelope protein are provided by three separate helper plasmids that contain no regions of homology to the HIV-1-based vectors. Three separate recombination events would be required to produce replication competent virus. The combined choice of the multiple packaging plasmids and the replication defective nature of the vector used will prevent the production of helper/replication competent virus by the transduced cells, reducing the risk to the environment.

Virus particles will be used to infect primary neural stem cells prepared from post-natal mice (PO-P1 0). They will also be used to infect cells from patient-derived glioma stem cells (prepared at the MRC Centre for Regenerative Medicine, Edinburgh). These patient derived cells have been obtained following local ethical board approval and are part of a bank resource of glioma stem cells generated in the MRC Centre for Regenerative Medicine, Edinburgh. Virus particles will also be injected directly into the brains of mice to either delete genes, induce activation of fluorescent proteins and ultimately generate gliomas in mouse brains.

DNA constructs will be electroporated into primary mouse neural stem cells prepared from pos-natal mice (PO-P1 0). They will also be used to infect cells from patient-derived glioma stem cells (prepared at the MRC Centre for Regenerative Medicine, Edinburgh). DNA constructs will also be injected directly into the brains of mice and then electroporated to either delete genes, induce activation of fluorescent proteins and ultimately generate gliomas in mouse brains. No oncogenes (EGRFvlll/PDGFRA) will be integrated via the lentiviral system.

The PiggyBac transposon system will be used to allow insertion of larger pieces of genetically modified DNA into the recipient genome. The system consists of a PiggyBac Vector and the a PiggyBac Transposase which recognizes transposon-specific inverted terminal repeats (ITRs) and efficiently integrates the ITRs find intervening DNA into the genome. The PiggyBac Transposase is delivered to the cell via the PiggyBac Transposase Expression Vector, which is co-transfected with one or more PiggyBac Vectors. Full integration of the plasmid into the genome is only possible when both PiggyBac and Piggybase are expressed concomitantly.

The mouse lines which will be used are commercially available (Jax laboratories) of have been received from the laboratories where they were generated under an MT A. Other non-GM mice will be acquired from commercial breeders (C57Blackl6, CDI NuNu, NSGs).

Host/vector system

PGEM series pcDNA3.1, pUC series, pAlter, pcDNA3, pTOPO, pCineo, pBUDCE4, pYac4 and their derivatives.
Helper-vectors:
Lentiviral vectors: pRSREV, pMD2G, pMDL, RRE, D8.9, VSVg

Lentiviruses will be used that lack viral auxiliary genes together with second generation packaging helper vectors such as pRSREV, pMD2G, pMDL, D8.9, VSVg or RRE. Second generation helper packaging plasmids will be used to ensure that the viruses produced are replication-incompetent.

Origin & function

The mouse lines which will be used are commercially available (Jax laboratories) or have been received from the laboratories where they were generated under an MTA. Other non-GM mice will be acquired from commercial breeders (C57Black/6, CDI NuNu, NSGs).

Evaluation of foreseeable effects

Lentiviral Vectors used in this project are unable to replicate and three separate plasmids are required to produce infectious particle and it is very unlikely to occur in the laboratory. All viral work will be carried out in dedicated level II containment facility. No sharps or needles will be used in any viral manipulations. These measures will ensure minimal or no infection to the user or the environment.

The Piggybac transposon system used in this project requires the simultaneous expression of PiggyBase and PiggyBac in order to effect integration of the plasmid. This will not occur outside of the host system and has no associated hazards to human health.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The mice used under this application are either from commercial suppliers, or recognised breeding establishments. These are laboratory strains of mice that have had no exposure to the threats of the natural environment and would therefore be badly adapted to survive in the wild or compete with wild strains. These laboratory animals would be extremely unlikely to be able to mate with other animals so would be unable to transfer the inserted genetic material to another animal. Therefore there is negligible risk of disseminating or displacing other animals in the environment.

The mice are kept and maintained in the UCL Central BSU in IVC racks under strict guidelines from the UCL Biological Safety Unit. Standard operating procedures are in place for working with the animals. Everyone working with animals is required to undergo an induction for work within the unit and an assessment by occupational health for any allergies or breathing issues which may be exacerbated by exposure to animal allergens. Everyone working with animals is fully trained and assessed prior to working in the BSU.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For waste produced as a result of, working with mice all PPE are disposed of after use and incinerated. Carcasses are incinerated or macerated after storage at -20°C. Sharps and neeples are disposed of in yellow burn bins and incinerated.

Solid waste generated through production of viral particles will be disposed of in double transparent autoclavable bags and will be destined for autoclaving in the Paul O’Gorman Building. There are 2 autoclaves in the Paul O’Gorman.
building, so a back-up if one breaks down. If both fail, waste is held in designated clinical/lab waste room which is access to staff only.

Contaminated glassware is disinfected first with 50/0 Distel (Trigene) for at least 1 hour, before heat sterilizing on site. Distel is a high level disinfectant. Plasticware that has come into contact with organisms is autoclaved on site (126°C 20 min, effective kill 1000/0) and then put into tiger stripe yellow bags by the building services team for treatment on site by the UCL waste contractors as offensive waste.

Liquid waste will be deactivated by a minimum of 12 hour exposure to Distel (100/0) disinfection. Disinfected liquids will be disposed of via tissue culture specific drains with excess water. The degree of kill is expected to be 1000/0. According to our supplier of Distel, StarLab, this compound at 10/0 concentration is highly active virucidal agent. The killing of several viral strains, including HIV, has been tested by using EPA protocol and complete deactivation was observed. Acknowledged and recommended by professional societies, public and private sector healthcare institutions http://www.medi-mark.co.uk/images/uploads/lTriGene_2p_animal.pdf

The GMSC approved the risk assessment as activity class 2 after minor modifications were made.

29/01/2020   | GMP Manufacture of autologous CD34+ haematopoietic stem cells transduced ex vivo | Class 2 | < 1 Litre |
with the lentiviral vector

Historical Significant Changes
Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use

Manufacture of advance therapy medicinal product (ATMP) for the treatment of patients with:
• Severe combined immunodeficiency due to adenosine deaminase deficiency: ADA
• X-linked severe combined immunodeficiency: IL2RG
• Mucopolysaccharidosis type IIa: SGSH
• Autosomal recessive chronic granulomatous disease: NCF1
• Familial hemophagocytic lymphohistiocytosis type 2: PRF1

The ATMP is a formulation of autologous CD34+ haematopoietic stem cells transduced ex vivo with the SIN lentiviral vector. To create the aforementioned IMP product, autologous CD34+ cells HSCs from patients with the above disorders will be genetically modified using a self-inactivating (SIN) lentiviral vector. These transduced cells will then be cryopreserved until such time of infusion back to the patients. The cryopreserved formulation will be thawed at the patient's bedside and infused directly without any further manipulation. The cells may also be given back to the patients in a fresh formulation which will be dependent on the protocol of the trial.

Recipient or parental organism

Autologous hematopoietic stem and progenitor cells (HSPCs) from patients or healthy donors. No producer cell line will be handled for this project as the LVVs are manufactured by external companies.

Host/vector system

All vectors covered by this RA are integrative, 3rd generation replication-defective, self-inactivating (SIN) HIV-1 derived LVVs, with a mutated Woodchuck hepatitis virus Post-transcriptional Regulatory Element (WPRE) sequence. They direct the expression of different therapeutic transgenes (the transgene used varies according to the disease to be treated in each clinical trial). There are all human physiological genes that are provided within the vector as an extra copy of the same gene that is mutated in the treated patients. The expression of the transgene is controlled in all cases by an internal physiological human promoter.

HIV-1 derived LVVs have been chosen because they are genetically stable, permanently integrate into the genome of transduced cells, and provide long-term gene expression in vitro and in vivo. The transduction HSPCs with such LVVs...
can be achieved after limited pre-stimulation of the cells in short-term cultures with cytokines, in conditions that are compatible with the preservation of the self-renewing capacities of these cells. Gammaretroviral vectors were used in the first gene therapy clinical trials, leading to disease restoration but in some case to malignant transformation (leukemia and myelodysplastic syndromes). This malignant transformation is known as insertional mutagenesis and it is produced when these vectors integrate close to regulatory regions of proto-oncongenes. The full viral L TRs present in these vectors were able to transactivate those regulatory regions, leading to the over expression of the protooncogene and to the subsequent malignant transformation. SIN LVVs represent a much safer approach for human application as: 1) the L TRs have been modified to lack promoter/enhancer activity and 2) they do no integrate in regulatory regions.

The modifications introduced into the organisation of the parental HIV1 genome are described below:
- Replication defective: The HIV-1 genome is split into 4 constructs consisting of 3 packaging plasmids and one (transfer plasmid, which are co-transfected for the production of an infectious particle. The packaging of the particle is therefore conditional on the Rev and gag-pol genes, which are expressed in trans on separate plasmids. The minimal homology between the various cassettes for packaging and gene transfer minimizes the likelihood of homologous recombination events and the generation of replication-competent HIV particles (RCI).
- SIN design: A 400 base pair deletion was introduced in the 3'L TR to remove major transcription factor binding sites. Reverse transcription, which generates both U3 regions from the 3' of the viral genome, transfers the deletion to the 5' L TR of the proviral DNA. The integrated provirus therefore contains the therapeutic transgene flanked by two transcriptionally inactive L TRs with U3 deletions.
- Mutated WPRE: This element is used to enhance the transgene expression in vivo and to increase viral titers during the manufacturing process. It has however been incriminated as the cause of hepatocellular carcinomas observed in mice treated with an equine LVV. Although such concern has not been evidenced in mice treated with HIV1 derived LVVs with the same WPRE, a mutated WPRE is used in order to prevent any issues.
- VSV-G envelope: VSV-G has been chosen because it has a broad tropism, and in particular the ability to target HSPCs.

The intended function of the genetic material is to correct the genetic mutation present in patient HSCs according to the disease being treated.
Therapeutic transgenes: this is different for each of the diseases to be treated
- Severe combined immunodeficiency due to adenosine deaminase deficiency: ADA
- X-linked severe combined immunodeficiency: IL2RG
- Mucopolysaccharidosis type IIIA: SGSH
- Autosomal recessive chronic granulomatous disease: NCF1
- Familial hemophagocytic lymphohistiocytosis type 2: PRF1
- Wpre* (mutated)

Evaluation of foreseeable effects

The host organism (HSPCs) do not represent any risk for the human health and safety as prior to collection, the donors are tested for an extended microbiology and virology panel. Moreover, cells area manipulated at all times inside an isolator (used primarily for product protection) and no direct contact between the operators and the cells is expected. Regarding the LLVs used, the risk of pathogenicity or toxicity in human cells is negligible. Cases of insertional mutagenesis have been reported in a small number of patients treated with gene therapy for immunodeficient diseases utilising retroviral vectors. However, the risk of accidental inoculation with lentiviral vector and the
development of insertional mutagenesis is considered negligible for the following reasons:
1. The risk of insertional mutagenesis is considered to be lower with lentiviral vectors than gammaretroviral vectors.
2. The current vector has been designed with the view to reducing the risks of insertional mutagenesis
3. Only HIV negative patients will be used as donors for this project so the possibility of recombination with the wildtype virus is negligible.
For all the above reason, the risks to human health and safety is considered negligible
The inserted genetic material is not known to have any known harmful effects.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Disposed of solid waste is conducted following the GOSH Pathology waste disposal policy. A double autoclave bag is used to contain the solid waste. It is placed into dedicated plastic bins with lids and collected by the GOSH central collection service for infectious waste and incinerated. All sharps are placed in puncture-proof containers and disposed of through the central collection service for contaminated/infectious waste, as above.
Liquid waste is disinfected using Haz-tab (effervescent chlorine tablets) overnight before being disposed of down the sink.
Although not used as the principle means of inactivation, autoclaves are available for use in the building; on the ground floor of UCL GOS Institute of Child Health and in the 4th floor laboratory area.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment
Approved by the GM safety committee as a class 2 activity, due to the use of sharps in the experimental procedure.
Corrections were requested by the committee on review and these have been made prior to submission.

The use of lentiviral vectors as pseudovirus to assess susceptibility of cells to infection by SARS-CoV2

We will purchase commercially available pseudotyped lentiviral particles which use GFP as a reporter to determine if human thymus cells and lymphocytes are susceptible to infection by SARS-CoV-2. The SARS-CoV-2 Spike Pseudotyped Lentivirus was produced with SARS-CoV-2 Spike (Genbank Accession #QHD43416.1) as the envelope glycoproteins instead of the commonly used VSV-G. These pseudovirions also contain enhanced GFP gene driven by a CMV promoter, therefore, spike-mediated cell entry can be conveniently determined via eGFP activity.

The SARS-CoV-2 Spike pseudotyped lentivirus can be used to measure the activity of neutralizing antibody against SARS-CoV-2 in a containment level 2 facility. This is a second generation lentiviral vector containing WPRE and so will be a class 2 activity.

Recipient or parental organism

Mammalian cells (human thymus cells and lymphocytes). These are primary human cells that are not immortalised.

Host/vector system

Pseudotyped lentivirus in which the SARS-CoV-2 spike protein (Genbank Accession #QHD43416.1) is the envelope glycoprotein instead of the commonly used VSV-G. As control, Bald Lentiviral Pseudovirion (eGFP reporter) will be used (the same construct lacking the spike protein). The pseudotyped lentiviruses are replication-incompetent. None of the HIV genes (gag, pol, rev) will be expressed in the transduced cells, as they are expressed from packaging plasmids lacking the packing signal. This is a
second generation vector which contains a WPRE.

Origin & function
Enhanced GFP (as a reporter for viral uptake).

Evaluation of foreseeable effects
Risk of pathogenicity or toxicity in human cells by this gene modification is negligible, and would not be expected to cause harm. The only genetic material we will introduce is enhanced GFP. We will not construct lentiviral constructs ourselves, but use commercial viral particles.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Solid waste will consist of plastic-ware used in tissue culture and viral preparation including pipettes, tips, culture dishes and flasks. This waste will be double-bagged and then autoclaved at 132°C for 15mins, then removed for off-site incineration. Liquid waste will consist of cells, cell culture supernatant and liquid containing viral vectors. Liquid waste will be treated for 30 minutes with PRESEPT effervescent disinfecting tablets (2.5g/tablet in 2-5 litres) or Distel (at dilution 1:10, according to manufacturer's instructions). Both PRESEPT effervescent disinfecting tablets and Distel are certified by Public Health England (PHE) to provide 100% virucidal kill under these conditions. Following chemical treatment, liquid waste will be placed in sealed containers and disposed of for off-site incineration.

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

Pseudotyped HIV virus particles will be produced using a two-vector system, consisting of a packaging plasmid (encoding different HIV Env proteins or VSV-G) and a plasmid containing the defective HIV genome (env-depleted). Co-transfection of these plasmids results in production of self-inactivating virus, which can undergo only one round of replication. The possibility of recombination of the plasmids is very low but potentially possible, therefore the experiments will be carried out in a MSC class I or MSC class II cabinet in a CL3 laboratory.

**Recipient or parental organism**

Human cell lines HEK293T and TZM-bl.

**Host/vector system**

Plasmids encoding different HIV env proteins will be co-transfected with a plasmid containing the env-depleted HIV genome with minimal sequence-overlap. This two-plasmid system to produce HIV Env-pseudotyped viral particles ensures that the replication is self-limiting to one round of replication and the possibility of recombination to wild-type HIV is minimal.

**Origin & function**

Different HIV Env sequences will be used in neutralisation assays using patient plasma to determine the amount of neutralising antibodies.
Transfection of 293T cells and transduction of TZM-bl cells will result in stable integration of defective HIV genome onto the recipient cells. This will result in expression of some HIV proteins and cell-toxicity, but not the expression of full-length HIV genome. The risk of recombination and therefore production of replication-competent HIV is low.

Evaluation of foreseeable effects

Not applicable

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All disposal of solid and liquid waste will be carried out according to the detail in the Risk Assessment. Solid waste will be double bagged and sealed inside the safety cabinet and subsequently autoclaved. Autoclaved waste will then be incinerated off-site. Liquid waste will be inactivated with 10% Distel or 3% Virkon over night before disposal to drain in the facility.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The proposed project was reviewed in December 2019, brought as a class 2 assessment. The principal recommendation at that time was to split into two activities, one at class 1 and another at class 3. The assessment was edited and has now been submitted as a class 3 project, with the class 1 activities assessed separately and already approved. Following second review, the activity was approved by the committee as a class 3 activity.

Project Additional Information

Purposes of the contained use
To investigate the 4D structure of the CAR-T immune synapse.

Recipient or parental organism
Human T-cells from healthy donor blood.

Host/vector system
No host / vector system in use in this activity.
The GM T-cells proposed in this activity are prepared using self-inactivating lentivirus vectors to create chimaeric antigen receptors against CD19. This activity is carried out at Great Ormond Street Institute for Child Health under a separate Class 2 GM notification. Only the GM T-cells are being used for the microscopy.

Origin & function
All material is human. The GM component is a T-Cell surface protein (anti-CD19)

Evaluation of foreseeable effects
Any exposure to the GM material by workers can be expected to result in prompt rejection of the allogeneic cells. Therefore there are no foreseeable effects to humans.
GM cells will be unable to survive outside of specialised cell culture conditions. There are therefore no foreseeable effects to the environment.
However, as the original source of T-cells is healthy human donors, the presence of (currently unknown) adventitious viruses cannot be excluded. Although very unlikely, the foreseeable effects of these potential hazards cannot be quantified, hence the Class 2.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
No derogations applied for.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All solid Class 2 waste shall be autoclaved at the standard 121°C / 15 minute standard. As the waste may potentially contain chemical waste, the waste will then be removed from the building as clinical waste for incineration.
All liquid class 2 waste shall be deactivated using bleach.

Is an emergency plan required according to regulation 20? [N]
If yes, tick to confirm that it is attached to this form [N]
Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Approved by the GM safety committee as a class 2 activity.

**Project Additional Information**

Purposes of the contained use

We wish to use third generation lentiviral vectors (PCDH family; Systems Biosciences) to express ion channel genes in neurons and neuronal cell lines. While these lentiviral vectors are deactivated using several approaches and are regarded as a very low risk for recombination (details at www.systembio.com) there remains a
theoretical risk. For this reason, and to protect the target mammalian cells from contamination, as is usual for tissue culture experiments, we will conduct work in containment level 2 facilities. All live animal work will be done in containment level 2 as well.

Recipient or parental organism

The GMOs will be lentiviral particles containing sequences encoding ion channel genes. These viruses will be H
terecombination deficient, but will be capable of transducing individual mammalian cells (including handlers, if skin is L
broken). Any inoculation with these GMOs should be restricted to the subset of cells that come immediately in H
contact, but will not spread. The genes carried by the GMOs will be expressed in inoculated cells, but these genes H
/ion channels/ are not dangerous to neighboring cells.

Host/vector system

The vector system used will be the Systems biosciences PCDH lentiviral kit. These lentiviral vectors are third H
generation and represent a low risk of recombination or of infection. They are self-inactivated, Tat deleted, have the H
packaging genes split on to three separate packing vectors, and mature virus particles (the GMOs) will contain no H
original packaging genes. However as developments in lentiviral research provide safer alternatives we will continue
upgrading our choice of viral system, always in the direction of reduced ability to recombine and increased safety.

Origin & function

The genetic material will be cloned cDNA from human tissues. These cDNAs will encode ion channels that are H
associated with inherited diseases in humans. We have a large collection of mutations in different ion channel genes I
(an expanding group including: SCNs, CACNA1A, KCNA1, and accessory subunits), that have been identified with H
patients presenting with various neurological disorders (including epilepsy, ataxia, and migraine). None of the ion H
channel genes are thought to be oncogenic or dangerous on their own or in combination with other genes. They are L
not secreted but remain in the membranes and cytosol of the cells expressing them. The genes encode ion H
channels and their accessory subunits that allow cells, generally neurons or muscles, to respond to stimuli by H
passing ions across their membranes. We will analyse how the ability to pass ions across the membranes is altered H
when mutations associated with human diseases are expressed in the ion channels. All work with patient DNA is H
done under appropriate ethical approval and consent. H

The neurological nature of the diseases that we are studying, and the specialized nature of the ion channels we are H
studying requires that we explore the behavior of these genes in neurons and muscles. While much of our work can H
be done in vitro, the actual functioning of neurons and muscles in vivo, when expressing the target genes (wild-type H
vs. mutant) will be key to understanding how different ion channels are capable of causing different neurological H
disorders. We hope to investigate the ability of cells inoculated with viruses in vivo (in rodents only) to survive, H
propagate action potentials and to communicate with other neurons, especially when expressing ion channel H
mutants that in humans have been shown to disrupt these processes.

Evaluation of foreseeable effects

We anticipate that the primary effects will be the limited expression of our genes of interest in the desired H
mammalian cells, In general this will have modest effects on the infected cells behaviour, but should not lead to H
changes in neighboring cells. It is possible that the virus particles could infect any human cells including those of H
workers, if they contacted broken skin (i.e. with a sharp glass pipette or syringe needle). Such an infection with an H
inactivated non-replicable virus is likely to present a very small risk to the worker. Individual cells infected by the H
virus would express only the ion channel genes encoded in them and the effects of these genes would be limited to H
the infected cells. However it has been shown in some circumstances where large amounts of virus are used to H
infect embryonic or stem cells that tumors may be produced, although the mechanism has not been clearly linked to the viruses. For these reasons, as well as to maintain the sterility of our tissue culture stocks, and the health of animals during surgery, we will conduct all experiments with viral particles in containment level 2 cabinets. In addition all plasticware, sharps and media that comes in contact with the virus particles will be disinfected with bleach. Innoculated animals will be maintained in containment level 2 conditions and animal remains will be disposed of in sealed containment level 2 clinical waste bags. No animals inoculated with viral particles will be allowed to breed, and no GM animals will be generated.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

n/a Although we hope to use viruses to express human genes in selected animal tissues, we will not breed GM animals for this project (only non-breeding animals will be used).

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| Both liquid and solid waste will be treated with bleach solutions (degree of kill effectively 100% for both virus particles and transformed mammalian cells). The effectiveness of these solutions is monitored routinely by the p1-1 indicating properties of the media, and bleach is stored in solid form to prevent inactivation. After disinfection with bleach solid waste is disposed as clinical waste. Surfaces in contact with media and virus will be sterilized with ethanol, and will be routinely (usually daily or, exceptionally, weekly) UV irradiation. Animal remains will be disposed of in sealed class 2 clinical waste bags. Live animals will be maintained in Class 2 containment facilities, and used cages will be autoclaved before cleaning. |

**Project Additional Information**

**Purposes of the contained use**

To prevent the exposure of humans to risks associated with the Eukaryotic expression of human oncogenes. It is not likely that DNA or cells will infect humans and therefore there is no foreseeable effect. All activity will be Class 2 with special provisions of "no shards".

**Recipient or parental organism**

Disabled strain of E.Coli and tissue culture cell lines as detailed below.

**Host/vector system**

pBl-EEFP, pIIIRES type bicostronic vectors, pTREX toruse in Eukaryotic cells.

In cell lines, Hela, MCF7, HRIE7, ARPE19, CAL02, A431, MRC5, HopI2.cos-1, cos 7. MDCK, CHU, CHUKI, NIH3T3, SWISS 3T3, EPNT.

For prokaryotes pBluescript, pCRII, pBLUNJ, pRSET, TrCHISA, pGEX, pUBEX in TOP10F, E.Coli XL-Blue, E.Coli JM83, BL21, DHSx

**Origin & function**

Human oncogenes have originally been cloned from human tissues, the precise function of which are largely unknown. They will be studied during this project.
Evaluation of foreseeable effects

So long as DNA or transfected cells are not introduced directly to humans there are no foreseeable effects. Class 2 activity is determined due to the expression of human (potential) oncogenes. We will not use any vectors which will directly infect human or animals such as viruses. We will in all instances adhere to precautions and procedures described in ‘Guidance and Construction of Recombinants containing potentially oncogenic nucleic acid servences.’ Para 13-15 GMAC Category 2 containment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

None

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All end waste from this project will be autoclaved. Autoclave indicator tape will be used to determine that effective autoclaving has taken place. We have previously determined that autoclave is 100% effective in killing all tissue culture cell lines and all strains of E.Coli used.

### Project Additional Information

#### Purposes of the contained use

Purpose of contained use is to minimise/prevent the exposure of humans to risks associated with the eukaryotic expression of a variety of signalling proteins expressed through a human lentiviral gene transfer system. It is not likely that transduced cell lines will produce viable progeny and therefore only handling of the producer cell line with expression vectors and isolated viral particles can be considered a risk. All this activity will be carried out in class II biological safety cabinets and in category containment laboratory facilities.

#### Recipient or parental organism

Strains of E. coli bacteria and a range of human and tissue culture cell lines as detailed below.

#### Host/vector system

<table>
<thead>
<tr>
<th>Hosts</th>
<th>E. coli DH5 alpha</th>

<td>pLENT16/V5 (invitrogen)</td>
</tr>
</tbody>
</table>

#### Origin & function

A range of cell adhesion molecules and signalling proteins have originally been cloned from human/rat tissues. The functions of all the proteins are generally known. No human oncogenes will be used.

#### Evaluation of foreseeable effects

As long as the DNA or transfected cell are not directly introduced to humans there is no foreseeable effects. Class II activity is determined to minimise exposure to virus-producing cell lines.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMO waste from this project will be autoclaved immediately. Autoclave indicator tape will be used to determine that autoclaving has reached correct temperature and pressure. We have previously determined that autoclaving results in 100% kill of the GMO used in this project.

Similar work using recombinant lentiviral vectors is currently ongoing at this centre. The local GMAC is happy that the work proposed in this application can proceed safely.

**Purposes of the contained use**

The purpose of the contained use is to prevent the exposure of humans to risk associated with the eukaryotic expression of c-myc. It is not likely the DNA or cells will infect humans and therefore there is no foreseeable effects, all activity will be class II with specific provisions of "no sharps".

**Recipient or parental organism**

Tissue culture cell lines as detailed below.

**Host/vector system**

The vector is the pLNC-cmyc ER virus. The virus will be used to transduce primary epithelial cells.

**Origin & function**

Human c-myc was originally cloned from human cells, but its precise functions are largely unknown. The virus will be destroyed during the project.

**Evaluation of foreseeable effects**

So long as the DNA or transfected cells are not introduced directly to humans there are no foreseeable effects. Class II activity is determined due to the expression of human (potential) oncogenes. We will not use any vectors which will directly infect humans or animals. We will in all instances adhere to precautions and procedures described in "evidence and construction of recombinants containing potentially oncogenic nucleic acid sequences" PARA 13-15 GMAC category II containment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

None

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid cultures of viruses, or cells infected with viruses including all tissue culture plasticware will be autoclaved for 30 mins at 121 degrees C under 115lb/sq in pressure. This is effective in producing 100% kill of viruses as assessed by replating 10(6) CFU of autoclaved viruses on indicator cell lines and observing the appearance of no transduced cells. Each autoclaved sample will be marked with autoclave indicator tape. Each load will not be regarded as safe unless indicator tape shows that correct autoclaved parameters have been achieved. In addition we will also include thermosticks with each load to ensure the centre of the load has reached the correct working temperature and pressure. Autoclaves are routinely serviced to ensure correct working temperatures and pressures. Autoclaved material will be marked "inactivated GM waste" discarded to clinical waste and removed from the site by an authorised contractor.

02/03/2022
The identification of novel targets for treating neovascular eye disorders

Purposes of the contained use

To work with the transforming oncogene polyomavirus middle T antigen and the growth factors VEGF and Notch ligands in a disabled lentiviral expression system

Recipient or parental organism

In most cases, mammalian gene sequences will be used. Polyomavirus represents the only pathogenic donor organism, the middle T antigen being its transforming oncogene.

Cultured mammalian cells will be transfected with bacterial plasmids containing mammalian gene sequences or transduced with viral vectors containing mammalian gene sequences

Host/vector system

pPICZ yeast expression vectors and bacterial cloning vectors will be used for cloning/expression of VEGF120/121, VEGF164/165 and mutant variants, VEGF 188/189, PIGF and mutant variants, VEGFR-1/2, neuropilin of the pUC series as well as mammalian expression vectors will be used for cloning/expression of Moesin and mutant
variants, PV-1 and mutant variants, Ezrin, Radixin, Caveolin, C5A, Integrins, Notch ligands and receptors, PI GF and PDGF and mutant variants, Hey-1 and -2 and mutant variants, polyoma middle T antigen, and micro RNA sequences for RNA interference of target genes.

ViraPower Lentiviral expression systems (Invitrogen) will be used for cloning/expression of VEGF120/121, VEGF164/165 and mutant variants, VEGF188/189, VEGFR-1/2, neuropilin-1/2, notch ligands and notch receptors and their mutant variants, PV-1 and mutant variants, moesin and mutant variants, polyoma middle T antigen and mutant variants.

Vectors will be introduced into bacteria by heat transformation or by electroporation using a BioRad GenePulser Xcell electroporactor. Vectors will be introduced into yeast cells by electroporation. Vectors will be introduced into mammalian cells in a class 2 safety cabinet either by electroporation using an Amaxa Nucleofector II, or by chemical transfection using lipid based transfection reagents.

Of the inserts to be used, VEGF, PI GF and Notch ligands are growth factors, and VEGFR1/2, neuropilin-1/2 and notch are growth factor receptors; Hey-1 and Hey-2 are nuclear proteins and downstream genes of the notch pathway; moesin, PV-1, radixin and caveolin are structural proteins, linked to the actin cytoskeleton, and it is thought that certain mutant variants of moesin and PV-1 may disrupt cytoskeletal arrangements and affect cell structure; integrins are involved in cell-cell and cell-matrix interactions; C5a, LFA1, CD46, CD55 and Mac-1 are involved in the immune system, C5a Mac-1, CD46 and CD55 in the complement cascade, LFA1 in immune cell recruitment RBP4 is a specific retinol-binding protein; polyoma middle T antigen is a transforming oncogene, and Src, PI3K and Ras are components of the polyoma middle T signalling pathway, and it is thought that mutant variants of polyoma middle T, Src, PI3K and Ras may disable aspects of their activity and therefore affect cell transformation.

MicroRNA sequences are designed with the aim of causing reduced expression of a target gene.

Origin & function

VEGF is a pro-angiogenic and pro-inflammatory growth factor which may exert harmful effects if over-expressed at high levels in the tissue, but with low severity because of the short half-life of the protein. VEGFR1/2 and neuropilin-1/2 are receptors and co-receptors, respectively, which mediate VEGF signalling. Notch ligands and Notch receptors are growth factors and receptors, respectively, and unregulated expression of their mutants variants has been linked to tumorigenesis, but with low severity and a self-limited localisation. C5a, LFA1, CD46, CD55 and Mac-1 may cause transient local inflammation if expressed at high levels locally, but with low severity. Polyoma middle T-antigen is a transforming oncogene with the potential to induce tumour growth, although the severity would be likely to be low and limited to immune-deficient individuals. Src, PI3K and Ras are involved in the Polyoma middle T-antigen signal transduction pathway and may be involved in its transforming ability, indicating a potential for harm, but effects would be limited, localised and transient with low severity. The use of low volumes of culture medium and replication-deficient lentivirus reduce the risk to humans. Sharps will not be used when handling potentially harmful sequences; this will significantly reduce the risk of DNA transfer through needlestick or other puncture injury. Other proteins including the structural proteins such as PV-1 and nuclear proteins such as Hey-2 have no documented risk of causing diseases in humans.

Evaluation of foreseeable effects

VEGF is a pro-angiogenic and pro-inflammatory growth factor which may exert harmful effects if over-expressed at high levels in the tissue, but with low severity because of the short half-life of the protein. VEGFR1/2 and neuropilin-1/2 are receptors and co-receptors, respectively, which mediate VEGF signalling. Notch ligands and Notch receptors are growth factors and receptors, respectively, and unregulated expression of their mutants variants has been linked to tumorigenesis, but with low severity and a self-limited localisation. C5a, LFA1, CD46, CD55 and Mac-1 may cause transient local inflammation if expressed at high levels locally, but with low severity. Polyoma middle T-antigen is a transforming oncogene with the potential to induce tumour growth, although the severity would be likely to be low and limited to immune-deficient individuals. Src, PI3K and Ras are involved in the Polyoma middle T-antigen signal transduction pathway and may be involved in its transforming ability, indicating a potential for harm, but effects would be limited, localised and transient with low severity. The use of low volumes of culture medium and replication-deficient lentivirus reduce the risk to humans. Sharps will not be used when handling potentially harmful sequences; this will significantly reduce the risk of DNA transfer through needlestick or other puncture injury. Other proteins including the structural proteins such as PV-1 and nuclear proteins such as Hey-2 have no documented risk of causing diseases in humans.

pPICZ yeast expression vectors contain the TEF1 and EM7 promoters, which drive the expression of the gene coding for resistance to the antibiotic Zeocin in yeast and prokaryotes, respectively. Insert expression in pPICZ vectors is controlled by the AOX1 promoter, which is induced by methanol. Gene expression is therefore suppressed in the absence of methanol. Bacterial plasmid vectors contain the prokaryotic lac, EM7, T7 and SP6 promoters, and the cytomegalovirus (CMV) immediate-early promoter and the simian virus (SV) 40 promoter for expression in mammalian cells. All bacterial plasmid vectors used are non-mobile, and are therefore unable to transfer into wild-type bacteria in the environment.

The ViraPower Lentiviral expression systems which will be used are derived from HIV-1 but have a number of inbuilt safety features. There are no longer terminal repeats (LTR) in the packaging plasmids, so that HIV-1 structural genes are only expressed in the producer cell and never packaged into virions. Secondly, viral particles are replication incompetent, and they only carry the gene of interest, so that no other viral proteins are produced. Additionally, these viruses have a deletion in the 3’ LTR which makes the virus “self-inactivating”; transduced and integrated lentiviral vectors are no longer capable of producing a packagable viral genome. The insertion of genes would be unlikely to affect the behaviour of the viral vectors.

Cultured mammalian cells transfected with bacterial plasmids containing mammalian gene sequences or transduced with viral vectors containing mammalian gene
sequences may display altered signalling, growth or viability but due to the fact that these cell lines rely on specific culture conditions and would be unlikely to survive outside the laboratory culture conditions, this would not pose a risk to humans. The insertion of genes would be unlikely to alter the recipient organisms' ability to survive in the environment, compete with other organisms or transfer to them the inserted sequences.

The majority of materials used in this project are not considered hazardous to handlers. The transforming oncogene polyoma middle T antigen and the VEGF isoforms and receptors have a potential to cause harmful effects. In the case of the vectors used for VEGF, the risk of natural gene transfer is very low. The most hazardous GMM is disabled lentivirus containing the polyoma middle T sequence, and any procedure in which this construct is handled, particularly with a view to transducing cells, is likely to be the most hazardous.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The inactivation measures which will be used, as appropriate, are chemical disinfection with a 1% solution of Virkon disinfectant for 10 minutes or a 105 bleach (sodium hypochlorite) solution, treatment with UV light, and autoclaving. Virkon disinfectant has been proven to kill 99.999% of microorganisms in less than 10 minutes, and is the disinfectant of choice for inactivating viruses. Sodium hypochlorite is a commonly-used wide-spectrum disinfectant. Autoclaving involves treatment with high pressure steam at 121°C for 15-20 minutes, which kills all bacteria and viruses. The inactivation of bacteria and yeast should be confirmed by spreading treated liquid waste onto the appropriate solid growth medium, incubating overnight at the optimum temperature and checking for micro-organism growth. The inactivation of virus should be confirmed by attempting to infect host cells and testing for infectivity or expression of proteins coded by the viral vector. Inactivated contaminated solid waste should be disposed of in Biohazard bags, and inactivated contaminated sharps in Biohazard sharps bins. Inactivated contaminated liquid waste may be disposed of in normal waste water drains.

**Project Additional Information**

**Purposes of the contained use**

Our group aims to contribute to the development of novel methodologies of human disease treatment through identification of novel targets of diseases and their characterisation using in vitro and in vivo systems. We are particularly interested in cancer and ocular disorders. Recently our studies have identified that the small leucine rich proteoglycan family members may inhibit tumourigenesis. To examine this possibility, it is essential to analyse the effect of their activation in in vitro and in vivo cancer models. To this end, the third generation lentivirus system is ideal because it is very safe and can easily produce stable expression. So far, there is no effective treatment of many types of cancer. If the activation is effective, this may provide a novel strategy of cancer treatment.

**Recipient or parental organism**

**Virus:**

The third generation lentiviruses such as Lenti-X system (Clontech), SIN third generation (Gentarget, OpenBiosystem). 

**Cells:**

Non-transformed cells 293, NHU-hTERT
ATCC supplied established human cancer cell lines such as Hela, EJ28, J82, RT112, 253 JBV, and MCF7.

Corneal cells: epithelium, endothelium, and fibroblast

Animals: mouse

Host/vector system

To construct viral vectors, the following intermediate constructs will be made using general lab strain of E. coli. There is no potential for harm to health and/or harm to the environment.

Commercially available packaging vectors are used such as pMDL, prev, and pVSVG.

Lentiviral transfer vectors containing inserted genes of interest will be constructed using commonly used safe vectors such as pLVX-Tight-Puro (Clontech), LT-Exp1 (Gentarget), plenti vectors (Invitrogen), and Express-In™ (Openbiosystems).

Origin & function

Origin: human, mouse, Xenopus (OMD, PRELP), P1 bacteriophage (Cre recombinase), E.coli (Tet-on)

Functions:
OMD and PRELP are secreted proteins in the small elucine rich proteoglycan family. These proteins regulate cellular signalling from extracellular space. We expect that overexpression of these genes show negative effect on tumour cell growth.

Cre recombinase has the activity to induce recombination through the Cre-lox system.

Tet-on (for inducible system) is used for suppression of spontaneous expression of introduced genes.

Evaluation of foreseeable effects

The third generation lentivirus system has been recognised as a very safe system. The inserted DNA and virus are unlikely to be pathogenic. However, the most hazardous GMO is recombinant lentivirus. There is the possibility of mutagenesis caused by random insertion of viral sequences, but the risk of foreseeable adverse effects is very low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Infection of mice will be performed in the animal facility. The protocols are set out in the Home Office Animal Project Licence (PPL70/6750). The mice will be always kept in the animal facility.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The viruses, cells and animals cannot survive in natural conditions. They will be killed by standard methods.

E. coli and eukaryotic cells are inactivated by treatment with Virkon. Also, all waste and used glassware are autoclaved. The autoclaved waste will be discarded using plastic bags. We expect to kill 100% of cells and mice. The conditions are approved to kill E. coli, mammalian cell lines, and mice. Mammalian cells are confirmed by lysis of structure. Death of mice is confirmed by eye. The dead mice will be packed in plastic bags. The bags are temporarily kept in designated -20 freezer in the animal facility.
Then, the dead animals are incinerated by the designated special facility.

Prof O has submitted a new Class 2 risk assessment using third generation lentiviruses. The risk with this proposal lies in the possibility of random positional integration into the genome and the unpredictable effects this could have. The committee reviewed the risk assessment forms and the following points were raised.

GMM1 & 2
- Section 1.11 mentions xenopus but not section 1.13
- Section 2.06 states there is no risk. Clearly there is a risk but this is controlled.
- Section 2.09 - The risk should be low not zero

HSE Risk assessment
- As the form will be submitted to the HSE it must be accurate.
- Section 2.13 needs to be more specific. It is not acceptable to state "such as Virkon" or "suitable bags".
- Section 2.07 again states there is no risk. This needs to be amended.
- We need to make it clear in the risk assessment why we believe the proposal is Class 2, i.e. because of the level of virus titre being used and the injection into animals.

CU2 form
- The sentences relating to the Home Office need to be removed. The HSE are interested in the disposal of the carcasses not how the animals will be killed

Please enter comments on the GM safety committee on the risk assessment

| 24/04/2012  | Propagation and use of tumour replicating viral vectors for use in cancer gene therapy. | Class 2 | < 1 Litre

24/04/2012
The purpose of this project is to develop strategies to improve the in vitro and in vivo function of viral vectors for potential use in cancer gene therapy.

Recipient or parental organism

Well characterised, ACDP Class 1 mammalian cell lines (e.g. A549, CaLu 6, CT26, B16-F10, HeLa) well characterised, ACDP Class 2 mammalian cell lines (e.g. HEK293, COS-7, SVEC 4-10, 2F2B) Murine embryonic stem cell line (E4Tg2a) and murine primary cell C57B16, Oalb/c and CD1 immunocompetent mice Athymic (nude) immunodeficient mice

Host/vector system

1. Wild-type Reovirus is replication competent. However, its replication is selective to cells that have an activated Ras signalling pathway (Curr Opin Mol Ther. 2006 Jun; 8(3):249-60)
2. Tumour-replicating Adenovirus. ICOVIR-5 (Ad-DM-E2F-K-Delta24RGD) is an optimised oncolytic adenovirus that combines Ela transcriptional control by an insulated form of the E2F promoter with Delta24 mutation of Ela to improve the therapeutic index of AdDelta24RGD (Mo! Ther. 2007 Sep; 15(9): 1607-15)

Origin & function

Reovirus will be provided by Oncolytics Siotech Inc. Calgary, Canada (Reolysin). This product is currently being used in clinical trials and we wish to investigate its oncolytic potential in cancer gene therapy. The virus is not genetically modified.
ICOVIR has an Ela gene deletion in the retinoblastoma (Rb) protein-binding region, substitution of the Ela promoter for E2F-responsive elements and an RGD-4C peptide motif inserted into the adenoviral fibre to enhance adenoviral tropism.

Evaluation of foreseeable effects

Reovirus will infect human cells however, it is only replication competent in cells with an activated ras signalling pathway therefore, the risk to human cells is minimised. Ras mutations and overexpression of the ras signalling pathway are most frequently associated with a transformed phenotype and the development of malignancy. However, there is a theoretical risk that ras signalling may be activated in growth factor-stimulated cells, cells that proliferate (wound healing) or in people with cellular proliferative
disorders. Therefore we cannot exclude the possibility that Reovirus (Reolysin) might infect and replicate in apparently normal cells, causing lysis. Furthermore, the release of tumour associated antigens following lysis may modify the host immune system to infected cells. However, this is unlikely to result in adverse disease. Reovirus will also be readily transmitted via aerosols. Therefore, to protect people from the potential risk of infection all work associated with the virus will be carried out at Class 2.

ICOVIR is replication defective in normal, healthy cells, However, if ICOVIR were to recombine resulting in replication competence it would be comparable to wild type adenovirus since it contains no additional genetic material. All strains of adenovirus 5 are non-oncogenic. Wild-type Ad5 may cause mild respiratory diseases in children. Primary infection of adenovirus is thought to generate life-long immunity and it is thought that the majority of the adult population are likely to have antibodies to the wild-type virus. Although replication has been shown to occur in the lungs of experimentally infected cotton rats administered with high doses of virus, there is no evidence that adenoviruses can naturally colonise non-human hosts and therefore pose no significant harm to animals, plants or ecosystems.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Wild type Reovirus or Adenovirus-infected animals may excrete (shed) adenovirus (especially in the first 72 hours after infection). Precautions must be taken not to create aerosols when emptying animal waste material, washing cages or cleaning the room. Handling is carried out in Class 2 microbiological cabinet.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation required.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be treated with a 1% Yukon solution for at least 3 hrs. It can then safely be disposed of in the laboratory sink. All surfaces coming in contact with liquid waste will be washed with 1% Virkon and/or 70% isopropanol and/or a mild detergent (e.g. SDS). Plastic tips, syringes, etc or glassware that was used to hold or dispense virus will similarly be soaked in:

1% Virkon solution for at least 3 hrs, but overnight in most cases. The liquid will be disposed of in the laboratory sink, and the remaining solid waste will be collected in the laboratory solids bins.

1% Virkon has activity equivalent to 1000 p.p.m. chlorine without hazards, corrosion potential and loss of activity due to organic challenge.

(Antiviral Res. Inactivation of adenovirus types 5 and 6 by Virkon S. 2004 Oct;64(1):27-33.)

All other solid waste will be inactivated by autoclaving. The autoclave will be validated by external contractors at least once per year and the day to day operation monitored using the instrument readouts of temperature, pressure and time. The autoclaves used for waste also indicate a failed cycle if the required parameters are not met.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The committee feel that the proposed research using replication deficient viruses and tumour replicative competent viruses that are dependent upon ras signaling for adenoviral infection are safe. This research is a continuation of work currently being conducted within other UK institutions, using similar protocols. In these proposed experiments reporter genes are used as markers for transfection efficiency and translation. All cell lines used in these experiments are well characterized and if handled correctly, according to well developed protocols, will not pose any difficulties concerns, even for those cell line assigned at class 2 containment. The proposed experiments are very timely and need to be conducted without undue delay. There are no additional unknown risks associated with using nude mice in these proposed studies as similar studies have been carried out using the very similar experimental protocols as outlined in this proposal.

What happens if humans with cancer (in early stages people might not know that they have cancer) would work with Tumouronly replicative viruses? The worst case scenario would be that of the wild-type viruses. Is it really likely that all of these cell lines will be used? Yes, cell lines held by this laboratory have been acquired specifically for their different properties/species specificity.

The School requires double HEPA filters for Class II Microbiological Safety Cabinets used for GM work. Other points of clarification were dealt with at the draft stage for the Risk Assessment.

## Project Additional Information

### Purposes of the contained use

We aim to identify the molecular targets for our small antibacterial molecules using a multicopy suppression strategy. This requires the creation of a shot-gun library of Clostridium difficile DNA in specific vectors. These will then be transferred back into Clostridium difficile with the aim of identifying clones that are resistant to our molecules. Further to this our potential targets will be cloned to confirm their role in resistance. An alternative approach to this will be by creating a transposon library of random mutants and testing these for sensitivity against our compounds.

### Recipient or parental organism

Clostridium difficile strains are ACDP hazard category 2. Clostridium difficile R20291 is regarded as the PCR ribotype 027 reference strains. Strains produced in this study are not likely to be more virulent than this. Clostridium difficile 630 and 630 delta erm will also be used in this study but are known to be less virulent than strain R20291. Initial cloning will take place in E.coli and plasmids will be screened to ensure those containing toxin genes will not be placed in C.difficile as the additive effect is unknown. C. difficile only presents a hazard when the normal bacterial flora is compromised and is carried by 25% of the population with no effect to health.

### Host/vector system

The disabled E.coli strains TOP10, JM109 and CA434 will be used as the plasmid host and are not pathogenic. Due to the differences in codon usage between E.coli and C.difficile, it is very unlikely that expression of C.difficile genes will occur in E.coli. Also due to the random fragmentation of the genomic DNA the required elements for expression may not be cloned with the genomic DNA. The pMTL vectors based on the CoIE1 replicon will be used as shuttle vectors in E.coli and C.difficile. These plasmids are nic mob minus and are derived from Gram positive and negative components, many of which (except the Gram positive replicon) do not function in clostridia. These plasmids will also contain antibiotic resistance markers which are regularly used in the laboratory environment and E.coli. The plasmids are not self-transmissible.

### Origin & function

Genomic DNA will be extracted from the Clostridium difficile sequence strains CD630 and R20291. Fragmented segments of this DNA will then be cloned into pMTL80000 series vectors for propagation in E.coli and conjugation into Clostridium difficile. The approach of creating mutants for testing, either by deletion of a gene or insertion of a transposon will make the GMM less virulent. The majority of the genes to be expressed are innocuous bacterial enzymes used for basic metabolic functions and they are unlikely to function in isolation or in E.coli.

### Evaluation of foreseeable effects

**C.difficile:**
The duplication of metabolic genes in the multicopy suppression studies are highly unlikely to increase virulence or survival in the environment.

The effect of gene dosage on the only known virulence determinants of C. difficile, toxins A and B is unknown. Expression levels of the genes encoding toxin A and B vary widely in clinical strains and the experiments here are unlikely to exceed clinical levels even in the worst case scenario.

Random mutagenesis or directed gene deletion may increase or decrease virulence factor expression. None of the antibiotic markers used correspond to antibiotics that are routinely used to treat C. difficile infection.

**E.coli:**
The strains used are disabled, non-pathogenic laboratory strains which are unlikely to cause disease even with the addition of fragmented clostridial DNA or genes. As such infection with recombinant E.coli or survival in the environment is deemed highly unlikely.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste will be autoclaved to achieve 100% kill and will then be sent to landfill after processing by approved waste disposal contractors.

Is an emergency plan required according to regulation 20?

N

Please enter comments on the GM safety committee on the risk assessment

The GMSC has considered the proposal for work with C. difficile, and after initial discussion to clarify the text of the risk assessment we have no concerns about the genetic modification as planned, and note that it is highly unlikely that a GMO more hazardous than the host will be generated. The main concerns expressed were regarding the safe transport, handling and disposal of the pathogenic host organism. Acceptable safe working practices have been cited in the risk assessment, and reference has been included to indicate the expertise and experience of the key post-doc who has safely and successfully worked with C. difficile, and with other Level 2 and 3 pathogens for 11 years. One committee member has extensive experience of pathogen work including MRSA and has no problem with this straightforward application using category 2 bacteria. The GMSC has approved this proposal.

## Project Additional Information

### Purposes of the contained use

The purpose of this programme of work is to examine the role of integrins and cell surface receptors in tissue repair and pathology. The genes for integrins/cell receptors will be cloned and expressed or knocked out in human cell lines and primary cultures of human cells.

### Recipient or parental organism

The recipient cells will either be human cell lines of mesenchymal origin (e.g., epithelial/keratinocyte cell lines) or primary cultures of human mesenchymal cells (e.g., muscle myoblasts). The human cell lines that will be used in this programme of work are cells which have been in safe use for over ten years in a number of laboratories. The primary human cells on the other hand represent a greater inherent risk as they may contain adventitious agents.

### Host/vector system

The hosts will be either human primary mesenchymal cells or human cell lines with a safe record of use such as H357. A number of viral vector systems will be used which lack the structural genes for particle formation and replication. In particular PRcCMV, PBAbePuro, pLXIN, and pLXSN will be used in conjunction with the packaging cell lines AM12, E86, and PT67.

### Origin & function

The genetic material will be obtained from human cells and will code for integrins/cell surface receptors. These genes will be inserted into host cells which lack the proteins they encode so as to determine the role played by these molecules in cell-cell and cell-extracellular matrix interaction.

### Evaluation of foreseeable effects

Parental and recipient cells: The cell lines to be used in this programme of work have been in safe use for over ten years and are unlikely to cause harm to humans or the environment. The human primary cell could contain adventitious agents which may cause harm to humans.

Viral vector systems: The viral vector systems to be used are disabled and as such to not represent a risk to humans or the environment.

GMMs: The GMMs constructed in this programme of work will express integrin/cell surface receptors that may alter their tissue tropism. Thus while these GMMs represent no risk to the environment it is possible that they may cause harm to humans.

### Containment and control measures for GMOs that are not microorganisms (e.g., GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Conditioned media from GMMs and contaminated cell culture plasticware will be treated with a 1% solution of Virkon (final concentration) prior to disposal as clinical waste for incineration. Virkon treatment has been shown to rapidly produce 99.9999% virucidal, bactericidal and fungicidal activity. Contaminated serological pipettes and pipette tips will be autoclaved at 121 degrees C for 20 minutes prior to disposal as clinical waste for incineration. The autoclave to be used is regularly validated and serviced.
The work proposed in this programme of work was viewed as principally activity class 1. However it was felt that altering the expression of integrins on the cell surface may alter tissue tropism and thus may conceivably result in the GMO posing a risk to human health.

Project Ref  596/06.1

Date Ackn'd  24/04/2012

CU2 Project Title

The molecular basis of resuscitation of Campylobacter jejuni from a viable but not-culturable (VBNC) state.

Class  2

CulturVolClass2  < 1 Litre

CulturVolumeClass3-4

Non-GMM Consent Granted

Not Applicable

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Withdrawn  N

Tick if notifying a connected programme of work  N
Purposes of the contained use

Construction and complementation of defined Campylobacter jejuni mutants to investigate the function of genes potentially involved in resuscitation from the viable but non-culturable state.

Recipient or parental organism

Campylobacter jejuni NCTC 11168
Campylobacter jejuni 81-176

Host/vector system

Genes encoding putative resuscitation factors will be cloned in E. coli using the plasmid pGEM-T-Easy (Promega UK Ltd., classified as non-mobiliseable (Bom-, Mob- and Tra-minus) by the ACGM). These genes will be inactivated by insertion of a gene encoding kanamycin resistance (aphA3) and re-introduced into C. jejuni NCTC 11168 and 81-176. As pGEM-T-Easy is not able to replicate in C. jejuni, double cross-over homologous recombination events will direct allelic replacement of the chromosomal wild-type copy of the gene with the mutated allele present in the vector. pGEM-T-Easy carries an ampicillin resistance gene.

Genetic complementation will be done using an E. coli vector (pRRC) that delivers, by homologous recombination, cloned genes (under the control of a Campylobacter-derived promoter) into the 16S-28S rRNA spacer regions on the C. jejuni chromosome (Karlyshev and Wren 2005. Appl. Environ. Microbiol. 71:4004). This vector is not able to replicate in C. jejuni, is classified as non-mobiliseable (Bom-, Mob- and Tra-minus) by the ACGM and carries a chloramphenicol resistance gene.

Origin & function

C. jejuni genes encoding potential resuscitation factors (Genome sequence Genbank NC_002163; gene ID 904972, possible secreted transglycosylase; gene ID 904469, unknown function; gene ID 905140, possible secreted transflycosylase) will be amplified by PCR from genomic DNA of strain 11168.

Evaluation of foreseeable effects

Although the genetically modified organisms produced in this project will be resistant to kanamycin or to both kanamycin and chloramphenicol, neither are antibiotics of choice for treatment of Campylobacter infections. Therefore the potential risks associated with the genetically modified organisms are the same as those of the parental strains and the likelihood of these risks being realised is low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The project will generate the following waste: broth- (of 100 ml maximum volume) and agar plate cultures of the GMOs, contaminated pipettes, pipette tips and glassware. All contaminated waste, will be autoclaved on a "kill cycle" ensuring that the waste is held at a holding temperature of 121 degrees C for at least 15 minutes. This will kill all GMOs. Autoclaves contain temperature probes to check the heat penetration and sterilisation indicator strips are also included in each run. Autoclaved liquid waste will be disposed of by autoclaving on a kill cycle.
disposed down sinks. Autoclaved solid waste will be sent for incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form N

Please enter comments on the GM safety committee on the risk assessment

Part 1
The committee noted that this project was similar in nature to a programme of work previously approved by the HSE (GM596/99.1) but had the safety advantage over that programme of work in that the vector systems to be used could not replicate in the host organisms under any conditions. The committee also recommended that the inexperienced research on the grant be sent on a training course in good microbiological practice which has now been done.

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

Generation of PINK-1 gene knockout human cell lines in order to create a model for the study of Parkinson's Disease.

**Recipient or parental organism**

Human cell lines.

**Host/vector system**

Human cell lines such as HEK293, SOAS2, human neuroblastoma cell lines and 197VM human neural stem cells (ReNeuron). JS4, a recA-derivative of E. coli MC1061, a disabled K12 strain. Phoenix ampho cells, a non-mobilisable derivative of HEK293, free of adventitious agents. Vectors: PSUPERretro-puro, PWZLneo EcoR(non-mobilisable), PWZL BlastF(non-mobilisable) and PWZL BlastF EcoR

**Origin & function**

64i nucleotide RNAi constructs designed to knockout PINK-1 expression(Sigma Genesis Ltd). EcoRI fragment of the murine cationic transporter from Julian Downward as pWZLneoEcoR, originally made by D. Conklin.

**Evaluation of foreseeable effects**

Human cell lines will have ability to be infected by murine ecotropic viruses. The gene function of PINK-1 could be knocked out if the PINK-1 RNAi sequences were transferred to a human organism. The consequences of this are not clearly known, although loss of PINK-1 function is thought to be the underlying mechanism in autosomal recisive Parkinson's disease and is therefore associated with neurodegeneration in humans.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

No GM animals or plants will be produced.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
No derogation required.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste and plastic disposable pipettes are chemically decontaminated with either 10,000ppm Chloros or 1% Virkon, followed by incineration (solid material).

E. coli contaminated solid waste (agar plates, tips, pipettes is autoclaved at 121 C for 20 mins, followed by incineration. Solid waste from tissue culture such as dishes, tubes and flasks are also autoclaved before incineration.

Project Additional Information

Purposes of the contained use
To generate and use stable producer cell lines that produce high titre replication defective amphotropic retroviruses to be used for the immortalisation of freshly isolated primary human cells.

Recipient or parental organism
JS4, a recA-derivative of E.coli MC1061 (a disabled K12 strain). PA371, a non-mobilisable second generation mouse amphotropic producer cell line; TEFLYA and RD cells, both derivatived from TE671 cells, non-mobilisable. Phoenix ampho cells, non-mobilisable derivatives of HEK293, and primary human somatic cells.

Host/vector system
SV40 large T antigen and mutants.
Human catalytic subunit of telomerase and human papilloma virus 16/18.
E7 and E6 gene; Polyoma virus T antigens and mutants; Adenovirus E1A and mutants.
P53 GSE fragment and full length ORF for cellular genes.

Origin & function
SV40 T antigen, the catalytic of human telomerase, HPV E7 and E6 proteins, Polyoma virus T antigens, Adenovirus E1A and p53GSE are all immortalising genes that have the potential to extend the proliferative life span of normal somatic cells.

Evaluation of foreseeable effects
No GM animals or plants will be produced.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
No derogation required.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
No derogation required.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Solid waste such as dishes and flasks will be immersed in 1% Virkon for >10 minutes, followed by autoclaving and then incineration.
E.coli liquid waste is inactivated by treatment with 1% Virkon for >10 minutes.
Liquid tissue culture medium is collected into containers containing sufficient Virkon for final concentration of not less than 1% and left for >10 minutes.
E.coli solid waste (agar plates, tips and pipettes) is autoclaved followed by incineration.
Solid waste from tissue culture (tubes, dishes, flasks and pipettes) is autoclaved followed by incineration.

After autoclaving or chemical disinfection, waste is put into yellow clinical waste bags or containers, collected centrally and transported by an approved waste route for incineration.

Established inactivation procedures in molecular biology laboratories, giving effectively 100% kill.

Records of each autoclave run are made and held by the Safety Officer.

Is an emergency plan required according to regulation 20? N

Class 2 < 1 Litre

Non-GMM Consent Granted

Project notified under transitional arrangements N

02/03/2022 Page 953 of 15326
Human neurons expressing either full-length normal or mutant Htt will be generated using STROC05 and 197VM neural stem cell lines transduced with pMSCV-based retroviral constructs. They will then be differentiated into neurons by the removal of key growth factors, which can then be used to set up co-cultures of primary human monocytes and macrophages isolated from Huntington's disease patients and control subjects to investigate neuronal-myeloid cell interactions.

The retroviral vectors to be used contain the full-length sequence of the HTT with either a normal (15Q) or mutant (138Q) CAG repeat length encoding the wild-type and mutant Htt proteins respectively. DNA prepared from E. coli bacterial cultures is packaged as a retrovirus by co-transfection into either HEK293 or BOSC23 cells with separate gag/pol and env packaging co-factor plasmids.

E.coli K12 strains (eg DH5α, TOP10)

HEK293T cells (human cell line for retroviral packaging)

BOSC23 cells (human cell line for retroviral packaging)

U937 cells (human lymphoma cell line)

STROC05 cells (human striatal neural stem cell line)

ReNcell 197VM cells (human neural stem cell line)

pMSCVpuro-10366-Htt15Q

pMSCVhyg-10366-Htt138Q

gag/pol+ & env plasmids

The inserted genetic material will encode the full-length human HTT (huntingtin) sequence (with either 15 or 138 glutamine repeats in exon 1 of the gene). Expression of Htt with an expansion in the number of glutamine residues in its exon 1 (>36Q; mHtt) is thought to be the key pathogenic determinant of Huntington’s disease, an inherited neurodegenerative disorder in humans. Htt is widely expressed in human tissue, but its function is unclear. The protein has no sequence homology to other proteins, but it is known to regulate gene expression and may have a functional role in cytoskeletal anchoring or transport of mitochondria or vesicle trafficking. We intend to study the cellular effects of expression of htt in human neural stem cells.
mHTt expression in neurons is thought to be the underlying cause of Huntington’s disease in humans; the inserted gene product could be harmful to health in the event of its expression in the CNS. Viruses packaged from the pMSCV vector are capable of infecting human cells itself, but are unable to replicate because the viral structural genes are absent. Integrated proviruses are capable of being mobilized by superinfection with helper virus, but the likelihood is low because the cells to be used are not known to produce helper viruses and transduced cells will be cultured in isolation from other cell cultures. The GMOs themselves are not able to establish infection and maintain propagation in humans or other species. Cultured mammalian cells, transduced or otherwise, are unable to survive outside of the laboratory environment and are not infectious. The E. coli bacterial strains are disabled, lack the necessary pathogenic mechanisms required to cause infection and will only have limited survival in the environment. Retroviral particles could conceivably infect cells of other species, resulting in the transfer of genetic material. Effects due to expression of target genes would be unlikely, but they could result in disruption of host genes depending on the site of insertion. Such effects would be limited by the inability of the virus to subsequently replicate. The absence of any potential of direct contact and the lack of survival of any of the proposed GMOs limits the potential effects on other species or the environment.

Contents and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be decontaminated with 1% Virkon for a minimum of two hours, prior to disposal with plenty of running water down a suitable designated sink. The degree of kill using 1% Virkon is 100%, as per supplier’s information, and this procedure is well established in molecular/cell biology laboratories. Solid waste such as culture dishes and flasks will be decontaminated with 1% Virkon overnight. Solid waste from mammalian cell culture is autoclaved prior to incineration; this is a standard Departmental procedure for those areas in which Containment level 2 work is carried out. Following chemical disinfection (and autoclaving), all solid waste waste is put into yellow clinical waste bags or containers for collection in designated yellow bins and transport by an approved waste disposal route for incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The project was approved by the GM 669 committee. This work poses no risks to personnel or the environment when local rules and decontamination procedures are practised in conjunction with the engineering and administrative control measures for work at containment level 2.

Project transferred to GM14 on closure of GM669

**Project Additional Information**

**Purposes of the contained use**

To employ eukaryotic expression systems to produce the normal cellular form of the murine prion protein. The advantage of using such systems is they enable proper protein folding, disulphide bond formation, and posttranslational modifications such as signal cleavage, proteolytic cleavage, or-and glycosylation that we cannot
obtain when using prokaryotic systems.

**Recipient or parental organism**

- Insect cells: Spodoptera frugiperda 9 (Sf9)
- Mammalian cells: Chinese hamster ovary (CHO), human embryonic kidney cells (HEK.293)

**Host/vector system**

- pTriEx, pFastBac HT and other commercially available vectors to be used as necessary for baculovirus expression
- PTriEx, pSV and pCMV series of vectors and other commercially available vectors to be used for expression in mammalian cells.

**Origin & function**

The vectors used are standard commercially available ones and are designed to allow the expression of the gene of interest. The mouse prion gene may be cloned from mouse cDNA or synthesised by commercial gene synthesis.

**Evaluation of foreseeable effects**

None of the strains of GMMs used are able to survive outside of a laboratory. The baculoviruses used are polyhedrin negative and have a much reduced survival time owing to increased susceptibility to dessication and ultraviolet light. The vectors used will confer antibiotic resistance to antibiotics commonly used in the laboratory, namely ampicillin, blasticidin, zeocin or hygromycin.

Although it is theoretically possible that the prion protein could misfold from the cellular form to the disease associated form that could be harmful to health, even were this highly unlikely event to occur, the very low infectious titre of any material in combination with the transmission barrier for prions between mouse and human makes detrimental impact on human health extremely unlikely. The prion protein has been expressed by other laboratories with no reports of changes to the pathogenicity of the host.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be treated with 20,000 ppm sodium hypochlorite for one hour, or where this is not suitable then sodium hydroxide to a final concentration of 1 M will be used. GMM material will then be autoclaved prior to disposal by incineration.

Liquid waste will be treated with 20,000 ppm sodium hypochlorite for one hour, or where this is not suitable then sodium hydroxide to a final concentration of 1 M will be used prior to disposal down the drain.

These represent established protocols for the inactivation of prions and should achieve a 100% "kill rate"

Page 959 of 15326
This programme of work will use lentiviruses to deliver cDNA encoding specific genes or RNAi to knockout specific genes into various rodent and human cell lines. Established model systems will then assess the effect of these upregulated or downregulated genes in vitro or in cells.

Recipient or parental organism

Replication-defective 2nd and 3rd generation HIV lentiviral vectors and modified vectors constructed in house will be packaged by transient transfection of plasmids into HEK 293T cells. Rodent and human cells will be infected with the packaged lentiviruses. Cell lines are free of adventitious agents, and have a history of safe usage in the laboratory, equivalent to containment level 1.

Host/vector system

Replication-defective lentiviruses used for gene transfer in this study are 2nd and 3rd generation HIV lentiviral
These lentiviruses have a wider tropism than wild-type HIV because the VSV-G Env permits entry into all cells. The virus produced is replication-defective, and all chances of recombination leading to a replicative virus is considered negligible.

### Origin & function

We wish to use lentiviruses to express:

1. P13K isoforms and P13K signalling pathway kinases, phosphatases and other pathway components (bovine, human or mouse) and mutant oncogenic forms of these, identified in various cancers. Of the 8 catalytic subunits of the P13K family, only p11 Oalpha has so far been found to be mutated in cancer. These mutations increase the enzymatic activity of p11 Oalpha. p11 Oalpha mutations can be concurrent with mutations in other genes encoding proteins such as Ras, p53, PTEN, etc. Overexpression of p11 Oalpha in cells has recently been shown to induce p53-mediated growth arrest and mutational inactivation of p53 is required in order for cells to become transformed (Kim JS et al. 2007, MCB, 27(2):662). Ectopic overexpression of wild-type forms of the catalytic subunits p11 Obeta, p11 Odelta and p11 Ogamma can transform avian fibroblasts (Kang et al., 2006, PNAS, 103(5):1289), but there is no evidence for a similar effect in mammalian cells.

2. We also wish to use RNA1 to target the same classes of molecules described in 1. above.

4. Resistance Genes: Neomycin, hygromycin, zeocin resistance genes used as positive selection markers. No potential hazard, have a well-established record of safe use.

5. Gene Regulation: Proteins required for tetracycline regulated expression of genes from tetracycline responsive promoters. These include TetA, TetA2S-M2 and TetR-KRAB; these molecules bind DNA through variants of the tetracycline repressor and do not bind specific eukaryotic DNA sequences. Gre and FLP recombinase. Used to catalyse the site-specific recombination of DNA between loxP sites (Gre) or between FRT sites (FLP). Gre or FLP-coding lentiviruses will be used for infections of cells derived from mice bearing conditional mutations of the genes described above.

### Evaluation of foreseeable effects

2nd generation lentiviral vectors have the genes and sequences for lentivirus formation split between 3 vectors. The backbone of the lentiviral vector only retains the packaging signal and the LTRs between which transgenes of interest are inserted (pHR or similar). Other genes required for synthesis of lentiviruses are supplied in trans on plasmid vectors and are encoded from CMV promoters.

From one plasmid the VSV-G Env protein is expressed (pVSV-G or similar) and from a second plasmid Gag, Pol, Tat and Rev are encoded (pCMV 8.91 or similar). In 3rd generation lentivirus vectors, the LTRs are also self-inactivating, such that upon reverse transcription they are also deleted. Most experiments will use the 3rd generation lentiviral vectors. A favourable system is the ViraPower Lentiviral Expression System (Invitrogen) which combines a mixture of 3 plasmids pLP1, pLP2 and pLPIVSVG encoding gag/pol and Rev response element, Rev, VSV-G env respectively. These are co-transfected with the packaging vector (four are available eg pLenti4N5-DEST) containing the insert of interest.

For the introduction of RNAi to knockdown specific genes, systems such as the pGIPZ from Open Biosystems will be used (http://www.openbiosystems.com/RNAi/shRNAmirLibraries/c3lpzLentiviralshRNAmir).

Lentiviruses have the capacity to infect human cells so infection of normal and HIV infected cells must be considered. Infection of normal cells will result in promoter/transgene incorporation into the genome. Harmful effects could be caused by transgene expression or due to insertional mutagenesis. The lentivirus vectors are replication defective, but there is a theoretical risk of recombination with wild-type HIV-1 or HIV-2. However, there is no report of this ever happening. In any case, recombination restoring all HIV genes — which is necessary to produce a replication - competent virus - would delete the transgene, converting the recombinant virus to wild-type. In order to reduce the risk further, the use of lentiviruses will be at ACGM Containment Level 2.

The recombinant viruses can only be packaged by cotransfecting the plasmid components of the vector system into 293T cells. Transfected cells producing the recombinant virus must be maintained in tissue culture and cannot survive outside the laboratory. Recombinant lentiviruses, are also unstable and unlikely to survive for long with survival time dependent on factors such as temperature and pH. Although theoretically the lentiviruses would be able to infect other animal species such as rodents, the likelihood of this occurring accidentally is negligible. In the event that this did occur, the recombinant virus would be unable to propagate. This programme of work does not include deliberate infection of animal species with lentivirus vectors. No harm to the environment is envisaged.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All basic molecular biology manipulations that do not result in production of virions will be conducted on the bench at Containment Level 1 using GLP. All steps involved in production of infectious virions will be Containment level 2.

Experienced staff used to work in a containment level 2 environment will conduct the experiments. Strict local rules describing protective wear, handling and disposing of
infectious materials will be adhered to. All liquid waste is decontaminated with 1% Virkon overnight. Any potentially contaminated material eg plastic is also soaked in 1% Virkon overnight, double-bagged, transported in leak proof containers to an autoclave in the same building and autoclaved. All equipment that has come into contact with lentivirus will be autoclaved before cleaning or disposal. Aerosols may be produced during the preparation of lentivirus and infection of HEK 293 cells. To prevent the dispersal of aerosols, preparation and infection of the virus will be carried out in a biological safety cabinet class II. All work surfaces will be thoroughly cleaned with disinfectant solution followed by 70% ethanol. Sharps will be used with special care and disposed of into sharps bins. Needles will not be re-sheated before disposal.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste will be decontaminated by soaking in 1% virkon, then disposed in sealed double-bags which will be autoclaved and incinerated in accordance with local and country regulations for the disposal of biohazardous waste. Inactivation of lentivirus by autoclaving at 121°C for 15 minutes, will give effectively 100% kill. Using a higher temperature, or a longer time, is permissible. Waste will be transported in leak proof containers to autoclaves by trained staff and immediately placed in the autoclave for discard.

If live cells infected with lentiviruses are to be taken out of the Containment Level 2 lab and cultivated elsewhere, they must be tested for replication-competent virus first. In addition it should be noted that live cells infected with lentivirus that are to be used for experiments outside of the isolation room must be transported inside SEALED containers that are wiped over with microsol prior to leaving the hood and then only opened in areas designated as category 2 and for use with lentiviral infected cells. Otherwise cells should be fixed or lysed prior to removal from the hood in the isolation room.

THE ROLE OF THE PROMYEOCYTIC LEUKAEMIA GENE (PML) DAXX AND C-JUN/C-JUN-N-TERMINAL KINASE 1/2 IN THE RESPONSE TO VARIOUS CELLULAR STRESSES

Purposes of the contained use

To study the effect of overexpression or down regulation of PML and DAXX on apoptosis and the regulation of the response to irradiation. The c-Jun and June-N-terminal kinase 1/2 pathway regulates apoptosis induced by UV radiation. We wish to test the effect of the siRNA-based downregulation or functional inactivation of various components of this pathway on the response to UV.

Recipient or parental organism

Mouse and human primary keratinocytes, mouse embryo fibroblasts, mouse bone marrow cells, mouse foetal liver cells, 293 cells (epithelial cell line), primary mouse cerebellum granule cells, neuroblastoma cell lines and adrenal chromaffine cells.

Origin & function

PML and DAXX cDNAs are from human and mouse origin. siRNA oligos for PML, DAXX, c-JUN and JNK1/2 will be designed based on mouse and human sequences.
the genes we intend to study are involved in the regulation of apoptosis.

Evaluation of foreseeable effects

There is a potential risk of infection at the stage of packaging and infection while using the lentiviral vectors, however the inserts we plan to transduce are not a hazard to human health. The host cells and plasmids generated by the parental virus are not harmful. The virus can infect the cells with which it comes into contact but cannot replicate, therefore the hazards to human health are low and containment level 2 is appropriate.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste:
Solid waste will be treated with hypochlorite (10,000ppm) before being autoclaved prior to disposal (100% kill). The sterile waste is then sent for incineration by authorised contractors.

Liquid waste:
Liquid waste will be treated with hypochlorite (concentration 10,000ppm available chlorine) overnight and autoclaved before disposal. Any spillages will be cleaned with chlorine disinfectant and the waste paper autoclaved and incinerated.

Autoclave cycle - 121 degrees C for 15 minutes. The autoclaves are validated annually in the MRC Toxicology Unit.

## Project Additional Information

### Purposes of the contained use

| Propagation and in-vitro characterisation of attenuated MVs expressing murine and human GM-CSF and IL-12 in-vivo characterisation in mice transgenic for the human MV receptor, CD46. Determination of in-vivo oncolytic effects in relevant tumour models. |

### Recipient or parental organism

| Attenuated (vaccine) strain of MV |

### Host/vector system

| Vector: cDNA encoding murine and human growth factors expressed as additional transcription units of attenuated MV. |
| Hosts: |
| 1. For DNA preparation, K12 strains of E. Coli will be used, typically TOP10 strain. |
| 2. Attenuated (vaccine) strains of MV will express the growth factors. |
| 3. Established mammalian cell lines will be infected by the modified viruses: 293 (human embryonal kidney) Vero (African green monkey kidney), Raji, DOHH2, (human B cell lymphoma). 293-3-46 (modified 293 cells expressing attenuated MV proteins, intended for the rescue of infectious MV from the full-length anti-genomic plasmid). |
| 4. Mice transgenic for the human MV receptor, CD46 and SCId mice bearing humaning tumour xenografts will be intentionally infected by these viruses by various route of infection. |

### Origin & function

| Origins: cDNA encoding GM-CSF cDNA originally purchased from commercial sources (In-vivogen (murine) and ATCC (human)). |
| Full-length MV plasmid obtained from Dr Roberto Cattaneo, Mayo Clinic, Rochester, MN, USA. This plasmid and its use to rescue infectious MV owas originally described in Radecke F, et al Rescue of measles viruses from cloned DNA. EMBO J. 1995, 14:5773. |
| MV GM-CSF constructed in the laboratory of the applicant from starting materials above (Grote et al Cancer Res 2003; 63 6463) |
MV-IL-12 obtained from Dr Roberto Cattaneo (Singh M, Billeter MA. A recombinant measles virus expressing biologically active human interleukin-12. J Gen Virol. 1999, 8:101)

Intended functions:
Infectious MV expressing murine GM-CSF has been used by the applicants laboratory as an oncolytic agent in murine models (Grote et al Cancer Res 2003;63 6463) and is shows greater efficacy than the unmodified parental MV by virtue of stimulating a neutrophil infiltration of the tumors. We are currently further assessing its activity and mode of action. MV expressing human GM-CSF will be used to evaluate the effect on various human cell lines in-vitro. MV expressing murine and human IL-12 will be used similarly.

Evaluation of foreseeable effects

We and others have previously worked with attenuated MVs expressing growth factors and have had the opportunity to evaluate their effects in 2 different in-vivo models. A transgenic murine model expressing human CD46 (which has been accepted by the USA Food and Drug Administration as a suitable model in which to evaluate the toxicity of genetically modified MVs about to enter the clinic in phase 1 human studies) has been used to study the in-vivo effects of attenuated MV expressing murine GM-CSF. Second, a non-human primate model has been used to evaluate an MV expressing human IL-12. In this application, we are thus able to consider the theoretical effects of accidental infection with a growth factor expressing, replicating attenuated MV in the light of in-vivo data. Naive mice were infected by various routes using MV expressing murine GM-CSF and suffered no ill effects. A low level of GM-CSF was detected in the blood at day 3 post-infection, which returned to background levels after that time. No effect was observed on the blood counts. Infection was terminated by an immune response. (Grote et al Cancer Res 2003-63 6463). MV expressing human IL-12 has been administered to non-human primates without ill effects. The virus was eliminated by an immune response (R Cattaneo, personal communication).

Potential Effects on Human Health
The vaccine strains of MV themselves are not pathogens in immune competent individuals, but can cause fever and sometimes a mild rash in approximately 10% of vaccinees. Should humans become accidentally infected by attenuated MVs expressing a growth factor, it is considered that the virus would propagate to a limited extent, allowing some local production of growth factor before being limited by an immune response. By extrapolation from the animal data, it would not be expected that sufficient quantities of growth factor would be produced to cause systemic effects. All workers will be ensured to be immune to MV. Additionally, should all containment be breached, most adult individuals in the Western world, either by prior infection of vaccination. In the very remote case of an unimmunised individual being infected unintentionally, an immune response would be expected to limit infection albeit slightly slower than in a previously immune individual.

Growth factors such as GM-CSF and IL-12 are known to have pleotropic effects on human cells and their functions. Both of these growth factors have been used clinically and their range of effects are well characterised in humans in a variety of clinical scenarios. GM-CSF is a licensed product in fairly common clinical use. IL-12 has also been evaluated in clinical study. At very high doses, however, both GM-CSF and IL-12 can have harmful effects. Our animal data suggested that such toxic dose levels are not achievable when the growth factors are expressed from an attenuated replicating MV.

Bacterial vectors:
MV is a negative strand RNA virus, cDNA encoding the anti-genomic MV plasmid is not infectious, nor can it be used alone to generate infectious virus. Thus there is no foreseeable harm to human health from propagating standard laboratory strain of E coli harbouring MV plasmids since no expression will occur.

Cell lines:
When mammalian cell lines are infected by MVs expressing growth factors, infectious virus is released from the cells, although most of the virus remains cell-associated. Growth factor is secreted into the medium. Concentrations of GM-CSF in the medium are in the ng/ml range. MV-infected cells are the source of stocks of virus to be generated by freeze-thawing of infected cells. Virus concentration in stocks is usually about a million to ten million plaque forming units per millilitre. Average volumes harvested are around 1 to 3 ml. Sharps are not used when working with the cells, accidental inoculation with virus-infected cells is unlikely.

Mice:
Mice do not excrete MV in appreciable quantities. In the event of a worker being bitten by a mouse infected with MV expressing murine GM-CSF, it is unlikely that any
harm would ensue, since the worker would be immune to MV, as discussed above. Additionally, where murine experiments take place, the murine growth factor is expressed. In the case of GM-CSF, there is little or no activity of the murine factor at the human receptor.

Potential Effects on the Environment

Bacterial Vectors
There is no foreseeable risk to the environment in the event of release of bacterial vectors.

Cell Lines
Would not survive outside the controlled environment of the laboratory and thus present no risk to the environment.

Mice
The only natural host for MV is humans. Normal mice are not infectable by MV, hence there is no risk to other mice in the facility nor to animals outside the facility, should a total breach of containment occur. Should MV-infected SCID mice escape into the environment, they would not survive beyond the confines of the laboratory and rapidly perish. Should the MV-infected SCID mice escape into the environment, they would not survive beyond the confines of the laboratory and rapidly perish. They would not be able to infect normal mice with MV. If by chance, these mice bred with local mice, and lost homozygosity for CD46, they would no longer be infectable by MV. It should also be noted that CD46 transgenic mice CANNOT BE INFECTED BY WILD TYPE MV, which uses SLAM and not CD46 as a receptor. Finally, the mouse escape policy from the CBU at the RFH, which demonstrates the very unlikely nature of such an escape, is appended.

Spillage of virus stocks
In the very unlikely event of a spill outside the laboratory, where decontamination procedures for some reason were not able to be applied, which is extraordinarily unlikely, survival outside a host is brief. MV is inactivated by heat and light. Aerosols remain infectious for approximately 30 minutes and survival on surfaces is less than 2 hours. The virus is very unlikely to encounter wild-type strains, for the same reason, and also because in general such strains are usually not circulating in the community. However, considering this very remote possibility, MV is extremely genetically stable and recombination is very unlikely.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste generated will fall into the categories below:

Contaminated tissue culture plastics.
Solid waste, for example plastics will be decontaminated within the hood with 1% Virkon before disposal within autoclave bags to be autoclaved before eventual disposal according to the institutional system.

Plastic pipettes and pipette tips.
Will be placed into a rigid container within the hood and eventually, the capped container will be autoclaved before disposal, as above.

Liquid waste
Will be decontaminated with 1% Virkon or 1% sodium hypochlorite before disposal in the drains.
Animal carcasses
Animal carcasses will be disposed of within autoclave bags and autoclaved before disposal according to the institutional system.

Sharps (used during inoculation of animals)
Will be disposed of within an approved sharps container.

Virkon or sodium hypochlorite can destroy the virus so that no detectable virus remains after contact with the agents. No special monitoring will be necessary to monitor decontamination.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment
All non-procedural comments are included (comments such as 'what room will this work be carried out in' are, for example, excluded). Replies are also included.

Comment: Will any primary cells be used?
Reply: There are no immediate plans to use primary cells.

Comment: Consider any risk from various MV-infected mice to humans or the environment.
Reply: possible risks to staff working with MV-infected mice.
Work carried out over the past 4 years at the Mayo Clinic did not require veterinary technical staff performing general housekeeping duties with mice used for similar projects be subjected to the same Occupational Health concerns as staff employed specifically for the projects. Mice infected with vaccine strains of MV do not excrete the virus to any quantifiable extent. In fact, it is rarely even possible to re-isolate the virus directly from MV-infected tissues (for example, lung, spleen) of CD46 transgenic mice by co-culture of tissue with highly permissive cells. Thus, the risk of workers handling the mice and cages for husbandry purposes actually coming into any contact with the virus can be supposed to be extremely low. The case of a person being bitten by a GM MV-infected animal has been considered in this assessment. This situation was discussed at length during the establishment of the policies at the applicant's previous institution. It was felt that no specific action would be needed in the case of an appropriately vaccinated worker, other than general measures, appropriately recording the incident and monitoring the health of the worker. In fact, this incident did occur, approximately 2 years ago, during the applicant's previous post. No harm ensued.

Comment: If new workers join the project, will these issues be addressed through the occupational Health Dept?
Reply: Yes, when new workers join the project, the issue of MV immunity will be addressed through Occupational Health.

Comments:
Pipettes, tips, culture plates etc. do not require disinfection prior to autoclaving.

Dry discard containers with screw caps should be used for tips rather than discard pots.
Reply: Comments are duly noted and will be acted upon.

Comment: Can project staff be named?
Reply: A technician has now been appointed and named.

Comment: Does vaccine mediated immunity protect equally well against the proposed genetically modified strains?
Reply: Murine data from our lab suggest that immunity to the GM-CSF-expressing genetically modified strain of MV is the same in magnitude and timing as to the unmodified MV.

? has sent these comments in after closure regarding your projects.
Comment: It will be important to monitor levels of anti MV immunity in people on the project and in people closely associated with it and to have a program of vaccination in place to boost levels of low response.

Reply: Titres will be checked at starting and if inadequate (<25iu/ml), project workers will be immunised. Regarding further boosting: immunity to MV after natural infection or adequate vaccination is generally accepted to be lifelong. It should not be necessary to boost. There are no data on which to base a scheme of re-testing and possible re-vaccination, this would have to be empirically determined. If it is deemed necessary, I would consult with virology and vaccine experts to try and devise an appropriate scheme.

Project Containment

## Project Ref 99/04.1

**Project Additional Information**

**Purposes of the contained use**

Primary human cells will be isolated from patients: either liver taken at resection or time of transplant, placenta, amnion, bone marrow or peripheral blood, will be immortalised and transformed either by retroviral vector mediated, lentiviral mediated, lipofection, or by electroporation introduction of genes associated with cell cycle and senescence; some of these will be oncogenes. The resulting cells will be grown in vitro, to establish their proliferative and differentiative properties. Suitable cell lines may be chosen as the biological component of a bio-artificial liver machine (should this project be successful their use in a bioartificial liver would be the subject of a future application). A subsequent addendum to this application will be made if and when cell lines have been generated to test the proliferative capacity of these cells in vivo, by injection into nude mice; this will be in conjunction with a home office licence application to use nude mice.

**Recipient or parental organism**

Retroviral vectorial vectors based on murine moloney leukaemia virus: Vectors lack pol and env sequences and only encode a short sequence of ATG negative gag. Third generation Lin X (derivative of 293T) packaging cell lines will be used to produce replication-incompetent virus. The gag, pol and env genes are integrated into the genome or expressed from a Bovine Papiloma Virus based episomal vector that contains no regions of homology to the MMLV based vectors. Three separate recombination events would be required to produce replication-competent virus. The cell line has been tested exhaustively for production of replication competent virus; none was
detected. The combined choice of the packaging cell lines and the replication defective nature of the vector used will prevent the production of helper/replication competent virus by the transduced cells, reducing the risk to the environment. Lentivirus vectors: cPPT-CMV and pCMV 8.91 plasmid) vector is an HIV based vector described in full by Zennou et al (2000). The replication defective virus is produced in TRANS with structural components supplied by the pCMVr8.2 helper plasmid carrying gal, pol, tat, and rev. The vector is pseudo-typed with VSV-G, supplied in trans by the plasmid pMDG. At least 2 independent recombination events with a helper free genome would be required to recreate a viable pathogenic genome.

The second lentiviral gene delivery system involves three plasmids that are transfected into virus producing cell line, the 293t cell line. The lentiviral system is secured by gene removal such that no new particles can be produced from infected cells. This system functions as the host 293t cell express.

1. The viral envelope protein (CVSV-G envelope) from pVSVg.
2. The modified HIV-1 genome with the transgene (modified HIV-1 with deleted envelope and accessory genes)
3. The HIV-1 genome (from the pCMV plasmid 8.91)

The vector can stably integrate into DNA for sustained long-term expression of the transgene. The vector has the ability to infect human primary and stem cells, with subsequent expression of the foreign gene in these cells and their progeny. No new HIV-1 virions can be synthesised by the infected cells due to the deletions in the genome - and they are termed self-inactivating. The VSV-G envelop allows a broader cell target range than HIV1 and is included for this reason.

Host/vector system

Hosts: E.coli strains DH5alpha, DH10B, mammalian cells; primary epithelial and mesenchymal cells derived from human liver, peripheral blood, human placenta and amnion, human stem cells Hepatocyte cell lines Hep G2, human fibroblasts and lines ImR90, packaging cells LinX A and LinX E, 293T cells.

Vectors: pBabe, pWZL, MARX vectors (Genetica Inc, Cambridge, MA USA); LN series (LN, LNSX, LNCX, Miller et al 1989); cPPT-CMV-(eGFP); cPPT-CMV-(hTERT); pCMV 8.91

Origin & function

hTERT (telemersase), myc oncogene E7 oncoprotein, p53 tumour suppressor, E1A (early region 1A adenoviral sequence), mdm2oncogene, cyclin D1, p16 and p189 cyclin dependent kinase inhibitors, SV40 large t antigen, GreenFluorescentPortein, B-galactosidase.
All oncogene-virus constructs will be obtained from Wolfson Institute for Biomedical Research, UCL.

Evaluation of foreseeable effects

Primary human cells may contain adventitious agents and should be handled in containment level 2 according to COSHH. The other human cell lines are established long term lines anad can be regarded as belonging to ACGM activity class 1. The linX amphotropic virus is incapable of replication outside of its packaging cell for following reasons. Third generation LinX (derivative of 293T) packaging cell lines will be used to produce replication-incompetent virus. The gag, pol and env genes are integrated into the genome or expressed from a BPV based episomal vector that contains no regions of homology to the MMLV based vectors. Three separate recombination events would be required to produce replication-competent virus. The cell line has been tested exhaustively for production of replication competent virus; none was detected. The combined choice of the packaging cell lines and the replication defective nature of the vector used will prevent the production of helper/replication competent virus by the transduced cells, reducing the risk to the environment.

Lentivirus vectors: cPPT-CMV and pCMV 8.91 plasmid) vector is an HIV based vector described in full by Zennou et al (2000). The replication defective virus is produced in TRANS with structural components supplied by the pCMVr8.2 helper plasmid carrying gal, pol, tat, and rev. The vector is pseudo-typed with VSV-G, supplied in trans by the plasmid pMDG. At least 2 independent recombination events with a helper free genome would be required to recreate a viable pathogenic genome.

The second lentiviral gene delivery system involves three plasmids that are transfected into virus producing cell line, the 293t cell line. The lentiviral system is secured by gene removal such that no new particles can be produced from infected cells. This system functions as the host 293t cell express.
1. The viral envelope protein (CVSV-G envelope) from pVSVg.
2. The modified HIV-1 genome with the transgene (modified HIV-1 with deleted envelope and accessory genes)
3. The HIV-1 genome (from the pCMV plasmid 8.91)

The vector can stably integrate into DNA for sustained long-term expression of the transgene. The vector has the ability to infect human primary and stem cells, with subsequent expression of the foreign gene in these cells and their progeny. No new HIV-1 virions can be synthesised by the infected cells due to the deletions in the genome - and they are termed self-inactivating. The VSV-G envelop allows a broader cell target range than HIV1 and is included for this reason.

The HIV-1 vectors being used are attenuated and cannot replicate once cells have been infected. The transgene has the potential to be expressed in infected human cells. Because some of the transgenes are potential oncogenes they could, when expressed in cells, give the cells the ability to proliferate. The vector does not replicate, reducing the risk of harm significantly. Aerosol contamination is not possible - the virus can only infect when normal barriers (skin/mucosal membranes) have been penetrated. All work will be carried out in a containment level 2 laboratory, with protective clothing and no sharps inside the safety cabinets. The vector has a small and insignificant potential to become replication competent if combined with wild-type vector. We prevent this by having no live HIV-1 experimentally in the laboratory. All workers on the project will be required to attend Occupational Health department to discuss the risk potential. The overall risk of infection and harm is therefore low.

The project involves the generation of cells with a prolonged cellular lifespan; it is possible that one or several oncogenes could be enriched in some of the cell lines. Genes could belong to any of the categories above but only genes involved with senescence, cell cycle and differentiation will be selected for.

Several oncogenes will be used as controls for the experiments. The effect of an oncogene or tumour suppressor on different cell types is very difficult to predict. For example, myc immortalises prostate epithelial cells but causes terminal differentiation in keratinocytes. Introduction of a single oncogene, however rarily results in malignant transformation. The hazards involved in naked oncogenic DNA will be addressed according to COSHH. Specifically naked oncogenic DNA will be handled in accordance with the "Advisory Committee on Genetic Modification Compendium, Part 3A - Annex 1. Containment level 2 is appropriate. The risk from the viral vectors themselves are minimal.

The main risk is introduction of an amphotropic virus containing an oncogenic sequence into the cells of a worker via a needlestick injury. This may result in the infection of the workers' cells and expression of the oncogene. The number of cells is likely to be small. Entry would have to take place through broken skin or mucosal tissue. The virus is incapable of replication once in the cells and the introduction of a single oncogene into a small number of cells is unlikely to result in tumour formation. This is before we consider the protective measures afforded by level 2 containment required and the class II cabinet that work must be conducted in, without the use of shpms in the hoods. The other risk is that transformed human cells may be introduced via needlestick or mucosal spillage. Because the cells are not derived from the worker they are unlikely to survive for long after entry.

There is no foreseeable risk to the environment in the event of the release of the bacterial vectors or GMMs. The transformed cell lines would not be able to survive outside of the laboratory and also present no risk to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Containment level 2: negative pressure relative to the pressure of the immediate surrounds: "required where and to the extent the risk assessment shows it is required". The tissue culture laboratories are constructed to Medicines Control Agency specifications and are therefore at a slight positive pressure with respect to their immediate surroundings, the anteroom. The anteroom is negative pressure with respect to the corridor (ie with respect to outside the tissue culture suite). Cell cultures will be manipulated only in Class II microbiological safety cabinets which are at negative pressure. In the event of a breach of containment outside the safety cabinet, GMM cell lines would not survive and would not pose a risk by the respiratory route.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Cell culture: All work with mammalian cells will be manipulated in Class II safety cbinets in designated tissue culture laboratories. All laboratory areas are designated
containment level 2. Level 2 procedures will be observed.

Liquid waste: Liquid waste is treated with 1% Virkon or 1% Presept overnight and autoclaved before being discarded down the sink.

Solid waste: non-sharps plastics will be decontaminated within the class II cabinet, before autoclaving at 131 degrees C for 30 min and subsequent discarding as clinical waste.

Plastic pipettes and tips are decontaminated in a rigid but autoclavable container before disposal as per other solid waste.

Sharps: Sharps put into a sharps bin for off-site incineration.

The expected level of kill should be included. This need not be precise eg "approximately 4 logs reduction in viability" or "below detectable level" is acceptable.

#Contact time should be at least one hour.

Autoclave: Length of sterilisation cycle (min): 30

Temperature of sterilisation cycle: 131 C

This is checked using autoclave tape and by inspection of the printout of each autoclave cycle.

Note: If no validation for a disinfectant exists (ie the degree of kill for a particular organism is unknown) then laboratory testing could be required to establish its efficacy.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMSC considered
- Containment level is sufficient
- that sharps injury may be considered serious when handling immortalised cells
- the consideration of using temperature sensitive antigens instead of wild type
- the handling of one oncogene containing cell line at one time
- the production of transient cultures rather than stable cell lines for vector production
- the storage of vectors and cells
- risk to health of accidental insertion of the gene sequence into humans
- checks in place to ensure that staff are immunocompetent
- the laboratory facilities and procedures

FOR FULL DETAILS - PLEASE SEE THE WRITTEN NOTIFICATION
Purposes of the contained use

Recombinant vaccinia viruses (NYCBH strain) expressing two HSV-2 genes (UL-7 and UL-46) will be used to infect BSC-40 cells and the cell lysates used in immunological assays. These HSV genes encode viral tegument proteins which are present in the virus particle as well as infected cells and have recently been shown to be targets of the cellular immune response. The viruses have already been prepared by University of Washington, USA. The ability of the vector to replicate is not affected by the insertion of either of the two HSV-2 genes.

Recipient or parental organism

The two HSV-2 genes encoded by the recombinant vaccinia viruses are highly unlikely to alter the tropism of vaccinia or to enhance (or diminish) its inherent pathogenic
potential. The tropism of vaccinia virus will not be affected by the expression of these two HSV proteins, which although present in HSV-2 virus particles, are internal in that structure and not known to play a role in the attachment and receptor-mediated entry of HSV-2 into target cells.

**Host/vector system**

Homologous recombination is a recognised natural event in the replication of poxviruses and although we may grow wild type vaccinia virus the possibility of erroneously co-infecting cells resulting in the acquisition of the HSV-2 genes is extremely low. The two HSV-2 genes would not be predicted to alter the tropism and replication properties of the vaccinia vector alone. Vaccinia virus is not present in the human population and therefore in the case of an individual becoming infected with recombinant vaccinia, there would be no opportunity for wild-type virus to acquire the inserted genetic sequences. Vaccinia virus can infect a number of animal species and any risk of release of virus into the environment by an animal source will be avoided by the physical containment of the work within a restricted access (keycode entry) category 2 containment laboratory. Acquisition of the HSV-2 sequences could not occur in a related micro-organism in the environment as wild-type vaccinia virus is not present in any animal species in the UK. No genetic modification work will be carried out, as the recombinant construct will only be propagated in BSC-40 cells.

**Origin & function**

Recombinant vaccinia expressing two HSV proteins obtained from our collaborator will be grown in BSC-40 cells and the lysates will be used for immunological assays.

**Evaluation of foreseeable effects**

Vaccinia virus, classified as a hazard group II pathogen, may cause severe disease in people with active skin disorders such as eczema or psoriasis or in immunocomprised individuals such as those with HIV. The addition of an HSV regiment protein gene in the recombinant vaccinia would not be predicted to enhance or diminish its ability to cause disease in comparison to the vaccinia virus vector alone (NYCBH strain). All the work will be carried out at containment level 2, in a single laboratory with restricted access (keycode entry, laboratory personnel only, the Department of Virology has swipe card entry system) and appropriate signs will be posted to indicate vaccinia work is being conducted, outlining persons who are potentially at risk. All members of the department will be informed. Vaccinia virus is not present in the human population and therefore in the case of an individual becoming infected with recombinant vaccinia, there would be no opportunity for wild-type virus to acquire the inserted genetic sequences.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

General disinfectant will be 70% ethanol (contact time, 5 min). Bench disinfectant to be used will be Chloros at 1000 parts per million. All liquid and solid/plasticware waste will be double-bagged in autoclave bags and transported in metal tins to the autoclave facility housed within the Department of Virology. For plasticware, autoclave conditions are 10 min sterilisation cycle at 134 degrees C and for fluids, 25 min at 123 degrees C. Each run on the autoclave is validated (pass/fail) and written records kept and the autoclave is services every 6 months by specialist engineers. Spillage procedures are displayed in the laboratories where the work will be carried out (titled ‘Disinfection procedures for GMO spillages’). No sharps will be used, and aerosols will be kept to a minimum as all handling of the viral cultures will be in a class II microbiology safety (serviced every 6 months).

Project Additional Information

Purposes of the contained use

To gain an understanding of the entry pathways of herpesviruses and the roles played by individual viral proteins in mediating virus entry.
Recipient or parental organism

Recipient/parental viruses:
HSV and HCMV are category 2 human pathogens. They can be propagated and handed under category 2 laboratory conditions. They are routinely cultured in this laboratory under category 2 conditions.
Both viruses are common in the general population and are clinically benign in immunocompetent individuals.
Close contact is generally required for transmission of HSV and HCMV.
Laboratory associated infection with HSV might occur if virus is introduced to the eyes (e.g. by splashing). This risk is minimised by wearing eye protection and working in a class 2 hood. Laboratory associated infection with HCMV is considered to be highly unlikely.
Environmentally, these viruses pose a very low risk. Herpesviruses are enveloped and consequently are labile. Infectivity is completely destroyed by dessication, which is likely to occur in the event of a small laboratory spill. Neither virus has any natural host other than humans, so persistence in the environment, such as in rodents or insects, is considered to be very unlikely.
All the viruses covered by this application retain the necessary genes to confer sensitivity to the licensed anti-viral drugs.

Host/vector system

Characteristics of GMO:
The recombinant viruses fall into two groups;
i) Those in which a gene (or genes) has been disrupted by addition of a stop codon or deleted and replaced with beta-galactosidase, green fluorescent protein (GFP), or derivative, or other marker gene; these viruses are used to probe the function of the deleted gene product.
ii) Those in which GFP (or derivatives) is fused to one or more viral proteins; Incorporation of GFP into these viruses means that they are fluorescent. These viruses are used to track the pathways used for entry into the cell.

Forseeable effects

A: Health
i) Deletion mutants: There is no reason to suppose that the pathogenicity of these viruses is, or will be, increased. Some of the viruses are attenuated in animal models, others are equivalent to wild type. None is known to have enhanced pathogenicity. ii) Fluorescent viruses; In all cases, these viruses are indistinguishable from wild type (other than the presence of the transgenes), indeed they would be of no use experimentally if they did not mimic wild type virus.
Summary; The viruses are considered to be either equivalent to wild type virus or less pathogenic than wild type virus. HSV and HCMV are category II pathogens, thus handling of the recombinant viruses under category II laboratory conditions is considered to be sufficient for containing the risk to health.
In general, close contact is required to infect an individual with HSV or HCMV. The risk of this is minimised by handling the viruses under category II laboratory conditions. Wild type HSV and HCMV are handled routinely and safely in the laboratory in this way.

B: Environment
Herpesviruses are encased in a lipid envelope and thus are labile. They are rapidly inactivated by dehydration or mild detergent. They are very unlikely to persist in the environment.
Neither HSV nor HCMV is known to have any natural non-human hosts, (although HSV can infect laboratory rodents). This lack of natural hosts combined with the environmental instability of the virus particle makes inadvertent transmission to rodents or other wild animals very unlikely.

Origin & function

Origin of viral genomic DNA:
Mutant viruses are constructed by homologous recombination. For HCMV the starting material is a bacterial artificial chromosome (BAC) clone of the HCMV genome. For HSV, purified wild type viral DNA is used. In each case, virus is reconstituted by transfection into a producer cell. All procedures in the protocol prior to the transfection are carried out in E.coli and as such present no infection risk.
Herpesviral genomic DNA can initiate virus production when introduced into a target cell. However, this is very unlikely to happen to a laboratory worker during laboratory manipulation.
Sharps are not used and good laboratory practice means the risk is negligible.
The viruses fall into two categories:
i) Deletion mutants: in which a viral gene is deleted and replaced by marker gene expression cassette encoding beta-galactosidase, GFP (or derivatives), or another
fluorescent protein. In these viruses the function of the inserted genetic material is a) to facilitate selection of recombinant viruses and b) to use as a marker of infection.

ii) Fluorescent viruses: in which one more viral genes is fused in frame with GFP (or derivatives), or other fluorescent protein-encoding genes. These viruses are intrinsically fluorescent and are in all other respects comparable to wild type.

In these viruses the function of the inserted genetic material is to make the virus particles fluorescent, while retaining other wild type characteristics, so that the viruses can be used in fluorescence-microscopic studies of viral entry pathways.

Origins of the inserted genetic material:

Beta-galactosidase: this gene encodes an enzyme that digests lactose or other related substrates. It is widely used in molecular biology. The gene originates from E.coli.

GFP (and related fluorescent proteins): these genes are obtained from jelly fish (Aequoria victoria). They form distinct globular domains that can be fused to other proteins retaining function and rendering those proteins fluorescent, They are widely used in molecular biology.

Evaluation of foreseeable effects

These are detailed in the above sections.

Summary: HSV and HCMV are category II pathogens and so can be handled safely in the laboratory under category II working practice. Close contact is required for infection to occur. Laboratory associated infection is a small risk and this is reduced by the use of appropriate protective clothing.

None of the recombinant viruses is anticipated to be more pathogenic than the parental virus.

HSV and HCMV are rapidly inactivated by dessication and neither virus has a natural non-human host so the risk to the environment in the event of a spill is judged to be minimal.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Herpesviruses are 100% inactivated by autoclaving.

All GMM waste, solid (eg flasks, tubes, tips, plates) and liquid (eg culture medium, used virus aliquots) is autoclaved in the department. (Standard discard cycle is 135 degrees C, 3150 mBar, 10 minutes)

Temperature and pressure parameters of each autoclave cycle are recorded and reviewed. Additionally, Browns tubes and autoclave tape are used to assess each run. The autoclave is maintained to a high standard, sufficient for HPA accreditation, by regular servicing and testing with a 12 point thermocouple. Records are kept in the Department.

All autoclaved waste is placed in yellow biohazard bags and taken for incineration.

Is an emergency plan required according to regulation 20? Y

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
This project (local (GM99) reference: F1C36/07) received approval from a panel of advisers representing the Centre GM Safety Committee at a meeting held on Thursday 8 November 2007. The panel agreed with the classification of the activity and further agreed that the precautionary measures stated in the risk assessment were suitable for these laboratory procedures.

**Project Ref** 99/10.1

- **Date Ackn'd**: 24/04/2012
- **CU2 Project Title**: Use of lentiviral vectors as gene delivery systems for immunotherapy
- **Class**: Class 2
- **Culture Vol Class**: 1-50 Litres
- **Consent Granted**: Non-GMM Consent Granted

**Historical Significant Changes**
- **Historical Date of Additional Info**: Withdrawn
- **Significant Change ID**: N
- **Date of Significant Change**: N

**Project Additional Information**

**Purposes of the contained use**

The projects covered under this application aim to exploit lentiviral vectors as gene delivery systems for immunotherapy. To this end we have 2 complementary approaches. The first involves the use of lentiviral vectors to deliver immune-modulating (for example, T cell receptors, co stimulatory molecules or cytokines) into immune cells. Genes encoding immune modulating genes will be cloned into lentiviral vectors, and lentiviral particles will be used to transduce mouse or human immune cells or...
haematopoietic cells for the production of modified immune cells which can be used for immunotherapy of cancer. The second approach involves using lentiviral vectors for vaccination strategies. In this case lentiviral vectors encoding model or tumour-associated antigens are used to immunise mice. It has previously been shown that lentiviral vectors are very potent immunising agents and we will be investigating how the immune responses are activated, and whether they would be appropriate immune responses to control an emerging tumour, for example in an in vivo model of leukaemia.

Recipient or parental organism

GMO is the lentivector: 3rd generation HIV vector with virulence genes deleted, on split plasmids

Lentiviral particles will be used to transduce a range of cells in the laboratory: standard laboratory cell lines (e.g. 293T, HeLa, NIH3T3 etc.). Human and mouse haematopoietic cells (in particular T cells and Dendritic cells as well as other immune cells).

The viral vectors themselves are not pathogenic to humans, all virulence genes have been deleted from the original parent viral sequences. However, since these vectors have the potential to integrate into human DNA there is a low risk that infection could damage the health of the laboratory worker directly handling the viruses. We are planning to use self-inactivating (SIN) vectors to make viral particles that have been shown to significantly reduce the risk of insertional mutagenesis. In addition lentiviral vectors have been demonstrated to insert preferentially into coding regions of DNA, rather than the more risky promoter or control regions. Therefore, when considering all these factors the risk to humans is very low.

Because the lentiviral vectors are replication deficient and undergo a single infection of initial target cells, there is no risk of spread to other recipients. The vectors will only be used as an antigen delivery system to immunise, once the viral vector is injected into mice the immunised animal is not considered genetically modified and the viral vector no longer exists. Thus, there is no risk from this point.

A WPRE element is included in these vectors to aid translation of the inserted gene. This encodes a putatively oncogenic protein (protein X) which has been mutated in all vectors. The X protein could potentially be a risk factor, but the use of vectors with non-functional X proteins negates this risk.

The vector particles are produced with a broad host specificity by using the Vesicular Stomatitis virus (VSV) G protein or other coat proteins. This may increase the susceptibility of different cells to the virus, but will not increase the risk of insertional mutagenesis.

Host/vector system

Vectors are standard microbiology plasmids. All cloning is performed using commercial disabled bacterial strains that are not harmful to health or the environment. The promoters used for gene expression in the lentivector are not generally expressed in bacteria.

pUC derivatives or standard molecular biology cloning vectors such as the following, or related vectors: pCMVR8.91 (packaging plasmid), pMD-G (VSV-G envelope plasmid) & pHR'SIN (vector plasmid Dermaison et al (2002) Human Gene Therapy 13:630-640.).

Some vector plasmids obtained from Prof. M C's laboratory at UCL may contain sequences to enhance expression in transduced cells (vFLIP latent gene expressed by KSHV) such as dendritic cells or T cells. Human and mouse genes of the NF-kB pathway. MAPK activators: MKK6EE kinase (p38 activator), MEK1 N3 ED kinase (ERK activator) and MKK7-JNK1 (JNK1 activator).

Origin & function

The genetic material will be of bacterial origin for cloning as follows:

HB101, DH5alpha & other common disabled E. coli K-12 or B derivatives. Only disabled bacterial strains will be used.

The inserted sequences may be amplified originally from mouse or human genomic DNA or cDNA before cloning into bacteria.

For work investigating lentivectors as immunisation agents, the majority of the inserted nucleic acid encodes model antigens. These are inert gene products that do not have a biological function in the transduced cells, and will not effect growth and survival of cells.
receiving these vectors. For the delivery of immunomodulating genes there are genes encoding immune modulating proteins which may alter the immune function of the cells they are expressed in, but it is highly unlikely that this would lead to transformation of the cells in question.

Genes such as the vFLIP latent gene from KSHV or MAPK activators may occasionally be incorporated into lentiviral vectors to enhance immune responses to the inserted gene. It is not expected that these genes will alter the biological activity of inserts encoded in the same vector. However these sequences do have the potential to effect expression of an oncogene or tumour progression factor depending on the site of integration of the vector.

A WPRE element is also included in the vector plasmid to aid translation of the inserted gene or sequence. This encodes a putatively oncogenic protein (protein X) which has been mutated in all vectors and is not functional.

The model antigens, genes encoding immune modulating genes and mutated WPRE element are unlikely to cause harm if accidentally transferred into humans. We do identify an increased risk when using KSHV or MAPK activating genes. It is possible that in the unlikely event of a breach of containment, accidental injection into workers may result in the undesirable insertion of these genes next to an oncogene. However, this risk on insertion at a site such as this is extremely low and it is unlikely that any one gene has the capacity to act as an oncogene on its own.

**Evaluation of foreseeable effects**

For generation of lentiviral vectors only disabled bacterial strains will be used and we do not foresee any effects.

The most hazardous GMMs are the HIV-based vectors. The most hazardous step and the only risk that we identify at the moment is injection of the transducing particles into mice because this involves the use of needles and the risk of personal injury.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

All GMOs in this assessment are micro-organisms.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

For immunisation of mice with lentiviral particles it is requested that the animals are injected in a level 2 designated room, but outside a laminar flow hood. Lentiviral particles are extremely sensitive to desiccation and no risk associated with infection due to air-borne particles has been identified. Injection of mice while in a laminar flow hood restricts the movement and in fact increases the risk of needle stick injuries due to the difficulty of manouvering in the confined space. The site of injection is sprayed with ethanol to inactivate any lentiviral particles leaking from the injection site (though this volume is typically less than 10-20 μl).

Once the lentiviral particles are injected into mice, the inserts will be permanently integrated into the genomes of host cells, and no new viral particles will be produced. Therefore, subsequent to immunisation the mice are not considered genetically modified organisms and no risk is associated with their handling and housing. All waste from the housing of mice is disposed of by incineration and this therefore remains the appropriate method of disposal for waste from animals immunised with lentiviral vectors. Likewise cadavers will also be disposed of by incineration according to standard UCL procedure.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

GMM/1: line 1.29 or GMM/2: lines 2.13 (as applicable)

For routine cleaning, all surfaces will be wiped down with 70% alcohol after use which is known to be effective against enveloped viruses. Liquid GMM waste will first be disinfected using Presept overnight (effervescent disinfection tablet containing Troclosene Sodium) to give a final concentration of 2500ppm available chlorine (1x2.5g tablet/500ml waste) before being disposed of down the sink. This is a standard procedure and viability is below detectable levels. Solid GMM waste will be placed in autoclave bag, and autoclaved via the central collection service for GM waste.

The autoclave sterilizing cycle is carried out at 135°C for 5 minutes. All sharp objects, such as pipette tips are placed in a rigid plastic container prior to disposal in autoclave bags. Needles (without dissociation from the attached syringes) are placed in sharps bins which are sealed before being added to the autoclave bag.
It is not possible to estimate a degree of kill for a non-replicative virus. However, autoclaving and 2500ppm available chlorine is sufficient for a 100% inactivation of enveloped viruses.

For immunisation of mice all needles will be disposed of in dedicated sharps bins (without dissociation from the attached syringe). The sharps bins are then placed in autoclave bags and autoclaved via the central collection service for GM waste.

Note that in the event of spills, 70% ethanol will be used for surface disinfection. This agent is effective and widely used for inactivating enveloped viruses. Absorbent tissues will be used to mop the affected area and will then be disposed of by autoclaving as described above.

Temperature and pressure parameters for each autoclave run are recorded on a printout and reviewed. The autoclave is checked weekly and a 12 point thermocouple test is performed annually. The autoclave validation records are audited annually and a certificate is issued.

All solid waste (including sharps) are placed in autoclave bags and collected from the department to be taken to the central autoclave. The bags are transported to the autoclave in a rigid, lidded container.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
1.10 Immuno-modulating genes such as T cell receptors, co-stimulatory molecules, cytokines/chemokines and the receptors for cytokines/chemokines will be studied for their function in the engineered cells. MicroRNA or siRNA sequences to control expression of inserted sequences in specific cell types. For example, the microRNA mir142 restricts expression of upstream genes to non-haematopoietic cells only (Brown et al (2006) Nat Med 12:585). Alternative micro RNA sequences may be used to allow expression only in immune cells, especially dendritic cells. SiRNA would be used to specifically down-modulate protein levels of a gene of interest in transduced cells, for example, a co-stimulatory molecule or cytokine or the endogenous T cell receptor genes.

1.12 Some vector plasmids obtained from Prof. M Cs’ laboratory may contain sequences to enhance expression in transduced cells such as dendritic cells or T cells.

1.13 Cells: standard laboratory cell lines (e.g. 293T, HeLa, NIH3T3 etc.). Human and mouse haematopoietic cells (in particular T cells and Dendritic cells as well as other immune cells).

1.25 They indicate the autoclave waste will be "autoclaved later" is there any issue with waste hanging around to be autoclaved and how long "later" actually would be?. All GM waste is placed in Autoclave bags which are changed on a regular basis. All autoclave bags are kept in rigid containers, All sharps are placed in lidded containers. They are then collected by the porter, who autoclaves them on the service floor. This is what was meant by autoclaved later.

GMM2

2.16 Question: Does your laboratory operating procedure permit the use of sharps (including glass pipettes)?
Answer: No. But they intend to use sharps to inject the lentiviral vectors into mice or does the question relate only to the portion of the work which will be done in the lab rather than in CBU.
Yes, we meant that no sharps are used in the laboratory setting, but of course they are used in the animal house.

Project Ref 18/01.10

Date Ackn'd CU2 Project Title  Class CultureVolClass2 CultureVolumeClass3-4

02/03/2022
**Purposes of the contained use**

a) clone genes involved in the development of human malignancies.
b) study the normal biological functions of these genes and how these are altered in cancer.

**Recipient or parental organism**

- E. coli K12 and derivatives.
- Saccharomyces cervisiae.
- Cultured mamalian cells.
- Cultured insect cells.

**Host/vector system**

- E. coli: Plasmids, Cosmids, Bacterial artificial chromosomes, (upside down y) vectors, Expression vectors.
- Saccharomyces cervisiae: Yeast artificial chromosomes, Expression vectors.
- Mammalian cells: Mammalian expression vectors.
- Insect cells: Baculovirus expression vectors.

**Origin & function**

Known human oncogenes and tumour suppressor genes, and uncharacterised genes involved in human cancer.

**Evaluation of foreseeable effects**

Organisms will be modified E. coli, S. cervisiae, and mamalian and insect cells expressing potentially oncogenic sequences.

Possible hazards to human health arise from E. coli expressing high levels of potentially oncogenic proteins, and from the use of poorly characterised mamalian cells.

The only viral vectors used (Baculovirus) are disabled vectors that produce unstable, poorly infectious virus that should pose no environmental risk to insects with the
standard containment procedures used (ACBM Annex III).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Some procedures within the overall project only require level 1 containment.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste:
Plastics and paper: autoclaved, then into normal refuse.
Animal waste: incinerated or autoclaved as above.
Glass: autoclaved or soaked in disinfectant, then into normal refuse.

Liquid waste:
Autoclaved, the into drains.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

Discussed and approved by local Biological and Genetic Modification Safety Committee on 3 July 2000.

**Project Additional Information**

**Purposes of the contained use**
Experiments will be carried out in order to evaluate the avidity of the CD8+ CTL response by InsHA mice to pancreatic Islet beta cell-expressed HA. InsHA mice will be immunized with recombinant Vaccinia-Virus expressing either the whole HA protein, or the dominant MHC Class 1 K HA epitope in order to generate K HA-specific CTL. Several murine cell types will be inoculated with the same recombinant vaccinia virus for use as target cells or stimulator cells for the HA-specific CTL.

**Recipient or parental organism**
Both Vaccinia virus Vacc-HA and Vacc-KdHA were kind gifts from Laboratory of Jack Bennink and Johnathan Yewdell at the NIH, Bethesda, USA. Briefly the recombinants were prepared using an isolate of Vaccinia Virus WR. Vaccinia virus HA was produced following in vivo recombination using S variant Vaccinia Virus VTK 79 as rescuing virus and a donor plasmid pDP122B (Panicali et al., 1983 PNAS 80 5364-68).

Vaccinia virus K HA contains the minigene K HA(518-526)-VAC construct, composed of a signal sequence from the adenovirus E3/19K glycoprotein expressing the 9-amino-acid HA natural MHC class 1 determinant 1YSTVASSL.

**Host/vector system**
The parental Vaccinia virus S-variant VTK 79 contains a deletions in the open reading frames of the Thymidine Kinase (TK), gene involved in nucleotide metabolism.

**Origin & function**
The influenza virus HA whole protein and the K HA-epitope in recombinant Vaccinia Virus are for use in studying K HA-specific CTL responses for use in initiating auto-immune responses to tissues expressing HA as well as in vaccination strategies that generate immunity to HA.
Evaluation of foreseeable effects

As a result of the TK deletions both recombinants are highly attenuated and are unable to replicate effectively in TK negative cell types. Replication in TK positive cell types results in the production of non-recombinant wild type Vaccinia Virus having lost the inserted gene.

With regard to the inserted genes, both are derived from mouse-adapted influenza Virus A/PR/8 H1N1. Any accidental release of either the HA gene or the K HA gene would not pose any threat to the environment, or be of hazard to humans.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste, both from the level 2 containment laboratories and rooms within the vivarium, will be autoclaved. Transfer vessels ie pipettes tubes, will be soaked in 10% bleach before autoclaving.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

The Biological and Genetic Modification Committee Meeting of 11/07/01 discussed the fact that the thymidine negative mutant of the WR Vaccinia virus was no longer considered to be apathogenic to humans following the hospitalisation of a laboratory worker. Part 2B Annex III para 71 of the Compendium states “a TK minus phenotype is believed to reduce the virulence of the virus in mice but it is debatable whether this should be taken to imply lower virulence in man or whether this should allow a down-grading of categorisation. *Therefore all work with TK minus Vaccinia virus to be carried out at level 2 containment.*
Further understanding of processing in sensory neurons

The parental strain of the virus to be used is an attenuated form of herpes simplex virus-1 (HSV-1). The wild type human herpes simplex (HSV) type 1 virus is a common human pathogen that causes mucocutaneous lesions usually limited to the oropharyngeal area. Following primary infection, the virus remains dormant in the sensory neurons and may reactivate when virus seeds to epithelium and replicates to infect many epithelial cells. Wild-type HSV1 is listed in ACPD Hazard Group 2. There are attenuated strains of HSV1 that we propose to use, the KOS strain, the ICP4-negative and the ICP34.5-negative strains have deletions of genes essential for viral replication in neurones. These strains of HSV1 are extremely labile. Virus is easily inactivated by drying, lipid solvents such as 50% ethanol, mild detergents and 5% chlorine-based bleach, or by autoclaving.

The cyclooxygenase isoforms are expressed endogenously in the nervous system. COX-2 is dramatically upregulated in many different tumours, and treatment of tumours with selective COX-2 inhibitors can reduce metastasis formation, and cause tumour regression. Although it is not yet clear whether COX-2 upregulation is the
causal event in tumourigenesis, it may play a role, as COX-2 inhibition can result in apoptosis. There is now some evidence that COX-1 may have an oncogenic role in gastrointestinal tumours, and it has also been implicated in some of the pathological features of Alzheimer's disease. There is some evidence that voltage gates potassium channels may be involved in mitogenesis, and that increased voltage gated sodium channel activity may decrease cell proliferation. In addition, voltage gated sodium channels are extremely important in the generation and conduction of action potentials in nerve fibres. As the majority of the studies planned are to introduce antisense constructs against the voltage-gated sodium channels, this may result in altered neuronal properties by inhibition of action potential generation.

As the cDNAs to be expressed may have potential harmful effects on other organisms, and the cloning of these cDNAs is designed to lead to expression in mammalian systems (albeit unlikely that accidental infection could occur in humans), the viral host/vector system requires containment at ACGM level 2. (see also attached risk assessment for further detail).

Origin & function

Cyclooxygenase enzymes and neuropeptides:
Origin: All cDNAs are full open reading frames cloned from rat.
Intended function:
1. to express antisense cDNA (either full length or partial cDNAs) to inhibit expression of a specific gene product in sensory neurons.
2. to express sense cDNA (full coding region) in either mice null for the gene product of interest, or in normal mice or rats.
Sodium and potassium ion channel subunits.
Origin: Rat cDNAs encoding either full open reading frame, or partial fragment.
1. to express antisense cDNA (either full length or partial cDNAs) to inhibit expression of a specific ion channel subunit in sensory neurons.

Evaluation of foreseeable effects

Foreseeable effects relevant to human health and safety.
Direct infection in humans on contact with virus is unlikely, as these strains of HSV-1 cannot infect intact skin. The only site where they may be a risk of infection is the cornea. HSV strains are not infective through an aerosol route but will be handled in a Class II safety cabinet nonetheless. In addition eye protection is mandatory when using these viruses in case of accidental splashes. Barrier methods such as use of appropriate gloves and laboratory clothing will be routine, and, in addition to the above methods of disinfection should be adequate to prevent accidental infection of humans. Recombination of either parental strain with wild type virus after infection in a human is extremely unlikely, as this would require direct contact between an active infection in a human and the laboratory strain. Lab members with such active herpes infections (for example cold sores) would be excluded from working with the recombinant viruses.

TK-negative HSV strains such as recombinant KOS are resistant to acyclovir, which is a potential concern with respect to treatment of an accidental infection. Tis may preclude the use of this vector for gene therapy applications, but with suitable containment in the laboratory this should not present a significant problem for the proposed use. In the unlikely event that an accidental infection does occur, these viruses are still susceptible to "Foscarnet". ICP34.5- and ribonucleotide reductase-negative HSV-1 strains are not resistant to acyclovir.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste likely to be generated is of the following forms and types:
1. Liquid waste from culture sin generation of viral vectors and recombinant virus.
   Liquid waste from all stages of the project will be disinfected immediately by direct drainage into 5% chlorine bleach, followed by further treatment with 1% chlorine bleach prior to disposal.
2. Disposable dry waste eg. contaminated plastics and sharps.
All disposable plastics contaminated with GMMs in this study will be chemically disinfected and autoclaved prior to disposal. Use of sharps with recombinant virus is avoided where possible. Where use of sharps is unavoidable, such as an injection of animals, sharps will be placed in a non-piercable container (Cin-Bin), sealed and incinerated.

3. Non-disposable dry waste eg contaminated glassware.

Laboratory glassware will be chemically disinfected with 5% then 1% chlorine based bleach, will be washed in mild detergent and then autoclaved prior to re-use. All of these procedures will inactivate all wild type and recombinant HSV-1 present, as the HSV1 strains are extremely labile.

Virus is easily inactivated by desiccation, lipid solvents such as 50% ethanol, mild detergents and 5% chlorine-based bleach, or by autoclaving.

</tr>
</tbody>
</table>

---

At the meeting on 11/07/01 the committee felt that the strains of HSV were not sufficiently attenuated for this project to be level 1 containment, hence HSE notification.
In the proposed clinical trial programme, angiogenic gene therapy product, consisting of a recombinant adenovirus (human serotype 5) containing the human gene for the fibroblast growth factor 4, and referred to as Ad5FGF-4, will be investigated as a treatment for patients with chronic stable angina due to coronary artery disease (CAD). Generation of new blood supply in the diseased heart by intracoronary administration of angiogenic gene therapy product represents a potential new therapeutic approach to relieve this condition.

Recipient or parental organism

The Ad5FGF-4 gene therapy product consists of a recombinant adenovirus vector (human serotype 5, Ad5) with a deletion in the E1 region; from map unit 1.3 to 8.7 of wild-type virus (entire E1A and most of E1B are eliminated). The FGF-4 transgene is inserted, driven by CMV promoter.

Origin & function

The FGF-4 gene was originally isolated from a cDNA library which was constructed from mRNA of Kaposi's sarcoma DNA transformed NIH3T3 cells. The intended function is angiogenesis, the formation of new blood vessels.

Evaluation of foreseeable effects

The probability of adverse consequences resulting from deliberate or accidental release of the gene therapy product Ad5FGF-4 are minimal to nonexistent. Hazards resulting from environmental release (viral shedding from treated persons, inadvertent contamination of the product prior to administration) are negligible or nonexistent for the following reason; infection requires large numbers of infectious vectors, and transfection (expression of the inserted gene) requires a multitude of infectious particles.

Hazards associated with the adenoviral vector can be described as having low potential of adverse environmental consequences in humans or animals. The theoretical consequences to humans of several of the hazards associated with ectopic transgene expression, if they actually occurred, could be considered moderately severe (e.g. promotion of existent malignancy, unknown risk to foetus). However, since any unintended or accidental exposure would most likely be a fraction of the total dose being administered to patients for therapeutic purposes, the relative risk of the occurrence of these types of adverse effects should be very low.

The possible risks to the environment could be assessed as low to effectively zero. This is based on the low probability of infectious adenoviral particles escaping into the environment either therough viral shedding by patients that have received the product, or by incidental exposure during administration procedures. Even if viruses were shed or product spillage occurred the number of infectious viral particles would be too small to result in infection of exposed tissues. The risk to the non-human environment is extremely low to effectively zero because of the species specificity of adenovirus 5, which by natural exposure is only known to infect humans.
The above indicates that the product could be classified as Class 1. However, as a precautionary measure, due to the limited experience available, the product is currently being classified as Class 2. Reclassification into Class 1 may be considered if based on increased data and experience.

02/03/2022
Project Additional Information

Purposes of the contained use

Storage, transformation and culture of recombinant trypanosomes with bacterial genes for drug resistance, heterologous reporter genes and trypanosome genes in order to study trypanosome genetics and gene expression for research purposes only.

Recipient or parental organism

African trypanosomes are protozoan parasites of mammals, with an invertebrate vector, the tsetse fly. Neither these trypanosomes nor the insect vector is found naturally occurring in the UK, and the requirement of the insect vector for tropical climatic conditions mean that the natural transmission cycle could not establish itself. The trypanosomes are obligate parasites and required specialized culture conditions. They are not transmissible by aerosol. Genetic modification is not envisaged to render the trypanosomes more hazardous than wildtype. The antibiotic resistance genes used are unrelated to any drugs currently used for treatment of either humans or livestock.

Wildtype trypanosome species are subject to ACPD category 2 and 3 containment and also to handling conditions attached to our MAFF Special Animal Pathogens Order licence. We have a set of Standard Operating Procedures covering all experimental procedures used.
Level 2: Trypanosoma brucei brucei, T. b. gambiense, T. congolense are handled under level 2 containment.
Level 3: Trypanosoma brucei rhodesiense is a derogated ACDP 3 pathogen (exemption certificate No: COSHH/HD/1998/1) and is also handled under derogated level 3 containment.

Host/vector system

Host: Trypanosoma brucei ssp., Trypanosoma congolense

Vector: Plasmid (pGEM) expression vectors for trypanosomes with trypanosome promoter and processing sequences.

Origin & function

1. Bacterial genes for drug resistance, eg hyg, neo, ble.
2. Reporter genes, eg Green fluorescent protein from Aequoria victoria.
3. Trypanosome genes for functional analysis, eg surface coat protein gens, serum resistance antigen genes.

Evaluation of foreseeable effects

1. Trypanosomes are tropical pathogens of humans and livestock. Genetically modified organisms are not envisaged to be more hazardous than unmodified organisms and will be handled under the same stringent safety conditions appropriate for ACDP 2 and derogated ACDP 3 pathogens and MAFF Specified Animal Pathogens Order. These stringent containment conditions ensure negligible environmental risk.
2. The bacterial drug resistance genes confer resistance to antibiotics, which are not related to the drugs currently used for treatment of trypanosomiasis.
3. The heterologous genes are introduced by homologous recombination into the trypanosome genome. The risk of transfer to other organisms is therefore negligible.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Trypanosoma brucei rhodesiense is classified as a derogated ACDP 3 pathogen (Certificate of exemption No: COSHH/HD/1998/1). It is not transmissible by aerosol. We therefore request permission to handle it under derogated level 3 containment, ie laboratory does not need to be sealable for fumigation and does not need negative air pressure; extract and input air from the laboratory do not need to be HEPA filtered; aerosol dissemination needs to be minimized, but not prevented.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The GMO's are simple eukaryote cells without any protective cell wall; therefore they are easily destroyed by hypotonic lysis, heat, dessication or freezing. We already have stringent waste disposal measures in place, since all waste is treated and disposed of according to ACDP 2 guidelines and Standard Operating Procedures attached to our licence issued under the MAFF Special Animals Pathogens Order as follows:

1. Plastic and glassware should be sterilised by complete immersion in 1% Chloros for at least 10 minutes. The liquid waste is then safe to dispose of via the drains and the plastic/glassware autoclaved before disposal.
2. Liquid waste, including unwanted cultures, infected blood or stabilates, is rendered safe by addition of Chloros to 1%, holding for 10 minutes minimum and autoclaving before disposal.
3. Litter from mouse cages is sealed in plastic bags and incinerated. Dead mice are sealed in double plastic bags and frozen before subsequent incineration.
4. Insect (Tsetse fly) dissection waste should be sterilised by complete immersion in 1% Chloros for at least 10 minutes and autoclaved before disposal.

# Project Additional Information

## Purposes of the contained use

The GMMs that will be used in these studies are all knock-out mutants created by insertional mutagenesis. These GMM strains will be compared to the parental strains to ascertain the roles of the surface proteins and regulatory genes. Studies will be carried out during infection of animals to determine the pathogenicity of the GMM relative to the wild type parental strains. Further work will introduce environmental stress factors, such as dessication, heat, low pH and biocides, to monitor the mutated organism's ability to survive these pressures. These studies should allow more effective means of eliminating Campylobacter spp. from the food chain and provide valuable information about the pathogenesis of Campylobacter spp.

## Recipient or parental organism

- **Campylobacter fetus**
- **Campylobacter jejuni**

## Host/vector system

### Deletion mutagenesis in:

**C.fetus:**

Previous generated mutants (Dworkin and Blaser 1997) will be used in addition to novel mutants which will be generated using the same methods. The vector used in pLL570 (Labigne et al 1991), a suicide shuttle vector which only replicates in E. coli strains harbouring the helper plasmid pK212.1 (Figurski et al. 1976). Manipulation of pLL570 is followed by transformation into E. coli:HB 101 harbouring pK212.1. Conjugation facilitates transfer of the plasmid into C.fetus. Within C.fetus the plasmid is unable to replicate and recombination with the host element is only possible with DNA that is homologous with both plasmid and host. Using this method there is a negligible chance of transfer of the DNA to any organisms other than the vector hosts. Transformed hosts have genes insertionally mutated, with antibiotic resistant gene cassettes, by a double cross over recombination event.

**C.jejuni:**

The parent strains are modified by insertional mutagenesis into genes encoding surface structures or global regulators (Linton et al 2000a, 2000b). The inserted gene encodes resistance to an antibiotic eg kanamycin.

## Origin & function

All genetic material originates from Campylobacter sp. The kanamycin resistance cassettes are from C.jejuni, chloramphenicol resistance from C.coli and tetracycline resistance from C.jejuni. Plasmids are derived from E. coli (pLL570, pK212.1) and C.fetus (pLL570) strains.

02/03/2022
Evaluation of foreseeable effects

The GMOs in this study are all knockout mutants. Therefore any manipulated organism is likely to be less viable than the well characterised parental strains. It is very unlikely that these deletions will cause a more virulent organism. The resistance cassettes are introduced into the host cells but only at the expense of the important pathogenic factors under study.

Any release into the environment is unlikely to cause damaging sequelae. The GMMs are all expected to be less viable and highly unlikely to be more dangerous than the parental strains. Appropriate containment level II procedures should ensure that environmental release is highly unlikely.

The organisms under study are responsible for a range of clinical diseases in humans, the majority of being cases of bacterial enteritis. As the GMMs are expected to be no more virulent than parent strains this would not pose a major hazard and the risks of infection would be low due to containment level II controls.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Strict adherence to containment level II control measures including disinfection of all laboratory surfaces after use with validated disinfectant. All bacterial cultures and waste containing GMO's will be autoclaved including agar plates, sharps and glass ware. All animal waste, bedding etc. incinerated on site. Formaldehyde fumigation of all animal rooms after use.

### Project Additional Information

**Purposes of the contained use**
It is important to determine what genetic factors determine survival of Salmonella under stress commonly encountered in both natural and man-made habitats in order to assess the effectiveness of different measures to prevent Salmonella from contaminating food. It is even more pertinent to assess if some genetic factors have a possible dual role in promoting survival and virulence in different animal models.

**Recipient or parental organism**
The wild type Salmonella serovars in this project are considered to be analogous to biological agents listed in ACDP Hazard Group 2. The Salmonella strains may be able to colonise humans and animals and cause gastrointestinal disease.

**Host/vector system**
Mutants constructed may be able to survive as well as the wild type Salmonella parent strain in the environment. Salmonella mutants, in which genes related to surface structures eg fimD, pepC, IpfC, flIC, agfA, sefA, motAB, sefA and cheA, global regulatory systems eg rpoS, rpoH, rpoE and bipA or carbon metabolism eg gig genes have been inactivated by the insertion of a gene cassette encoding resistance to an antibiotic eg kanamycin or ampicillin, are unlikely to pose a greater health risk than the parent strain itself. In order to measure the expression of the RpoS protein the following vectors will be used: pSB367 (pUC 18 backbone) and pTopo (pCR2. 1-TOPO backbone); these are non-mobilisable thus reducing the possible hazards from gene transfer. The pSB367 vector contains the spvR gene, the spvA promoterregion and the luxCDABE genes. Most wild type Salmonella strains already contain the spvR gene, the product of this gene has no known toxic function and the expressed protein is therefore not considered to increase pathogenicity. The luxCDABE genes encode the luciferase enzyme and the aldehyde substrate and are not considered to increase the level of risk. The pTopo vector also contains the spvR gene in addition to a gene encoding a green fluorescent protein. The produce of this latter gene is also not considered to
increase pathogenicity.
The role of the genes described above in animals will be investigated using Balb/C mice, chicks and laying hens.

Origin & function

The genetic material involved is normally present in Salmonella strains except for the luxACDABE and gfp genes which originate from Photobacterium fischeri and Actinomyces victoria, respectively.
The genes encoding resistance to different antibiotics originate from a variety of bacteria including E. coli. These genes are used to express a phenotype (bioluminescent, fluorescent or ability to grow in the presence of a certain antibiotic) which will reflect expression of a particular protein (RpoS) or ensure that an intended gene has been disrupted.

Evaluation of foreseeable effects

It is unlikely that wild type strains containing either the antibiotic cassettes or the expression plasmids will be more harmful than the original (wild type) strain itself. There are no particular environmental factors that might affect the likelihood that harm may occur. Given the level 2 containment and control measures it is unlikely that the GMMs will reach the environment and cause harm to humans or animals outside the laboratory. Transmission to people within the laboratory is most likely by ingestion route (medium likelihood). The likelihood of hand to mouth transmission will be reduced to a minimum by observing good laboratory practise appropriate for containment level 2. Access to the facility will be restricted, and appropriate disinfection and waste management procedures are in place. These measures will reduce the likelihood of all hazards to negligible. The overall risk is therefore effectively minimal with the proposed containment and control measures.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All bacterial cultures and waste containing GMOs will be autoclaved including agar plates, sharps and glass ware. All potential formites (eg gloves) will be autoclaved.
All animals in contact with bacteria will be killed, double-bagged, and incinerated.

Is an emergency plan required according to regulation 20?

02/03/2022
**Project Additional Information**

**Purposes of the contained use**
To create a novel form of recombinant human adenovirus vector that is an improvement on the ones currently widely used.

**Recipient or parental organism**
Class 2 activities;
The E. coli K-12 derivative DH5a, which is recognised as non-colonising and disabled, and may be considered to be equivalent ACDP biological agents hazard group 1.
The recombinant virus vector, adenovirus that is placed in ACDP biological agents hazard group 2. The monkey cell line CV-1 and the human cell line 293 (Human embryonic kidney cell line containing the adenovirus E1 region) which are recognised as non-colonising and disabled.

**Host/vector system**
Class 2 activities:
Host: Escherichia coli K-12 strain DH5a, Monkey Kidney cell line CV-1 HEK cell line 293. A novel CV-1 cell line will be made which will constitutively express the Cre recombinase.
Vectors: Cloning of sequences into recombinant plasmids designed to generate recombinant E1 deleted and E3 deleted adenoviruses based on the human adenovirus serotype 5. The vectors to be used will all be derived from the commercial company Microbix (www.microbix.com) and the details of their plasmids including the sequences are available for them. All the plasmids used are based on pBR322 or pUC. For the generation of the CV-1 based cell line the Cre recombinase will be PCR amplified from the Microbix plasmids and expressed using a pcDNA3.1 based plasmid (available from invitrogen) which is derived from the pUC series of plasmids. The hygromycin marker gene will be introduced from the plasmid pTKHyg available from Clontech and is also based on the pUC series.

Origin & function

The genes are derived from human adenovirus type 5 or from other commercially available sources (eg Hygromycin, EGFP etc). In addition we will generate clones of the E1 region from laboratory isolated wt adenovirus DNA.

Evaluation of foreseeable effects

Will result in the generation of recombinant adenovirus. Some of these will be replication competent in human cells. However all the viruses generated will be less fit than the wild type from which they were derived.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

There is no case for seeking derogation on any of the work.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Class 2 activities.

All biological waste containing GMMs will be inactivated before disposal in accordance with the University Biosafety regulations. Liquid waste (used cultures, culture media, supernatants, and any other solutions which have come into contact with live cells) will be autoclaved at 121 degrees C for 30 minutes before disposal to ensure 100% kill rate of the GMM. Contaminated glassware, re-usable plasticware (eg centrifuge bottles and tubes) and solid waste will be similarly autoclaved before disposal, washing or re-use. The autoclave to be used is housed in the building and is maintained regularly. Each cycle will be monitored using an approved thermosensitive testing strip. Contaminated pipettes will be autoclaved.

Project Containment

Project discussed at the meeting of 7 July 2002 and agreed that it is an activity that must be notified to the HSE.
### Project Additional Information

**Purposes of the contained use**

Investigate the mechanism of action of CTLA3-Ig by comparing its ability to prevent transplant rejection with that of molecules carrying mutations of known functional significance. If delivered systemically CTLA4-Ig prevents transplant rejection and autoimmune disease and has entered phase one clinical trials. This work will further investigate the mechanism of action of this molecule, facilitating its optimal use.

**Recipient or parental organism**

An E1/E3 deleted replication deficient Ad5 vector (AdEasy) will be used to deliver molecules capable of preventing transplant rejection (GTLA4-Ig) to pancreatic islets of Langerhans. Virus will be generated in human kidney 293 cells. Purified murine islets will then be infected with virus by overnight culture and then transplanted into recipient animals (mice) and transplant survival monitored. Generation of virus and infection of islets will take place in a category II facility. Transplants will be performed and animals will be housed in a category II facility in the University of Bristol Medical School animal house.
The likelihood of infection from the mouse is extremely low. No more than 1000 islets are transplanted into each mouse, each islet containing 500-1000 cells. Transfection efficiency is low (approximately 10%). As the virus is non-replicative the number of virus particles in the mouse is thus very low. Although the adenovirus is replication defective, it could be mobilised by co-infection with wild-type adenovirus. Human adenoviruses do not infect mice and the likelihood of this happening with transmission to a second individual is therefore negligible. All waste, including animal bedding, is autoclaved then incinerated.

Host/vector system

The vector to be used is a replication defective E1/E3 deleted Ad5 vector using a CMV promoter. Adenovirus 5 are associated with mild respiratory infections and are non-oncogenic. Replication defective adenoviral vectors have no mechanism for long term maintenance in cells and are unlikely to cause disease. Plasmids expressing CTLA4-ig and mutant molecules will be constructed by cloning into a transfer vector using E. coli. This transfer vector does not contain viral sequences. The inserted gene is under control of a eukaryotic expression vector which does not function in E. coli. Thus, organisms of pathogenic phenotype will not be generated. Recombinant adenovirus vectors will be constructed by homologous recombination in E. Coli of strain BJ5183, which is K12 derived and therefore not pathogenic in man. The vector is non-mobilisable and contains an active resistance gene (kanamycin) for selection. Virus will be generated by transfection of human kidney 293 cells with this recombinant adenoviral vector. Bacteria transformed with plasmids will be stored as glycerol stocks at - 80 degrees C in volumes <5ml.

Origin & function

The inserted gene encodes a fusion protein consisting of murine CTLA4 and murine IgG2a constant regions. This construct was generated by Dr A Gelman, Boston having cloned the respective genes from murine lymphocytes. CTLA4-ig will prevent the immune response to the transplant prolonging transplant survival. Similar work to that proposed here, using vectors containing this insert, has been published (Feng et al Transplantation 1999 67:1607). Plasmids encoding loss of function mutant CTLA4-ig molecules will be generated using site directed mutagenesis. The mutations encode single amino acid substitutions in the mutant molecules resulting in them being defective in binding to selected cell surface ligands. It is predicted that this will inhibit the ability of these molecules to prevent transplant rejection allowing the importance of these interactions to be studied by comparison of the mutant molecule with native CTLA4-ig.

Evaluation of foreseeable effects

Adenoviral vector construction. The inserted gene is under control of a eukaryotic expression vector which does not function in E. coli. All fectors are non-mobilisable and contain an active resistance gene (kanamycin) for selection. Thus, organisms of pathogenic phenotype will not be generated. Freezers containing glycerol stocks will be labelled to indicate that GMOs are stored there. In the event of freezer breakdown or sample spillage storage areas will be disinfected and waste autoclaved before disposal.

Adenovirus will be generated by transfection of human kidney 293 cells. This cell line has been tested for the presence of potentially harmful adventitious agents. The parental organism is a non-pathogenic adenovirus. The insert codes for a molecule capable of inhibiting immune responses. All work will therefore be carried out to ACGM level 2 in a facility which has a class II microbiological safety cabinet for virus handling, designated incubator and equipment necessary for virus isolation and purification. Islets will be infected in this facility. Transplants will take place and animals will be housed in an ACGM level 2 animal facility in the University of Bristol Medical School animal house. Islets will be transferred between these facilities in sealed tissue culture flasks in a sealed box, islets will be washed and resuspended in medium containing no free virus prior to transport. The likelihood of infection from animals receiving transplants is extremely low. No more than 1000 islets are transplanted into each mouse, each islet containing 500-1000 cells. Transfection efficiency is low (approximately 10%). As the virus is non-replicative the number of virus particles in the mouse is very low. All waste, including animal bedding, is autoclaved then incinerated.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All animals receiving islet transplants infected with adenovirus will be contained with the ACGM level 2 animal facility in the University of Bristol Medical School animal house.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All liquid waste will be treated with 10% bleach (10,000 ppm sodium hypochlorite) then autoclaved. All solid waste, including animal bedding, will be autoclaved then incinerated. Animal carcasses will be incinerated.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Discussed at meeting of 10.7.02, E. coli BJ5185 from commercially available kit. Agreed that project must be notified to HSE.

Project Ref 18/02.8

Date Ackn’d 06/11/2002

CU2 Project Title CONDITIONAL IMMORTALISATION OF HUMAN PODOCYTE AND ENDOTHELIAL CELLS.

Class 2

Consent Granted not applicable

Project notified under transitional arrangements N

Historical Significant Changes

Historical Date of Additional Info
### Project Additional Information

#### Purposes of the contained use
Stable transfection of primary cultured cells with an immortalising gene construct, using amphotrophic retrovirus as the vector.

#### Recipient or parental organism
Cultured mammalian cells.

#### Host/vector system
Amphotrophic retrovirus in cultured PA317 mouse fibroblast cells.

#### Origin & function
- SV40 T antigen - immortalising gene construct
- Human telomerase gene - cell survival gene.

#### Evaluation of foreseeable effects
The retrovirus is replication deficient, and is capable of infecting human cells. There is therefore a theoretical risk to the operator of introducing the described oncogene.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable.

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Not applicable.

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
- Plastics and paper: into yellow bag refuse for incineration
- Glass: autoclaved or soaked in disinfectant, then into normal refuse
- Liquid waste: disinfected with Virkon, then into drains.

All these measures will be expected to result in 100% kill of cultured cells.

**Project Additional Information**

**Purposes of the contained use**

Essential hypertension remains a highly widespread and damaging disease leading to high morbidity and mortality rates in the industrial countries, such as UK. We have currently obtained financial support to investigate molecular mechanisms of pathological hypertension. Changes in biochemical and biophysical properties of brain neurones which could underlay human hypertension and related disturbances of homeostasis will be studies in animal models of hypertension. A variety of genetic
constructs will be expressed in brain cells in order to a) visualise various stages of intracellular signalling using fluorescently tagged molecules; b) study physiological consequences of suppression of an intracellular signalling cascade.

Examples of "a" are: fusion proteins incorporating mutants of the green fluorescent protein (ie eNOS-EGFP or angiotensin AT1 - receptor-EYPF or ARNO-ECFP), Examples of "b" are dominant negative forms of G-proteins nitric oxide synthases and protein kinase B.

Most of our constructs will utilise cell specific promoters to restrict the expression to selected subpopulations of brain neurones. This research will help to clarify the biochemical pathways responsible for pathological hypertension anre reveal novel targets for drug therapies with a prospect of genetic therapy.

Recipient or parental organism

Viral vectors will be either delivered into the brain of rats (normotensive strains, such as Wistar, or spontaneously hypertensive rat, SHR) or applied to slice cultures made from the brain of these animals or to the acutey prepared brain slices of the rat. As a preliminary step required for construct screening cell lines such as (C12, Neuro2A, CHO, HEK293 will be used.

Rats injected with the viral vectors will be housed within the transgenic facilities of the UOB. Slice cultures will be prepared under sterile conditions and kept in designated incubators for > 7 days before use. It has been demonstrated that once injected of have been applied to cultured cells the viral particles cannot re-infect any other tissue. This can be demonstrated by application of tissue homogenates to a receptive cell line, such as HEK293 showing that no infection will occur.

Host/vector system

Self-inactivating lentivirus (T. lwakuma, Y. Cui, L.-J Chang. Virology 261:120-132, 1999) is a self-inactivating vector with extensive deletions and modifications in both long terminal repeats. Originally derived from HIV, these vectors contain a substitution in the 5’ end promoter, the 3’ end deletion and a number of further modifications which theoretically make formation of replication-competent virus impossible. These and further deletions introduced University of Florida, USA are also thought to also have abolished the potential oncogenic capacity of the native lentiviruses. The self-inactivating lentivirua we intend to use is unable to replicate in any known system and is very unstable in the normal environment.

Replication - deficient adenovirus derived from human adenovirus type 5 with E1a - or combined E1a&E3 deletions have been used extensively around the world for several years. It can replicate only in special cell lines (like HEK 293) and should be unable to recombine to form a replication-competent virus: this has been confirmed by years of its world-wide use.

Origin & function

The self-inactivating lentivirus has been originally developed by the group of Fr. L-J Chang (University of Florida, USA and further modified in the laboratory of Prof M Raizada (University of Florida) to delete vpr, vif and vpu genes for additional safety and we have already gained experience with these vectors through our collaboration with Prof Raizada’s group (see Coleman, J. E. et al, 2003 Physiological Genomics 12, 221-228). The systems for creation of the replication-deficient adenoviral vectors are available commercially from Microbix and Clonetech. We will use the Microbix system as we already have experience with it and have used it for the last three years under supervision of Prof D Murphy (UOB Centre for Neuroendocrinology). This is reflected in a number of publications from our laboratories (ie Kasperov, S. et al., 2002 Experimental Physiology 87, 715-724; Paton, J. F. R. 2001, Acta Physiologica Scandinavica 173, 127-137; Paton J. F. R. et al, 2001, Journal of Physiology 531, 445-458; Waki, H. et al., 2003, Journal of Physiology 546, 233-242; Wong, L. F. et al, 2002 FASEB Journal 16, 1595-1601).

Genes to be cloned into the vectors will come either through third parties (collaborators) or by cloning from cDNA libraries using standard methods. Some of the genes (fluorescent proteins) will be purchased from companies, such as Clonetech. We will concentrate primarily on vectors, which will be targeted to specific populations of brain neurones using specific promoter sequences (ie PRSx8 promoter selective for noradrenergic neurones (Hwang et al, 2001, Human Gene Therapy 12, 1731-1740) supplied by our collaborator K. -S Kim, Harvard University, USA). These constructs therefore will not express transgenes in peripheral tissues. Oncogenes or genes involved in cell division will not be used.
The genes to be expressed
- The main family of transgenes we want to place into the viral vectors will express fluorescent proteins or their fusions (EGFP, HcRed, eNOS-EGFP or angiotensin AT1-receptor-EYPF, PHD-EGFP, synaptophysin-ECFP or ARNO-ECFP). Fluorescent proteins such as EGFP and HcRed will be placed under control of cell-specific promoters (ie PRSx8 promoter selective for noradrenergic cells or neuron-specific NSE promoter which leads to expression in neurones but not any other cell type). They will used to visualise the fine details of connectivity in living neurones using live cells confocal imaging (Kasparov, S. et al, 2002, Experimental Physiology 87, 715-724). The fluorescent fusions will either have no biological activity at all (PHD-EGFP) or be based on signalling molecules, which according do not trigger cell division (ie eNOS-EGFP, AT1 receptor-EYPF, synaptophysin-ECP, ARNO-ECFP). These molecules can be used as tracers for various types of cellular biochemical activity as they are thought to translocate between cellular compartments upon activation of certain signalling cascades. For example, PHD-EGFP contains a sequence which enables it to move towards the plasma membrane in response to PIP3 accumulation. Hence it can be used to visualise PIP3 signalling in living cells such as brain neurones. We will need to use both, cell-specific promoters and HCMV for neuronal types for which no specific promoters are available.

- The other family of vectors will contain dominant negative proteins, which again do not have any known oncogenic properties. We need to generate dominant negative mutants for nitric oxide synthase (NOS), protein kinase B, PIP3-kinase or G-proteins. Such constructs (using HCMV promoter) have been made previously by others and no stimulatory effects on cell division have been reported. Some of these vectors were used in our recent studies (ie Wong L.-F. et al, 2002) but we will need to place them under control of cell-specific promoters in order to identify their site of action. As stated above, most of our constructs will use cell-specific promoters (ie neuron-specific NSE promoter or PRS8 noradrenergic promoter). Viruses with these promoters only express transgenes in neurones or selected neuronal subpopulations. In the event of an accident there is no feasible route by which these viruses may reach susceptible brain cells. Cells outside of brain-blood barrier transfected with a denoviral vectors get rapidly eliminated and as further infection/viral multiplication may not occur the transgene from the peripheral tissues will be eliminated naturally. Fluorescent proteins such as EGFP are not toxic to cells and there are many transgenic animals where EGFP is continuously expressed in some cells.

### Evaluation of foreseeable effects

**Viral vectors potentially can be harmful for humans. This will require that these vectors could a) infect humans; b) multiply in human body; c) bare genes of harmful nature.**

- **a)** both lentivirus and adenovirus can infect humans if delivered to the receptive tissue. As known from HIV, lentivirus has extremely low infectivity unless injected directly into the tissues. Adenovirus can infect human respiratory tract via aerosol route. However, given the use of class II biological safety cabinet, an ACPD category II facility and high degree of worker training and awareness, the risk is greatly minimised. Furthermore, the immune cells in the respiratory epithelium will immediately phagocyte and destroy the viral particles. Given that the volumes used for injection into brain are <2ul and in slice culture/acute slice are ~ 20 ul, the amount of the viral particles which could escape into aerosol should be extremely small (for comparison >10 (to the power of 12) viral particles have been injected into blood during clinical trials). After application to brain slices or cultures or injection into animals, viruses capable of infection may NOT be recovered.

- **b)** neither vector can replicate in a human body. Adenovirus can proliferate in specific cell lines which supply the E1a product in trans, while the lentiviral vector cannot replicate in any system because it lacks most of the original genome and further self-inactivates upon integration into the host genome.

- **c)** in the lentivirus vector all active promoter-like elements have been removed and the only active promoter is the one which is chosen to drive the expression of the transgene. This vector has been modified in such a way that after integration it has no transcriptionally active long terminal repeats anymore. This minimises the risk of detrimental effects of the lentiviral genome itself. The genome of the replication-deficient adenoviral vectors has no known cytotoxic or oncogenic genes. However the transgenes placed in any vector may be harmful, if they have toxic of oncogenic potential, for example, apoptotic genes or constitutively active forms of protein kinases involved in cell division. We will NOT use any such genes and sequences encoding for genes of known harmful potention.

- In addition, the expression of a transgene is dependent on the promoter use. Some promoters, such as the HCMV (human cytomegalovirus promoter) are active in a wide variety of cells while others are selectively active only is some cell types. In this study we intend to use both, cell specific promoters to target selected neuronal populations in the brain and H?CMV for the neuronal populations for which no specific promoters are available. Importantly the cell specific promoters will restrict expression of any transgene to central neurones to which any viral vectors generated in this study may have access only if directly delivered into the brain or put on the neuronal cells of that phenotype in vitro.
Experimentators may potentially have contact with the vectors at two stages: during viral preparation and during their application to the brain cells in vivo or in vitro. During the preparation all required safety measures will be observed and most of the work with recombinant viral particles will be carried out in the class II safety cabinets. The only stage where live viral stock will need to be handled outside of the hoods is the ultracentrifugation but during this step the virus will be hermetically sealed in special tubes. The ultracentrifuge also will be treated with 10% Vircon (antiviral and antiseptic reagent). The same chemical will be also used to neutralise any other contaminated materials, which then will be autoclaved. Transfected animals will be incinerated.

Application of viruses to brain slices (acutely prepared or in organotypic cultures) will also be done in the class II safety cabinets. Microinjection into the brain of experimental animals (rodents) will be carried out in the Cat II designated facility. Adenovirus can infect human respiratory tract via aerosol route while the lentivirus apparently cannot. Considering the use of a class II safety cabinet, an ACDP category II facility, the high degree of worker awareness and qualification and the fact that the viruses are replication-deficient, the risk to the worker is greatly diminished. The volumes used in transfection experiments are very small (2-10-20 ul, containing approximately 2 * 10^7 viral particles). The maximum volume injected into an animal is 2ul and the glass needles will be filled in a category II safety cabinet and buffered by paraffin oil. These considerations make formation of any substantial amounts of aerosol highly unfeasible. Once injected into animals the viral particles cannot re-infect any other tissues and the injected animals are not infectious to the others. Moreover there is no known way for these constructs to re-appear as infection-capable viral particles.

Animals injected with the lentiviral and adenoviral vectors are not infectious and represent no threat to the environment or personal. They will need to be maintained for up to 2 months in the animal facility of the UOB (<20 animals at a time).

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All general laboratory waste used for cloning will be collected into the special bags, autoclaved and disposed according to the University regulations. All materials which were in contact with viral suspensions will be neutralised with 10% Vircon and Hycolin and then autoclaved at 121 degrees C for 45 minutes to ensure 100% destruction of any GMM. Pasteur pipettes and similar glass sharps will be avoided to prevent the risk of skin puncture. Scalpel blades will be put into the designated lockable containers and incinerated. Waste materials used for cloning (ie plastic tips etc.) will be collected into designated containers and incinerated. Transfected animals will be incinerated.

Please enter comments on the GM safety committee on the risk assessment

Discussed at meeting of 20 November 2002 and Committee agreed that insufficient information had been supplied. Project re submitted to Committee at meeting of 19 February 2003 and agreed that the content was not satisfactory. To be submitted to HSE.
**Project Additional Information**

**Purposes of the contained use**

Fundamental research aimed at understanding the molecular and cellular mechanisms of intracellular survival using bacterial models. Our principal model organisms are *Listeria monocytogenes* and *Rhodococcus equi*. Our experimental approach involves the inactivation of selected genes of these bacteria by standard laboratory protocols and the analysis of the effect of the gene-disabling mutations on the bacterial intracellular proliferation capacity in vitro, on virulence in vivo, and on the response of the whole bacterial genome as assessed by DNA chip and proteomic technologies. The ultimate goal of this research is to identify targets for new vaccines, antimicrobial therapies and diagnostic tools to combat infections due to intracellular parasites.

**Recipient or parental organism**

The research will involve the generation of four types of GMMs.

1. Derivatives of *L. monocytogenes* and *R. equi* in which selected genes have been “surgically” inactivated to deduce their function by phenotypic comparison with the wild-type parental strain. Gene inactivation will usually be carried out by in-frame deletion, a technique that does not leave any trace of foreign DNA in the bacterial
genome. With this technique, GMMs only differ from their parental organism in that they lack a DNA fragment corresponding to the deleted gene(s).

2. Gene-inactivated derivatives of L. monocytogenes and R. equi in which a wild-type copy of the gene under study has been reintroduced to confirm that the observed phenotype is actually due to this gene(s) and not to a secondary, spontaneous mutation affecting other unrelated loci.

3. Non-pathogenic cloning hosts carrying sequences of our model organisms (L. monocytogenes or R. equi), required for the construction of the gene-deletion derivatives described in (1) or for gene function studies. As recipient organisms we will use the following non-pathogenic bacteria:
   - Escherichia coli K-12 or B disabled derivatives (strains DH5α, HB101, C600, HB101, XL1-Blue, etc)
   - Bacillus subtilis
   - Lactococcus lactis
   - Listeria innocua, a non-pathogenic Listeria sp which lacks all known listerial virulence genes
   - A well-characterised derivative of L. monocytogenes (prfA, picA, hly, plcB, actA) which was irreversibly rendered totally non-pathogenic by deletion of multiple essential virulence genes

4. Miscellaneous GMMs. The following GM bacteria may be incorporated as controls in some of our experiments:
   - Salmonella typhimurium SL1344sifA, a derivative of the laboratory strain SL1344 lacking SifA, a protein required for the maintenance of the vacuole in which Salmonella replicates intracellularly
   - Shigella flexneri laboratory strain SC560, rendered non-pathogenic due to an icsA-disabling mutation which impedes host tissue colonisation
   - Yersinia enterocolitica WA-314 attenuated derivatives due to disabling mutations in the sodA (superoxide dismutase) and irp (invasion associated protein), virulence genes.

Host/vector system

For routine gene cloning we will use non-mobilisable or mobilisation-defective plasmid vectors, such as pUC series-based vectors, pBR322 or pBluescript II for E. coli, and pE194 derivatives for gram-positive bacteria (B. subtilis, L. lactis or Listeria spp). To produce gene-disabling mutations we will use thermosensitive derivatives of pE194 in Listeria and pUC derivatives in R. equi. For inactivation of the uhpT gene in Salmonella typhimurium SL1344sifA and Shigella flexneri SC560 (see below) we may use the "suicide" vector pGP704. This vector can only replicate in, and be mobilised from, strain SM10Lpir, a host E. coli C600 derivative engineered to contain the RP4 mobilisation and R6K replication functions integrated in the chromosome. Once conjugally transferred from this host strain, plasmid pGP704 cannot replicate and be mobilised further.

Origin & function

From Listeria monocytogenes.
In the context of a major EU-funded collaborative initiative in functional genomics of Listeria spp., our group will be allocated a number of L. monocytogenes genes to inactivate them by in-frame deletion. A complete description of the 2,853 genes of the L. monocytogenes genome and their predicted products is publicly available at http://genolist.pasteur.fr/ListiList. All the gene-disabled derivatives contributed by the collaborating European partners will then be sytematically analysed in the different laboratories by a number of approaches, including DNA chip technology and proteomics. Our research will particularly focus on the following Listeria genes.

- prfA, encoding a regulatory factory homologous to CAP/Crp from E. coli
- actA, encoding a surface protein involved in actin-based motility
- plcA, plcB and smcL, encoding phospholipases active on phosphatidylcholine and sphingomyelin, respectively
- hpt, encoding a sugar phosphate transporter homologous to the E. coli Uhp T permease
- ptsH, encoding a putative glucose-specific enzyme II permease component of a phosphoenolpyruvate sugar phosphotransferase system (PTS)
- bvrABC, encoding a PTS permease system specific for beta-glucoside sugars
- agl, encoding a two-component regulatory system
- luxS, encoding a putative quorum-sensing signalling system.
From R. equi
Our work will focus on choE and choD genes, encoding cholesterol oxidases that are widespread among saprophyte soil dwelling actinomycetes (eg Streptomyces spp). We believe that these enzymes may contribute to the capacity of R. equi to survive within eukaryotic host cells, whether they are mammalian microphages or soil bacteriovorous protists.

From S. typhimurium and S. flexneri
Our work will focus on the uhpT gene, encoding a glucose phosphate transporter identical to that present in E. coli K-12 and widely distributed among bacteria. We believe that this transporter may play a role in the uptake of sugar phosphates in vivo when bacteria are within host cells.

### Evaluation of foreseeable effects

#### Hazards to human health

L. monocytogenes and R. equi, in which we are going to produce gene-disabling mutations, live as saprophytes in the soil and are widespread in nature. Occasionally, they can cause opportunistic infections in humans and animals and are thus classified in hazard group 2 in the Approved List of Biological Agents. Clinical infections occur only rarely, require a predisposing underlying condition and, presumably also, a high exposure. Both L. monocytogenes and R. equi are considered to have low infectivity and virulence. Under the designation L. monocytogenes we also include the closely related species L. ivanovii (formerly known as L. monocytogenes serovar 5), which is less virulent and has a narrower host spectrum than L. monocytogenes (L. ivanovii is not recognised as human pathogen). The gene "knock-out" derivatives of these bacteria will have the same low virulence as the parent strain if the deleted loci do not play a role in infection, or a lower virulence if the deleted genes play a role in infection. The "reconstituted" mutants, in which the deleted gene is reintroduced back for confirmation that the target gene is responsible for the observed phenotype, will have at most the same virulence as the parent strain. All these GMMs will therefore be handled under containment level 2.

The heterologous bacterial hosts that will be used as recipients of intermediate constructs for deletion mutant construction or to study gene function by complementation (E. coli K-12 or B disabled derivatives, B subtilis, L. lactis or L. innocua) are not considered pathogenic for humans or animals (hazard group 1). The attenuated L. monocytogenes (prfA, plcA, hly, plcB, actA) derivative lacks several critical virulence genes and consequently is entirely avirulent and non-pathogenic. The multiple gene deletions in this L. monocytogenes derivative guarantee that it is stably attenuated, there is no real possibility of reversion, and thus is a totally safe host strain.

Thanks to our participation in the Listeria sequencing projects we have precise information on the putative activities of the products encoded by L. monocytogenes. None of the L. monocytogenes genes code for known dangerous toxins, highly aggressive virulence factors or harmful products which can act directly to cause damage, allergy, oncogenesis or growth modulation. In the case where they do contribute to virulence, their role in infection is always subtle and they need to act alongside a number of other virulence and regulatory factors with which they have co-evolved in the source organisms. Therefore, the risk for one of the above heterologous non-pathogenic host organisms gaining virulence by introduction of L. monocytogenes sequences is negligible. Although in principle they might be handled under containment level 1, as a precaution and because they will be handled in parallel with the other bacteria, they will effectively be worked under containment level 2.

The miscellaneous bacteria that we may incorporate in our experiments all have disabling mutations that attenuate their virulence. S. typhimurium SL1344sifA, lacking the protein SifA required for the maintenance of the vacuole in which Salmonella replicates intracellularly, shows impaired replication in macrophages. The S. flexneri icsA derivative SC560 is virtually non-pathogenic (in fact one of its derivatives, strain SC602, is used at the institut Pasteur as the basis for the development of a vaccine against Shigella infection in humans). Yersinia enterocolitica WA-314, with disabling mutations in the virulence-associated sodA and irp genes, has impaired capacity to survive in vivo in animal tissues and is also used as the basis for a live oral vaccine. Nevertheless, these bacteria can have some residual virulence and therefore will be handled under the containment level required by their corresponding wild-type parental strains, which are classified in hazard group 2 (ie level 2).

The cholesterol oxidase genes choE and choD from R. equi, which are widespread among non-pathogenic actinomycetes (eg Streptomyces spp., Brevibacterium sterolicum), and the uhpT gene from S. typhimurium, encoding a sugar phosphate transporter also widely distributed among bacteria, are not expected to confer any virulence property to a non-pathogenic heterologous host.

The resistance genes used as selection markers in the cloning vectors have been approved for use at containment level 1 and confer resistance to "old" antibiotics for which resistance in clinical isolates is already widespread (and therefore are no longer used in clinical practice).
Hazards to the environment
None of the bacteria we will work with are exotic to the UK, are pathogenic to plants, or cause notifiable diseases under specific surveillance by DEFRA. They are already ubiquitous in the environment and are frequently carried by healthy animals. In some cases they may cause opportunistic infections in these animals.

The gene-disabling mutations introduced in the bacteria (in most cases by in-frame deletion, which does not leave any trace of foreign DNA) should normally lead to attenuation in vivo. Although these mutants may retain some of the original virulence of the parent strains, they will complete less well within an animal host and will be cleared from the infected tissues sooner than the wild type. The risk of pathogenicity is therefore reduced and less important than with the corresponding parent strain. The loss of a trait or genetic sequence that has been selected for through evolution is likely to reduce the fitness of the gene-deleted derivative to establish and survive in nature. Consequently, the gene-disabled derivatives, if accidentally released to the environment, are not expected to displace any indigenous population.

Listeria or R. equi bacteria in which the original phenotype has been restored by introduction of the wild-type allele in a plasmid vector always tend to lose these constructs because the vector is not naturally adapted to these host bacteria and represents a physiological burden (being thus rapidly lost in the absence of selective marker pressure). The non-pathogenic cloning hosts containing sequences from Listeria or R. equi are not expected to become established or be hazardous to the environment because the plasmid vectors will not be mobilised and the foreign genes, which are derived from ubiquitous soil dwelling bacteria, are already present in nature as a result of natural decay processes.

The likelihood of accidental environmental release of the GMMs is very low or negligible given the measures that will be applied to control any risk to human health and safety (level 2 containment). If release was to occur, the consequences can also be graded as very low or negligible. Therefore, the environmental risk can be judged as effectively zero.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
The GMM-contaminated waste will consist of broth/agar cultures, plastic labware and glassware. All this material will be inactivated in the building by autoclaving at 121 degrees C for 20 min (100% kill) prior to disposal or recycling. Carcasses of experimentally contaminated animals will be incinerated on site (100% kill). Non-contaminated general waste generated in the containment level 2 facilities and thus potentially exposed to the GMMs will be incinerated.

Please enter comments on the GM safety committee on the risk assessment
Discussed at Committee meeting of 19 February 2003 - extra information required re target genes and comment re pregnant workers suggested.
The research project aims to define the role of alternative pathways in the mitochondrial respiration of filamentous plant pathogenic fungi. It involves cloning genes coding for alternative oxidase and alternative NAD(P)H dehydrogenase, and exploring function through inactivating either gene and comparison with the wild-type in biochemical and infectivity assays. The coding sequence will be disrupted by insertion within each gene of non-coding plasmid DNA. The plasmid construct will also contain a hygromycin resistance gene from E.coli, allowing direct selection of fungal transformants. Sequence identity between the fungal gene and flanking coding sequences of the disrupted gene will allow the targeted replacement of the wild-type gene with the inactivated one. In separate experiments linked reporter genes such as GFP will be cloned into the 3' -end of these fungal genes, in order to define the spatial relationship of alternative components and the core respiratory chain.
Botrytis cinerea (grey mould) laboratory haploid strain Bo5.10
Mycosphaerella graminicola (wheat leaf blotch)

**Host/vector system**

The fungi will be transformed by integrating vectors based on pUC, using protoplast based procedures.

**Origin & function**

The selectable marker for fungal transformation driven from a variety of fungal promoters will be hygromycin B phosphotransferase from E. coli. Green Fluorescent Protein (GFP) from the jellyfish Aequorea victoria will be used as a reporter gene for visualisation of hyphae. The plasmids for construction of gene replacement vectors will carry the E. coli hygromycin resistance gene. This will be under the control of either the promoter and terminator for B. cinerea B-tubulin, or the oliC promoter and trpC terminator from Aspergillus nidulans. Constructs will be based on standard E. coli plasmids, namely pUC and pBluescript.

**Evaluation of foreseeable effects**

Neither of the fungi under study is a pathogen of man or animals. There is no reason to suppose that any of the modifications to be performed will lead to human or animal pathogenicity. Thus there is no risk to health from this work and the containment measures are being used solely for environmental protection. Transformation of the fungi per se is likely to be neutral in effect. The transformation markers do not involve resistance to commercial fungicides, so the resulting transformants are unlikely to have an advantage over untransformed strains. Introduction of reporter genes is unlikely to give the transformant any advantage over wild-type strains. Inactivation of genes by targeted disruption or insertional mutagenesis is likely to be detrimental to the fungus and will certainly not provide a long term advantage compared to wild-type strains.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste generated by this work will be autoclaved prior to disposal. Any spillages of cultures will be decontaminated by treatment with hypochlorite (3-5 %), while all swabbing materials will be autoclaved prior to disposal. Any potential contaminated surfaces will be sterilised by swabbing with 70% ethanol.

### Purposes of the contained use

The research project involves analysis of the organisation of intracellular membranes and the study of the trafficking of molecules between these membranes along cytoskeletal filaments. It involves cloning of markers of intracellular structures and reporters to monitor transport between these structures. Coding sequences will be inserted into replication defective adenoviruses and baculoviruses for the production of proteins in mammalian and insect cells. Markers and reporters will be cloned as fusions with autofluorescent protein coding genes such as that for GFP from the jellyfish Aequoria victoria. This will facilitate imaging of the interrelationships between
these structures and the mechanisms by which transport between compartments occurs.

Recipient or parental organism

Adenovirus (replication defective)
Baculovirus (replication defective)
E. coli
Cultured mammalian cell lines.

Host/vector system

AdEasy adenovirus expression system (Stratagene); viruses generated will be used to infect mammalian cells.
Bac-to-Bac baculovirus expression system (Invitrogen); viruses generated will be used to infect Spodoptera frugiperda cells (Sf9 and Sf21).
Constructs are based on standard E. coli cloning vectors namely pUC, pBR and pBluescript.
Expressed genes will be under the control of polyhedrin and/or p10 promoters in baculovirus and CMV or SV40 promoters in Adenovirus constructs.

Origin & function

Genes encoding markers of membranes and transport pathways will be cloned from mammalian cDNA libraries or obtained from collaborating labs. Where possible, human cDNAs will be obtained (eg COPI and COPII, cytoskeletal markers, Golgi markers;)
GFP from Aequoria victoria, HcRed from Heteractis crispa and DsRed from Discosoma sp. And spectral variants thereof will be used as fluorescent reporters.

Evaluation of foreseeable effects

Adenoviral vectors are capable of infecting human cells. However, the virus used is replication defective. It has been generally accepted that baculovirus cannot infect animal or plant cells however, some recent studies do show a capability for expression of genes from mammalian promoters from baculovirus vectors. Mammalian promoters will not be used in these baculovirus studies. Baculoviruses used are polyhedrin negative and therefore susceptible to insect larval gut conditions, desiccation and environmental conditions such as UV light. The majority of inserted genes are not known to be pathogenic and are unlikely to modify the properties of the host.
Overexpression of inserted genes could result in general disruption of intracellular membrane and cytoskeleton organisation, signalling and ion transport.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste generated by these procedures will be autoclaved prior to disposal.
Any spillages of liquid will be decontaminated with 5% HiSpec. solution and all swabbing material autoclaved before disposal.
Any potentially contaminated surfaces will be sterilised by swabbing with 70% ethanol.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
Project discussed at meeting 19 February 2003, agreed project should be notified because baculoviruses can infect mammalian cells and even though this is a polyhedrin minus strain it contains full length sequences that are biologically active ie could be a hazard to the worker.

Origin & function

Genetic material will be derived from FFV strain F17, obtained from the American Type Culture Collection (ATCC VR889). The virus will be used in infection studies and manipulated by standard molecular techniques to create replication competent and replication incompetent viral vectors.

1. The entire genome of feline spumavirus (FFV, strain F17, a wild type strain) will be cloned into pCR2.1 and pSport1 (Invitrogen) and transformed into DH5alpha and Stbl-2 E. coli (Invitrogen). The plasmid will be isolated from small scale culture (10ml) and checked by transfection into CRFK and FKCU feline cell lines. Production of wild type virus produces CPE in these cells.

2. Removal of the Bel 1 (transactivator) gene from pCR2.1/F17. This will be undertaken using conventional restriction enzyme digestion or site directed mutagenesis to insert multiple stop codons into the sequence.

3. Insertion of a CMVpromotor-eGFP-polyA signal expression cassette into the region vacated by the Bel 1 gene and transformation of Stbl-2 E.coli and small scale culture and plasmid purification.

4. Cloning and expression of the Bel 1 gene (transactivator) from FFV/F17 in pQE30 and pQE31 (Qiagen) with expression in XL1-blue and M15 (prep4) E. coli (Stratagene and Qiagen). Also cloning and expression of the Bel 1 gene using the Gateway cloning system (Invitrogen) and pDonr 201 and pDest 17 with expression in BL21-SI E.coli.
5. Construction of a helper cell line for the propagation of replication deficient FFV. The Bel 1 gene of FFV will be cloned into pHook3 (Invitrogen) and transfected into CRFK and FKCU feline cells. Cells containing the plasmid will be selected by Zeocin resistance and cloned by limiting dilution. We will also transfet CRFK and FKCU cells with pHook3/beta gal (a control plasmid in the kit) and stain for beta gal expression.

6. Stably transfected CRFK and FKCU cells thought to be expressing Bel 1 (see 5) will be transfected with the reporter plasmid pLTRI(FFV)B-gal (a plasmid containing the LTR of FFV controlling the B-galactosidase gene. A gift from Prof A Rethwilm, University of Dresden, Germany). pLTR1(FFV)B-gal will be grown in DH5alpha E.coli CRFK or FKCU cells expressing Bel 1 will switch on the LTR and cause expression of B-gal which can be detected by staining.

7. Stably transfected helper CRFK and FKCU cells shown to be expressing Bel 1 (from 6) will be transfected with pCR2.1/F17eGFP (from 3). These cells should produce viable viral particles able to infect other feline cells. Viral CPE will be monitored and virus harvested and transferred to fresh CRFK or FKCU cells where the eGFP gene should be delivered, as monitored by eGFP fluorescence. There should be no viral replication in these cells since they lack the Bel 1 gene and this will be monitored by serial passage into fresh cells.

8. Insertion of a V5 epitope (gly-lys-pro-ile-pro-asn-pro-leu-gly-leu-asp-ser-thr) into the ENV and GAG genes of the parental FFV F17 virus (step 1 above), growth in stbl-e cells (10-50mL) and transfection into CRFK and FKCU cells. Work to date using the plasmid generated in step 3 has not shown the production of any viral particles carrying eGFP. Hence it is proposed to insert the small V5 epitope into the ENV and GAG genes of the parental viral clone generated in step 1 and monitor viral production by immunofluorescent microscopy. It is hoped that this change will be less "invasive" and allow production of viable viral particles. The V5 epitope is a tag and will allow detection of the modified virus, it has no biological activity and would be unlikely to change the viral pathogenicity. Recent work on the insertion of the V5 epitope into the ENV gene, which could alter the viral host range, has proved unsuccessful with no viral particles being produced invitro. Further work is in progress to insert the V5 epitope into the GAG gene, it is not expected that this will alter the host range or pathogenicity. Due to the very limited amount of time remaining on this project it is not anticipated that any other sequences or genes will be cloned into the parental FFV plasmid. Should it become possible to use other genes we will notify the change to the HSE.

9. Expression of FFV GAG, POL and ENV proteins in baculovirus. The GAG, POL and ENV genes from FFV F17 will be amplified by PCR and cloned into the Gateway cloning system (Invitrogen) using pDonr 201 and growth in DH5a E.coli. The resulting plasmids will be used to generate baculovirus expression vectors using the pDest 10 vector and DH10Bac E.coli (Invitrogen). The resulting baculovirus will be grown in SF9 insect cells.

10. Depending on the results of the invitro work to generate modified spumavirus (all of which have failed to date) future work will aim to use these modified vectors as gene delivery systems in the cat. However, due to the limited time left on the project it is unlikely to progress to the cat model system. If it were to become possible to use the cat model system we would notify any change to the HSE.

**Evaluation of foreseeable effects**

Feline foamy virus (FFV) has not been well classified and has hence been assigned to containment level 2. There is no evidence of feline spumavirus infection in humans (Butera et al., 2000, Winkler et al., 1997) and this hazard is considered negligible (Rethwilm, 1996), with infection of humans by FFV not having been reported, despite serological investigations of high-risk groups (Butera et al., 2000).

There is no conclusive evidence that feline spumavirus is a pathogen of cats (Alke et al., 2000, Pedersen et al., 1980, Winkler et al., 1999). FFVs are endemic in the cat population with no evidence of disease causality (Alke et al., 2000 Liniel, 2000, Meiering & Liniel, 2001). The greatest risk of spread would be to the feral cat population. However, FFV is cell associated and spread by contact or droplet, not by air. Cell free virus does not survive in the environment. Hence it is unlikely to spread outside the laboratory, especially when handled under containment level 2 conditions. FFV with a V5 modification would be replication competent, but again would be handled under containment level 2 and no hazards are associated with the V5 epitope.

FFV has not been shown to be pathogenic in cats and hence is unlikely to be pathogenic in other species. FVs experimentally infected into alternative hosts (HFV into rabbits) has been reported as non-pathogenic (Saib et al., 1997), with virus persisting in a defective form.

It is possible for baculovirus to express proteins in mammalian cells, but only when mammalian promotors are use. Hence there is a possibility of gene transfer (FFV GAG, POL and Env) to cats and humans. However, the GAG POL and ENV genes are not modified and the polyhedrin promoter will be used, so expression of these gene
products in humans or cats is unlikely. Recombinant baculovirus lacks the polyhedrin gene making it very susceptible to UV light, desiccation and digestion by insects. Its infectivity is also much lower than the parental virus.

The Bel1 gene is a transactivator. There is very little identify with the transactivator of human FVs, hence it is unlikely that Bel1 could control HFV. The eGFP, GAG, POL and ENV genes and V5 epitope pose no hazards. Alterations to the FFV envelope gene (insertion of a V5 epitope) may change the host range of the virus. Expression of FFV GAG, POL and ENV in baculovirus are unlikely to alter its host range.

REFERENCES

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be disposed of by autoclaving. Tissue waste will be bagged and incinerated. Liquid waste will be treated with fresh 1% Virkon (for FFV and baculovirus) or autoclaved directly (for bacterial work). Glass pasteur pipettes will be immediately discarded into a glass sharps bin for incineration. 70% ethanol will be applied to surfaces for use with E. coli and 1% Virkon for use with spumavirus and baculovirus. Also 10% Microsol (Anachem) will be used for culture surfaces (Incubator and laminar flow hood). Both Virkon and Microsol disinfectants will be used in accordance with manufacturer's recommended instructions to ensure 100% kill. Cultures of E. coli will be handled in a tray to contain spillages. Local rules for handling spills will be followed. Areas will be decontaminated with the appropriate disinfectant (see above). Contaminated lab coats will be placed in autoclave bags and autoclaved prior to washing.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
This project was initially approved at containment level 1 in July 1994. Following the GM inspection in November 2002 the Committee were asked to review the risk assessment. As a result of the meeting of 19/02/03 it was decided that all work with viruses would be Class 2 unless they were sufficiently disabled and could therefore be downgraded to Class 1. Discussion re spumaviruses decided that the virus was not well classified and should therefore be a class 2 project and notified to the HSE.

Significant Change ID 18/04.6

Date of Significant Change 07/09/2004
Purposes of the contained use

The aim of this project is to modify the Invitrogen Lentiviral "Gateway" vectors pLenti6/V5-DEST and pLenti4/V5-DEST (encoding blasticidin and zeocin resistance respectively), to create vectors that will allow the control of cloned gene expression (via LacO/LacR and IPTG) in cell lines and transgenic mice stably expressing the lac repressor (characterised in GMMs by Amann et al., 1983).

This will be achieved by the removal of the indigenous CMV promoter from the vectors and its replacement with the SV40 LacO promoter (SV40 promoter containing a lac repressor binding site between the TATA box and start of transcription - created by Hu and Davidson, 1987). This promoter is completely inactive within mammalian cells expressing lac repressor from the SyunLacR construct (lac repressor gene flanked by non-coding mouse B-globin sequences - created by Cronin et al, 2001), and active when IPTG (non-toxic lactose homologue) is added to remove lac repression. This promoter is also active within cells that do not express Lac repressor. The promoters UbC (Ubiquitous), Pax, Hox, H19, Oct4 and Nanog (stem cell-specific) are also to be modified with the lac repressor binding site and inserted into the pLenti vectors.

These regulatable vectors will be further modified to include an internal ribosome entry site (IRES) and yellow fluorescent protein gene (EYFP) downstream of the vector's multible-cloning "att" sites. The IRES-EYFP-poly A will removed from Clontech's pIRES-EYFP vector to achieve this. This feature will allow monitoring of the effectiveness of the inducible system via plasmid cotransfection experiments, and will add an important safety feature - if a worker were to contaminate their skin with lentivirus, the infected area would glow bright yellow under 513nm light (as produced by a standard fluorescence microscopy bulb). The EYFP protein is thought to be harmless as healthy transgenic mice that express it are readily producible (Hadjantonakis et al., 2002).

Initial cloning procedures will be performed in non-pathogenic, competent DH5a E.coli (Invitrogen).

Subsequent introduction of genes for expression into the pLenti vector "att" sites will be performed using pENTR plasmids and the Invitrogen Gateway recombinase-based cloning system. Non-pathogenic competent DB3.1 E.coli (Invitrogen) will be used for these latter cloning procedures. Human insulin-like growth factor 2 (IGF2 - over-expressed in a variety of cancers), IGF2R (Potentially anti-cancerous) or oncogene-silencing siRNA genes (Cancer Research UK), Luciferase, B-galactosidase, viral thymidine kinase are the genes that are to be introduced into these modified pLenti vectors.

The engineered pLenti vectors will finally be used to create replication-deficient lentiviruses using the Invitrogen VirPower kit. These lentiviruses will be used to infect and stably transduce mouse stem cell lines expressing lac repressor. Transduced mouse stem cells may be used to create transgenic mice following bastocyst injection, or to generate teratocarcoma tumours, when expanded cell populations are injected under the kidney capsule.

Recipient or parental organism

The bacteria to be used for cloning pose no hazard. The lentiviral vector does. It is non-replicative and non-pathogenic, but could trigger cancer or disease by random insertional mutation of human chromosomes. Once stably transduced into a cell, the lentiviral vector is present permanently, and the infected cell may not be detected by the immune system. If transduced into a germline cell or gamete it could become heritable. High titre viruses used in human gene therapy have resulted in insertional mutagenesis and leukaemia (Hacein-Bey-Abina 2003). The number of separate integration sites varies, but can be up to 20 depending on number of competent infectious particles. One way of limiting the number of viral integrations, and consequently the risk of insertional mutagenesis, is to adopt low viral titres for experimental testing and to adopt a split-component strategy with self-inactivating LTRs as described (Connolly 2002, Hacein-Bey-Abina 2003). Further, the presence of an insert means there is a possibility that lentivirus particles with altered physical properties could be generated, eg due to the presence of a transgene product on the viral envelope. To present this, only cells stably-expressing the SynLacR repressor will be used for lentiviral work.

One cells have been stably infected by viral integration, growth in culture will facilitate testing of cell phenotype in vivo. Infection and selection of mouse embryonic stem
Host/vector system

The LTR promoters in the pLenti vectors are disabled and the vector can only be packaged into infectious lentivirus particles inside SV40 large T antigen-expressing 293FT cells cotransfected with plasmids pLP1, pLP2 and pLP/VSVG (Invitrogen). The virus particles obtained can infect and stably transduce any mammalian cell, yet are completely replication deficient and lack any viral pathogenicity. The virus genomes also lack any substantial regions of homology to any other viruses, and self-disable their 3LTR upon chromosomal insertion, making recombination with active viruses very unlikely. Whilst these modifications improve the safety of these vectors, they are also more efficient and should retain the same containment approach as retroviral vectors.

The E. coli strains that will be used are all non-pathogenic K12 derivatives.

The plasmid vectors all have a safe history.

The inserts may code for proteins that are harmful to humans if over-expressed.

The lentiviruses, although non-replicative and made safe in many ways, are still potentially hazardous to humans.

In a breach of containment the lentivirus is a risk to human health, although not to the environment. The lentivirus is non-mobilisable and self-inactivating.

Origin & function

The most hazardous part of this project will be the creation of a lentivirus that expresses the human IGF2 gene (Obtained from ATTC or similar scientific sources). This is both a growth factor and oncogene (Hassan and Howell, 2000; Burns and Hassan, 2001). The creation of lentiviruses that express IGF2R or anti-cancer siRNA genes are potentially less hazardous, but still a danger. During these stages of the project (where infectious viral particles are present), stringent containment level 2 safety procedures will be followed. The genetic modifications will neither broaden the host range of the lentivirus nor alter pathogenic traits and tropism.

Use of an inducible system with lac repressor, lac operator modified promoters and IPTG with fluorescent reporter genes means the hazards are minimised. The functions of cancer promoters such as IGF2, and promoters of cancer regression (siGF2R) will be tested in mouse primary cells (fibroblasts and embryonic stem cells), embryos and transplanted tumours. The ultimate aim is to establish novel therapeutic proteins for the treatment of human cancer, delivered by protein infusion and not by these types of vectors.

Evaluation of foreseeable effects

One cells have been stably infected by viral integration, growth in culture will facilitate testing of cell phenotype in vivo. Infection and selection of mouse embryonic stem cells will facilitate the use of this technology to the generation of germline transgenesis. This will be achieved by injection of embryonic stem cells into the blastocyst to generate chimeras. No risk of furthe viral particle production is expected, as the vectors are all self-inactivating (Pfiefer et al 2002). The gene IGF2 should promote cell growth in all systems, with increased survival and proliferation of cells, increased in the size of mouse embryos. The antagonist, IGF2R, should prevent this occurring. Therefore, the considered inserts are potentially harmful to mammals. IGF2 is a growth factor and a potential oncogene. IGF2R is a membrane receptor for IGF2. siRNA genes that silence oncogenes may have undesirable effects in mammalian stem cells. IRES-EYFP is thought to be harmless. The presence of an insert also raises the possibility of creating recombinant lentivirus with altered physical properties (eg through expression of a transgene product on the envelope). To prevent this, only cells stably-transfected with SynLacR will be used for lentiviral work. Mutagenesis secondary to viral integration may occur, but the risk of this will be lessened by using low viral titres to infect. Careful monitoring of tumours and embryos will be performed to identify such events.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Work involving tissue culture cells and lentiviral particles has been provisionally assigned to containment level 2, but as potentially oncogenic viruses may be generated, additional physical barriers will be adopted to further minimise accidental exposure.

(1) GMM lentivirus production will occur in a lockable, HSE-specified containment level 2 tissue culture laboratory (F55, Pathology and Microbiology). There will be dedicated and labelled incubator, fridge and freezer space that will only be used for lentiviral work. There will be appropriate biohazard labelling, fly screens, a rodent control program, eye wash (along with other first aid provisions) and a notice of emergency contact telephone numbers and procedures. All workers will have appropriate training.
HSE biological containment level 2 guidelines are to be strictly adhered to.

Work involving open containers of lentivirus is to be carried out inside a services, labelled level 2 containment safety cabinet, that will not be used for any other work until first cleaned with 1% Virkon, then 70% alcohol, then internally treated for at least 1 hour with UVC light. The cabinet will be treated with formaldehyde fumes (outside working hours) prior to servicing.

A notice will be placed on the lab door prior to work in progress.

There will be no glassware, blades, needles or sharps used in work involving lentivirus particles.

Only 5 experienced molecular biologists may work with the lentivirus particles: Bibe are unnybicinorinuses,

Great care will be taken not to contaminate the mouth, skin or eyes with lentivirus.

There will be a surgical washbasin in the lab with handwash containing alcohol. Hands must be washed and dried before exiting the lab.

1% Virkon and 70% alcohol sprays will be kept to hand at all times for cleaning purposes and for decontamination of spillages. 70% alcohol is not to be sprayed near flames.

Workers must wear clean lab coats, goggles, surgical masks, and two layers of disposable blue vinyl gloves, which must be carefully removed (one layer at a time) for autoclaving after use. These protective items are not to be worn outside the tissue culture lab. Gloves must not be used to handle "clean" surfaces (eg telephone)

Splashes and the creation of aerosols will be avoided.

Screw-on caps are to be used to cover centrifuge rotor heads when in use.

Spills and accidents will be reported to the laboratory director.

Animals not involved in the work are not permitted in the lab.

ADDITIONAL MEASURES

A Bunsen is to be lit near any work involving unopened containers of lentivirus on the bench (eg study of lentivirus-producing tissue cultures under the microscope). This is to help protect workers from any aerosol resulting from accidental spillage.

Production of lentiviral transduced cells will be performed in bulk to minimise the number of times people are exposed to risk.

Containers (eg freezing vials) of lentivirus are not to be more than half-filled and always stored upright, in order to avoid contamination of lids (and subsequently of fingers).

Lentivirus work will always be stored on a bottommost shelf, so as to prevent any spillage contaminating work below.

Stable-transductants are not to be removed from the containment level 2 lab until they have been pelleted and washed at least ten times (in ten volumes of medium).
This should greatly reduce the number of infectious viral particles potentially present, but their presence can never be completely ruled out (by any test). As all constructs will have reporter genes, these will be used to determine the potency of viral integration.

(xx) Matrigel will be used to contain stably transduced cells for transplant into mice.

(xxii) If a worker suspects they have contaminated their skin with lentivirus, they should spray the affected area thoroughly with 70% alcohol, rinse thoroughly with water, then wash with soap. The skin should be subsequently monitored with 513nm light to see if there is any yellow fluorescence. If there is, this area could ater (if oncogenicity is suspected) be treated by laser surgery. Because lentivirus is an enveloped virus, alcohol or soap should be sufficient to inactivate it. Virkon is not suitable for use on human skin.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1. Liquid waste containing cellular debris and viral particles will be treated with 1% Virkon; plastic pipette tips and disposables will be completely submerged in 1% Virkon in a container in the safety cabinet for at least 1 hour prior to autoclaving and disposal. This applies to primary cell culture media, and post-cell wash supernatants which contain viral particles. All disposal will be performed within the dedicated class II tissue culture facility.

2. There will be a labelled, leak-proof stainless steel autoclave bin (with sealable lid) exclusively for the autoclaving of waste from the lentiviral work.

3. Any equipment used to work with stable transductants must be thoroughly cleaned after use (e.g. a flow cytometer should be flushed-through with paraformaldehyde, then extran, then water. The waste tank should be treated with Virkon prior to disposal of run-off).

Is an emergency plan required according to regulation 20? N

Tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Discussed at committee meeting of 18 Feb 2004 and agreed that it was a class 2 activity and therefore should be notified to the HSE.

Project Additional Information

Purposes of the contained use

The aim of the project is to enhance the quality of tissue engineered cartilage using gene transfer technology. Sense and antisense sequences of genes of interest will be transferred to mammalian chondrocytes or bone marrow stromal cells. These cells will be seeded onto scaffolds and incubated to generate a new engineered cartilage. Transient expression of sequences will be achieved using commercially available plasmid-based vectors while for long-term expression a commercially available pantropic retroviral vector system will be used. These gene-modified cells will be used for in vitro studies only.

Recipient or parental organism

A Pantropic Retroviral Expression System (Clontech UK) will be used to stably introduce recombinant DNA into dividing cells. This system produces high-titer virus capable of infecting the broadest possible range of mammalian and nonmammalian cells. The Pantropic System uses VSV-G, an envelope glycoprotein from the vesicular stomatitis virus that is not dependent on a cell surface receptor; instead, it mediates viral entry through lipid binding and plasma membrane fusion. The cell line included with the system is GP2-293, and HEK 293 based cell line. The cell line stably expresses the viral gag and pol proteins, but since the VSV-G envelope protein is somewhat toxic to cells, it is not integrated into the genome of the cell line. GP2-293 must be cotransfected with pVSV-G and an expression vector to produce high-titer, replication-incompetent virus. Virus produced can infect target cells and transmit target genes; however, it cannot replicate within target cells because the viral structural genes are absent. Studies of the transient expression will use standard disabled strains of E.coli for propagation of expression vectors. Target cells will include primary cells of musculoskeletal origin such as chondrocytes, synoviocytes and bone marrow stromal cells. These cells pose no significant risk to health although strict ACGM level 2 guidelines will be adhered to during cell isolation from tissue.

Host/vector system

02/03/2022
Laboratory facilities

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

If infection of humans were allowed to occur the outcome could be insertional mutagenesis of host cells.

ii) Exposure to open wounds: Individuals with open wounds will not be allowed access to the tissue culture facility.

i) Needle stick injuries: This project however does not require inoculation using needles and therefore there is no risk of needle stick injury.

The pantropic viruses produced are defective and helper-free. Although not infectious from one human to another they do not have the potential to infect humans through:

- experimental procedures involving the use of human tissue will be carried out in an ACGM category II facility.
- VSV-G envelope protein is toxic, this protein is expressed transiently from pVSV-G. Although the virus can infect target cell lines and transmit a target gene, it cannot replicate because the target cell lines lack the viral structural genes. The separate introduction and integration of the structural genes into the packaging cell line minimizes the chances of producing replication-competent virus due to recombination events during cell proliferation. By using the minimal viral sequences and separately introducing the structural genes into the packaging cell line, the chance of producing replication-competent virus due to recombination events is minimized.

Evaluation of foreseeable effects

The vector to be used transient expression analysis is a pUC series plasmid that is non-mobilisable and propagates in standard disabled strains of E.coli. The vector to be used for long term-expression is pLXRN. It does not contain the structural genes necessary for viral particle formation and replication. The genes encoding the viral gag and pol proteins are stably integrated into GP-293. This cell line has a safe history of use and would be rejected by human hosts if accidentally inoculated. Because the VSV-G envelope protein is toxic, this protein is expressed transiently from pVSV-G. Although the virus can infect target cell lines and transmit a target gene, it cannot replicate because the target cell lines lack the viral structural genes. The separate introduction and integration of the structural genes into the packaging cell line minimizes the chances of producing replication-competent virus due to recombination events during cell proliferation. By using the minimal viral sequences and separately introducing the structural genes into the packaging cell line, the chance of producing replication-competent virus due to recombination events is minimized.

The inserts to be used will include one of the following:

1) TGF-beta and IGF-1 - they drive cell growth and differentiation in a wide variety of cells. TGF-beta was shown to inhibit the initiation stages of oncogenesis but may promote tumour growth later. IGF - 1 is not known to have oncogenic effect on cells. The potential risk therefore of these genes incidentally transferring and expressing to human subjects is minimum.

2) Fibromodulins - these are structural proteins thought to control fibril formation during matrix synthesis by chondrocytes. Their gene product is not known to contribute or have an oncogenic activity.

3) Promoter sequences for genes such as telomerase or nucleostemin. The sequences will be cloned in a plasmid vector for transient expression to drive GFP or firefly luciferase genes. Both are established, harmless reporter genes.

The recipient cells will be primary mammalian musculoskeletal cells such as chondrocytes and bone marrow stromal cells. These cells are non-mobilisable and are therefore effectively safe. they do however carry a risk to human health that is inherent in all primary cells - they may be infected with an unknown infectious agent. All experimental procedures involving the use of human tissue will be carried out in an ACGM category II facility.

The pantropic viruses produced are defective and helper-free. Although not infectious from one human to another they do not have the potential to infect humans through:

- Needle stick injuries: This project however does not require inoculation using needles and therefore there is no risk of needle stick injury.
- Exposure to open wounds: Individuals with open wounds will not be allowed access to this culture facility.

If infection of humans were allowed to occur the outcome could be insertional mutagenesis of host cells.

Origin & function

A variety of genes will be inserted in either vector. The genes of their antisense can be divided into 3 categories: 1) Growth and differentiation genes: this will include TGF-beta and IGF-1. Both are established growth factors that enhance matrix synthesis by chondrocytes and drive the differentiation of bone marrow stromal cells to chondrocytes. Such growth factors may be involved in promoting tumours activity, however their role in initiating tumours is unknown. 2) Structural genes: these include fibromodulins such as decorin, lumican and fibromodulin. these are small leucine rich proteoglycans believed to control collagen fibril size during fibrillogenesis. 3) Promoter sequences: this includes telomerase gene promoter and nucleostemin gene promoter. The study will involve detecting telomerase activity or nucleostemin expression in transfected cells using vectors encoding green fluorescence protein (GFP) or firefly luciferase protein under the control of each gene-specific promoter. The promoter sequences should not have adverse effects on transfected cells since they do not drive the endogenous genes.

For long-term expression studies, the vector to be used is pLXRN from Clontech (Catalogue K1063-1). It contains elements derived from Moloney murine leukemia virus (MoMuLV) and Moloney murine sarcoma virus (MoMuSV), and is designed for retroviral gene delivery and expression. The vector contains the extended retroviral packaging signal, w+, which promotes high-titer virus production and long terminal repeat (LTR) promoter for driving high level expression of target gene. pLXRN can be cotransfected with pVSV-G into the GP-293 Packaging Cell Line (Burns et al 1993) to produce infectious, replication-competent pantropic retrovirus. Dr Jane Burns, the creator of the system, has provided us with written approval for transducing human cells using this system. Indeed, the system has recently been used to infect huan bone marrow stromal cells in vitro (Transfiguracion et al 2003). For transient expression studies, pUC series plasmid vectors, such as pcDNA6 from Invitrogen (Catalogue V22220), will be used. These vectors are designed for overproduction of recombinant proteins in mammalian cells under the control of promoters such as the cytomegalovirus (CMG) promoter or the human elongation factor -1 (EF-1) promoter.
The Academic Rheumatology Group is based on the ground floor of the Avon Orthopaedic Centre at Southmead Hospital, Bristol which is accessible to University staff only. All experimental procedures using the retroviral vectors to transfect human cells, as describe in the attached risk assessment, will be carried out in a recently refurbished ACGM category II facility that is accessible only to trained scientific personnel. As well as negative air pressure generated by the Class II cabinets within the facility, this lab has been designed with and anti-room to prevent the air within the laboratory mixing with the air outside.

Personal exposure
To prevent exposure of skin to naked DNA personal protective clothing (fully-fastened Howie coats, gloves and safety spectacles) will be worn during the experimental procedure. Sharps and needles are not required for this procedure and therefore will not pose a risk. Tissue culture flasks will only be opened inside a class II safety cabinet that undergoes a routine safety check and KI inspection every 6 months.

RISK
When high class II containment levels and controls are in place the risk will be LOW-EFFECTIVELY ZERO.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Means of Inactivation
All solid waste used in this project (plastic pipettes and tissue culture flasks) will be soaked in a 1:100 dilution of Virkon S, and anti-viral agent commercially available from Antecint International. Details of virucidal properties against retroviruses are available on http://www.antecint.co.uk/. Briefly, testing of Virkon against retroviral vectors was carried out at the Central Veterinary Laboratory in November 1997 and a 1:100 dilution was shown to be effective against retrovirus. After soaking in 1:100 dilution of Virkon S for 24 hours the solid waste will be autoclaved at 120 degrees for 15 mins prior to incineration. The autoclave is housed in a small room adjacent to the tissue culture facility. All liquid waste will be treated with Virkon at the appropriate dilution then autoclaved. These measures will be expected to result in 100% kill of retroviruses or their host cells.

### Project Additional Information

**Purposes of the contained use**

The purpose of this project is to understand how regulatory proteins control the formation and turnover of cytoskeletal structures and how these structures contribute to cellular processes such as migration. Lentiviral vectors will be used to infect mammalian immune cells with the cDNAs of cytoskeletal regulators (CRs) to assess their function in cells. Lentiviruses are very efficient vectors for this type of cell which are otherwise very hard to transfect.

**Recipient or parental organism**

The recipient cells will primarily be obtained from wild type and transgenic mice engineered to lack specific cytoskeletal regulators (for example the Wiskott Aldrich-Syndrome Protein, WASP). Immune cells will be purified from bone marrow and spleen and grown in culture. Other cell types may also be purified in a similar fashion. All murine cells/dead mice will be obtained from external sources (not from animals kept within the University). Primary human cells may also be harvested, passaged and transfected in a similar fashion.

**Host/vector system**

The vector used for transfection of cells is an HIV based lentiviral vector. This has been VSV-G pseudotyped giving it a wide cell type target range. It has a heterologous spleen focus forming virus (SFFV) LTR. It contains a U3 deletion in its 3' LTR and is self-inactivating. It is derived from the HIV provirus and has been engineered such that the virulence factors - vpr, vif, vpu and nef genes have been deleted. Pol, rev and tat gene3s are also deleted. Gag and env genes have been truncated and inactivated. Therefore, the viral RNA encompasses, from the 5’ to 3’ end, the HIV 5’ LTR, the leader sequence and the 5’ splice donor site, truncated gag, the rev response...
element (RRE) and a splice acceptor site, an SFFV promoter, cytoskeletal regulator cDNA, and the HIV 3' LTR with U3 deletion.

Origin & function

The cDNAs delivered by the lentiviral vector will be of human, bovine or rodent origin. They may be tagged at their 5' end with enhanced green fluorescent protein (EGFP). WASP/WAVE are proteins that can induce actin polymerisation within cells and are therefore capable of changing cellular morphology. They have no reported oncogenic properties. Wild type and constitutively active and inactive WASP mutants will be studied with respect to their ability to alter the actin based cell morphology of mammalian immune cells and related functions such as endocytosis. These aspects will be monitored using fluorescent microscopy. cDNAs of other regulatory proteins such as protein kinases and Rho family GTPases that impinge on cytoskeletal function may also be used. Examples of kinases used include wild type dominant negative forms of Src family kinases such as Hck. While v-src has oncogenic properties, wild type Src kinases are not known to be oncogenic. RhoGTPases are required for Ras transformation of cells but are not known to have oncogenic properties on their own. To reduce the risk of any oncogenic activity, activated mutants of these molecules will not be used.

Evaluation of foreseeable effects

The host range of the recombinant virus includes human, rat and mouse cells. The virus is self inactivating ensuring that non-specific promoter activity is eliminated. This greatly reduces the risk of non-specific activation of oncogenes following viral insertion. The virus is replication deficient ensuring that the virus will not spread should containment be breached. The insert of cDNAs do not encode active forms of any known oncogenes, significantly lowering the probability that the insert of cDNA will induce oncogenic transformation of infected cells. The risk to humans or the environment should escape/infection occur is extremely low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste will be autoclaved.
All liquid waste will be treated with 10% chloros followed by autoclaving.
Surfaces will be cleaned with 10% chloros/virkon as appropriate.
All waste will be kept separate from other material.

Purposes of the contained use

The purpose of the contained use is to produce recombinant coronaviruses and autonomously replicating coronavirus RNAs (replicons) that contain defined mutations in amino acid and nucleic acid sequences. This will allow us to investigate the role of cis-acting RNA elements and individual viral proteins in the replication and pathogenesis of coronaviruses. By studying the biological and biochemical properties of recombinant viruses and replicons, our understanding of coronavirus replication and novel antiviral control agents in the future.

Experimental details

In order to produce recombinant coronaviruses and replicons, we shall use a system that is based on vaccinia virus cloning vectors (Thiel and Siddell, 2004). The basic strategy for the generation of recombinant coronaviruses can be divided into three phases.

The assembly of a full-length coronavirus genomic cDNA. This normally involves the generation of numerous subgenomic cDNA fragments that are either amplified as
bacterial plasmid DNA or prepared in large amounts by preparative reverse-transcriptase polymerase-chain reaction (RT-PCR). The cDNAs are then ligated sequentially, in vitro, to produce a small number of cDNAs that encompass the entire genome. The specific ligation strategy is dictated by the sequence of the coronavirus in question but a common feature is the use of convenient, naturally occurring or engineered restriction sites. It is also necessary to modify the cDNAs that represent the 5' and 3' ends of the coronavirus genome. Normally, a transcription promoter sequence for the bacteriophage T7 RNA polymerase is positioned upstream of the coronavirus genome and a (unique) restriction site, followed by the hepatitis ribozyme is placed downstream of the poly-A tail of the coronavirus genome. The terminal cDNA constructs must also have appropriate restriction sites to facilitate cloning into a unique NotI restriction site present in the genomic DNA of vaccinia virus, strain vNotI/tk.

The cloning and propagation of the coronavirus genomic cDNA in vaccinia virus vectors. The next stage is to ligate, in vitro, the coronavirus cDNA fragments and the long and short arms of NotI-cleaved vMptI/tk genomic DNA. This ligation is done in the presence of NotI to prevent religation of the vaccinia virus DNA. Subsequently, the ligation reaction is transfected into mammalian cells that have been previously infected with fowlpox virus. Recombinant vaccinia virus, the genome of which includes a full-length copy of the coronavirus genome, is rescued.

Rescue of recombinant coronaviruses. Essentially, recombinant coronaviruses are rescued by generating genomic-length RNA transcripts from the coronavirus component of the recombinant vaccinia virus DNA template. These transcripts are then transfected into permissive cells. The transcription reaction is normally done in vitro but it is also possible to rescue recombinant coronaviruses via the transcription of template DNA in the permissive cell itself. Also, we have found that the ability to rescue recombinant coronaviruses is significantly enhanced (but not dependent upon) the directed expression of the coronavirus nucleocapsid protein in the transfected cells.

Rescue of recombinant coronavirus replicons. Coronavirus replicons are comprised of the cis-acting elements and viral genes (the non-structural or replicase protein genes) necessary for replication and transcription of the viral RNA. They are devoid of one or more of the viral structural protein genes and, therefore cannot give rise to infectious virus particles. They are constructed as described above for recombinant coronavirus genomes and are rescued by generating replicon-length RNA transcripts from the coronavirus component of the recombinant vaccinia virus DNA template. These transcripts are generated in vitro using bacteriophage T7 RNA polymerase and are then transfected into permissive cells. They may be transiently replicated or, if a gene encoding a selectable marker is incorporated into the replicon, they may be propagated in a stably transfected cell line.

Vaccinia virus-mediated homologous recombination to introduce specific mutations into the coronavirus genomic cDNA. One major advantage of using vaccinia virus as a cloning vector is that the cloned coronavirus cDNA is amenable to site-directed mutagenesis using vaccinia virus-mediated homologous recombination. Essentially, the procedure is based on using the E. coli guanine-phosphoribosyl transferase gene (gpt) as both a positive and negative selection marker. First, a specific region of the coronavirus genome is replaced by the E. coli gpt gene. To do this, we transfect recombinant vaccinia virus-infected CV-1 cells with a plasmid DNA containing the E. coli gpt gene located downstream of a vaccinia virus promoter and flanked by coronavirus sequences that facilitate recombination. Two days post-infection/ transfection, a vaccinia virus stock is prepared and gpt-containing vaccinia viruses are isolated by plaque purification under gpt-positive selection in the presence of mycophenolic acid, xanthine and hypoxanthine. In a second step, we replace the E. coli gpt gene by the mutated coronavirus gene. CV-1 cells are infected with the gpt-containing vaccinia virus and transfected with a plasmid DNA encoding the mutated coronavirus gene. Again, after two days, a vaccinia virus stock is collected from the infected/transfected cells and recombinant viruses are isolated on HeLa-D980R cells under conditions that allow for the selection of vaccinia viruses that have lost the expression of gpt.

Recipient or parental organism

**Donor organisms - non-recombinant coronaviruses**
**Parental organisms - non-recombinant vaccinia virus (strain WR), non-recombinant fowlpoxvirus.**

**Recipient organisms - recombinant coronaviruses (GMO), Recombinant coronavirus replicons (GMO).**

In addition, subgenomic coronavirus cDNA fragments will be cloned in E. coli K-12 derivative DH5a using plasmids of the pUC, pBluescript, pGEM, pBR322 and prSET plasmid lineages. This work is registered as Project 618 at the University of Bristol and has been approved at ACGM containment Level.
Non-recombinant coronaviruses
Coronaviruses are enveloped, positive strand RNA viruses that are associated with respiratory and enteric disease in animals and man. In livestock and companion animals, coronaviruses are responsible for diseases of economic importance and they represent a significant burden on animal health and welfare. Coronaviruses are generally considered to be species specific, although the possibility of zoonotic transmission to humans clearly exist. PLEASE NOTE: THIS APPLICATION DOES NOT INCLUDE THE SEVERE ACUTE RESPIRATORY SYNDROME CORONAVIRUS (SARSCoV).

Vectro organisms - recombinant vaccinia virus (GMO) recombinant N-protein expressing BHK cells (GMO)
Host organisms - non-recombinant BHK cells, human MRC-5 cells, human HRT-18 cells, monkey CV1 cells, murine 17 clone 1 cells, avian CK cells, freline FCWF cells, porcine ST cells, canine A72 cells.

Coronaviruses are pleomorphic but roughly spherical enveloped particles, 120-160 nm in diameter with a characteristic 'fringe' of surface projections 20 nm long. The genome of coronaviruses is a positive-strand RNA molecule of c. 27 000-31 500 nucleotides. The coronavirus genomic RNA has a 5' cap structure and is polyadenylated at their 3' end. The genomes of coronaviruses contain between 6 and 11 functional ORFs. The easiest to define are those located toward the 3' end of the genome, encoding the structural proteins: the surface (S), membrane (M), envelope (E) and nucleocapsid (N) proteins. The genomes of a subset of coronaviruses (eg HCoV OC43, MHV, BCoV) also contain an additional structural protein gene, the haemagglutinin esterase (HE) ORF. In ORFs that encode non-structural proteins, the coronavirus genome is dominated by the replicase (rep) gene (also referred to as the RNA polymerase gene or RNA polymerase locus). The replicase gene consists of 2 large ORFs encompassing 20 000 nt toward the 5'-end of the genome. In contrast to the replicase gene, the pattern and arrangement of the remaining accessory protein ORFs in the genomes of coronaviruses depend on the virus species. The 3' NTR of coronaviruses comprises 200-500 nt following the last functional ORF and preceding the polyadenylate tract.

Poxviruses
Non-recombinant vaccinia virus (strain WR)
Vaccinia virus is the prototype of the genus. Orthopoxvirus. It is a double-stranded DNA virus that has a broad host range. Multiple strains of vaccinia virus exist that have different levels of virulence for humans and animals. The WR strain, which is able to replicate in human cells, is a mouse neuroadapted derivative of the NYCBOH strain. Vaccinia virus can be genetically engineered to contain and express foreign DNA with or without impairing the ability of the virus to replicate. The outcome of accidental laboratory infection with vaccinia virus is varied. In immune persons the infection is usually mild and self-limited. In non-immune, non-immunosuppressed persons, the development of disease is largely dependent upon the site and dose of inoculation and may be mild or moderately severe. In immunosuppressed persons the infection may be systemic and severe.

Non-recombinant fowlpoxvirus (strain HP1.441)
Wild-type fowlpox viruses (FPV) cause proliferative skin lesions that are occasionally lethal in birds. The attenuated FPV strain HP1.441 was obtained from wild-type strain HP-1 by 441 passages in chick embryo fibroblasts.

Non-recombinant cell lines
A variety of continuous cell lines will be used as host organisms for coronavirus replicons. All lines have been screened for bacterial contamination, mycoplasma contamination and the production of virus particles as described by the ATCC.

Vector/recipient organisms
Recombinant vaccinia virus (GMO)
The vaccinia virus vector, vNotI/tk, has been derived from parental vaccinia virus (strain WR) by elimination of a unique NotI site in the Hind/III genomic DNA fragment F and the introduction of a new NotI site immediately after the translation initiation codeon of the thymidine kinase (tk) gene.

Full-length cDNA copies of the coronavirus genome will be inserted at this unique NotI site. The coronavirus sequences are flanked at the 5' end by a bacteriophage T7 promoter and at the 3' end by unique restriction enzyme cleavage sites (which differ depending upon the coronavirus cDNA in question) and a hepatitis virus ribozyme.
Recombinant nucleocapsid protein expressing BHK cells (GMO)

The rescue of recombinant coronaviruses is facilitated by the co-expression of nucleocapsid protein in BHK cells that are transfected with genomic RNA. In order to provide directed expression of the coronavirus N protein, we have produced stable BHK-21-derived cell lines that express coronavirus N proteins. These cell lines are based on the Tet/ON expression system and thus allow the controlled expression of the respective N proteins upon induction and doxycyclin.

Known hazards (e.g., toxicity, or oncogenicity) have not been associated with any of these proteins. Using the strategy described, we will produce a collection of mutated, recombinant coronaviruses. The mutations will be of several types. First, we will produce mutants that fail to express one or more viral genes as a functional protein. This will be achieved by deletion of the coding sequences from the genome, ablation of the cis-active elements necessary for transcription of specific mRNAs or mutation of the initiation codons for the translation of specific ORFs. Second, mutants will be produced by the alteration of catalytic site and/or structural residues when the enzymatic or structural determinants(s) of a specific protein have been identified or predicted by bioinformatics analysis. Third, we will introduce mutations that affect the structural integrity of cis-acting regulatory elements. The consequences of these mutations will be monitored in a number of different assays. In the context of recombinant coronaviruses, we will measure the kinetics and patterns of viral replication in cell culture. In collaboration with colleagues in the USA and Europe, we will also monitor the replication and pathogenesis of mutant viruses in appropriate animal models. These experiments will NOT be done in the UK. ALSO, PLEASE NOTE: WE WILL NOT PRODUCE INTERSPECIES, CHIMERIC RECOMBINANT CORONAVIRUSES. This is because it has been shown that, for example, the exchange of the murine and feline coronavirus surface protein ectodomains can alter the species specificity of coronaviruses in cell culture. We believe it is impossible to predict the biological properties of chimeric coronaviruses at the present time. In the context of the recombinant coronavirus replicons, we will monitor both replication and transcription by reporter gene assays in cell cultures.

Evaluation of foreseeable effects

Working with vaccinia virus

- The following people will be excluded from working with vaccinia virus:
  - People who have, or once had, skin conditions, (especially eczema or atopic dermatitis) or have temporary skin conditions such as burns, herpes or severe acne.
  - People with weakened immune systems, such as those are receiving steroid treatment
  - Pregnant women or women who are breastfeeding
  - People with known heart disease

- People who are allowed to work with vaccinia virus will be:
  - Regular health surveillance by the Occupational Health Nurse and referral to Occupational Health Physician if required
  - Consenting senior scientific or technical staff with training in good microbiological practice at ACGM containment level 2
  - People who are aware of the unusual stability of vaccinia virus and the most common routes of infection
  - People who are aware of the symptoms (especially skin lesions) of vaccinia virus infection and the possibility of transmission to close contacts (including pregnant women or immuno-compromised persons)
  - People wearing protective clothing, including disposable gloves and eye protection

In addition to the standard ACGM level 2 containment procedures, the following local rules will apply:

- Sharps will not be used in any procedure involving vaccinia virus.
- All manipulations with open vessels containing vaccinia virus will be done in Class II biological safety cabinets.
- Plugged pipettes and appendor tips will be used
- Transport of vaccinia virus cultures will be in sealed vessels
- Centrifugation of vaccinia virus cultures will be in sealed bottles
- Centrifuge rotors will be routinely decontamination with either 70% ethanol or 10% SDS
- Any spillages will be immediately decontaminated with 70% ethyl alcohol in water or a 2% sodium hypochlorite solution

In accordance with current practise in the UK, persons working with vaccinia virus will not be routinely vaccinated. Access to areas in which vaccinia virus is handled will be
restricted to authorised workers. All personnel with access to the ACGM level 2 laboratory will be made aware of the symptoms of vaccinia virus infection.

Please note that we have also considered using highly attenuated strains of vaccinia virus (such as MVA) as virus vectors for the coronavirus reverse genetic system. However, this is not possible because MVA has become extensively host range restricted during multiple passage in chick embryo fibroblast cells (essentially the only cell in which it will now replicate efficiently). As, in our system, the recovery of recombinant vaccinia virus from DNA is dependent upon using fowlpox as a helper virus, the use of CEF cells as a host is excluded.

The insertion of coronavirus genomic cDNA in the vaccinia virus genome

Insertion of non-expressed foreign sequences at the vaccinia virus tk locus generally attenuates the pathogenicity of the recombinant vaccinia virus compared to the parental strain. In our strategy, coronavirus genomic cDNAs will be inserted in to the tk locus, downstream from the weak, early tk promoter. Thus, vaccinia virus RNA polymerase activity could, potentially, result in transcripts that include the complete coronavirus genome and, at least theoretically, might give rise to a productive coronavirus infection. However, for a number of reasons, we consider this extremely unlikely. First, the coronavirus cDNA sequences will be flanked at their 5’ end by heterologous bacteriophage and vaccinia virus elements, which should prevent the addition of authentic “cap” structures that facilitate the infectivity of the coronavirus genomic RNA. Second, the vaccinia virus early RNA polymerase termination signal (US5NU) occurs many times in all coronavirus genomic sequences (for example 18 times in the MHV sequence). Thus, it is extremely unlikely that vaccinia virus early RNA transcription will be able to produce a full-length copy of the coronavirus template. Finally, if, against all expectations, an infectious coronavirus genomic RNA was produced in a cell that had been infected with recombinant vaccinia virus, we also think it would be extremely unlikely that a productive coronavirus infection would be established. Vaccinia virus replicates much faster than any coronavirus and essentially destroys the integrity of cellular membranes which are the sites of coronavirus replication. Field trials with recombinant vaccinia virus that express rabies virus antigens have shown that there is little evidence of animal to animal spread of vaccinia virus in the environment.

For these reasons, we are confident that even in the event of a breach of containment, recombinant vaccinia virus vectors would be unlikely to cause disease or illness in humans, animals or plants and they are unlikely to cause adverse effects in the environment.

Recombinant coronaviruses

The available evidence suggests that the ablation or mutation of coronavirus protein genes leads to attenuation of the recombinant virus. For example, de Haan and colleagues have shown that deletion of the MH V accessory protein nspX4 and nspX5a has no effect upon virus replication in tissue culture but severely attenuates virulence in vivo. Similarly, Rottier and his colleagues have shown that deletion of the feline infectious peritonitis nspX3 gene cluster, or the nspX7a and nspX7b genes attenuates virus replication in kittens but not in cell culture. Also, Lavi and colleagues have identified mutations in the surface protein gene of the murine hepatitis virus that abolish demyelination or interfere with virulence and hepatitis. Thus we have no reason to expect that deletion or alteration of coronavirus genes will increase the virulence, pathogenicity or species tropism of the virus.

Furthermore, it is well known that recombination is an important component in the evolution of coronaviruses. Therefore, it is likely that deletion mutations of the type we intend to introduce, occur at high frequency in nature. However, as they are at a selective disadvantage, these mutations will not evolve as a major component of the viral quasispecies.

For these reasons, we are confident that even in the event of a breach of containment, recombinant coronaviruses would be unlikely to cause more severe disease or illness in humans, animals or plants than the parental viruses and they are unlikely to cause adverse effects in the environment.

Recombinant coronavirus replicons

Per definition, coronavirus replicons will not produce infectious virus particles and will not have the ability to spread in the extracellular environment. Also, the replicons we produce will only be maintained within the cell under selection with antibiotic analogues. Once the selection medium has been removed, the replicons will be lost from the cell. Moreover, coronavirus replicons are non-cytopathogenic and, as far as is known, do not exert or confer any deleterious or pathogenic properties on the cell. Also, we will not introduce any replicons or sets of replicons to the cell that contain genetic elements that could, theoretically, recombine to produce infectious virus particles.

For these reasons, we are confident that even in the event of a breach of containment, recombinant coronavirus replicons would be unlikely to cause disease or illness in humans, animals or plants and they are unlikely to cause adverse effects in the environment.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All biological waste containing GMOs will be inactivated before disposal in accordance with the University Biosafety regulations. Liquid waste (used cultures, culture media, supernatants, and any other solutions which have come into contact with infectious material or live cells will be inactivated by spraying with 2% Virkon and autoclaved at 121 degrees C for 30 minutes before disposal to ensure 100% kill rate of the GMO. Contaminated glassware, re-usable plasticware (eg centrifuge bottles and tubes) and solid waste will be similarly disinfected by spraying with 2% Virkon before being autoclaved before disposal, washing or reuse. The autoclave to be used is housed in the building and is maintained regularly. Each cycle will be monitored using an approved thermosensitive testing strip. Pipettes will be disinfected before being washed in the normal manner by total immersion for a minimum of 16 hours in a pipette jar containing a freshly prepared 5% solution of hypochlorite which is made up daily. The pipette disinfection procedure will be tested before use and then periodically to ensure the disinfection procedure maintains a 100% kill rate. Laboratory coats will be autoclaved before being sent for laundry.

Materials that contain or have come into contact with parental or recombinant vaccinia virus will be double-bagged before autoclaving and, after sterilisation, will be disposed of by burning. Any spillages will be decontaminated by wiping with 70% ethyl alcohol in water or a 2% solution of sodium hypochlorite. Accidents, incidents and infections will be reported to the University Safety Officer and Competent Authority.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Agreed by Committee that use of coronavirus would require a Class II designation and thus to be notified to HSE.

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

**Project Additional Information**

**Purposes of the contained use**

The proposed work aims to study mechanisms underlying G protein-coupled receptor (GPCR) desensitisation. This will be achieved by expression of GPCRs and other related signalling molecules in mammalian cells in culture or in slice preparations of mature CNS neurons infected with recombinant viruses either directly or by prior injection into the brain of live rodents. Expression will be mediated by recombinant adenovirus when transient expression is adequate. Recombinant lentivirus will be used when prolonged expression is required and Sindbis virus for short term experiments on brain slices where very high expression levels are desirable.

**Recipient or parental organism**

Adenovirus serotype 5 with deletion of E1 gene to render it replication incompetent.

Lentivirus. The virus used is based on HIV, pseudotyped with alternative envelope proteins eg. VSV-G. The virus used is defective, requiring packing genes and the envelope gene to be provided by helper plasmids, and is engineered to be self-inactivating following integration.

Sindbis virus in which the genes encoding structural proteins have been deleted and must be supplied on a helper construct.

Rats, primary cultures of rat neurons and established mammalian cell lines will be infected with virus.

**Host/vector system**

Recombinant adenovirus and lentivirus will be injected directly into rat brain.

Recombinant sindbis virus will be injected into slices of rat brain in culture.

All three virus types will be used to infect mammalian cells in culture, including established cell lines and primary cultures of rat locus coeruleus and other neurons.

**Origin & function**

The genetic material to be expressed encodes G-protein coupled receptors, in the first instance splice variants of the rat u-opioid receptor (MOR1) and other signalling proteins.
molecules, including wild type and mutant forms of G protein-coupled receptor kinases (GRKs), protein kinase C (PKC) isoforms, arrestins, dynamin and EPS-15. These are from a variety of mammalian species, including rat, human and bovine cDNAs. Their intended function is to modify the response of MOR1 in order to elucidate the mechanism of action of morphine and other agonists of this receptor.

Evaluation of foreseeable effects

The inserted DNAs do not encode known oncogenes, however the mutant versions of these signalling molecules could potentially interfere with the function of the endogenous proteins. However, all vectors used are disabled and are highly unlikely to survive long enough in the environment for gene transfer to occur.

Adenovirus can infect humans but the use of a replication-deficient virus, a class II biological safety cabinet, an ACDP category 2 facility, the high degree of worker training and awareness and methods of waste disposal and disinfection (see below) will greatly minimise the risk to the worker. The vector used cannot replicate in host cells unless the E1 sequence is provided in trans (eg in HEK 293 cells). The risk of recombination to give replication competent virus is extremely low.

The lentiviral vectors are derived from HIV. The system proposed here uses a 2nd generation packaging system which lacks auxiliary viral genes. Furthermore, the transfer vector contains a self-inactivating sequence so that the transcripional capacity of the viral long terminal repeat (LTR) is lost after transfer to target cells. This minimizes the risk of emergence of replication competent recombinants (RCR) and avoids problems linked to promoter interference. ACDP category facilities are appropriate for these disabled viruses.

Sindbis virus has a low level of pathogenicity in humans and handling in a class II biological safety cabinet in an ACDP category 2 facility is appropriate. The recombinant particles produced by co-transfection of the replicon RNA and helper RNA can infect cells but have little or no plaque forming capability. The helper RNAs lack a packaging signal so replicon RNA is the predominant RNA packaged. However, helper RNA can be packaged at very low levels and hence pseudovirion preparations may have a very low capacity for replication.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Infected rats will be housed in class 2 facilities until the first feed post-infection and all waste autoclaved before disposal. Subsequently, it is extremely unlikely that any infectious virus remains and no further special precautions are necessary.

Rats are housed in cages in a secure facility.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All virally infected solid and liquid waste will be collected into closed containers. It will be autoclaved by the Department of Pathology and Microbiology's waste disposal service, to give 100% kill before final disposal by incineration. These facilities are already used to dispose of viral waste from other projects in the School of Medical Sciences. Syringes used for injecting rat brains will be disinfected with 1% virkon and work surfaces swabbed with 1% Virkon after use. Virkon solution will be replaced weekly of when colour fades, if earlier, in accordance with manufacturer's recommendations.
This proposal was considered in detail and approved by the University of Bristol's Biological and Genetic Modification Safety Committee (BGMSC) at its meeting of 7th July 2005. No significant issues were raised by members of that Committee.

**Project Additional Information**

**Purposes of the contained use**

The overall aim of this project is to modulate the expression of genes involved in the development of human cancers (specifically childhood cancers), in order to study their function in normal development and in carcinogenesis. Gene expression will be modulated in cultured cells.
The work will involve 2 complimentary strategies:
1) Knockout the genomic sequences controlling the expression of cancer-associated genes using recombinant adeno-associated virus (AAV).
2) Knock-down of the expression of cancer-associated genes, using RNA silencing (siRNA) via the introduction of lentiviral vectors.

Recipient or parental organism

The initial cloning of recombinant plasmids required for the production of the final viruses will be carried out in K12 derivatives of E.coli and therefore non-hazardous.

Human cultured cells used to produce virus (293 cells) and the cells that will be the target of viral infection are well-established cell lines and therefore non-hazardous.

Ad-CMV-cre (recombinant adenovirus expressing are recombinase for the activation of pSico/pSicoR in lentiviral transduced cells) is replication deficient and therefore non-pathogenic. The nature of the insert (cre) makes it of low risk to human health.

Host/vector system

1) Recombinant adeno-associated virus (AAV) used to knockout genomic sequences controlling the expression of cancer-associated genes.

The system to be used is a gene knockout system based on adeno-associated virus (AVV), a small, ubiquitous single-stranded DNA virus of the Paroviridae subfamily. Kohi et al (2004) Facile methods for generating human somatic cell gene knockouts using recombinant adeno-associated viruses. Nucleic Acids Res. 32 (1):e3. Genomic DNA sequences flanking the region to be knocked out are amplified by PCR, using tagged primers. PCR-based recombination is then used to produce a fusion of these sequences with an antibiotic resistance cassette. The fusion product is then cloned into the AVV vector using standard E.Coli K12 systems. This plasmid is transfected into 293 cells with 2 other helper plasmids and recombinant AVV produced. The recombinant AAV is used to infect cultured human cells (in this case established human cancer cell lines) and hopefully the insert undergoes homologous recombination with the targeted sequence and the antibiotic cassette replaces the sequence, allowing selection of resistant clones. These clones are then grown up, characterized to determine whether the knock-out has been successful; and used in vitro experiments.

This is a "gutless" vector in which all Rep and Cap genes have been deleted, leaving the cloned insert flanked by ITRs. Recombinant virus is thus replication-deficient. Recombinant virus will be produced by co-transfecting the AAV recombinant plasmid into 293 cells, together with pAAV-RC plasmid and pHelper (both commercially available from Stratagene). 293 cells contain adenoviral E1 genes, which together with E2A, E4 and VA genes on proteins needed for AAV replication and packaging are provided by the pAAV-RC.

The advantage of the AVV system is its ability to infect a wide range of human cells and in the specific example here, to produce high efficiency gene knockout. There is a lot of data showing safe use of AVV vectors as both laboratory vectors and gene therapy vectors in humans. AVV vectors used in humans have elicited minimal immune response and no acute toxicity. In vivo experiments have failed to rescue recombinant AAV by superinfection with helper virus. In AVV vectors, site-specific integration is lost, so insertional mutagenesis is a theoretical possibility. In a single report, the use of an AVV vector in mice caused liver tumours but without evidence of insertional mutagenesis and it is unclear what caused these tumours.

2) Lentiviral vectors used to knock-down the expression of cancer-associated genes, using RNA silencing.

The system to be used delivers short hairpin RNAs (targeted to the genes of interest) into cultured cells using a lentiviral vector, in order to down-regulate target gene expression in cultured cells via RNA interference. Oligos containing shRNAs will be ligated into the lentiviral vector, cloned in standard E.Coli K12 and the recombinant lentiviral vector will then be used to infect established human tissue culture cells. The vector system is a cre-regulation with a cre-expressing recombinant adenovirus.

The vectors to be used are third generation lentiviral vectors, which use a split-genome conditional packaging system and a self-inactivating terminal repeats in the final lentivirus, to ensure that the virus is replication-deficient. The packaging system (ViraPower; Invitrogen) uses 3 separate vectors to provide essential viral genes:plLP1 deficient. The plasmids have all been engineered to remove regions of homology, to prevent recombination events that could lead to the production of replication competent virus. The plasmids are co-transfected into 293 cells to produce viral particles. The viral particles, although replication-deficient, are capable of infecting human
cells and the pSico and pSicoR vectors contain the WPRE sequence, which has been suggested to be potentially oncogenic (SACGM information note, 19th November 2004).

The lentiviral vector is HIV-based and there the theoretical possibility of recombination with endogenous retrovirus (as is true for any retroviral delivery system). However, there are no HIV accessory genes in the lentiviral system, so there should be no chance of generating wild-type virus.

There is also a risk to insertional mutagenesis with lentiviral vectors, although this has been minimised by the use of self-inactivating LTRs, which should prevent activation of adjacent host genes at viral insertion sites.

**Origin & function**

The primary focus of this study will initially be the WT1 tumour suppressor gene, which is inactivated in a subset of Wilms' tumours (a common childhood kidney cancer) and acute myeloid leukaemias [Little & Wells (1997) Hum.Mutation 9:209-225]. We have shown that sequences within intron 1 of WT1 control the expression of imprinted transcripts and that expression of these transcripts is deregulated in Wilms' tumour [Malik et al (1995) Oncogene 11:1589-1595; Malik et al (2000) Cancer Res. 60:2356-2360; Dallosso et al (2004) Hum.Mol.Genet.13:405-415]. The purpose of knocking out these sequences is to test whether their removal has any physiological effect on cultured cells by altering WT1 expression.

Future work may carry out similar experiments on cancer-associated genes identified by genomic microarray screening procedures e.g. to identify novel tumour suppressor genes inactivated by epigenetic silencing.

All the targets of this work are thus potentially oncogenic.

**Evaluation of foreseeable effects**

For human, the major hazard is of unintentional infection of a laboratory worker with recombinant virus, but the restrictions on workers with open wounds etc, elimination of sharps and other containment measures will make this very unlikely. Recombination events leading to the production of replication-competent virus are highly unlikely, because neither the AVV or lentiviral vectors carry any viral genes, so any infection would be limited in its consequences to the injured person. The oncogenic sequences cloned into the recombinant viral vectors (WT1 initially) are not thought to be capable of directly initiating cancer development in a single event ie they would require additional genetic alterations. However, infection with one if the recombinant viruses should be considered as potentially oncogenic. In addition, there is a risk of insertional mutagenesis after viral integration, although there is little direct evidence for this in AVV vectors, whilst the lentiviral vectors have self-inactivating LTRs designed to avoid this risk.

The recombinant adenovirus expressing cre-recombinase for activation of pSico/pSioR is replication deficient and therefore non-pathogenic. The nature of the insert (cre) makes it of low risk to human health.

AAV and amphotropic lentiviruses can infect a wide range of mammals, so escape of virus into the environment could harm other animal species. However, the containment procedures used should effectively eliminate any risk to animals. Hazards caused by the viruses to other animals would presumably be the same as to humans ie possibility of oncogenic effects.

The cells used as targets for viral infection are well-characterised, established human cell lines that should not pose any hazard. The genetic modification of these cells will not lead to the production of any adventitious agents (all recombinant viruses are replication deficient) and therefore should not be hazardous after the initial viral infection.
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be treated with 1% Virkon overnight, then disposed of to the drains. Manufacturers data sheets indicate that Virkon is virucidal for lentivirus and paravirus (>99.99% kill). Solid waste (plastic pipettes, tips etc.) will be autoclaved before disposal. Autoclaves are tested monthly with a thermocouple.

Please enter comments on the GM safety committee on the risk assessment

The committee discussed the appropriate containment measures for handling tumour cell lines and recommended that these be handled at Containment Level 2 as a control measure for the purposes of COSHH. Notification of activities involving these cell lines following modification of WT-1 gene expression using lentiviral or AAV vectors was judged appropriate due to a perceived increase risk from the genetic modification. Concern was expressed regarding the broad statement defining future work. While this sets the scope of work the committee will require that the PI submits more information on potential candidate "cancer-associated" genes as it becomes available from microarray studies. However, the committee were satisfied that the risk assessment was adequate and that the control measures described and in place were sufficient to protect human health and the environment for the project as presently proposed. Activities involving plasmid manipulation in E. coli, handling unmodified cell lines and cell lines infected with recombinant adenovirus were approved as Class 1 activities and generation of AAV and lentiviral vectors and work with cell lines infected with these were approved as notifiable Class 2 activities at the Bristol University GMSC Meeting 10th November, 2006.

Date Ackn’d  31/05/2007
CU2 Project Title  Infection and immunity of the bordetellae.

Date Project Ceased  02/03/2022

Non-GMM  Consent Granted  Not Applicable
This project is an investigation into the molecular basis for Bordetella infection and immunity. It attempts to elucidate the processes by which these bacteria colonise the host tissues, multiply within these tissues, cause pathology, transmit to other hosts and how the host immune response reacts to the bacteria. In particular, it studies the genetic and cellular basis for these processes. Data arising from this project will obviously expand understanding of the infection biology of these bacteria. However the Bordetella are models for numerous processes that are of general interest to the infection and immunity field, including control of gene expression, interactions with ciliated respiratory epithelia, mucosal immunity in the respiratory tract, host-adaptation and the evolution of virulence.

This project involves studies at the cellular level using whole bacteria and at the molecular level using purified bacterial components (proteins, nucleic acids, carbohydrates, lipids and glycolipids.

Recipient or parental organism

Laboratory strains of Escherichia coli. These strains are used for plasmid maintenance and plasmid amplification and recombinant protein expression. They are non-infectious due to stable mutations. These strains are well characterised, and used extensively world wide for these purposes.

Species of Bordetella B.pertussis and B.parapertussis are pathogens of the human respiratory tract and the causative agents of whooping cough. Infants who have yet to receive the full schedule of pertussis vaccinations are susceptible to whooping cough. Adolescents and adults for whom vaccine or infection induced immunity has waned are susceptible to chronic cough and are sources of infection of susceptible infants. Pertussis is naturally endemic in the human population. Little is known about the contribution of B.parapertussis to the burden of whooping cough disease. Thus, laboratory workers are at risk from infection but the morbidity from such infection is very low. Appropriate control measures to prevent exposure should be used (see below).

B.bronchiseptica infects a very wide range of mammals but is described as a pathogen of just a few (cats, dogs, pigs), causing a relatively mild respiratory tract infection. Human infections are rare and almost always associated with immuno-compromised people or close contact with infected animals. It is not considered a risk to healthy humans. It is a DEFRA controlled organism. B.avium infects mainly turkeys and wild fowl to cause rhinotracheitis. There are no reports of avium infection in humans or mammals.

The other bordetellae cause sporadic disease in humans including respiratory disease and specticaemia. Risk factors for infection by these organisms are unknown, as is their true pathogenic potential. Although infections by these bacteria are rare, appropriate control measures are sensible.

Workers may spread the bacteria, particularly B.avium and B.bronchiseptica, to other susceptible animals if they are carried out of the lab on clothing or person. All workers will be made explicitly aware of the need to maintain rigourous standards of occupational hygiene to minimize the risk of this. All workers will be required to sign that they understand this risk and the control measures required to prevent it on personal safety training/risk assessment records.

Importantly, horizontal gene transfer among the bordetellae is rare. Infact, B.pertussis and B.parapertussis evolved through genome reduction. Thus, they are low risk in terms of transfer of genetic material to other bacteria.
Host/vector system

- pUC based plasmids, pBluescript plasmids, pEX100T, pSS2141, pET vectors, pBBR1 series vectors, pprobe series vectors.

Origin & function

Bordetella DNA will be cloned, maintained and manipulated in lab strains of E.coli. The main purpose for this is to introduce defined mutations into the DNA and then to move the mutate loci back into Bordetella to generate allelic replacement mutants. Mostly, mutations will be constructed by inserting an antibiotic resistance cassette into the Bordetella locus.

The creation of defined bacterial mutants via allelic exchange mutagenesis is a powerful technique for elucidating gene function, is a standard technique in my laboratory and forms the majority of genetic manipulation in this project. The phenotype of the wild type parental stain is compared to that of the isogenic mutants. Changes in phenotype are correlated to the genotype. This approach is a powerful technique for ascribing gene function, for elucidating the role of that gene in the biology of the host organism and is used in studies of bacterial pathogenicity.

Some Bordetella mutants will be used to infect mice to test their phenotype in an in vivo model of infection and immunity. The mouse model of Bordetella infection is well characterised and has been instrumental in understanding the infection biology of these bacteria.

In other cases, Bordetella genes will be cloned in order to express them from the recombinant plasmids ans is also used to study gene function. Complementation of mutations is used to confirm that a mutant phenotype is due to the experimentally constructed mutation and not a secondary effect or artifact. Expression of genes in heterologous hosts is used to identify possible functions of the gene by analysing the phenotypes of the recombinant, purifiable protein for in vitro studies of protein function.

Evaluation of foreseeable effects

It is considered very unlikely that using lab strains of E.coli in this way will result in a pathogenic phenotype. A vast majority of DNA constructs used will not encode functional proteins. Bordetella promoters are not well recognised in E.coli. In the very rare instances where a Bordetella encoded protein is expressed in these E.coli hosts, it is highly unlikely to convert them to an infectious phenotype. Deliberately expressed recombinant proteins will be metabolic enzymes involved in polysaccharide synthesis and not virulence factors.

Deleterious effects from mutating Bordetella are unlikely. Most mutations are of lower virulence/fitness than the parental wild type strains (for example see: Pilione, M.R., Pishko, E.J., Preston, A., Maskell, DJ and Harvill, E.T. 2004. PagP is required for resistance to antibody-mediated complement lysis during Bordetella bronchiseptica respiratory infection. Infect. Immun. 72:2837-42; Burns V.C., Pishko E.J., Preston, A., Maskell, DJ and Harvill, E.T. 2003. The role of Bordetella O-antigen in respiratory tract infection. Infect. Immun. 71:86-94; Cotter, P.A., Allen, A.G., Maskell, D.J and Miller, J.F. 2000. Multiple roles for Bordetella lipopolysaccharide molecules during respiratory tract infection. Infect. Immun. 68:6720-8). To my knowledge, there is no report of a Bordetella mutant showing increased infectivity or causing greater pathology compared to its wild type. There is clear scientific evidence that the host ranges of these bacteria is determined by multiple factors (multiple different adhesions are used, multiple toxins interact with different components of the host immune system, defective metabolic pathways (eg glycolysis, cysteine synthesis) contain multiple genetic deficiencies and thus would not be activated by gain of a single gene.

There are no foreseeable adverse effects from performing in vivo work with Bordetella mutants. The bacteria will be handled in containment level two facilities and infected animals housed in isolator facilities that will not permit release of bacteria in to the environment or to other animals.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Solid and liquid waste and contaminated glassware will be inactivated by autoclaving. Autoclaves are validated by temperature probe. Contaminated surfaces will be disinfected using 70% ethonal. 70% ethanol validated by

Historical Significant Changes

Historical Date of Additional Info
The work aims to study and optimise the intracranial administration of therapeutic agents by a novel technique termed convection-enhanced delivery (CED). This work is focusing on the delivery of both non-viral and viral vectors expressing marker genes or fluorescent tags. The project may progress to the delivery of therapeutic transgenes such as neurotrophic factors, depending on the results of our initial studies. The normal blood-brain barrier profoundly limits the access of potentially therapeutic agents to the brain, when administered systemically. Convection-enhanced delivery (CED) circumvents the blood-brain barrier by utilising extremely fine intracranial catheters and very low infusion rates, to deliver agents directly into the brain extracellular space. Whereas the blood-brain barrier can be a significant obstacle to systemically administered drugs, CED can utilise this to compartmentalise agents that would not normally cross this barrier, such as viruses and proteins, within the brain, potentially limiting systemic toxicity.

We have access to a number of viral and non-viral vectors that are suitable for the delivery of therapeutic genes into the brain. We are primarily interested in the delivery of non-viral, adenovirus and HSV-mediated gene therapy for brain tumours and adeno-associated virus (MV) and lentivirus-mediated gene therapy for neurodegenerative diseases.

The primary objectives of the project are:

• Understand the important factors in achieving convection-enhanced delivery.
• Evaluate and optimise the administration of viral and non-viral vectors within disease-specific neuroanatomical structures.
• Evaluate and minimise the immune response to various therapeutic agents.
• Evaluate different MR acquisitions in visualising drug distribution.
• Develop mathematical models of drug distribution by convection-enhanced delivery.
• Evaluate and optimise the delivery of other therapeutic agents including monoclonal antibodies, neurotrophic proteins and conventional chemotherapeutic agents.

At present viral vector production is carried out externally to this GMAG application, therefore it use replication- incompetent viruses expressing EGFP and 3-Gal vectors to be utilised in this study will be:

- Adenoviral vectors
- Adeno associated viral vectors
- Lentiviral vectors
- Herpes Simplex viral vectors

The nature of the viral systems to be used:

At present viral vector production is carried out externally to this HSE/GMAG application, as we are working in collaboration with both academic and Bio scientific companies. Vectors to be utilised in this study will be:

- Adenoviral vectors
- Adeno associated viral vectors
- Lentiviral vectors
- Herpes Simplex vectors

The project will at a later stage, will progress to produce viral vectors - We intend to use two commercially available viral systems for the expression of the sequences detailed later; the ViraPower Lentiviral System from Invitrogen and the adenoviral systems Adenovirus (Tet-on system developed locally and AdEasy from Stratagene as
well as vectorbiolabs. All of these systems produce replication-competent, self-inactivating pseudoviral particles that can be used to transduce almost any cell including post-mitotic and non-proliferating cells such as neurons.

### Origin & function

**Nature of the genetic material involved:**
Initially all vectors will be obtained from collaborators and will only include marker sequences:
- **EGFP**
- **13-Gal**

In the future the following gene inserts may be used:
- neurotrophic factors, such as glial cell line derived neurotrophic factor (GDNF) within the Adenoviral and lentiviral vectors.
- human and mouse 3-hexosaminidase (a and b subunits) within the AAV vectors.
- Gibbon Ape Leukaemia Virus (GALV) fusogenic membrane protein (FMP) GALV contain a 16 amino acid truncation in the transmembrane R-peptide of the wild type protein. This 16 amino acid sequence normally serves to restrict fusion of the envelope until it has been cleaved during viral infection. The alteration in the glycoproteins renders the proteins constitutively highly fusogenic, and therefore cytotoxic to human tumour cells (2000) Diaz Gene Ther.7(19):1656-63 (in the presence of the prodrug), will be incorporated in HSV vectors supplied by biovex.

### Evaluation of foreseeable effects

**Genetic Material:**

**Viral Production.**
All the cloning vectors used to construct the viruses (E.coli K-12 strains and 8L21) are laboratory adapted and are not considered hazardous to humans. The cell lines used as targets for viral infection (HEK 293) are well characterised, established human cell lines that should not pose any hazard. The genetic modification of these cells will not lead to the production of any adventitious agents (all recombinant viruses are replication deficient) and therefore should not be hazardous after the initial viral infection.

Risks for humans: the major hazard is of unintentional infection of a laboratory worker with recombinant virus where it is appropriate work will be carried out in a biological safety cabinet, which will minimise the risk to workers.

If all containment measures are followed this is very unlikely.

All Recombination events leading to the production of replication-competent virus are highly unlikely, because the vectors do not carry any viral genes. In order to decrease the risk of insertional mutagenesis after viral integration, lentiviral vectors have self-inactivating LTRs designed to avoid this risk. However, infection with one of the recombinant viruses should be considered as potentially oncogenic.

**Risks for Animals:**
The containment procedures used should effectively eliminate any risk to animals. Hazards caused by the viruses to other animals would presumably be the same as to humans i.e. possibility of oncogenic effects.

**Gene Inserts**
The control inserts are deemed not to exert any hazardous effects on the recipient organism. The proposed inserts are also not deemed to be hazardous to the recipient organism.

EGFP and B gal are markers and are therefore not considered to be hazardous to humans or the environment. GDNF is a cell survival factor and human and mouse cx-hexosaminidase are also not considered hazardous. Gibbon Ape Leukaemia Virus (GALV) fusogenic protein consists of a 16 amino acid sequence that normally serves to restrict fusion of the envelope until it has been cleaved during viral infection. It is thought very unlikely that any of the products of this gene, particularly at the very low levels likely to be generated following accidental exposure, could cause untoward effects. This is only active in the presence of the prodrug (5-FC).

Since all of these inserts will be in non replication competent viruses, it is thought that the severity and likelihood of hazard to both humans and the environment is low.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
Derogation to animal containment level 1 for animal handling and holding facilities. Once injected the risk to human health from these animals is considered to be low. In most cases the GMO will be restricted to the brain and in animals that have been injected intravenously the risk to humans from bites and scratches during animal handling is considered to be minimal due to the nature of the inserts and the amount of non-replicative GMO in the circulation. The extra precautions described in the risk assessment will be taken to reduce the risk from any virus that is shed from any animals that may be injected intravenously in the future. Should an animal escape containment (which is unlikely due to the design of the animal facility) we consider the risk to the environment from these animals to be low due to the nature of the genes that would be expressed.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The Functional Neurosurgery Research Group (FNRG) AOC waste policy will be followed. Specifically:
- Solid waste coming into contact with GMMs will be stored in ‘yellow bins’ All plastic consumables and solids will be deposited into “Biohazard” marked bags and either autoclaved or incinerated via the University hazardous waste stream.
- Liquid Waste (e.g. samples, culture supernatants, tissue culture media) will be made safe by 1% Virkon used (with at least 10 mm contact time) and discharged to drains.
- Viral samples will be treated with a 1% Virkon disinfectant solution or equivalent (at least 10mm contact time — but usually hours) and discharged to drains.
- Sharps waste. Needles will be disposed of directly into sharps bins and incinerated via the University hazardous sharps waste system.
- Spillages In the case of any spillages, the spilled materials will be soaked up using a spill kit located in the containment level 2 facility and disposed of as solid, contaminated waste. Chemical (Virkon) disinfection: used at 1%, mm contact time 10 mins.
- General Disinfectant procedure 1% Virkon disinfectant solution should be used to decontaminate surfaces (at least 10mm contact time).
- Work within ASU theatres. All the above will be done to inactivate the waste created whilst surgical procedures are carried out.
- The disposal of carcasses will be performed by the ASU staff. Carcases will ultimately be disposed of by incineration (University licensed incinerator).

Validation.

Virkon, made fresh, effectively inactivates 100% of all viral vectors in use, under the above conditions (Manufacturers efficacy data: http://www.antecint.co.uk/mainfftpfiles.htm)

Incineration effectively inactivates 100% of all viral vectors in use (licensed incinerator).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The risk assessment was discussed at the meeting of Bristol GMSC on 21 January 2008. The researchers were asked to clarify the expected effects of GALV expression. The committee were also concerned that insertion of a gene encoding a potentially fusogenic protein into a lentiviral vector may have profound effects upon the vector phenotype and consequently the risks from that vector. The researchers were also advised to provide information on risks and precautions for animal care workers as necessary and to ensure that such information had been communicated and discussed with these workers or their line managers. The research team have confirmed that only the short 16 amino acid sequence of the GALV fusogenic membrane glycoprotein will be expressed and that insertion will be restricted to the HSV vector.

Project Containment

Laboratory Activities

Glass Houses

Growth Rooms

02/03/2022
The overall aim of this project is to modulate the expression of genes involved in the development of murine regulatory T cells (Tregs), in order to study their function in normal differentiation of Tregs within a transgenic TCR mouse model. Gene expression will be modulated in primary cells. The work will involve two complementary strategies:
1. Over expression of cDNA sequences of genes that have been associated with Treg development
2. Knock-down of the expression of Treg associated genes, using RNA silencing (51RNA)

The introduction of genetic material into primary lymphocytes for research purposes is associated with a number of practical problems, primarily the extremely low rate of transfection achieved by standard plasmid transfection methods. An alternative method for introducing genes into a number of cells types is to use replication deficient retrovirus as a transfer tool. Retroviruses efficiently infect dividing cells and integrate into the host cells genome, thus creating stably transfected cells that can be used for further studies. Because such vectors are replication deficient, once applied to cultured cells, they cannot proliferate or re infect other cells types or organisms. This work aims to develop a method of generating replication deficient MSCV-based retroviral constructs (Clontech) and introducing them into primary murine cells. MSCV vectors will be used as they have been shown to infect primary lymphocytes at a higher efficiency that MuLV-based vectors.

The work also aims to create bone marrow chimeras using donor cells that have been infected in vitro with commercially available retroviral vectors which include...
pSuper.Retro (OligoEngine Inc), pMSCV (Clontech) derivation retroviral vectors which have all been designed specifically for biosafety. These vectors generate replication incompetent viruses through separation of the packaging function, addition of self inactivation, deletions and the use of packaging cell lines which restrict viral tropism. The packaging cell line tropism will be modified to generate ecotropic viruses which will recognise only mouse and rat cells. The viral vectors will be used to infect and stably transduce mouse cells derived from existing University colonies.

Bone marrow has the ability to differentiate into a wide range of haemopoietic cells types and provides a way to circumvent many of the difficulties arising from the use of fully differentiated T lymphocytes, and offers the potential to generate adult mice that cannot be generated from modifying pre-implantation embryos (ie pronuclei injection and creation of ES chimeras). The use of syngeneic strains will also circumvent any rejection issues arising from cell transfer.

### Recipient or parental organism

Primary murine cells i.e. bone marrow and lymphocyte cultures

### Host/vector system

Viral vector particles based on pMSVC will be generated by a two-plasmid co-transfection system (of human 293T cells) in which plasmids containing the genome (pMSCV, or pSUPER.retro) or gag/polfenv proteins (pCL.Eco) are used as a mixed DNA preparation. This significantly reduces the probability of the production of replication competent virus.

- **pMSCV**: Clontech
- **pCL.Eco**: Retromax Retroviral system, Imgenex Corporation
- **pSUPER.retro RNAi System**: OligoEngine, Inc.

### Origin & function

Retroviral and helper plasmids purchased from commercial sources (Addgene, Imgenex, OligoEngine)

All cDNAs generated from cDNA libraries using cloning standard techniques or to be purchased from IMAGE collection (MRC) where possible

All siRNA oligos to be purchased from OligoEngine

### Evaluation of foreseeable effects

Wsx I and irf-1 have not been identified as potentially oncogenic. However, both molecules are required for the development and function of Th1 cells. Murine over-expression and knock-out studies of both wsx 1 and irf-1 have resulted in impaired cytokine signalling and immune dysregulation, but have not shown an increase in survival or tropism for cells expressing these genes. Conversely, both conventional knock-out studies of wsx 1 and irf 1 mice have shown some immune dysregulation, but no increase in either survival, tropism or infectivity in these animals.

EGFP has no known toxic or oncogenic potential

None of the gene products form secreted proteins

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All animal work will be carried out within local designated facilities following their rules regarding animal containment and welfare. At no time will live animals be removed from this facility. By following the procedures for washing and preparation of infected cells for transfer, no free virus should be introduced into the animal facility. The cells carrying the modification will carry some viral sequences, but will only express the transgenes of interest, as is the case when making stable transfectants using non-viral vectors. No increase in infectivity or tropism is expected in the infected cells, nor are the protein products of the modification excreted in vivo or into the environment. Based on this risk assessment, the work with GM animals is considered to be equivalent to a class 1 activity and not notifiable. Animals will be housed within the designated LAF cabinets under a minimum of animal containment level 1 and in accordance with local rules. Analysis of tissue from chimeras will be undertaken post-sacrifice. Animal waste will be incinerated post-sacrifice.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Because of their lipid-derived membrane, recombinant retroviruses are extremely labile and are inactivated by ethanol, detergents, or bleach. Liquid waste will be inactivated by exposure to 1% yukon for a minimum of 25 minutes (a procedure shown to completely inactivate retrovirus particles by the manufacturer). Solid waste will be inactivated in the same way, all within a microbiological safety cabinet. The solid waste will than be placed in autoclavable bags, sealed and disposed of by autoclaving in accordance with current departmental procedures regarding solid biological waste.

Before removing cells that have been infected with recombinant viruses from the tissue culture laboratory for further experimentation, they will be rendered non-infectious by thorough washing with ice cold PBS.

MSCV particles are extremely heat labile and washing in this way removes free virus particle from cultures and dramatically reduces the infective half-life of any particles that may remain.

Autoclave — effectively 100% kill. Autoclaves undergo a 12-point thermocouple validation every 3 months and all runs are monitored and recorded.

The committee asked that the group demonstrate either experimentally or by reference to published data that the washing procedure proposed effectively removes free virus from cell cultures or reduces infectivity before the first transfer of cultures to animal and FACS analysis facilities for downstream applications. The committee must also be kept informed of any significant changes to the risk assessment as a result of new inserts identified by microarray analysis.

Project Additional Information

Purposes of the contained use

To investigate the role of red blood cell adhesion molecules! red cell membrane Band 3 complex proteins, apoptotic pathway proteins, signalling molecules! transcription factors and the role of protein trafficking and internalisation and autophagy of these molecules in human erythropoiesis (red blood cell production).

Recipient or parental organism

1. Lentivirus-based plasmids will be propagated in laboratory strains of the bacterium E.coli. There are no foreseeable effects except that the GMM will be transformed to antibiotic(ampicillin) resistance to facilitate selection. The GMM will not express the target genetic material and, like the parent bacterial strain, will be unable to survive outside the laboratory nor colonise mammalian gut.
2. Lentivirus-based transduction particles will be produced in a cultured, human, embryonic kidney cell line. There are no foreseeable effects - the GMM will not express the target genetic material, will be cultured transiently and will be unable to survive outside the laboratory.
3. Cultured, human, haematopoietic, progenitor cells and cultured, human, haematopoietic cell lines will be transduced using these particles and thus rendered resistant to an antibiotic (puromycin) to facilitate selection. The GMM will express the target genetic material but will be unable to survive outside the laboratory.

Host/vector system

1. Lentivirus based plasmid vectors:
   - Transfer vectors - pLKO. 1, Sigma, St Louis, USA or pTRIP transfer vector, Chameau et al., Gene Ther. 2001, 8(3):190-8, or pTRIPZ vector purchased from Open Biosystems;
   - Compatible packaging vectors - Sigma Mission ShRNA or psPAX2, Chameau et al., Gene Ther. 2001, 8(3): 190-8, now sold by Addgene;
   - Compatible envelope vector - pCMV-VSV-G, Sigma, St Louis, USA or pMD2-VSV-G; Steward et al., RNA 2003, 493-501, now sold by Addgene.
   These vectors will be propagated in XL-1 blue E. coli cells.
2. Lentivirus-based transduction particles will be produced in HEK293T, a human embryonic kidney epithelial cell line.
3. The ultimate host will be cultured, human, haematopoietic, progenitor cells or cultured, human, haematopoietic cell lines. These cells will be transduced using lentivirus-based transduction particles produced as above.

Origin & function
Genetic materials are small, inhibitory RNA sequences (short hairpin RNA or shRNA) or cDNA sequences for the human genes of the proteins listed below:

1. Green fluorescent protein — a control protein used to determine multiplicity of infection values and to demonstrate effectiveness of transduction or knockdown protocols.

2. Cell adhesion molecules — found on many normal human cells and expressed during erythroid development (e.g. ICAM-4 [CD242]; Lutheran blood group protein [CD239]). Tetraspannins — cell adhesion accessory molecules found on many normal human cells and expressed during erythroid development (e.g. CD81;CD82; CD51).

3. Band 3 (CD233 the chloride/bicarbonate exchange transport protein) macromolecular complexes. Includes some blood cell restricted molecules such as the blood group active proteins glycoporphin A, ICAM-4 and RhD/CE; Rh associated glycoprotein and other, more widely expressed, proteins such as CD47. Includes associated structural/cytoskeletal proteins such as ankyrin and its isoforms and protein band 4.2 and also cellular proteins involved in the efficient trafficking of Band 3 and associated proteins. The overall function of the complex is gas-exchange between the red cell and tissues.

4. Other well characterised mammalian membrane transport proteins found on red blood cells (including Kidd blood group active protein [urea transporter]: glucose transporter Glut-1 and CD98 an amino acid transporter).

5. Red cell membrane proteins that form structural complexes involved in the maintenance of red cell integrity (including glycoporphin C and associated cytoskeletal proteins such as protein band 4.1, actin and spectrin).

6. Transcription factors - these control gene expression in a tissue dependent manner and thus direct cell differentiation and function. Examples are well characterised human haematopoietic transcription factors GATA-1 KLF1 and Spi-1. Haematopoietic transcription factors will be targeted. These molecules are normally expressed during erythroid differentiation but inappropriate or mis-timed expression (such as in this case where expression will be driven from a viral promoter) or knockdown of expression by siRNA may result in arrest of normal differentiation and therefore transformation of the target cell to immortality. For this reason, certain transcription factors such as Spi-1 may be considered as oncogenic or leukaemogenic and their encoding sequences as oncogenes.

7. Intracellular signalling molecules with a role in erythropoiesis. Target molecules include kinases and phosphatases of the Src and MAP pathways.

8. Proteins involved in apoptotic pathways in erythroid cells. Includes pro-apoptotic proteins such as Bak/Bax, BH3-only proteins, caspases, Fas & FasL and associated signalling molecules such as GSK-3.

9. Proteins functioning in the autophagy pathway and required for packaging/elimination of erythroid organelles. To include regulatory molecules such as Beclin-1 and components of the autophagosome biogenesis pathway such as Atg4 (mammalian orthologues A, B, C, D), Atg5, Atg7, Atg8 (mammalian orthologues include LC3, GATE-16, GABARAP L1-3).

The intended use is to enable the study of loss of function or rescue of function of the targeted proteins within a tissue culture, laboratory model of human red blood cell maturation (erythropoiesis). Ongoing screens might identify novel proteins that fall into one of these categories. The risk assessment will be reviewed to take account of such circumstances.

**Evaluation of foreseeable effects**

It is predicted that the GMOs produced in this study will have very similar characteristics to the host cells or organism. E.coli cells used to propagate plasmid vectors will be transformed to antibiotic (ampicillin) resistance but will not express proteins or shRNA encoded by the inserted genes within the vectors. Human embryonic kidney packaging cells will produce lentivirus-based transduction particles. Transduced, target, haematopoietic cells are predicted to be silenced for expression of the gene target sequence or to over-express the sequence but other characteristics are predicted to remain the same as the host cells. None of the GMOs will be capable of survival outside the exacting conditions of culture used in the laboratory. The system is designed such that virus that is capable of replicating within host cells is not produced.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

No plants or animals will be used in this study.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

1. Contaminated bacterial cultures, petri dishes, tips, etc. will be collected in an autoclave bag, sealed with an indicator tape and autoclaved for 30 minutes at 125°C. Degree of kill 100%. The bag will be inspected and if the indicator strip has changed colour, thus verifying the temperature and duration of heat treatment, the bag will be disposed of as non-hazardous waste. The autoclave is serviced annually.

2. Contaminated tissue culture plastic (dishes, tubes, pipette tips, pipettes etc.) will be transferred to a sealed, non-porous plastic ‘sweetie jar’ kept inside the class II
microbiological safety cabinet. Once full, the “sweetie jar” will be decontaminated on the outside with 1% w/v virkon and sent for autoclaving.
3. In the Class II microbiological safety cabinet, spent tissue culture medium, including those contaminated with lentivirus particles, will be transferred to discard containers containing 2% w/v Virkon. These will be filled until a 1% w/v virkon solution of Virkon has been reached and after a minimum of 10 minutes contact (usually much longer) contents discarded to drains as non-hazardous waste.

Inactivation methods:
Autoclaving, effectively 100% kill (annual validation) Incineration, effectively 100% kill (licensed incinerator)
Chemical disinfection with Virkon (dipotassium peroxodisulphate, Antec International, Sudbury), used according to manufacturers instructions under standard conditions, manufacturers validation (e.g. 99.998 % kill).
1% w/v Virkon disinfectant has been validated by the manufacturer to inactivate lentiviruses even in the presence of high concentrations of protein (such as inactivation of HIV in blood). To inactivate contaminated liquid, add an equal volume of 2% w/v Virkon (to obtain 1% w/v virkon final concentration) and leave for at least 10 minutes before disposal down the sink.

The risk assessment was discussed at the Bristol GMSC meeting of 5 June 2008. The committee generally agreed that the risk assessment was very detailed and clearly identified the risks and suitable control measures. It discussed the large number of inserts being manipulated in an activity being undertaken by one group. However, as the risk assessment now makes more clear! the work is being undertaken by two collaborating groups in the department and some of the work is also being undertaken by these groups at the National Blood Transfusion Service (GM176,for which a separate notification has been made) where honorary contracts are held. The risk assessment is intended to cover all anticipated future work that may be undertaken on University premises. The committee have asked the person responsible to seek further advice and review their risk assessment as on-going screening activities identify further proteins for manipulation.
Investigation into the proteins regulating transcription and nuclear function in mammalian cells: regulators of transcription, DNA replication, the cell cycle, RNA splicing and nuclear structure

### Purposes of the contained use

Wound healing is a dramatic regenerative episode which triggers cells that would otherwise be dormant to proliferate and migrate, and this in turn requires induction of numerous genes including those that encode for cell cycle regulators, matrix molecules, integrins, proteases, etc (reviewed in Martin, 1997, Science). We have recently shown that the expression of epigenetic regulators, including polycomb transcriptional repressors, DNA methyltransferases, and DNA demethylases, changes during mammalian wound repair. The objective of the proposed lentiviral experiments is to test whether the polycomb family of transcriptional repressors and/or DNA demethylases play key roles in regulating some of the genes that are activated at sites of wound repair.

### Recipient or parental organism

The microorganism is a lentivirus that will be used to infect primary and cultured cell lines as well as mice.

### Host/vector system

Virus production will be performed using a second generation 3 plasmid system. The first ‘transfer’ plasmid is either pLG3 or pLKO.1 and contains viral and insert DNA outlined in point 1 above. The second ‘packaging’ plasmid (pCMVdeltaR8.91) contains wild type gag, pol, rev and tat genes driven by a CMV promoter in a puci 8-derived vector. The third ‘envelope’ plasmid contains the VSV-G envelope protein driven by a CMV promoter. These are introduced into HEK 293 cells and virus harvested.

### Origin & function

Genes (Bmil, Eed, Ezh2, GADD45a) will be obtained either through GeneService (IMAGE clones), collaborators, or standard cloning techniques; short hairpin sequences for knock-down will be obtained from collaborators (pLKO.1-Scrambled from Addgene), or ordered from Invitrogen. Lentiviral vectors will be used to infect cells in culture (1. MOCK; 2. mIMCD3; 3. Swiss 3T3; 4. mouse embryonic fibroblasts; or 5. primary mouse keratinocytes) or in vivo mouse wounds with the cDNA5 of, or short hairpin sequences against, polycomb proteins Bmil, Eed, and Ezh2, as well as the demethylase GADD45.

### Evaluation of foreseeable effects

Based on the literature, it is thought that if a human were to be infected with the GMM thus altering the expression levels of the named genes, this could result in broad changes in gene expression, and consequently changes in the rate of cell proliferation, migration, and survival. Because of this ability to affect cell proliferation and survival, one could speculate that the absolute worst-case hazard for an infected human could be tumour formation; however, the instability of the virus together with proper handling of the lentivirus and infected animals and cells reduces this risk to virtually zero. There are no foreseeable effects on the environment.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Mice will be housed individually and wounds covered with Tegaderm or OpSite (surgical bandages impermeable to virus). In unlikely event that surgical bandages fail and wounds become exposed then research staff will be informed. Such exposure should only present a hazard for a short time after application. In such cases disinfection protocols will followed to decontaminate the cages and bedding (prior to incineration) to prevent spread of contamination. Handling procedures will minimise the risk to human health. However, as an extra precaution against transfer of virus animals will be handled while wearing gloves and cages will be disinfected after animals are removed. Bedding and animal carcasses will be incinerated. Infected animals will be well marked and animal facility staff will be trained on appropriate procedures for handling and husbandry. The animal facility is an isolated unit with restricted access. The genetically modified animal is, itself, considered no greater risk than the non-modified animal.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Infected solid material from tissue culture experiments will be kept separate from all other waste material and will be destroyed by autoclaving. Liquid material will be similarly kept separate from all other waste, and will be neutralised by using Virkon prepared as per manufacturer's instructions. Animal bedding will be incinerated with animal carcass waste.

Project Ref  18/09.1

Date Ackn'd  10/11/2009  CU2 Project Title  Use of bioluminescence to quantify bacteria in infection models

Date Project Ceased

Withdrawn  N  Tick if notifying a connected programme of work  N

Project notified under transitional arrangements  N
Our laboratory performs a number of murine bacterial infection models, which are used in the investigation of novel antimicrobial agents. The ability of the novel compounds to inhibit growth of bacteria is tested. The test will be a determination of the numbers of bacteria present and the hope is that treatment will reduce these numbers.

For some of our studies, we aim to quantify the numbers of bacteria at serial timepoints through the course of infection, by using non-invasive imaging methods during the in-life phase. In order to do this it is necessary to use bacteria which have been genetically modified to produce light (bioluminescence). These light-producing bacterial strains are commercially available and the light production is due to the introduction of a gene such as luciferase (exploiting the same principle as the production of light in many species in nature, for example the firefly). By quantifying the amount of light, the number of bacteria can be determined at several different timepoints during the course of infection.

This work encompasses the following bacterial strains: Staphylococcus aureus, Streptococci pneumoniae, Escherichia coli, Pseudomonas aeruginosa, and Acinetobacter baumannii.

These recipient (host) micro-organisms are bacteria which are ACDP hazard group 2 and are naturally present in the environment or in human hosts.

Acinetobacter is readily found throughout the environment including drinking and surface waters, soil, sewage and various types of foods. Escherichia coli is commonly found in the intestines & faeces of humans and animals. P. aeruginosa is commonly in soil and water. Staphylococcus aureus is a common coloniser of human skin and can be found on environmental surfaces around infected individuals. Streptococcus pneumoniae is part of the normal human upper respiratory tract flora & has been isolated from aquatic environments such as seawater.

These bacteria do not tend to cause disease in immunocompetent individuals, but can be problematic in the immunosupressed, neonates or the elderly.

The risk assessment outlines primary containment and PPE measures which have been assessed for the handling & containment of these organisms.

The host organisms covered by this risk assessment are bacteria which are ACDP hazard group 2 and are genetically modified to render them bioluminescent (in the
presence of luciferin substrate).

The genetically modified bacteria will be obtained from a commercial source (Caliper Life Sciences) or from a scientific collaborator. This risk assessment covers the use of genetically modified bacteria and their wild type equivalents (not the generation of genetically modified bacteria within this institution).

The genetic material is stably inserted into the bacterial genome. It does not alter the pathogenicity of the bacteria in vivo or in vitro. No host genes are inactivated or disturbed at the site of integration. The bacteria can be selectively grown on kanamycin.

The vector for bioluminescent transformation was the gram-positive lux transposon cassette, Tn4001 luxABCDE Kmr.

Examples of the transformation strategy are further detailed in K.P. Francis, et al, Infection & Immunity 2001 (69(5)3350-3358) and J.L. Kadurugamuwa et al Infection & Immunity, 203 (71(2) 882-890)

**Origin & function**

Insertion of genetic material from the luciferase gene (photorhabdus luminescens lux operon) renders the bacteria bioluminescent (in the presence of oxygen and the enzymatic substrate, luciferin), hence allow their detection using non-invasive in vivo imaging using a Caliper-Xenogen IVIS system.

**Evaluation of foreseeable effects**

The main risks of these products used relate to the risk to human health by these ACDP hazard group 2 organisms.

The bacteria used are each commonly found either in the environment or in human hosts. Furthermore, the genetically modified bioluminescent strains are no more virulent than the parental strains. This project should not contribute any additional risk to the environment even if there were to be an accidental release.

The containment & disposal measures detailed will minimise any chance of release of the viable bacteria into the environment

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

**Virkon** is a bacterial agent, which is used at a concentration of 1%. It has been shown to cause a 5-log reduction in bacterial counts (Hernandez, A 2000. Journal of Hospital Infection. 46: 203-209).

In vitro GMM liquid waste will be disposed of into 1% Virkon. After 24 hours, this will be discarded to drains. Bacterial plates will be sealed and autoclaved. Contaminated tips will be soaked in 1% Virkon prior to autoclaving. Any contaminated glassware (kept to minimum) will be soaked in Virkon for 24 hours, then rinsed prior to collection by media facility collection service.

Other solid waste (plasticware eg homogenizing tubes, pipettes, pipette tips, flasks, tubes) will be disposed of as biohazard waste (clear plastic bags) and autoclaved. Disposable plastic waste will be disposed of via the biological waste route. Biohazard waste will be removed from the laboratory through a central twice daily collection service which removes all biohazard waste to autoclaves for on site destruction.

Most solid (plasticware & pipettes) will be generated during the in vitro phase, with a bare minimum of plastic waste generated in ASU facilities (only gavage tube/needle
used for bacterial inoculation). Any such plastic waste created in ASU (eg gavage tubes) will be autoclaved then disposed of via the non hazardous waste route.

In vivo waste: cages and bedding will be autoclaved.

Autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-135°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

The risk assessment was reviewed at meetings of the Biological and Genetic Modification Safety Committee on 15th July 2009 and, following updated information requested regarding animal containment measures, on 14th October 2009. The committee agreed that there was no increase in risk to human health or the environment from the genetic modification and that measures selected were suitable for containment of both the wild-type and genetically modified Hazard Group 2 bacteria and the deliberately infected animals involved in the activity.

Project Ref 18/09.2

Date Ackn’d: 16/11/2009

CU2 Project Title: Containment of Influenza A viruses, for use in studies of vaccination or treatment of influenza infection

Class: Class 2

Culture Vol Class 2: < 1 Litre

Non-GMM Consent Granted

Date Project Ceased: 02/03/2022
Experiments will be carried out to establish the effectiveness of influenza vaccines & treatments in murine and ferret models. This work also encompasses propagation of established viral strains in eggs.

Immunologists studying influenza vaccines have realised that by combining wild type human influenza A strains with attenuated strains, they are able to achieve reassortant viruses with the properties of each, namely: a virus with the relative safety of an attenuated virus (PR8) yet possessing the ability to stimulate immune responses to surface viral proteins from wild type human influenza viruses (eg H3 & N2 or H5 & N1).

We wish to use an established ACDP hazard group 2 viruses available from the Health Protection Agency. For example, NIBRG-14 is a reassortant virus consisting of 6 genome segments from A/PR/8/34 (PR8)(H1N1 virus) and 2 genome segments A/Vietnam/1194/2004 (H5N1 virus). This was derived by a process of reverse genetics and the resulting virus is avirulent (or "de-pathogenised") compared to the parent H5N1 virus. This process involved deletion of sequences of the H5N1 haemagglutinin responsible for its virulence - hence the ACDP hazard group 2 designation. Other than the two surface haemagglutinin & neuraminidase genome encoded segments, the remainder of the genome is PR8. This virus has the ability to grow in eggs (a PR8 property) & is attenuated for human infection, but possesses the surface haemagglutinin & neuraminidase necessary to stimulate and investigate immune responses to H5 and N1.

PR8 has over 100 passages in mice, ferrets & embryonated chicken eggs, which has reulted in the complete attenuation of its ability to replicate man.

Reassortant influenza virus strains have been generated by recombining viral genome RNAs from established viral laboratory influenza strain PR8 (H1N1) with RNAs of other human infectious strains (eg H5N1) by reverse genetics, resulting in attenuation of pathogeneity of the latter.

As described above, the haemagglutinin & neuraminidase gene segments are derived from human influenza A viral strain. These are combined with established laboratory strain PR8, which is unable to replicate in man.

The inserted genetic material can be used to stimulate immune responses to influenza.

We will be using established ACDP hazard group 2 viruses available from the Health Protection Agency. For example, NIBRG-14 is a reassortant virus consisting of 6 genome segments from A/PR/8/34 (PR8)(H1N1 virus) and 2 genome segments of A/Vietnam/1194/2004 (H5N1 virus). This was derived by a process of reverse genetics.
and the resulting virus is avirulent (or "de-pathogenised") compared to the parent H5N1 virus. This process involved deletion of sequences of the H5N1 haemagglutinin responsible for its virulence - hence the ACDP hazard group 2 designation. Other than the two surface haemagglutinin and neuraminidase genome encoded segments the remainder of the genome is PR8. The resulting virus has the ability to grow in eggs (a PR8 property) & is attenuated for human infection (compared to the wild type virus), but possesses the surface haemagglutinin & neuraminidase necessary to stimulate and investigate immune responses to H5 and N1.

PR8 has over 100 passages in mice, ferrets & embryonated chicken eggs, which has resulted in the complete attenuation of its ability to replicate in man.

The attenuated viruses (eg NIBRG-14) do not pose a significant threat in terms of their replication in humans. However, if the virus were to enter a human who is already infected a human influenza virus (circulating in the population) then there is a theoretical risk of secondary reassortant to generate a new infectious human viral strain. The containment, PPE & other measures outlined in the accompanying risk assessment acknowledge this possibility and serve to minimise this risk.

The naturally occurring influenza virus in the human population evolves over time, with new variants emerging constantly (a phenomenon known as genetic or antigenic drift). In an attempt to keep pace with this, each year the composition of the influenza vaccine is designed to protect against the strains currently in circulation & most likely to be encountered the coming winter. Annual, seasonal influenza vaccines are available and routinely offered to at risk individuals, as defined by underlying chronic medical conditions.

Workers involved in this project (including animal husbandry) will be offered the annual, seasonal influenza vaccine. They will also be required not to work on the project if displaying flu-like symptoms. These measures, combined with relevant PPE constitute preventative measures to minimise any opportunity for viral strain reassortants.

Adherence to primary containment & PPE procedures will reduce the risk of any viral transmission outside of the designated rooms/units.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

In the case of waste generated from infection of eggs, this material will be put into pots containing chloros solution, then placed in an outer, sealed plastic bag, promptly removed to be autoclaved & sent then for incineration.

For in vivo elements of the study, bedding will be bagged for incineration. The cages are then washed and autoclaved. Animal carcasses should be double bagged prior to incineration.

Laboratory waste: Solid waste will be disposed of as biohazard waste (clear plastic bags) and autoclaved. Disposable plastic waste will be disposed of via the biological waste route. Biohazard waste will be removed from the laboratory through a central twice daily collection service which removes all biohazard waste to autoclaves for on site destruction.

Autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg tissue culture media) - treat overnight at room temperature using 10% sodium hypochlorite, always made fresh, then send for autoclaving. A 1% solution of sodium hypochlorite can be used for wiping down surfaces.
The Biological and Genetic Modification Safety Committee reviewed this revised risk assessment at its meeting on 14th October 2009. The committee had originally reviewed and approved the assessment under COSHH and University Policy for work with Hazard Group 2 biological agents. The revised assessment included work with an influenza virus produced by reverse genetics to be obtained from the Health Protection Agency and therefore requires notification under GMO(CU). The committee agreed (after further advice from HSE regarding hazard group classification) that containment level 2 measures with extra respiratory protection would be appropriate for this activity. RPE (FFP3-type masks) was advocated at all times when handling infected animals outside of primary containment. The committee had further concerns regarding the risk of viral reassortment should mixing occur between a virus carried by a worker naturally infected with seasonal (or other) influenza and the experimental viruses or should the different virus subtypes in used be accidentally inoculated into the same eggs for propagation. The committee therefore recommended additional measures to reduce the risk assessment. These measures included better management controls when propagating viruses (either purchasing sufficient virus or propagating one virus at any one time) and decontamination and disposal of contaminated egg material), a moratorium on workers (including animal husbandry staff) on handling differing animal models within the same 72 hour period (different species models are also located in different buildings), reinforcing the instructions given regarding signs of human infection and not undertaking this work if these become apparent; and recommending that workers are offered the seasonal influenza immunisation as an added measure while emphasising to staff that this is not for health protection. The practicability of immunisation of staff with a swine influenza vaccine will be kept under review.
The principal aim of the research activity is to understand the interplay between bacteria and their human host during colonisation and progression of disease. By understanding key mechanisms used by bacteria to interact with human cells and tissues candidates for intervention therapies can be identified. My research focuses on bacterial species residing within the respiratory tract and oral mucosa from these sites a number of bacterial species under investigation are able to disseminate and/or infection other regions of their human host.

I am currently involved in a number of projects which would benefit from genetic manipulation of bacteria in order to further elucidate mechanisms of pathogenesis. These projects principally include interactions of commonly isolated Gram negative and Gram positive bacterial species with mucosal associated tissue of the human respiratory tract and oral mucosa. In addition, other projects examine the association of bacterial species (principally Gram positive also commonly isolated from the respiratory tract) with cells associated with normal bone development, structure and function.

Collectively these projects examine bacterial species including Neisseria meningitidis (and related Neisserial species), Haemophilus influenzae, Moraxella catarrhalis, Streptococcus pneumoniae, Group A streptococcal species, Group B Streptococci, Pseudomonas aeruginosa, Staphylococcus aureus and commensal Staphylococcal species, Bordetella species and Fusobacterium species (all organisms listed fall under hazard groups 1-2). In addition, strains of E. coli will be used as vectors for plasmids containing genes from the bacterial species listed above and transient controlled expression of bacterial proteins.

Organisms to be used within these studies include Neisseria meningitidis (and related Neisserial species), Haemophilus influenzae, Moraxella catarrhalis, Streptococcus pneumoniae, Group A streptococcal species, Group B Streptococci, Pseudomonas aeruginosa, Staphylococcus aureus and commensal Staphylococcal species, Bordetella species and Fusobacterium species (all organisms listed fall under hazard groups 1-2). In addition, strains of E. coli will be used as vectors for plasmids containing genes from the bacterial species listed above and transient controlled expression of bacterial proteins.

Genes of interest will be PCR products from the appropriate bacterial species and vectors used as above. Firstly, the inserted DNA disrupts the function of known/putative virulence proteins within strains of the above mentioned bacteria invariably making the less or certainly no more virulent than the parent strain. In addition, the DNA will encode an antibiotic resistance cassette (e.g. kanamycin) allowing specific laboratory selection of the phenotype. Despite resistance to these antibiotics the strains will be

sensitive to the antibiotics used in the clinic e.g. penicillin, methicillin and vancomycin. Thus should a worst case scenario arise resulting in laboratory acquired infection this could be treated with antibiotics commonly used in the clinic. Note where clinical isolates of S. aureus are used strains will be resistotyped by the HPA prior to collection and high risk organisms e.g. MRSA/VRSA will not be used for GMO work.

Secondly, swapping existing putative virulence genes between strains of the same species is a process which occurs naturally in the wild leading to development of families of so called mosaic genes. This work will only be done in species where such events occur naturally, hence such work only mimic events in the real world. Such gene swapping will not lead to a strain that is anymore virulent than the host organisms form which the single gene is derived.

Both of the above rely on the genes of interest replacing an exiting region of DNA by homologous recombination from linear DNA hence no plasmid derived DNA will remain following outgrowth and selection of desired mutants.

Thirdly, expression of single putative virulence genes in E.coli using IPTG expression vectors presents a low risk the protein of interest will invariably not fold correctly under over expression conditions and bacteria will be quickly lysed to release the protein of interest for subsequent purification. Further no/low level protein expression will occur until the appropriate induction agent is added.

**Evaluation of foreseeable effects**

- **Evaluation of foreseeable effects**
  
  Whilst the majority of bacterial species are common colonisers of human skin and mucosa. The majority have the capacity to cause disease, particularly if there is an opportunity for the bacteria to enter the body. Illnesses such as skin and wound infections, urinary tract infections, pneumonia and bacteraemia (blood stream infection) may then develop if the bacteria enter the body. Toxins from certain strains of S. aureus can also cause food poisoning. Most strains of these bacteria are sensitive to many antibiotics, and infections can be effectively treated. The most common spread is still by human to human contact. Generally survival in the environment has not been widely studied but none of the organisms form endspores so survival should be limited. One exception is Pseudomonas aeruginosa which is commonly resident in soil and water naturally. It should be noted that risks associated with the GMMs are as those for parental bacterial species and as such will be treated like the wild-type hazard group 2 microorganism. Infections associated with the above species are wide ranging and include mild spots and boils to septicaemia and associated meningitis. In addition, these organisms are capable of causing infections of the respiratory tract and oral cavity and so have the potential to be spread via aerosol. Regarding swapping genes between strains of the same species is a process which occurs naturally in the wild leading to development of families of so called mosaic genes. This work will only be done in species where such events occur naturally, hence such work only mimic events in the real world. Such gene swapping will not lead to a strain that is anymore virulent than the host organisms form which the single gene is derived. Overall pathogenicity change from the parental strain will be minimal and in some cases diminished. The majority of bacterial species studies are naturally carried by high numbers of humans any way and this poses the greatest route of spread. Whilst some GMM’s will have antibiotic resistance genes introduced, the antibiotics in question are not generally used in the clinic to treat such infections.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All plastics coming in contact with GMM’s will be decontaminated by immersion in 1% Virkon for a minimum of 30 minutes sufficient to kill species from all genera listed in the work to be done (see efficacy pdf). All plastics will be subsequently autoclaved prior to disposal at landfill sites. Liquids/media containing GMM will be decontaminated by mixing with Virkon to a final concentration of 1% to ensure killing and incubated overnight prior to disposal down the sink. Following decontamination in Virkon any glassware will be washed and autoclaved for reuse.
The committee requested qualification of the types of genes that will be manipulated and "swapped" between bacterial species so that a more informed assessment could be made of the likely effects. This is reflected in the attached risk assessment. The activity was discussed at its meeting on January 27th 2010.

**Significant Change ID**: 

---

22/05/2012
Immune-mediated inflammatory eye disease (Uveitis) and retinal degenerative disorders including age related macular degeneration (AMD) account for the majority of visual handicap in the working age population and the ever increasing ageing population. Our research focuses on how one of the essential immune cells, the macrophage mediates damage and angiogenesis to the retina in models of uveitis, (experimental autoimmune uveoretinitis; EAU) and of age-related macular degeneration (laser-induced choroidal neovascular membranes (CNV)). Both EAU and CNV are established preclinical models that are widely used for the assessment of immunotherapeutic efficacy towards the translation of therapy, allowing us to see how we can inhibit damage and restore tissue function.

The recent advances in gene transfer techniques has lead to the use of retroviral and lentiviral based vectors to transduce tissues of the eye including the retina and retinal pigment epithelium, to achieve effective, stable long-term gene expression (Yanez-Munoz et al., 2006 Mar;12(3):348-53 Nat Medicine; Balaggan KS & Ali RR. Ocular gene delivery using lentiviral vectors. Gene Therapy 2012 19: 145-153). Lentiviral vectors can be used both to introduce a gene product into in vitro systems or animal models, but are also effective tools to block or "knock-down" expression of a specific gene using RNA interference technology.

The project seeks to establish whether lentiviral vectors that express anti-inflammatory cytokines or pro- or anti-angiogenic proteins, or "knock-down" vectors that express short-hairpin RNA (shRNA) to block expression of such proteins, when administered to the eye can directly modulate macrophage phenotype and thus influence severity in both EAU and CNV disease models. In another experimental approach, we will generate mouse chimeras following standard protocols, in which donor bone-marrow that is transfected with the "knock-down" gene expressing viral vectors is transferred, into irradiated recipients. To this end, mice will be injected, and animals sacrificed in the majority within 2 months and occasionally experiments extending up to 1 year post-injection where in all animals, tissues will be removed for histological assessment. To determine whether the expression of vectors influences the kinetics and degree of cellular infiltrate observed in the eye during disease, some eyes will be dissected and infiltrating immune cells isolated for full phenotypic characterisation by flow cytometry (FACS).

Cloning, generation and in vitro assessment of recombinant Lenti-viral vectors has already been conducted by our collaborators form the Molecular Therapy Division based at the Institute of Ophthalmology, University College London.

**Recipient or parental organism**

Human Immunodeficiency Virus (HIV) is in group 3 according to the ACDP definition of biological hazard and although HIV causes a fatal disease, the virus presents a low risk of spreading since retroviruses require close contact for their transmission, and survival in the environment is poor. The minimal HIV vectors have been developed to be replication defective, non-pathogenic and non-immunogenic. It is expected that both would have similar survival characteristics, and do not pose a risk to the environment. Since these vectors can not produce HIV in biological system, he risk of developing AIDS upon accidental injection of an individual is extremely low. Furthermore, the vectors have been designed to minimise the chance of any recombination events resulting in replication competent virus (RCV). Testing of the system for RCV has shown absence of detectable helper virus. Although the minimal HIV vector pseudotyped with the various envelopes can access all human cells, dissemination of the viral vector should not occur, which is in contrast to the wild type virus.

**Host/vector system**

HIV retroviral vector particles are produced by a standard three plasmid co-transfection procedure which has been designed to minimise the risk of generating replication competent virus. The vector genome pH4 is based on the HIV genome but has large deletions resulting in the absence of tat, vpr, vpu, vif and nef. The posttranscriptional transactivator rev and its responsive element (RRE) remain in the vector to increase transgene expression. The second component is an HIV gag/pol expression vector. The vectors have been designed to minimise the chance of any recombination events occurring where replication competent retroviruses (RCR) may result. The minimal HIV vector systems can access human cells by virtue of the amphotropic Moloney murine leukemia virus (MoMuLV), primate retroviral Gibbon ape leukemia virus (GALV) or vesicular stomatitis virus G-protein (VSV-G) envelope. VSV is a Biological Hazard Group 2 agent and should therefore be used at Containment level 2. The minimal HIV vector system, lacking tat, pseudotyped with one of these envelopes should be handled at a minimum of ACGM Containment level 2. The system has been tested for
RCR's and has been shown to be free of helper virus

Origin & function

All cDNA generated from cDNA libraries using standard cloning techniques.
sh RNA targeting sequences were designed using RNAi sequence design software and commercially synthesized.

The biological action of the proposed inserts are (1) immuno-modulatory, and are known to reduce inflammation and therefore regarded as immune- suppressive, including cytokines II-1Ra, II-4, IL-10 and other molecules CD200; or (2) anti-angiogenic, and inhibitors of vascular endothelium growth factor (VEGF) function and retinal neovascularisation, such as soluble Flt-1.

Evaluation of foreseeable effects

If rHIV were to infect another mammalian host, the risks would be minimal as the vector cannot recombine, and the genes expressed are not plasmid borne. The encoded genes could be expressed if they were transferred to another organism following a breach of containment, but the encoded products are not toxins or hormones and are unlikely to be expressed at levels high enough to have any systemic effect. The cDNA and shRNA inserts are mouse-specific so could have an effect in rodents however the vector is unlikely to survive in the environment long enough or be in a form that could readily affect an animal if containment were breached.

The cDNA or shRNA sequences are not associated with any risk such as an increase in pathogenicity and are not oncogenic so pose no risk to humans or animals. Recombiantion events leading to the production of recombinant viruses are unlikely, so an infection would be very limited in its consequence to exposed animals. It is unlikely that rHIV will survive outside of laboratory conditions.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Handling of mice that have been infected with rHIV poses no extra risk to Animal Unit Staff, as following injection of virus particles or transfected bone marrow cells, mice will only contain stably transfected cells and no free virus will be present. Therefore the use of standard personal protective equipment (gown, face-mask and gloves) as stated in the Animal Services Unit (ASU) standard operating procedures, will provide sufficient protection during all animal handling. There are potential hazards associated with injection of rHIV particles into wild-type or Genetically Altered (GA) mice, such as accidental needle-stick injury. To prevent this occuring only experienced and licensed staff will undertake any regulated procedures required for this part of the project.

The ASU animal house is a high security facility with many measures in place to prevent escape of mice into the environment. Mice are housed in secure cages in rooms designated to one individual research group per room. Rodent barriers exist to prevent mice from escaping and travelling between rooms and exits. Animal bait traps are placed throughout the facility and regular checks are made to ensure that if any cracks/holes in walls, doors etc appear they are repaired immediately. However, in the unlikely event that any experimental mice do escape, they would represent no more of a risk to the general population than conventional wild-type mice.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The departmental waste policy will be followed. Spesifically:

rHIV are extremely labile and are inactivated by ethanol, detergents or bleach.

All solid waste will initially be inactivated by exposure to 2% Virkon for at least 30 minutes. All solid waste (animal tissues, tissue culture plates) will be placed in
autoclavable bags, and (plastic tips, pipettes or slides with sections) in an appropriate BioBin or CinBin, sealed and disposed of by autoclaving (121-125°C for 15 mins) and discharged to drains.

Animal waste - carcasses will be disposed of by incineration following the Animal Services Unit rules.

For any minor spills of viral preparations, and all bench tops on which procedures involving virus has been used, 2% Virkon disinfectant solution will be used to decontaminate surfaces (10 min contact time), followed by 70% ethanol. Laboratory tissue waste will be disposed as potentially infectious solid waste via the autoclaving and incineration route: Autolaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)
Chemical disinfection with Virkon, used according to manufacturer's instructions under standard conditions, manufacturers validation (e.g. 99.998% kill).

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

The Bristol Biological and Genetic Modification Safety Committee reviewed this risk assessment at its meeting on 27th April 2012. The committee agreed that the work described involving lentivirus/inserts with extensive use of sharps in the work procedures would require containment level 2 measures specifically access restrictions and assessment of staff training and experience (recorded). They also agreed that following infection of animals and bone marrow for transplant and removal of free virus that the risk would be reduced to a level commensurate with containment level 1.

Our ultimate aim will be to use lentiviral vectors as tools for the generation of stable cell lines expressing immune molecules of interest, in order to advance our understanding of their functions and involvement in various disease settings.

Recipient mammalian cells to be transduced using lentiviral delivery will include either immortalised cell lines (e.g. Jurkats, HEK293T, C1Rs) purchased from commercial sources (e.g. ATCC) or peripheral blood mononuclear cells (PBMCs) obtained with appropriate ethical approval and informed consent (in the case of samples of human origin). This work involving lentiviral vector is considered to be a class 2 activity to be undertaken at containment level 2 (until cells are virus free).

The lentiviral vector being used in this study would be considered to be a hazard group 1 biological agent possessing the safety features of a 3rd generation system as discussed in the risk assessment (multiple plasmids, self-inactivating, lack of WPRE sequences). That said, some of the inserts in the modified virus, could under a worse case scenario if accidental exposure occurred, lead to inappropriate immune responses (e.g. autoimmunity). Although the virus is replication defective, there could be enhanced effects due to evasion of immune tolerance mechanisms by inadvertent modification of immune cells following any accidental exposure (e.g. leading to clonal expansion).

We consider that the likelihood of exposure in this study is low because:
• No sharps will be used
• Small volumes will be used
• Cell cultures require additional treatment for efficient transduction with lentivirus in vitro and so the likelihood of expression in vivo is likely to be lower even if exposure occurred.

However, exposure remains possible under certain circumstances e.g. due to skin conditions or mucosal contamination through splashing which would be reduced by the wearing of gloves and use of a microbiological safety cabinet (which are used anyway for work protection). SACGM guidance also recommends that a class 1 designation is not appropriate where inserts are considered to be “biologically active” as we feel is the case in this study and has been outlined in the first paragraph.

Once the mammalian cells have been transduced, washed free of virus and passaged, the cells would present the same hazards as the original unmodified cells. Cells, unless fixed chemically, are handled under containment level 2 conditions to protect from any native contaminants or other hazardous properties as considered in COSHH risk assessments that are already in place.

I am not claiming exemption from disclosure for sections of the risk assessment.

Summary of files attached to this notification
Attachments Uploaded
This notification therefore relates to the work with the genetically modified lentivirus vector at containment level 2 (GM class 2).

Origin & function

The inserts will fall into the following categories:
1) Immunoregulatory molecules (e.g. T-cell receptors, CD4/CD8 coreceptors, MHC-I/MHC-II molecules, coinhibitory/costimulatory and cytokine/chemokine receptors).
2) Reporter proteins (e.g. GFP, tCD34, rCD2).
3) Transgene expression enhancers (e.g. 2A peptide).
4) Mammalian target gene repressors (e.g siRNA).

The cDNA insert sequences are synthesised de novo and purchased from commercial suppliers (e.g. GeneArt) and are not sourced from any organism.
Evaluation of foreseeable effects

The lentiviral vector being used in this study would be considered to be a hazard group 1 biological agent possessing the safety features of a 3rd generation system as discussed in the risk assessment (multiple plasmids, self-inactivating, lack of WPRE sequences). That said, some of the inserts in the modified virus, could under a worse case scenario if accidental exposure occurred, lead to inappropriate immune responses (e.g. autoimmunity). Although the virus is replication defective, there could be enhanced effects due to evasion of immune tolerance mechanisms by inadvertent modification of immune cells following any accidental exposure (e.g. leading to clonal expansion).

We consider that the likelihood of exposure in this study is low because:
• No sharps will be used
• Small volumes will be used
• Cell cultures require additional treatment for efficient transduction with lentivirus in vitro and so the likelihood of expression in vivo is likely to be lower even if exposure occurred.

However, exposure remains possible under certain circumstances e.g. due to skin conditions or mucosal contamination through splashing which would be reduced by the wearing of gloves and use of a microbiological safety cabinet (which are used anyway for work protection). SACGM guidance also recommends that a class 1 designation is not appropriate where inserts are considered to be “biologically active” as we feel is the case in this study and has been outlined in the first paragraph.

Once the mammalian cells have been transduced, washed free of virus and passaged, the cells would present the same hazards as the original unmodified cells. Cells, unless fixed chemically, are handled under containment level 2 conditions to protect from any native contaminants or other hazardous properties as considered in COSHH risk assessments that are already in place.

This notification therefore relates to the work with the genetically modified lentivirus vector at containment level 2 (GM class 2).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid culture wastes are treated for 12 hours with sodium dichloroisocyanurate (Haz-tab granules; 10,000 ppm) and disposed to drain with a copious amount of running water. Disinfection validated for lentivirus in manufacturer’s data - referenced at http://guest-medical.co.uk/productspage/disinfectants/haz-tab-tablets/)
Solid waste such as pipette tips and plasticware, that has been in contact with lentivirus, is similarly decontaminated with sodium dichloroisocyanurate in situ prior to removal for autoclave sterilisation. Autoclaves are routinely maintained and validated and individual runs monitored. Autoclave sterilisation is considered to give 100% final kill.

The University Biological and Genetic Modification Safety Committee (BGMSC) reviewed this risk assessment and approved it for notification as a class 2 activity at its meeting on 5th February 2016. The committee discussed at length the arguments for and against a class 1 classification in relation to previous discussions with and presentations given by HSE. The arguments for a class 1 designation were based upon the safety features of the lentivirus vector, the small scale nature of the work and the elimination of sharps. However, the committee concluded that the PI had made a valid argument about the potential severity of any effects taking into account the inserts and although the likelihood of this being realised is not high, a class 2 designation would be consistent with previous activities reviewed by this committee and the guidance contained in the SACGM compendium for work with lentiviruses. The committee also agreed that a class 1 designation would be appropriate for virus-free modified cell cultures but that due to the inherent nature of these cells they should be handled under CL-2 conditions under COSHH until they had undergone chemical fixation.

Please enter comments on the GM safety committee on the risk assessment

The University Biological and Genetic Modification Safety Committee (BGMSC) reviewed this risk assessment and approved it for notification as a class 2 activity at its meeting on 5th February 2016. The committee discussed at length the arguments for and against a class 1 classification in relation to previous discussions with and presentations given by HSE. Project Additional Information

Purposes of the contained use

The purpose of the contained use is the deeper understanding of influenza virus and its dependence on host cell proteins. Reporter cells that have been genetically modified are used to facilitate the detection of virus infection and virus-host interactions.

Recipient or parental organism

CELL LINES
Cell lines used are already genetically modified A549GFP1-10, A549GFP1-9 (both human cell lines), and MDCK GFP1-10 (canine cell lines), all of which are for combinatorial use with a GMO influenza strain harbouring the GFP11 (11th beta strand of GFP) for complementation GFP fluorescence analyses. The genetically modified cell lines are considered no more harmful to human health than the non-modified cells. They will be handled at containment level 2 under COSHH and while lentivirus is present or until they have been chemically fixed.

BACTERIA (E. coli)
Used for plasmid manipulation and are non-pathogenic strains. This work is considered class 1/containment level 1.

INFLUENZA A VIRUS
The influenza viruses to be used are mouse-adapted WSN strains (H1N1) and considered hazard group 2. The work does not involve use of influenza viruses of pandemic potential or of avian origin.

Host/vector system

LENTIVIRUS
The lentiviral vector being used in this study would be considered a hazard group 2 biological agent due to it being 2nd generation in formation and used with biologically active inserts. Lentiviruses do not have the capacity to infect as airborne pathogens and no sharps are required for this work. The virus is replication defective but there could be enhanced effects due to evasion of immune tolerance mechanisms by inadvertent modification of immune cells following accidental exposure (e.g. leading to clonal expansion).

**INFLUENZA VIRUS AND INSERTED MATERIAL**

(A). WSN PA-GFP has been genetically modified to express GFP as a fusion protein at the C-terminal part of the Influenza viral polymerase subunit PA protein. The maximum yield of this genetically modified strain is $5 \times 10^6$ PFU/mL whereas the wild-type can reach over $1 \times 10^9$, thus the strain is 200-fold attenuated compared to wild type. The strain was provided by Seema Lakdawala (University of Pittsburgh).

(B). WSN PB2-GFP has been genetically modified to express a split GFP11 (16 amino acids the 11th beta-strand of GFP) as a fusion protein at the C-terminal part of the Influenza viral polymerase subunit PB2. Its yield can reach $1 \times 10^8$ PFU/mL and attenuated compared to wild-type. The strain was provided by Nadia Naffakh (Pasteur Institute).

**LENTIVIRUS / CELL LINES AND INSERTED MATERIAL**

Cell lines will be transduced with genetically modified lentivirus vectors to produce stable cell lines expressing genes of interest for interaction with influenza virus proteins. These are detailed in the risk assessment with examples and include organelle marker genes, cytoskeletal marker genes, camelid nanobodies and binder proteins and cell/nuclear transport molecules. These are all generated as oligonucleotides.

**Evaluation of foreseeable effects**

**CELL LINES**

The same hazards exist as for the GM lentivirus during cell culture with the virus present. Once cells have been passaged and washed free of virus the GM cell line isn’t any more hazardous than the original cell.

Many in vitro cell lines (including the ones used for lentiviral transduction) already have defects in tumour suppressor genes and are handled under containment level 2 conditions without additional precaution. Once fixed chemically, the inherent hazards with the cells due to potential contamination would also be reduced and as the likelihood of exposure is low the risk would therefore be much lower.

**LENTIVIRUS**

The vector being used in this study would be considered a hazard group 2 biological agent due to it being 2nd generation with biologically active inserts. The virus is replication defective but there could be enhanced effects due to
evasion of immune tolerance mechanisms by inadvertent modification of immune cells following accidental exposure (e.g. leading to clonal expansion). Some of the inserts in the modified virus could under a worstcase scenario if accidental exposure occurred lead to inappropriate immune responses (e.g. autoimmunity). In the most extreme outcome, viral vector/inserts could inactivate tumour suppressors in the accidentally infected person, triggering cellular transformation and oncogenesis.

Lentiviruses do not have the capacity to infect as airborne pathogens and no sharps are required for this work thus minimising the likelihood of exposure.

**INFLUENZA VIRUS**

In the most extreme case, a GMO influenza strain may revert to wild-type after several passages but will still be a minimal threat to the workers. Any other recombinant viruses (such as by accidental co-infection with another influenza strain) are unlikely to arise in the short length (under 12 hours) of our typical experiments. Long infection assays (up to 3 days) are performed only for the purpose of virus stock propagation which is always performed in a flask with a filtered lid thus minimising any risk of cross contamination of viral strains. It is highly unlikely that any higher pathogenic strains will arise as a result of the use of these GMO strains.

Mouse models of IAV are not suitable for transmission assays, since they do not display flu-like symptoms (sneezing, coughing) that are essential for animal-to-animal transmission. Therefore, even if an infected rodent escaped out of captivity it is unlikely it can be a source of transmission and contaminate wild life/other rodents. Furthermore, there are no rodent experiments planned in this IAV risk assessment using.

At the relatively low doses of viruses used in this assessment, it is highly unlikely that an escaped virus is capable of infecting animals outside of containment or contaminating plants and wild life in any way. Furthermore, removal of lab coats and hand washing following virus experiments substantially reduces the likelihood of viruses escaping outside containment.

The wild-type IAV may survive a few hours or days if released from containment in a micro droplet (e.g. aerosols, typically caused by sneezing or coughing of an infected human patient). If a viral particle escaped containment attached to clothing, for instance, they will still be susceptible to extermination without the protective environment of an aerosol within a short period of time.

Handling the genetically modified viruses has been assessed as a class 2 activity.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste e.g. contaminated plasticware will ultimately be autoclaved to sterilise. Waste will be removed from the laboratory through a central twice daily collection service which removes biohazard waste to autoclaves for on-site destruction prior to disposal. Autoclave runs are monitored and autoclaves validated for waste treatment. Liquid waste (e.g. cell culture media containing IAV and lentiviral particles) will be disinfected for 12 hours using Virkon which has been validated as effective at the final concentrations to be used by the manufacturer. Disinfected liquid waste is disposed to drain with copious amounts of water.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

The University GMSC discussed this work at its meeting on 14 February 2018. The committee agreed with the classification of the activity due to the work with influenza virus but it required clarification from the proposer regarding the generation of lentivirus system to be used, which wasn't clear in the original risk assessment, and consideration of environmental risks. Following receipt of further information and a revised risk assessment the committee approved the work for notification.

</table>
The aim of this programme is to determine how the fundamental function of eukaryotic trafficking and signalling pathways controls cell growth and division and how their dysregulation leads to health conditions such as cancer, chronic inflammation and cardiovascular disease. Cell growth and proliferation are dependent on an interplay of proteins regulating cell-cycle progression, DNA damage repair, signal transduction, cytoskeletal organisation and metabolism. Furthermore, proteins controlling cell growth also regulate homeostatic functions such as metabolism and immunity. Indeed, many noncanonical functions have recently been discovered for cell cycle genes in post-mitotic cells. Ultimately our research should identify new targets for the design of therapies to treat patients with chronic health conditions.

This programme involves use of viral vectors to express or modulate expression of cell cycle and DNA repair genes. Accidental infection of the researcher could potentially affect endogenous tumour suppressors and oncogenes. In the worst-case scenario, accidental infection may predispose to cellular transformation and tumorigenesis.

Recipient or parental organism
- Non-pathogenic strains of E. coli e.g. DH5α strains (class 1 activity)
- Plasmodium chabaudi (rodent pathogen, class 1 activity)
- Established mammalian cell lines e.g. HeLa, RPE-1, BJ5Ta, HEK-293
- Primary non-human cells e.g. mouse and rat fibroblasts
- Primary human cells e.g. hematopoietic, endothelial, keratinocytes
- Insect cell lines e.g. Sf9, SF2, Hi5

Host/vector system
- Non mobilisable plasmids including antibiotic resistance genes (e.g. Amp, Kan)
- Mammalian expression plasmids including antibiotic resistance genes (e.g.
Pur, Neo) and non-specific tissue promotors such as CMV, SV40 and tissue
specific promotors such as EF1-a
- CRISPR and shRNA plasmid vectors
- Adeno-associated virus AAV (disabled human vectors from helper virus free
systems lacking genes required for replication)
- Adenovirus (attenuated E1/E3 deleted Ad5 strains)
- Lentivirus (attenuated 3rd and 4th generation vector systems with SIN
sequences by preference. 2nd generation systems will only be used where
the insert/vector combinations already exist in these vectors as gifts or as
purchased or where absolutely required by the experimental design)
- Baculovirus (attenuated AcNPV)

Origin & function

All inserts will be amplified from mammalian cDNA by rtPCR or synthesised
oligos. The following categories of genes will be silenced, deleted or inserted
and expressed in the final recipient using the vector delivery systems stated.

Cell cycle genes
e.g. CDK6, p21cip
Regulating DNA replication, mitosis, microtubule dynamics, spindle
assembly checkpoints.

DNA repair genes
e.g. ATM, ATR, CHK1
Genes regulating DNA damage detection, checkpoint initiation, DNA repair,
apoptosis.

Cytoskeleton proteins, including motor proteins
e.g. Eg5, NEK2, dyneins, kinesins
Regulators of cell division, motility, intracellular trafficking.

Metabolism regulators
e.g. pentose phosphate genes, tafazzin
Regulators of energy production, mitochondrial function, biosynthetic
pathways.

Signal transduction genes
e.g. PKC, Rac, T-Cell Receptor
Cell surface receptors, kinases, phosphatases, enzymes catalysing posttranslational
modifications, proteases, cell-cell communication.

Regulators of cellular homeostasis
e.g. ATM, neutrophil elastase
e.g. ATM, neutrophil elastase
Proteases, genes involved with degradative pathways, such as autophagy,
immune defence, cellular stress response.

Structural proteins
e.g. Lamin A Histone H1
Nuclear proteins (eg. lamins), plasma membrane proteins, proteins involved
structural integrity, organisation and function of subcellular components.

Cytokines
**Evaluation of foreseeable effects**

**HUMAN HEALTH**
The vectors involved in this programme are generally considered to be crippled laboratory organisms, attenuated strains, or restricted to rodents. However, accidental infection with viral vectors remains a possibility and there is a risk of biological effects being realised when biologically active inserts are used, or genes are being targeted. The processes being targeted include human cell cycle proteins and their modification in experimenter’s cells after accidental infection could potentially modulate endogenous tumour suppressors or oncogenes. However, oncogenesis requires the concerted action of several oncogenes and modulation of a single gene does not lead to tumorigenesis. Nevertheless, in the worst-case scenario, accidental infection with any of the genetically modified viruses targeting these sequences may predispose to cellular transformation.

Regulatory sequences used will include promoters designed to drive high level expression in a broad range of tissue types and therefore the risk of effects from accidental infection is likely to be increased in these cases.

**ENVIRONMENTAL SAFETY**
We consider that all work in this programme is likely to be of more risk to human health and safety than to environmental safety because:

- E. coli strains that will be used are attenuated for laboratory use and cannot survive in the environment.
- The viral vectors to be used will also be defective such that they are unlikely to survive in the environment.
- Eukaryotic cell lines and primary cultures can only survive in specialised cell culture medium with optimised nutrients, pH and temperature.
- Animals infected with the P. chabaudi will not excrete the genetically modified parasite and the only way to transmit to other animals (rodents) in the environment would be via a mosquito bite which is extremely unlikely to happen in the animal containment facilities. The GMO is effectively contained in the animal until it is incinerated.
- We do not consider any planned modifications, including gene editing, to confer an advantage to the GMOs; indeed, the converse is most likely to be true, that we will in fact limit the ability of cells to divide.
### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable (animal infection studies only)

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

<table>
<thead>
<tr>
<th>Liquid waste (e.g. cell culture media containing lentiviral particles) will be disinfected based on individual risk assessments. Sodium dichloroisocyanurate will be used at 10,000 ppm for 12 hours contact time (manufacturers testing) or Virkon at 1% final concentration for at least 10 minutes, usually 12 hours, (manufacturers testing). Disinfected waste rendered safe to handle will be discarded to drains.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Solid waste will normally be autoclaved in the building using validated autoclaves (considered 100% deactivation) prior to disposal by land-fill or incineration (based on University waste contractor arrangements). Autoclave runs are monitored and logged. Solid class 1 waste and some class 2 waste may be deactivated and disposed of by incineration where an individual risk assessment has fully considered this method.</td>
</tr>
<tr>
<td>Sharps waste and infected animal carcases and tissues will be incinerated by the University's hazardous waste contractor. University hazardous waste collection and disposal contractors are fully audited by the University’s Hazardous Waste Manager to ensure compliance with requirements for the storage and transport of infectious goods. Audits also include GM premises registration checks.</td>
</tr>

Please enter comments on the GM safety committee on the risk assessment
The University GMSC has reviewed 2 risk assessments covering activities that are proposed under this CPW to date. The risk assessment example which is enclosed with this notification was reviewed at its meeting on 14th February 2018 but has not yet been notified. The committee agreed with the classification and made several recommendations that the investigator incorporated into the final risk classification and made several recommendations that the investigator incorporated into the final risk assessment.

The proposed CPW (and the second class 2 risk assessment) was discussed at its meeting on 2nd May 2018 and the committee agreed that the scope of work covered by these two risk assessments that is ready to take place and the anticipated work in this building was suitable for a CPW. The final CPW scoping document (also enclosed with this notification) was reviewed by the committee at its meeting on 5th September 2018 and notification approved. The committee concluded that this document and the limits set out in it can be used by the committee when considering any further risk assessments for activities to be covered by this CPW.

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

The aim of this connected programme of work is to develop innovative and efficacious prophylactic and therapeutic vaccines against infectious agents such as HIV and Influenza. Through this work we hope to develop the next generation of vaccine, and elucidate novel information pertaining to the basic biology of infection and how the immune system can be harnessed to prevent infection. We will use a variety of different vaccine technologies such as DNA, recombinant protein and nanoparticle-based immunogens to elicit protective immune responses. Additionally, our research aims to identify and develop novel adjuvants which can significantly augment anti-pathogen immune responses in the systemic circulation and at mucosal portals of entry.

**Recipient or parental organism**

- E. coli (non-pathogenic strains such as K-12 derivatives)
- Saccharomyces cerevisiae
- Mammalian cell lines
- Human Immunodeficiency Virus-1 (HIV-1)
- Influenza virus (no pandemic strains)

**Host/vector system**

- Lentivirus - modified vectors only. No full length (5'LTR-3'LTR inclusive), replication competent virus, will be inserted into pREC vectors.
- Standard non-mobilizable plasmids for routine cloning with antibiotic resistance genes e.g., ampicillin, kanamycin.
- Mammalian expression plasmids including antibiotic resistance genes e.g., puromycin, neomycin, blasticidin, hygromycin; promoter regions e.g., CMV, SV40, EF1-α, tetracycline-repressible promoters.

**Origin & function**

**Class 3 activity**

Near full length HIV genome (gag-3'LTR) or individual genes.

Source: PCR amplified from proviral DNA, RNA isolated from blood, or from DNA expression vectors.

Function: HIV protein expression for recombinant protein or nanoparticle self-assembly. Particle expressing plasmids do not have a 5'LTR, contain viral RNA packaging defects and a nonfunctional integrase. VLPs are therefore non-infectious particles, if transfecting with a complementing vector (pREC_Sbf1). Gene editing of HIV proteins (e.g. incorporating stabilizing disulphide bonds, amino acid sequence changes or glycan modification etc.) is expected to render the proteins more immunogenic while reducing the fitness of viruses that contain them.

**Class 2 activity**

Genes encoding Influenza HA, NA, M1 and M2.

Source: Purchased oligo or PCR amplicon from purchased plasmid vector.

Function: Produce Influenza proteins or nanoparticles using proteins expressed from genes isolated from lab adapted strains (X31, PR9 and WSN), and generally circulating influenza viruses such as H1N1 and H3N2. Pandemic and HPAI (e.g. H5, H7 and H9) are not being used. The HIV gag gene may be included into these constructs for studies involving RNA adjuvant packaging. Gene editing of HA and NA surface proteins (e.g. incorporating stabilizing disulphide bonds, amino acid sequence changes or glycan modification) is only expected to render the protein more immunogenic.

**All activities**

Immuno-stimulatory RNA motifs

Source: PCR amplicon from purchased plasmid vector
Function: Generates immunostimulatory RNA transcripts that can be used as exogenous adjuvants for vaccines or for selective packaging into particles. The RNA will trigger pattern recognition receptors (PRR) within cells.

Reporter genes e.g., GFP and luciferase
Source: Purchased oligo or PCR amplicon
Function: Reporter genes for quantifying cellular proliferation and subcellular localization of proteins

Evaluation of foreseeable effects

Full or partial Envelope (Env) genes cloned into the common HIV-1 backbone within our pREC vectors are not expected to have any alteration of existing traits beyond that observed with other characterized HIV-1 viruses as they are derived from individuals naturally infected with circulating viruses or lab adapted strains. The Env genes are expected to bind human CD4 and chemokine receptors just like those of known HIV strains. Env-deleted viruses pseudotyped with VSV-G would be capable of by-passing normal entry requirements and entering target cells by endocytosis. The VSV-G would only be used in conjunction with Env deleted vectors, making this a single round infection only.

Genetic modifications to the hemagglutinin and neuraminidase proteins of the influenza virus are expected to have either no effect, or will impair the viruses ability to replicate or increase its susceptibility to immune mediated clearance. In the unlikely event that the genetically modified virus recombines with another influenza virus, we would expect the resulting virus to either replicate as normal, be more susceptible to host mediated immunity, become attenuated or even inactivated.

We do not consider any of the planned modifications, including gene editing, to confer an advantage to the GMOs affecting environmental safety; indeed, the converse is most likely to be true, that any modification will be deleterious to the virus.

The virus like particles generated in these activities are devoid of viral genomes and due to the engineered modifications cannot replicate.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We seek 4 derogations for work involving HIV at CL3. Specifically:
1. Derogation from implementing an air pressure within the CL3 laboratory that is negative to atmospheric pressure.
2. Derogation from HEPA filtration of extracted air from the CL3 laboratory.
3. Derogation from using a laboratory that is sealable for fumigation.

Justified as HIV-1 cannot survive outside a host cell and outside optimal tissue culture settings degrades very rapidly. We have also minimized and compartmentalized the volumes of virus being grown and processed, have stringent disinfection procedures in place, and ensured multiple layers of containment during both transportation of virus between the MSC and incubator as well as within the centrifuge. There is no evidence for airborne transmission, none of the work will affect this and measures being taken will minimise the likelihood of aerosol release.

4. Derogation from the requirement to have an autoclave in the laboratory suite.

This can be justified using the same arguments as above regarding transmission route, limited survivability, compartmentalization of the volumes of virus being grown and processed and the stringent disinfection procedures in place. All waste will be disinfected before leaving the CL3 and/or will be in sealed containers and always handled by CL3 trained workers for immediate autoclaving. No waste will be stored outside the CL3. There is an autoclave in the same building as the laboratory.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Low titre liquid class 3 waste and all class 2 liquid waste – disinfection with 2% Distel or Virkon for 30 minutes minimum (in line with manufacturers microbiological testing
validation). This will render the liquid sufficiently safe for discard to drain.

High titre class 3 liquid waste – will be placed directly into a leakproof Dispo safe jar containing virucidal solution (final solution will not be less than 2% Virkon or Distel). Containers are then incubated for 30min, sealed, placed within autoclave basket lined with autoclavable Biohazard bag. Waste is then sent for autoclaving. Effectively non-hazardous waste discarded to drain.

All solid waste (e.g., plasticware) – disinfectant soak with 2% Distel or Virkon for 30 minutes minimum. Then autoclave sterilisation. Non-hazardous waste route for disposal.

Project Ref  85/08.1

Date Ackn'd  23/11/2017  
CU2 Project Title  Studying the function of putative virulence genes of S.aureus.

Class  Class 2  CultureVolClass2  1-50 Litres  CultureVolumeClass3-4
### Project Additional Information

#### Purposes of the contained use

Staphylococcus aureus is a major human pathogen and the purpose of our contained use will be to study the role specific genes play in diseases caused by the bacterium.

#### Recipient or parental organism

Wild type Staphylococcus aureus (ACDP category 2) will be used (e.g. strain 8325-4). E. coli strain DH5α (ACDP category 1) will be used (genotype: F- cp8OdlacZAM15 A(lacZYA-argF)U169 deoR, recA1 endA1 hsdRI7(rk- mk+ phoA supE44 A- thi-1 gyrA96 relA)). Wild type Lactococcus lactis strain MG1363 (ACDP category 1) will be used.

#### Host/vector system

pUC based plasmids e.g. the pLL plasmids (Luong et al. 2007. J. Micro. Methods. 70:186-190) and the p5K plasmids (Grkovic et al. 2003. Microbiology. 149:785-794) will be used to manipulate S. aureus. For expression in L. lactis the pKS8O plasmids will be used (Massey et al. 2001. Cell. Micro. 3:839-851). For purification the pQE vectors provided by Qiagen will be used. These plasmid contain a multiple cloning site into which the gene in question can be cloned. It results in the fusion of this gene to a poly-histidine tag which facilitates easy purification of the gene product.

#### Origin & function

This project will involve functional studies of genes believed to contribute to S. aureus' pathogenicity. Specifically, it will involve the cloning of pieces of DNA amplified from the chromosome of S. aureus by PCR into plasmid vectors in E. coli. In E. coli the genes may be further manipulated for example by performing site-directed mutagenesis (Strategene kit) to identify important amino acids. Proteins may be purified at the stage using a His-tag system. Where we need to inactivate genes in S. aureus a shuttle vector will be used. These are typically pUC based plasmid into which a S. aureus origin of replication has been cloned, which allows the plasmid to replicate in both host organisms. Gene inactivation will be performed as follow: an antibiotic resistance cassette will be cloned into the middle of the gene in E. coli. The resulting plasmid will be electroporated into the restriction minus, modification plus S. aureus lab strains RN4220. Here the temperature sensitive plasmid will be forced to jump into the chromosome by shifting between temperatures. From here the inactivated gene can be transduced using Phage 11 into the final recipient wild type S. aureus strain. S. aureus genes may also be cloned and expressed in the bacterium Lactococcus lactis. This bacterium is used as a heterologous expression system to study bacterial proteins in a non-invasive or non-pathogenic bacterium. Here the virulence genes will be cloned into the pKS8O plasmid.

The types of genes to be studied will be those involved in host-pathogen interactions. For example the fibronectin binding proteins, the Eap proteins. These are both involved in adherence of the bacterium to human tissues.
With good microbiological practice the host organisms pose minimal risk to human health. Expression of individual S. aureus proteins in either E. coli or L. lactis may make them behave more like this ACDP cat 2 organism but is unlikely to make them more pathogenic than S. aureus itself. There are no foreseeable hazards associated with inactivating these genes in S. aureus above what is already associated with working with wild-type S. aureus. If anything we will be making them less pathogenic. With good waste kill management and microbiological practice environmental contamination with these organisms is unlikely, however should a breach in procedure occur the genetic manipulations will make them less fit than wild type environmental organisms and they will therefore not be competitive. The plasmid vectors used in this study are not naturally mobilisable. They contain origins of replication specific to the host strains and antibiotic resistance cassettes, but not ability to form conjugative pili. Under laboratory conditions (e.g. electroporation of high concentrations of purified plasmid into a strain) they can be made to move between E. coli and S. aureus. But as neither of these organisms (nor L. lactis) are naturally transformable and neither have the ability to form conjugative pili, the plasmids are considered non-mobilisable from this point. Poor microbiological techniques are used it is possible that the GMMs could escape into the environment on the hands/clothes of laboratory workers. All workers will be trained in this and will not be allowed to work with the GMM5 until their techniques are considered adequate. If any of our decontaminating procedures could fail, for example the departmental autoclave could malfunction, resulting in the release of contaminated plasticware. Or an inactive batch of Virkon could be purchased, However control measure are in place to prevent this, such as regular testing of the efficacy of our Virkon, and routine servicing and testing of the departmental autoclave.

Is an emergency plan required according to regulation 20? N

comments on first draft of risk assessment:
Further detail on the following issues is needed as requested by the HSE advisors:
1. mobilisation of the vector
2. decontamination procedures
3. genetic characteristics of strains used (ie DH5a genotype)
These suggested amendments were all incorporated into this application and to the attached risk assessment. The final draft was then reassessed and considered to meet local requirements.

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information
Purposes of the contained use

The study of fungal virulence factors

Recipient or parental organism

Class 2 fungal species: Candida albicans, Candida spec., Sporothrix schenckii, and Cryptococcus neoformans var. neoformans C. neoformans var gattii.

Host/vector system

Vectors used to transfer fungal DNA onclude pBluescript derivatives, pSP72 derivatives, pUC19 and pUC derivatives

Origin & function

Genetic material involved originated from fungi, including the class 1 species Saccharomyces cerevisiae and Ashbya gossypii

Evaluation of foreseeable effects

We will delete or replace genes that are involved in diverse aspects of fungal virulence. Thus, we assume, that most strains created here will be less virulent due to reduced gene function

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid cultures will be treated with Dettol for 5 minutes. This is expected to kill >99% of microbes. Validation could be achieved by test plating of a de-contaminated culture prior to disposal. Solid cultures and contaminated solid waste will be collected in appropriate bins and autoclaved (126C, 30 minutes). Color-changing autoclave tape is used as the standard for a successful autoclave run. Autoclaving should eradicate all fungi completely.

Date Ackn’d            CU2 Project Title                     Class       CultureVolClass2       CultureVolumeClass3-4
01/12/2000             STRUCTURE OF V-TYPE ATPASE IN ENTEROCOCCUS HIRAE   Class 2       1-50 litres
Project Additional Information

Purposes of the contained use

Overproduction of the V-ATPase of *E. hirae* into which the V-ATPase operon has been cloned. (This work is self-cloning and the GMM has already been constructed and characterised elsewhere.)

The overproduction is wanted to allow purification of the V-ATPase for structural studies.

Recipient or parental organism

*Enterococcus hirae* (formerly *Streptococcus faecalis*), ATCC9790 and 25D.

Host/vector system

*E. hirae* (as above) as host; pHY300LK vector.

This is a commercially available, mobilisation defective vector from Yakuruto Co. (Japan). It is one of the smallest hybrids of a series of chimeric plasmids using the parental plasmids pACYC177 of *E. coli* and pAM-a of *Streptococcus faecalis*. This shuttle vector for *E. coli* and *B. subtilis* contains an RNA primer gene for ori-177; the R-Tc gene; the R-Ap gene; Rep-alpha-1 gene, which is the plasmid replication gene; two replication origins, one for *E. coli* and the other for *B. subtilis*; and a polylinker.

Origin & function

The genetic material cloned is derived from *E. hirae* and is cloned back into the micro-organism as host, i.e. the work is self-cloning. The resultant construct has already been characterised elsewhere (in Japan) and the work within the UK will involve growth, cell lysis and purification of the cloned protein.

Evaluation of foreseeable effects

*Enterococcus hirae* is a human commensal, which occurs in the intestine of normal healthy people and only occasionally causes disease due to getting into the wrong environment (e.g. the bloodstream). Since it can cause disease, it is classified as a Hazard Group 2 pathogen - in the same way as *Eschericia coli*.

The genetic modification involves self-cloning of an operon from *E. hirae*, in order to obtain increased yields of the protein product from this operon. The protein is membrane bound and will not increase the pathogenicity of the host (which has it naturally).

The only foreseeable affect is the disabling of the *E. hirae*, due to overproduction of one protein rather than the appropriate amount being made as in the wild-type cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only micro-organisms involved in this work.
Full containment level 2 will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

After growth, the micro-organisms will be centrifuged and collected. The culture supernatant will be disinfected with a clear phenolic disinfectant. During the initial experiments the optimum disinfection conditions will be determined, to obtain <1 viable cell/ml, and these conditions then be applied to all supernatants before discharge down the drain into the public sewer. The cell pellet will be resuspended and the cells lysed to prepare the protein. Any substantially solid residues will be inactivated by autoclaving at 135 for 15min, which is expected to give - 100% killing.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  Y

Please enter comments on the GM safety committee on the risk assessment

It was noted that E. hirae is the new name for Streptococcus faecalis, which is a normal component of the gut microflora in healthy individuals. However, since it does occasionally cause illness (mostly by infection of wounds) it is classified as Hazard Group 2 under ACDP guidelines.

Clones have already been constructed elsewhere, which have the V-ATPase operon self-cloned for high level expression in E. hirae. The vector is mobilisation defective.

It was agreed that neither the insert nor the vector increases the pathogenicity of the host, so this requires Containment Level 2 and is therefore Class 2.

**Project Additional Information**

### Purposes of the contained use

To study the control functions of the HIV LTR when inserted into the host cell genome by the viral integrase.

### Recipient or parental organism

Human tissue culture cell lines.

### Host/vector system

Laboratory strains of E. coli K12.

Tissue culture cells (human).

3rd generation HIV-based packaging constructs which give pseudo-typing with the envelope protein of vesicular stomatis virus, as described by Vigna & Naldini (J Gene Med, 2, 308-316 (2000)) and Dull et al. (J Virol, 72, 8463-8471 (1998)). This system involves co-transfection of the viral producer cells with separate plasmids expressing HIV gag-pol under the control of the CMV promoter, a Rev gene under the control of the RSV LTR, and a VSV envelope gene under the control of CMV.

### Origin & function

The inserts are a series or reporter genes, including luciferase genes, green fluorescent proteins (and their variants) and drug resistant genes, including neomycin, hygromycin and blastocidin resistance genes.

These inserts will be inserted under the control of the HIV LTR, in order to help in studying the control of transcription from this.

### Evaluation of foreseeable effects

The major potential hazard arises from the production of defective retrovirions, which are pseudo-typed with the VSV coat protein, following transfection of the t.c. cells. These will have a wide host range for infection, including humans. The inserted genes are all harmless reporter genes, which will not cause any hazard even if expressed in an unintended context.

The vectors being employed were developed for gene therapy and, despite being HIV-based, have a very low risk of any hazard other than that potentially arising from a single cycle infection with the inserted genes.

The classification of work with retroviral vectors is considered in ACGM Guidance Notes, Part 2B, Annex III paras. 14-34. The vector system for the eukaryotic work is based on HIV, which is a hazard group 3 pathogen. However, the individual plasmids do not contain a complete HIV genome between them, in particular lacking the tat.
env and nef genes. Moreover, in this 3rd generation packaging system the gag/pol and rev genes are on separate plasmids with no common sequences to allow homologous recombination and neither of these vectors has the packaging signals. This results in a particularly low recombination probability and no packaging of HIV genes. The only vector with packaging signals will contain only the inserted genes, which are of extremely low hazard and will not increase the pathogenicity of the cells in any way, although their expression might lead to cell death of individual cells.

Although the VSV-pseudo-typing of the defective retroviruses, produced from the packaging step in the t.c. cells, will broaden the host range, this is not considered to have any significant effect on the overall hazard, due to the very low hazard of the inserted genes in this work. It is therefore considered that Class 2 is appropriate for a provisional classification of the work in t.c. cells.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

| N/A |

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

| Full containment level 2 will be applied. |

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| Containment level 1 waste, generated during the preparative steps for the CL2 work, will be inactivated by either autoclaving, before discharge down the drain into the public sewer, or by incineration (in a registered facility). It is expected that these will give effectively 100% killing. Containment level 2 waste will be autoclaved (136C for 10min), before either subsequent discharge down the drain into the public sewer or incineration. It is expected that these will give effectively 100% killing. |

### Please enter comments on the GM safety committee on the risk assessment

This work involves the use of "third generation" HIV-based vectors to generate a retrovirus pseudo-typed with the vesicular stomatitis virus surface protein, which is capable of a single infective cycle in human cells. The intention is to obtain cell lines containing the gene for a reporter protein, under the control of the HIV LTR, which has been inserted into the cell genome by the normal function of the HIV integrase. The BSO pointed out that the ACGM Compendium of Guidance, Part 2B, Annex III, para. 26 says that work employing vectors based on primate lentiviruses should generally be Class 3, unless there is a clear justification for using a lower level of containment. The committee considered the particular vector system proposed for this work and concluded that it would require too many specific, non-homologous recombination steps for the generation of a normally infectious retrovirus to have anything more than a negligible likelihood. Moreover, the inserted genes are all for reporter proteins which do not pose any hazard to either humans or the environment. It was therefore agreed that there was a clear justification, in this case, for a lower level of containment and that the steps involving the production of the viral vector, infection of the host tissue culture cells and their subsequent propagation should be Class 2. The committee considered that any stable cell lines should be checked to ensure that they are not generating virions, by assaying the supernatants from cell cultures for reverse transcriptase, before they are brought out of CL2. The initial cloning steps, working with laboratory strains of E. coli K12, were considered to be class 1.

Withdrawn: **N**
Inserts used are all derived from mouse, human and Xenopus cDNA libraries and comprise wild type and mutated forms of Notch ligands, Notch receptors, suppressor of hairless homologues, mastermind homologues, and Notch target genes including the hairy/enhancer of split family of transcription factors. In addition mutant Xenopus beta catenin and mutants of MAP kinase will be expressed to determine how the Notch pathway interacts the wnt and Map kinase signalling pathways. Cell cycle inhibitory proteins such as p21Cip1 and Geminin will also be used.

In addition reporter constructs derived from the pGL3 series of vectors will be used; these consist of Notch and wnt responsive promoter elements, driving expression of the firefly and renilla luciferase genes. In some experiments green fluorescent protein will be expressed as a reporter.

The intended use is to study how these genetic elements control the cell development.

**Evaluation of foreseeable effects**

The main hazard arises directly from the recombinant retroviruses produced from the packaging cells. These yield both ecotropic and amphotropic retrovirions, depending upon the envelope protein supplied by the cell.

The packaging cell lines used to generate the retrovirus have either ecotropic or amphotropic envelope proteins, and the retrovirus therefore can either infect only mouse cells, or have a wider host range including human cells. Their infectivity is unstable and infection is only obtained by co-cultivation of the packaging cell line with ther recipient cells. The retrovirus is self-inactivating and there is thus no possibility of further transfer. With the ecotropic packaging cell line, there is therefore negligible risk to the worker or the environment.

With the amphotropic packaging cell line, the risk of infection of a worker during the packaging/infection step is small, but still not negligible. Although the inserted genes are not known to be oncogenic, they have this potential and it is considered that this part of the work is Class 2. In view of the, at worst, low-oncogenic nature of the inserted genes and also the self-inactivating nature of the retroviruses, there likelihood of any hazardous replication competent virus being generated is negligible and is no need to test for such RCV.

The single non-negligible hazard arises from the potentially oncogenic or cytotoxic nature of some of the inserts. This risk can be controlled if DNA grown up from such clones is handled appropriately; ie gloves should be worn, sharps avoided and allwastes be rendered harmless before disposal.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Only micro-organisms (including tissue culture cells) are involved in this work.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Full containment level 2 will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

If yes, tick to confirm that it is attached to this form

N
This work involved the cloning of some potentially oncogenic genes into disabled retrovirus vectors, with the use of packaging cell lines which have an amphotropic envelope protein.

From the ACGM Compendium of Guidance, Part 2B, Annexe III, particularly para. 30, this requires Class 2 (as already concluded in the risk assessment).

The Committee noted that the risk of the potentially oncogenic DNA had already been considered in the assessment.

<td>The plan is to use vectors based on pSUPER in which an RNA polymerase III promoter drives expression of a short (~25 mer) interfering RNA from a synthetic DNA insert. Details of the categories of interfering RNAs to be inserted are as follows:</td>
</tr>
</tbody>
</table>

A) RNAs which target DNA double-strand break repair pathways: The proteins encoded by BRCA1, BRCA2, RAD51 and its paralogs, Nbs1, ATM, ATR, Ku70, Ku80 and DNA-PK are nuclear molecules which participate in the sensing and repair of DNA double-strand breaks. In mice, homozygosity for null mutations in these genes leads to cell death, embryonal lethality and a DNA repair defect accompanied by genetic instability.

B) RNA which target cell cycle regulators: The proteins encoded by the mammalian cyclin/CDK genes, the mitotic kinases Pik1, nek1, Aurora-A/B/C, Bub1/BubR1 and the chromatid cohesion molecules Scc1, SMC1/3 and Eco1, are required for cell cycle progression and mitosis.

C) RNAs which target regulators of the G1, S and G2/M checkpoints: These inserts will include proteins encoded by checkpoint regulators such as p53, chk1/chk2 and chfr, or proteins involved in the downstream enforcement of these checkpoints (including cdc14, ranGAP, cyclin G, cdc25 or PP1).

Please enter comments on the GM safety committee on the risk assessment

This work involves the cloning of short DNA inserts under a eukaryotic promoter, in order to generate ~25-mer interfering RNA. The genes targeted in this work are those for sensing and repair of DNA double-stranded breaks, cell cycle progress and mitosis, and checkpoint regulators or downstream enforcement proteins. The cloned DNA is therefore potentially cytotoxic or oncogenic.

Initial cloning is into non-mobilisable vectors grown in laboratory E. coli K12 strains. The vectors are pUC-based and are disabled retroviral vectors, which require a helper t.c. line to produce virus, which in turn is only capable of a single infectious cycle. This stage is therefore Class 1.

Subsequently the retroviral vectors will be transfected into mouse emphotropic cell lines, with the packaging construct in more than one component, to produce the disabled retrovirus with an amphotropic envelope. Following consideration of the advice in the ACGM Compendium of Guidance, Part 2B, Annex III, paras 21-30, it was agreed that Class 2 is appropriate for this work. If cell lines are being maintained for a long time, consideration should be given to testing them for the presence of replication competent virus.

It was noted that appropriate precautions are already given for the naked DNA, to allow for its potentially cytotoxic or oncogenic nature.

### Project Additional Information

**Purposes of the contained use**

The project aims to determine the molecular basis of the differentiation of human and mouse epithelial cells. Pathways regulating differentiation include Notch, wnt and the MAP kinase signalling cascade. In addition we wish to explore the interaction of Notch with cell cycle regulators such as p21 Cip1 and Geminin.

**Recipient or parental organism**

Tissue culture cells of human or murine origin.

**Host/vector system**

Laboratory strains of E. coli K12 derivatives; tissue culture cells of human origin.

pUC-based plasmid vectors with RNA polymerase III promoter; Phoenix-amphotropic retroviral producer cells.

**Origin & function**

The expression of inserts encoding siRNAs, consisting of sense and antisense 21-29 base sequences derived from the coding region of the target mRNA with a spacer to generate a hairpin RNA, in human primary epidermal keratinocytes, mouse primary keratinocytes and mouse and human cell lines, including squamous carcinoma cells and telomerase immortalised keratinocytes. Once expressed the siRNA oligonucleotides are expected to decrease levels of RNA encoding the target protein by over 70%.

Target genes are those of the pathways regulating epithelial stem cell fate, including Notch receptors, suppressor of hairless homologues, mastermind homologues, and...
the hairy/enhancer of split family of transcription factors. In addition components of the MAP kinase and wnt kinase signalling pathways, and cell cycle regulatory proteins such as p21 Cip1 and Geminin will also be targeted.

Control siRNAs directed against enhanced green fluorescent protein and luciferase will be required for some experiments.

**Evaluation of foreseeable effects**

The inserts encode short interfering RNAs which are only active within the cell, and cannot encode an exogenously expressed protein. Expression of these RNAs will not enhance the pathogenicity of the host cells.

The effect of expression of the insert RNAs will be to functionally silence the target genes. In most cases, functional silencing is known to impair cellular function resulting in defective cell cycle progression or in genetic instability. In no instance is functional silencing of the target genes known to work directly to transform primary cell cultures.

A non-negligible hazard arises from the potentially oncogenic or cytotoxic nature of the cellular effects of some of the interfering RNA inserts. It is considered that DNA from such clones can be appropriately handled as set out in the ACGM Compendium of Guidance, Part 3A, Annex 1, paras. 8-10 in which the potential hazard is specifically considered.

**Historical Significant Changes**

- **Historical Date of Additional Info**
- **Significant Change ID**
**Purposes of the contained use**

A program for the discovery of gene function related to mammalian signal transduction.

Mammalian reporter cell lines will be constructed, with reporter genes or selectable markers cloned under the control of pathway specific promoters. These cell lines will be used to screen mammalian cDNA libraries, to identify genes acting in a particular pathway. Individual cDNAs will be identified, based on the phenotypic changes that they cause in the reporter cell line, and then studied further by truncation, point mutation etc.

**Recipient or parental organism**

Tissue culture cells of human or murine origin.

**Host/vector system**

- Laboratory strains of E. coli K12 derivatives;
- Tissue culture cells of human or murine origin.
- Retroviral producer cells, such as the Phoenix-ecotropic and amphotropic and VSV-G expressing retroviral producer cells.
- PUC-based plasmid vectors; Moloney Leukaemia virus based vectors.

**Origin & function**

- Reporter or selectable resistance genes, cloned under pathway specific promoters, to study changes in the control of the particular pathway.
- Mammalian cDNA libraries, to probe to select genes involved in the control of these specific pathways.
- Genes identified from this screen/selection, and altered forms of these genes, to study their role in controlling these specific pathways.

**Evaluation of foreseeable effects**

The initial inserts code for either marker proteins or resistance proteins which will allow quantitation and/or sorting or selection of the tissue culture cells which express them at sufficient levels. These are cloned under the control of pathway specific promoters, to allow study of the control of these pathways.

Subsequent cloning into these cells will be to screen cDNA libraries for genes which do control these pathways. Genes obtained in this way will then be modified (by truncation, point mutation or fusion to other genes), in order to gain an understanding of how they function in the cell.

These steps will be expected to alter the expression levels of the previously cloned marker or resistance proteins, with this alteration acting as the marker for the function of the controlling genes.

A non-negligible hazard arises from the risk of insertional mutagenesis and the potentially oncogenic or cytotoxic nature of some of the inserts. DNA grown up from such clones should be handled as set out in the ACGM Compendium of Guidance, Part 3A, Annex 1, paras. 8-10, ie gloves should be worn, sharps avoided and all wastes be rendered harmless before disposal.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Only micro-organisms (including tissue culture cells) are involved in this work.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
For the part of the work classified as Class 2, full containment level 2 will be applied

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 1 waste, generated during the initial steps, will be inactivated by either treatment with 1% v/v Clearsol, before discharge down the drain into the public sewer, or by incineration (in a registered facility). Data have been obtained from the manufacturer to show that the disinfection will achieve >10 (to the power of 5) loss of infectivity in the times used, while incineration will give effectively 100% killing.

Containment level 2 waste will be autoclaved (136 degrees C for 10 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that these will give effectively 100% killing.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

This is a project to study mammalian signal transduction, by establishing stable cell lines which have reporter genes under the control of various pathway specific promoters. These cells will then be challenged with cloned cDNAs which are thought to have a role in controlling these promoters and either up-or-down regulation be checked using the reporter protein. In some cases the reporter gene will code for a selectable marker, so that cells in which the promoter activity has been changed can be selected, rather than just quantitated.

The host cells are either standard E. coli K12 derivatives, used for generation of the cloned DNA, or standard mammalian t.c. cell lines. In addition various retroviral packaging cell lines will be used for the generation of replication-defective virions with ecotropic or amphotropic envelopes, or with VSV-G envelope protein. These retroviral packaging lines are based on the Phoenix system, with the helper functions in 3 separate parts of the genome, thus reducing the likelihood of recombination to produce replication competent virus to a negligible level. The host cells are all highly disabled. The vectors are either standard plasmids (with eukaryotic promoters were appropriate) (eg pUC-derivatives, wityout a promoter, or pCDNA), or disabled Moloney Murine Leukaemia virus (MMLV) based plasmids which can be used to generate disabled virions in the helper, packaging cell lines.

These vectors are all non-mobilisable in E. coli and also normal t.c. cells and neither they, nor the inserted transgenes, will increase the pathogenicity of the host cells.

The MMLV constructs are, by design, mobilised from the packaging cell lines, to generate defective virions, capable only of a single infective cycle, and even these have a limited efficiency of infection and special steps are usually taken to obtain a good infection rate. Depending upon the envelope protein, these virions may have a restricted or a wider host range.

It is considered that the precautions needed for safety of the workers will reduce the likelihood of hazard to the environment to a negligible level, with the resulting risk being effectively zero.

Having considered the potentially cytotoxic or oncogenic nature of some of the transgenes and the advice in the ACGM Compendium of Guidance, Part 2B, Annex III, paras, 14-34, it was agreed that the work is correctly classified as Class 1 for all the E. coli work and the work with t.c. cells and ecotropic retrovirus, and as Class 2 for the work with t.c. cells and amphotropic or VSV-G protein pseudo-typed retrovirus.

It is noted that the potential hazard of the naked DNA has already been considered in the risk assessment and that appropriate precautions are proposed.

Project Ref 20/03.4

Date Ackn'd CU2 Project Title

Class CultureVolClass2 CultureVolumeClass3-4
The project aims to determine the molecular basis of the differentiation of human and mouse epithelial cells. Pathways regulating differentiation include Notch, wnt and the MAP kinase signalling cascade. In addition we wish to explore the interaction of Notch with cell cycle regulators such as p21 Cip1 and Geminin.

Tissue culture cells of human or murine origin.

Laboratory strains of E. coli K12 derivatives; tissue culture cells of human or mouse origin, including murine cells expressing helper functions for defective retrovirus production.

pUC-based plasmid vectors with RNA polymerase III promoter; Plasmids containing lentiviral helper proteins - see diagrams attached to risk assessment.

The expression of inserts encoding siRNAs, consisting of sense and antisense 21-29 base sequences derived from the coding region of the target mRNA with a spacer to generate a hairpin RNA, in human primary epidermal keratinocytes, mouse primary keratinocytes and mouse and human cell lines, including squamous carcinoma cells and telomerase immortalised keratinocytes. These cells will include those infected with lentiviruses or retroviruses engineered to include a LoxP sequence flanked cDNA sequence.

Also expression of non-oncogenic genes involved in these pathways.

Target genes are those of the pathways regulating epithelial stem cell fate, including Notch receptors, suppressor or hairless homologues, mastermind homologues, and the hairy/enhancer of split family of transcription factors. In addition components of the MAP kinase and wnt kinase signalling pathways, and cell cycle regulatory proteins such as p21 Cip1 and Geminin will also be targeted.
Control siRNAs directed against enhanced green fluorescent protein and luciferase will be required for some experiments.

**Evaluation of foreseeable effects**

The inserts encode either non-oncogenic proteins or short interfering RNAs which are only active within the cell, and cannot encode an exogenously expressed protein. Expression of these RNAs will not enhance the pathogenicity of the host cells. The effect of expression of the insert RNAs will be to functionally silence the target genes. In most cases, functional silencing is known to impair cellular function resulting in defective cell cycle progression or in genetic instability. In no instance is functional silencing of the target genes known to work directly to transform primary cell cultures.

The expression of the Cre recombinase will recombine the LoxP sites. Among other resulting deletions will be the gene for Cre itself.

Anon-negligible hazard arises from the potentially oncogenic or cytotoxic nature of the cellular effects of some of the interfering RNA inserts. It is considered that DNA from such clones can be appropriately handled as set out in the ACGM Compendium of Guidance, Part 3A, Annex 1, paras. 8-10 in which the potential hazard is specifically considered.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Only micro-organisms (including tissue culture cells) are involved in this work.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Full containment level 2 will be applied.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Containment level 1 waste, generated during the preparative steps for the CL2 work, will be inactivated by either autoclaving, before discharge down the drain into the public sewer, or by incineration (in a registered facility). It is expected that these will give effectively 100% killing.

Containment level 2 waste will be autoclaved (136 degrees C for 10 min), before eit[e subsequent discharge down the drain into the public sewer or incineration. It is expected that these will give effectively 100% killing.

This work involves the cloning and expression of non-oncogenic proteins involved in pathways controlling epithelial cell fate. It also involves the cloning of short DNA inserts under a eukaryotic promoter, in order to generate ~25-mer interfering RNAs. These genes targeted in this work are those for pathways controlling epithelial stem cell fate, components of the MAP kinase and wnt kinase signalling pathways, and cell cycle regulatory proteins. The cloned DNA is therefore potentially cytotoxic or oncogenic.

Initial cloning is into non-mobilisable vectors grown in laboratory E. coli K12 strains. The vectors are pUC-based and are disabled lentiviral or retroviral vectors, which require a helper t.c. line (or helper plasmids in a t.c. cell line) to produce virus, which in turn is only capable of a single infectious cycle. This stage is therefore Class 1.

Subsequently the retroviral vectors will be transfected into mouse cell lines, together with plasmids supplying helper functions, which give either ecotropic or amphotropic envelopes, to produce the disabled lentivirus with either type of envelope. Following consideration of the advice in the ACGM Compendium of Guidance, Part 2B, Annex III, paras. 21-30, it was agreed that Class 1 is appropriate with the ecotropic envelope and Class 2 with the amphotropic.

It was noted that appropriate precautions are already given for the naked DNA, to allow for its potentially cytotoxic or oncogenic nature.

### Historical

Significant Changes

Date of Additional Info

Significant Change ID
**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

A study of the human FANCD2 gene, which is a downstream effector molecule in the Fanconi anaemia pathway. The cloned FANCD2 gene (and point mutants which are thought to be inactive for DNA repair) will be used to establish infection into human fibroblast cell lines that are mutant for FANCD2. Expression will be monitored and cells studied for complementation of the FA defect. Tagging of the gene will also be carried out to facilitate detection in cells. To establish complementation, cells will be studied for survival after exposure to DNA damaging agents, using FACS analysis, chromosome breakage studies and cell viability assays.

**Recipient or parental organism**

Tissue culture cells of human origin.

**Host/vector system**

Laboratory strains of E.coli K12 derivatives; Tissue culture cells of human or murine origin. Retroviral producer cells, such as the Phoenix-ecotropic and amphotropic and VSV-G expressing retroviral producer cells. pUC-based plasmid vectors; Moloney Leukaemia virus based vectors.

**Origin & function**

The human FANCD2 gene (and mutants thereof), to study their effect in complementing natural mutations.

**Evaluation of foreseeable effects**

The expected effect of expression of the transgene is a possible repair of the defective DNA repair of the defective DNA repair pathway in the original cell lines in which FANCD2 is mutant, if the inserted gene is either wild-type or contains a mutation which still allows it to complement the mutant already existing in the host cell line.

A non-negligible hazard arises from the risk of insertional mutagenesis and the potentially oncogenic or cytotoxic nature of some of the inserts. DNA grown up from such clones should be handled as set out in the ACGM Compendium of Guidance, Part 3A, Annex I, paras.8-10; i.e. gloves should be worn, sharps avoided and all wastes be rendered harmless before disposal.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Only micro-organisms (including tissue culture cells) are involved in this work.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Full containment level 2 will be applied.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Containment level 2 waste will be autoclaved (136 degrees for 10min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that these will give effectively 100% killing.

This work involves cloning the human FANCD2 gene (and point mutants thereof) into a defective Moloney murine leukaemia vector, using the Phoenix eco-and amphotropic packaging systems. The initial cloning is correctly assessed as Class 1. Since the mutant transgenes are considered as potentially oncogenic (in the absence of sufficient information to decide otherwise), the retroviral cloning was assessed in this light. With the ecotropic envelope, Class 1 complies with the ACGM Compendium of Guidance, Part 2B, Annex III, para.29 while with the amphotropic envelope this becomes Class 2, according to the ACGM Compendium of Guidance, Part 2b, Annex III, para.30.

It was also noted that the risk from the potentially oncogenic DNA has been considered and appropriate precautions proposed.

It was also noted that the risk from the potentially oncogenic DNA has been considered and appropriate precautions proposed.
**Project Additional Information**

**Purposes of the contained use**

A program for the discovery of gene function related to mammalian signal transduction. Mammalian reporter cell lines will be constructed, with reporter genes or selectable markers cloned under the control of pathway specific promoters. These cell lines will be used to screen mammalian cDNA libraries, to identify genes acting in a particular pathway. Individual cDNAs will be identified, based on the phenotypic changes that they cause in the reporter cell line, and then studied further by truncation, point mutation etc.

**Recipient or parental organism**

Tissue culture cells of human or murine origin.

**Host/vector system**

Laboratory strains of E.coli K12 derivatives; tissue culture cells of human or mouse origin. pUC-based plasmid vectors, including plasmids containing retroviral helper proteins.

**Origin & function**

A program for the discovery of gene function related to mammalian signal transduction. Mammalian reporter cell lines will be constructed, with reporter genes or selectable markers cloned under the control of pathway specific promoters. These cell lines will be used to screen mammalian cDNA libraries, to identify genes acting in a particular pathway. Individual cDNAs will be identified, based on the phenotypic changes that they cause in the reporter cell line, and then studied further by truncation, point mutation etc.

**Evaluation of foreseeable effects**

The initial inserts code for either marker proteins or resistance proteins which will allow quantitation and/or sorting or selection of the tissue culture cells which express them at sufficient levels. These are cloned under the control of pathway specific promoters, to allow study of the control of these pathways.

Subsequent cloning into these cells will be to screen cDNA libraries for genes which do control these pathways. Genes obtained in this way will then be modified (by truncation, point mutation or fusion to other genes), in order to gain an understanding of how they function in the cell. These steps will be expected to alter the expression levels of the previously cloned marker or resistance proteins, with this alteration acting as the marker for the function of the controlling gene.

A non-negligible hazard arises from the risk of insertional mutagenesis and the potentially oncogenic or cytotoxic nature of some of the inserts. DNA grown up from such clones should be handled as set out in the ACGM Compendium of Guidance, Part 3A, Annex I, paras. 8-10; i.e. gloves should be worn, sharps avoided and all wastes be rendered harmless before disposal.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Only micro-organisms (including tissue culture cells) are involved in this work.

**For only GMOs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

For the part of the work classified as Class 2, full containment level 2 will be applied.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
Containment level 1 waste, generated during the preparative steps for the CL2 work, will be inactivated by either autoclaving, before discharge down the drain into the public sewer, or by incineration (in a registered facility). It is expected that these will give effectively 100% killing.

Containment level 2 waste will be autoclaved (136 degrees C for 10 min), before either subsequent discharge down the drain into the public sewer or incineration. It is expected that these will give 100% killing.

This project is basically very similar to others already considered and approved (2003/004, HSE Ref. GM20/03.2; 2003/023), involving the same transgenes in defective retroviruses with eco- and amphotropic envelope proteins. The difference is that the current work, rather than employing a helper cell line which provides the necessary proteins for packaging and envelopment of the retroviral RNA, these functions will be provided by co-transfection of the packaging cell line with a helper plasmid, coding for these functions, as well as the plasmid producing the defective retroviral RNA with the transgene. The helper plasmid provides functions from the mink cell focus forming virus, with either ecotropic or amphotropic envelope protein, and is commercially marketed by Imegemex (Naviaux et al). It was agreed that this modification of how the helper functions are supplied does not alter the risk and that the work remains Class 1 for the initial cloning and ecotropic work, and Class 2 for the amphotropic work. It was noted that appropriate precautions are to be taken for handling the potentially oncogenic DNA.

Project Additional Information

Purposes of the contained use

To use somatic cell line knockout technology to generate assay reagents for combinatorial libraries of potential therapeutic compounds and for pathway analysis of potential new therapeutic targets.

This project requires gene disruption through homologous recombination in human epithelial cells in vitro; rAAV (adeno-associated virus) vectors permit such knockouts in human cells.

Inserts will encode LoxP sites, human genomic targets and positive selectable marker genes (e.g., neomycin or hygromycin). Target cells are human epithelial cell lines, including HCT-116, DLD1, A549, CAL51 and MT3 cell lines. These cells will be infected with rAAV (e.g., AAV-293).

Target genes are those of the pathways regulating DNA repair, apoptosis, histone acetylation, including BRCA2, HDCA1, SIRT1 and ADA3.

Recipient or parental organism

Tissue culture cells of human origin.

Host/vector system

Laboratory strains of E. coli K12 derivatives; Tissue culture cells of human origin.

Human t.c. lines both for recombinant virus production (e.g., AAV-293 cells derived from HEK 293 cells will be used as producer cells) and for subsequent infection to produce recombinant t.c. cell lines.

pUC-based plasmid vectors; Moloney Leukaemia virus based vectors.

AAV Helper-Free system (Stratagene) (pCMV-MCS for initial cloning, pAAV-LacZ to produce the ssDNA for encapsidation, pAAV-RC and pHelper to provide the adenoviral proteins required for encapsidation); the resulting recombinant adeno-associated viral vectors will be used for transduction of human cells.

Origin & function

Target genes are those of the pathways regulating DNA repair, apoptosis, histone acetylation, including BRCA2, HDCA1, SIRT1 and ADA3.

Evaluation of foreseeable effects

The planned knockout of the target genes in human t.c. cell lines is not foreseen as increasing their pathogenicity from its negligible level for the cell lines.

The one significant hazard arises from the rAAV produced from the packaging cells. This is capable of infecting human cells and contains inserts designed to knockout target genes in the pathways regulating DNA repair, apoptosis, histone acetylation, including BRCA2, HDCA1, SIRT1 and ADA3. Their effect is therefore considered as...
potentially oncogenic.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only micro-organisms (including tissue culture cells) are involved in this work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 2 waste will be autoclaved (136 degrees C for 10 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

Is an emergency plan required according to regulation 20? (Y/N) N

Tick to confirm that it is attached to this form (Y/N) N

Tick if you are claiming exemption from disclosure for section of the risk assessment (Y/N) N

Please enter comments on the GM safety committee on the risk assessment

The work involves the cloning of inserts to knockout various genes, their incorporation into recombinant adeno-associated virus (rAAV) and the subsequent infection of human epithelial cell lines, in order to establish stable cell lines with the appropriate genes knocked out. The target genes are those in the pathways regulating DNA repair, apoptosis and histone acetylation, including BRCA2, HDCA1, SITR1 and ADA3. The host cells are all highly disabled and the modifications will not increase their pathogenicity. With the exception of the rAAV, the vectors are non-mobilisable and present no risk. The exception is the AAV, which can infect human cells.

Knocking out the target genes is potentially oncogenic and, while this is highly unlikely to increase the pathogenicity of the intended host cells, it does present a risk to workers who might become infected with the rAAV.

For this reason the packaging and infection steps are considered as Class 2, while the preliminary cloning steps and subsequent propagation of any modified cells are Class 1.

(Note from BSO: I have taken advice from HSE and the Inspector, to whom I was referred, agreed with this assessment.)

Animal Units

Large Scale Activities

Human Clinical Applications

02/03/2022
Genetic analysis of the human Fanconi anaemia genes

Our studies will focus on the human genes that function in the Fanconi anaemia DNA repair pathway. The human Fanconi genes will be cloned into the vectors outlined. In addition to the known and established Fanconi genes, we wish to test other known DNA repair genes for their role in the FA pathway. In these instances, we plan to introduce these candidate genes into cells that harbour the Fanconi defect, but in which the mutated genes are have yet to be identified. These will then be used to establish infection into human immortalised fibroblasts or lymphoblasts that are either mutant for the relevant FA gene, or candidate FA gene. Expression of the recombinant FA gene will be monitored by western blot and the cells will be studied for complementation of FA defect.

To establish complementation, the cells will be studied for survival after exposure to DNA damaging agents. This will be done by FACS analysis, chromosome breakage studies and cell viability assays.

Recipient or parental organism

Tissue culture cells of human origin, from patients with Fanconi anaemia.

Host/vector system

E. coli K12 derivatives (for example DH5a, MC1061); human cell lines.
Retroviral producer cells: HEK293 derived lines, such as Phoenix-ecotropic, Phoenix-amphotropic, or VSV-G expressing retroviral producer cells.
Mammalian tissue culture cells, including human cell lines.
Target genes are those of the Fanconi anaemia pathway (usually involved in DNA repair) and candidate genes to test for presently unknown members of the pathway.

Evaluation of foreseeable effects

The work is to compare known and established Fanconi genes and also candidate genes, which are other known DNA repair genes, for their role in the FA pathway. These candidate genes will be introduced into cells that harbour the Fanconi defect, but in which the mutated genes are have yet to be identified.

To establish complementation, the cells will be studied for survival after exposure to DNA damaging agents. (This will be done by FACS analysis, chromosome breakage studies and cell viability assays). It is expected that the correct complementing gene will increase the survivability of the cells, while other genes will have minimal effect.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only micro-organisms (including tissue culture cells) are involved in this work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 2 waste will be autoclaved (136 degrees C for 10 minutes), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

This work involves cloning of genes on the Fanconi anaemia pathway, and also candidate genes, and their transfer into human primary fibroblasts which are mutant for the relevant FA gene. Candidate genes are known to be involved in DNA repair, but have not been definitely assigned to the Fanconi pathway and could be involved in some other pathways.

Initial cloning will be into pUC-based vectors and then the constructs transferred into disabled Moloney Murine Leukaemia-based plasmids, all of this work using laboratory E. coli K12 strains as host. Subsequently the plasmids will be transfected into t.c. cells of the Phoenix packaging lines (HEK293-derived), for production of disabled, single-cycle retroviruses, with ecotropic and amphotropic envelope proteins and also VSV-G protein pseudotyped.

Although wild type FA genes are tumour suppressing, there is a small, but not negligible, possibility that some of the candidate genes might be potentially oncogenic. With the ecotropic envelope, the work is correctly classified as Class 1 under ACGM guidance. However, with an amphotropic envelope (or VSV-G protein pseudotyping), the potential oncogenic nature of some inserts means that it becomes Class 2 during the packaging and infection stages. Once stable cell lines have been established free from residual virus, they can again be brought down to Class 1.

In practice, for in house convenience, the work will all be carried out in a Containment Level 2 facility, but this is only a safety requirement for the specific stages considered above.

It is noted that LREC clearance may well be required for obtaining and using the human tissues involved in the cell lines.

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use
Cancer cells exhibit abnormalities in cell cycle progression, chromosome structure and segregation and in the capacity to repair DNA damage that are central to transformation. These abnormalities are often the result of mutations in tumour suppressor genes, such as the breast cancer gene BRCA2. The overall goal of our studies is to ascertain the molecular basis for the abnormal division of cancer cells, and their increased genetic instability.

Recipient or parental organism
Murine-embryo-fibroblasts and HeLa and other cancer cell lines.
Host/vector system

E.coli laboratory K12 derivatives/pUC based vectors;
Vertebrate tissue culture cells including 293T cells, murine-embryo-fibroblasts and HeLa and other cancer cell lines/Lentiviral vectors, with polytropism through viral pseudo-typing using VSV-G protein.
Lentiviral system: The viral system to be used employs a well-characterised lentiviral vector and packaging cell lines(Refs below). A number of safety features are incorporated to eliminate or very greatly reduce the possibility of generating productive recombinants. The vector lacks gag, pol, env, tat, rev, vpr, vpu, vif and nef functions. A chimeric LTR offsets the requirement for Tat in expressing genes transcribed from the LTR. The Rev function is provided in trans from a separate plasmid in the packaging cells, as are the Gag/Pol functions. The viral vectors are self-inactivating due to deletions in both the LTRs, and thus incapable of replication after one round of infection of target cells. The packaging cell lines are effectively helper-free, since the rev, gag/pol and env (in this case, pseudo-typed with VSV-G protein) genes are expressed from separate plasmids. Rubinson et al Nat Genetics 34:231 (2003); Dull et al., J Virol 72:8463 (1998); Myoshi et al J. Virol 72:8150 (1998).

Origin & function

Specific aims with details of the categories of inserts to be used are as follows:

A) BRCA2-deficient cells exhibit defects in DNA repair (1). The defect is likely related to the inability of mutants BRCA2 to form functional complexes with RecA homologs in the Rad51 family (eg Rad51, xrcc2 & 3, Rad51B-D). The molecular basis for this phenotype will be studied by functional and biochemical analyses in transfected cells. Wild-type or mutant forms (including point mutations, deletions and fragments) will be studied.

B) Abnormalities of chromosome structure and number are abundant in BRCA2-deficient cells (2-4). To investigate the molecular basis for these phenotypes, the function of genes controlling chromatin structure (eg histones, histone-modifying-enzymes, HP1), the cell cycle (eg cyclins A, B, D, E; cdk1, 2 & 4, polo-like kinases), chromosome number and structure (eg SMCS1 & 3, sccl, Ecol), cytokinesis (eg chromokinesins, INCENP, surviving) and the centrosome cycle (eg nek1, nap, g-tubulin, aurora kinases) will be investigated by functional & biochemical analyses in transfected cells. Wild-type or mutant forms (including point mutations, deletions and fragments) will be studied.

C) We have shown that mutations inactivating mitotic checkpoint genes including Bub1 or Mad3L (BubR1), are necessary for the neoplastic transformation of cells lacking the BRCA2 tumour suppressor (5). Besides these, we will test the possibility that genes (eg chk1/chk2, cdc14A/cdc14B, PP1delta, cdc25C, m TERT or h TERT, ranGAP & cdh1) whose normal function is to regulate cell cycle progression and chromosome stability, particularly during the S phase and in mitosis, will be targets for inactivation by secondary genetic changes during tumour evolution in cells that lack genes such as BRCA2, using studies of transfected cells. Wild-type or mutant forms (including point mutations, deletions and fragments) will be studied.

D) To identify novel genes that regulate these processes, cells will need to be transfected with pools (libraries) of vertebrate cDNAs or short-hairpin RNA molecules that interfere with the expression of vertebrate genes, for phenotypic screens. Here, the precise nature of the insert cannot be specified in advance.

In A-C above, fusions of wild-type & mutant genes to GFP or other fluorescent tags will be used to determine intracellular localisation.

5) Lee et al., Molecular Cell 4:1-10 (1999)

Evaluation of foreseeable effects

Possible changes in the behaviour of cells in tissue culture, helping to elucidate the abnormal division of cancer cells, and their increased genetic instability.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only micro-organisms (including tissue culture cells) are involved in this work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Containment level 2 waste will be autoclaved (136 degrees C for 10 min), before subsequent discharge doen the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

Historical Significant Changes

Historical Date of Additional Info
**Purposes of the contained use**

It is planned to evolve antibodies and chemokines which inhibit HIV gp120-mediated cell entry of retroviral particles using compartmentalisation techniques.

**Recipient or parental organism**

CD4+human cell lines.

**Host/vector system**

Hosts: laboratory E.coli K12-derived strains (e.g. Top F10, Electro Ten blue); HEK293T cells, CD4 positive T-cells

Vectors: pUC-based vectors encoding MLV gag/pol and amphotropic envelope proteins (GaLVEnv, aMLV Env, VSV-G) but without any other retroviral sequences; further vectors generating packable RNA encoding either HIV env, vpu and nef (but lacking gag/pol and any HIV packaging signal), or antibody and chemokine libraries. These vectors contain MLV LTRs outside a packaging signal and the cloning site for the transfers.

**Origin & function**

In a first step, a CD4+ line expressing an antibody library will be generated by transduction with MLV vector particles pseudo-typed with amphotropic envelope proteins (e.g. GaLV Env, aMLV Env, VSV-G). To obtain these pseudo-type particles, HEK293T cells will be transfected with plasmids encoding MLV gag/pol and amphotropic envelope proteins but lacking any viral LTR and packaging signals. Furthermore, an MLV-packagable vector encoding membrane-anchored antibodies, which might have been pre-selected in other systems (phage-orribosme-display) for binding of HIV gp120, has to be generated and co-transfected. In particular, this vector will encode antibodies which have been fused to the N-terminus of the platelet-derived growth factor receptor transmembrane domain (PDGFR-TM) via a protease cleavage site. Furthermore, an antibiotic resistance marker will be encoded on the applied vector (inside the LTRs). In an alternative approach, diversified variants of RANTES (CCL5), also fused to the N-terminus of PDGFR-TM, will be used instead of antibodies. This library will be encoded on the same vector as described above.

In parallel, MLV(HIV Env) particles that have packaged a vector encoding the HIV genes env, vpu and nef will be generated. For this purpose HEK293T cells will be transfected with a plasmid encoding MLV gag/pol, an MLV-packagable vector encoding the HIV genes described above and a plasmid encoding a C terminally truncated variant of gp120 (exhibiting a cytoplasmic tail of only seven amino acids). Two days post-transfection the particles will be harvested and applied to the selection procedure.

**Evaluation of foreseeable effects**

Possible selection cells expressing antibodies or mutant chemokines which inhibit infection of CD4+cells by retroviruses with HIV envelope protein.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Only micro-organisms (including tissue culture cells) are involved in this work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full CL2 will be applied.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

CL2 waste will be autoclaved (136 degrees for 10min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.
This work involves various aspects of compartmentalisation of cells and their secretion products, but from the GM viewpoint it consists of essentially two main steps: the construction of human CD4+ cells expressing either antibodies, or variants of RANTES, as cell surface proteins; and the construction of retroviral particles, containing HIV env, vpu and nef genes under the control of murine leukaemia viral LTRs, with HIV envelope protein to test the ability of the antibodies or RANTES variants to block infectivity.

None of the single proteins, if released into the medium, poses any hazard and the sole concern is the HIV genes, particularly vpu and nef whose full functions are still rather obscure. It was therefore agreed that the preparatory work, using laboratory E.coli K12 derivatives as host and non-mobilisable vectors is correctly classified as Class 1.

The replication-defective pseudo-retroviruses will have HIV envelope protein, and therefore be capable of infecting human cells. With the non-hazardous inserted genes, they will be Class 1, but with HIV vpu and nef, and particularly with env, vpu and nef together, it was agreed that they are correctly assessed as Class 2.

It was noted that appropriate precautions are given for working with the naked DNA encoding the HIV env, vpu and nef genes.

Date of Significant Change

Project Additional Information

Purposes of the contained use

To understand whether/how RNA editing of glutamate receptors contributes to the formation and synaptic targeting of these receptors, and the potential role of this process in sporadic ALS (amyolateral sclerosis).

Recipient or parental organism

Primary neuronal cultures (cortical, spinal motor neurons);
organotypic brain slice cultures (derived from cortex, brainstem, spinal cord).

Host/vector system

Hosts:
E. coli (XL1 blue, DH5alpha);
Human embryonic kidney (Hek) 293 cells;
Primary neuronal cultures (cortical, spinal motor neurons); organotypic brain slice cultures (derived from cortex, brainstem, spinal cord).

Vector(s)
pUC-based lentiviral (HIC1) vectors, allowing for constitutive or conditional transgene expression, will be used for initial cloning and vector construction and then for production of pseudo-virions in Hek293 cells. These vectors contain the Woodchuck Hepatitis B virus WPRE.
The pseudo-virions will be used to infect the t.c. cells to study the effects of the transgenes.

Origin & function

Non-oncogenic cDNA variants of the GluR2 AMPA receptor subunit, under its native and under neuronal-specific promoters. To allow for RNA processing (ie alt. Splicing, A-1 editing) of the insert it will cloned as a cDNA : genomic DNA hybrid. Moreover, the insert will be tagged with peptide epitopes and, will be inserted upstream of a fluorescent marker, in a bi-cistronic fashion, to allow for optical identification of successfully targeted neurons. This design may be used for other glutamate receptor subunits. In some instances, the vector will also contain shRNAi modules, driven by a PolIII promoter, to specifically knock-down endogenous GluR2 message.
In addition antisense RNA molecules (such as sno [small nucleolar] RNAs) may be expressed under neuronal-specific promoters to interfere with RNA processing (splicing, editing) of iGluR receptor mRNAs in neurons.

Evaluation of foreseeable effects

The only effects foreseeable are on the formation and synaptic targeting of glutamate receptors, in both the primary neuronal cells and the cells in the organotypic brain slices due to the effects of RNA editing of the mRNA.
These will only be expressed in culture, as the cells and slices are cultures.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
No GM plants or animals are involved in this work. While the brain slices are not strictly micro-organisms, they are cultured in dishes in a very similar fashion and the containment is exactly the same as for micro-organisms of the same GM class.

For only GMMs - application for any derogation from full containment for the Class of activity.  (Measures & Justification)

Full containment level will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 2 waste will be autoclaved (136 degrees C for 10 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Is an emergency plan required according to regulation 20?  

Y

If yes, tick to confirm that it is attached to this form

N

Tick to confirm that you have attached a risk assessment to this form

Y

Tick if you are claiming exemption from disclosure for section of the risk assessment

N

The work involves the cloning of cDNA variants of the GlutamateR2 AMPA receptor subunit under its native and other neuronal-specific promoters, both alone and with peptide epitopes and as a fusion with fluorescent marker proteins (eg GFP).

Cloning will be into pUC-based lentiviral vectors, which contain the Woodchuck Hepatitis viral WPRE. Initial cloning will be in standard laboratory E. coli K12 derivative, then standard Phoenix HEK helper cells will be used to supply the helper functions for pseudo-virion production, using eco- and amphotropic envelope proteins and also pseudo-typing with the VSV-G protein. The replication-defective pseudo-viruses will be used to infect cells in primary neuronal cultures and also organotypic brain slice cultures.

The preliminary stages of the work are correctly assessed as Class 1, while the viral work is also correctly assessed as Class 2 due to the presence of the WPRE (otherwise it would also be class 1).

The potentially oncogenic nature of the isolated DNA, due to the WPREm is noted and appropriate precautions suggested.

The committee notes the training requirements of, at least one of, the workers and strongly recommends that he is trained, in the virological methods, by other workers who are already using this host/vector system in the laboratory.

02/03/2022
Rhomboid proteases play a critical role in regulation of the epidermal growth factor (EGF) receptor signalling in the fruit fly Drosophila melanogaster. Notably, deregulated EGF receptor activity contributes to cancer in humans; however, the role of Rhomboids in this process has not yet been investigated. Therefore, we propose to investigate the role played by mammalian rhomboid proteases and rhomboid-like proteins in human disease, including cancer.
cDNAs for mammalian rhomboids and their homologues will be expressed either in mammalian tissue culture cells or primary cells derived from transgenic mice. Co-transfection with fluorescent marker proteins (GEP or luciferase) will be used to determine successfully transfected cells. The substrates for rhomboids, such as epidermal growth factor, will be co-expressed with the expressing mammalian cDNAs for e.g. EGE rhomboids by
In addition, shRNAs will be expressed to specifically knockdown expression of the rhomboids

Evaluation of foreseeable effects

The rhomboids, their substrates and the shRNAs will not be expressed in E. coli, because the vectors do not contain suitable bacterial promoter or translational initiation sequence for these inserts. Expression of rhomboids and/or their substrates (e.g. EGF), or shRNAs designed to knockdown rhomboid expression, will not have any effect on the pathogenicity of the mammalian cell lines or primary murine cells.

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
Rhomboids are integral membrane proteases that cleave substrates to produce signalling molecules such as Epidermal Growth Factor (EGF). This project will express human rhomboids, EGFs, shRNAs to depress rhomboid expression and marker proteins (GFP, luciferase) using amphotrophic retroviruses, ecotropic retroviruses and lentiviruses in mouse primary cell cultures and standard tissue culture cells. The host cells for plasmid production (E. coli K12 laboratory strains) and the tissue culture cells are highly disabled and can be considered to be ACDP hazard group 1. All production of the pUC-based plasmid vectors in E. coli is correctly assessed as class 1. Ecotropic retroviruses are incapable of infection of human cells, so presenting negligible risk to the worker, and can also be considered to be HG1; expression of the reporter genes, rhomboids, shRNAs or EGFs will not alter the pathogenicity of the host therefore the work is correctly classified as class 1. In effect, for local convenience work of this nature is performed in the CL2 labs. All work using the amphotropic retroviruses containing the potentially oncogenic rhomboids and EGFs is correctly classified as class 2. It is noted that appropriate use of gloves, absence of sharps and appropriate disposal routes are recommended for handling potentially oncogenic naked DNA. All work using the lentiviruses, regardless of insert type, is class 2 due to the presence of the WPRE with the downstream X protein gene, despite a point mutation at the initiator Met.

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

Enzymatic modification of DNA leading to mutation is a molecular event essential to both innate and adaptive immunity. Both these processes are triggered by targeted deamination of deoxycytidine (dC) to deoxyuridine (dU) residues within the immunoglobulin locus - a process catalysed by the AID enzyme. The aim of the project is to further understand the AID pathway and how it is modulated.

**Recipient or parental organism**

Hosts: E.coli K12 derivatives (e.g. DH5a, MC1061);
Mammalian tissue cell lines (e.g. DT40, DG75, RAMOS, 293T).
Retroviral producer cells: HEK193, derived lines, such as Phoenix-ecotropic cells.
Primary mouse cells (for example B cells).

**Host/vector system**

Vectors:
Second generation HIV-based lentiviral system (plasmid pHRSinUBEm) containing WPRE and X gene (single inactivating mutation at initiator Met)

Helper plasmids pCMVR8.91 and pMD-G

**Origin & function**

cDNA inserts generally correspond to individual, well characterized ORFs (for example reporter genes such as GFP, transcription factors, AID and its relatives, AID-associated proteins, proteins implicated in nuclear trafficking) or their derivatives (for example, truncated, point mutated, or fused to other genes).

Work also includes the creation of lentiviral supernatants from mammalian cDNA libraries which may contain hazardous genes such as oncogenes.

**Evaluation of foreseeable effects**

cDNAs will not be expressed in E.coli because the vectors do not contain a suitable bacterial promoter or translation initiation sequence for these inserts. There is a small risk that some inserts (e.g. those encoding transcriptional factors or AID (or its interactors/homologues)) might increase the pathogenicity of the transduced cells. Whereas expression of reporter genes and those encoding nuclear trafficking proteins will have no effect. The expression of cDNA libraries from recombinant lentiviruses could result in the expression of oncogenes that could potentially transform mammalian cells.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

only GM micro-organisms will be produced in this work.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Full containment level 2 will be applied.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Containment level 2 waste will be autoclaved (136 degrees Centigrade for 10 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.
Enzymatic modification of DNA leading to mutation is a molecular event essential to both innate and adaptive immunity. Both these processes are triggered by targeted deamination of deoxyxytidine (dC) to deoxyuridine (dU) residues within the immunoglobulin locus - a process catalysed by the AID enzyme. This project will express cDNAs encoding AID, proteins involved in the AID pathway and standard protein markers (GFP, luciferase etc) using lentiviruses in mouse primary cell cultures and standard tissue culture strains. Project Ref 20/08.3

Date Ackn'd 03/12/2008

Role of innate immunity for the restriction of facultatively intracellular bacteria.

Class 2

Consent Granted

Project notified under transitional arrangements

Historical Significant Changes

Tick if notifying a connected programme of work
### Project Additional Information

**Purposes of the contained use**

Facultatively intracellular bacteria are able to proliferate in phagosomes of host cells, from where they occasionally escape into the cytosol. It is poorly understood how bacterial proliferation in the eukaryotic cytosol is restricted but the induction of inducible transcription factors of the IRF family is thought to be involved. The purpose of the current project is to investigate the role of the IRF pathway in the intracellular restriction of bacterial pathogens. To this end we will test how Salmonella typhimurium and Shigella flexneri behave if the IRF pathway is modulated.

**Recipient or parental organism**

- **Salmonella typhimurium**
  - S typhimurium strain 1344

S typhimurium strain 1344 contains GFP gene integrated into the genome; there are no plasmids involved and there are no antibiotic resistance genes integrated.

**Host/vector system**

- **Vectors:**
  - pDsRed2; pUC-based plasmid, ampicillin resistant, expressing a red fluorescent protein. This will be transformed into S typhimurium, wild-type.

**Origin & function**

- **GFP:** Green fluorescent protein from Aequorea victoria
- **DsRed2:** red fluorescent protein from Discosoma sp. red coral

**Evaluation of foreseeable effects**

The two strains of S typhimurium will be expressing fluorescent marker proteins, either dsRed or GFP, that will not alter the pathogenicity of the strains. Whilst no other proteins will be heterologously expressed in S typhimurium 1344, S typhimurium (pDsRed2) will also express the antibiotic resistance gene for ampicillin, but it will still be sensitive to quinolone antibiotics if treatment of an infection is ever necessary. The plasmid is based upon pUC and is non-mobilisable.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

- Only GM micro-organisms will be produced in this work.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 2 waste will be autoclaved (136°C for 10 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

---

Two hazard group 2 pathogens, Salmonella typhimurium and Shigella flexneri, will be grown to investigate the role of the IRF pathway in the intracellular restriction of bacterial pathogens. All experiments involving these bacteria are therefore class 2. The experiments require the growth of small volumes (1-3ml) of the bacteria, which can be accommodated in the bacterial CL2 lab B17. Two strains of genetically modified S.typhimurium will be used, each expressing either GFP or DsRed, neither of which will alter the pathogenicity of the bacteria.

The bacteria will be used to infect HeLa cells that have altered expression of IRF components, already assessed by the BSC in projects 2008/03 and 2008/04. Project 2008/03 was assessed as Class 2 and involves the expression of cDNAs encoding the IRF components in mammalian cells. Project 2008/04 was expressing the siRNAs in mammalian cells and was assessed as Class 1. Transfected mammalian cells will be brought to the bacterial CL2 lab in a sealed boxed and all further steps involving incubation with S.typhimurium and S.flexneri will be performed there. A class 1 Microbiological Safety Cabinet will be used for all manipulations with S.typhimurium and S.flexneri, the bacteria will be grown within CL2 lab and all wastes will be inactivated by autoclaving before incineration.

CU2 Project Title

Class

CultureVolClass2

CultureVolumeClass3-4
**Project Additional Information**

**Purposes of the contained use**

We wish to use replication deficient lentiviruses for the delivery of certain oncogenes and SiRNAs (in the form of shRNAs or microRNAs) to examine how oncogenic lesions perturb the processes of ribosome biogenesis and translation.

**Recipient or parental organism**

Hosts: E.coli K12 derivatives (eg DH5a, XL-10 gold);
Mammalian tissue cell lines (eg normal diploid fibroblasts and fibroblasts derived from patients with Schwachman-Diamond Syndrome (SDS) or Diamond Blackfan anaemia (DBA);
Primary mouse cells (mouse embryonic fibroblasts, bone marrow stem cells, neutrophils' and lymphocytes).

**Host/vector system**

Vectors:
Second generation HIV-based lentiviral system (plasmid pLKO1) and the retroviral vector pBABE
Helper plasmids pCMVR8.91 and pMD-G

**Origin & function**

cDNAs correspond to oncogenes and the siRNAs will be used to knock-down known tumour suppressor genes. These will be expressed in the mouse and human cell lines and the effects of their expression upon ribosome biosynthesis determined.

**Evaluation of foreseeable effects**

The cDNAs correspond to known oncogenes and the siRNAs are to known tumour suppressors. These will be expressed from amphotropic retroviruses and lentiviruses, both of which can infect human cells. It is well recognised that multiple oncogenic lesions are required before tumourigenesis, but expression of either the cDNAs or siRNAs will increase the probability of cell transformation and therefore there is a non-negligible risk to oncogenesis.
Three types of expression systems will be used. Ecotropic retroviruses will be used in studies on mouse primary cell lines; these can enter human cells and are of negligible risk and are not part of this Notification. Both amphotropic retroviruses and lentiviruses will be able to infect human cells and will be used to express oncogenic cDNAs or siRNAs to tumour suppressors. Even though oncogenesis requires multiple lesions, the recombinant amphotropic retroviruses and lentiviruses pose a small risk of oncogenesis if introduced into a worker. None of the inserts will alter the pathogenicity or tissue tropism of the retroviral or lentiviral vectors.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only GM micro-organisms will be produced in this work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 2 waste will be autoclaved (136°C for 10 mins), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

Is an emergency plan required according to regulation 20?  No

Tick to confirm that you have attached a risk assessment to this form  Yes

Tick if you are claiming exemption from disclosure for section of the risk assessment  No

Please enter comments on the GM safety committee on the risk assessment

Project 2008_08 describes work towards the study of ribosome biogenesis in mammalian cells. The work entails the expression of known oncogenes and the suppression with siRNAs of known tumour suppressor genes, using both retroviruses and lentiviruses in human cell lines. Plasmid construction will use non-mobilisable plasmids in laboratory strains of E.coli K12 where none of the inserts will be expressed; this aspect of the work is correctly assessed as Class 1. There are two aspects to the retroviral work. Ecotropic retroviruses will be used to express oncogenes and/or siRNAs in primary mouse cell lines. Ecotropic retroviruses cannot infect human cells, the inserts will not alter the pathogenicity or tissue tropism of the retroviruses and the cell lines are equivalent to ACDP HG1; this aspect of the work is correctly classified as class 1. Amphotropic retroviruses and lentiviruses will be used to infect primary human cell lines derived from donors with Scwachman-Diamond Syndrome (SDS) or Diamond Blackfan anaemia (DBA) or from healthy volunteers. The inserts will not affect the pathogenicity or tropism of the viruses, but both cDNA and siRNA inserts are potentially oncogenic. Although it is accepted that multiple events are required for tumourgenesis, there is a small but non-negligible risk to the operator. This aspect of the work is therefore class 2. The primary human cell lines have undergone multiple passage over at least two weeks and have been assessed as Class 1 in the associated risk assessment (HTA/2008_01); appropriate ethical consent has been obtained for both making the cell lines and for their usage.

**Project Additional Information**

**Purposes of the contained use**

Human cells contain a variety of factors that prevent unrestricted proliferation of bacteria and viruses that have entered the cytoplasm, which forms part of the innate immune system. This intracellular restriction can be caused by a large family of proteins called TRIM (Triparite Motif proteins). The aim of the project is study the molecular mechanisms of how they prevent the proliferation of intracellular pathogens.

**Recipient or parental organism**

Hosts: E.coli K12 derivatives (e.g. DH5a, XL10 gold);
Mammalian tissue cell lines (e.g. HEK293, HeLa, CRFK, C2C12).
Retroviral producer cells: HEK293 derived lines, such as Phoenix-ecotropic cells.

**Host/vector system**

pCNCG &pEXN=CMV, MLV based lentiviral vector expressing Red fluorescent protein or Neo, respectively.
pMDG=CMV-VSVG expresses VSV-G for pseudotyping of viral particles
pCMV1=MLV-Gag-Pol, helper plasmid expressing MLV gag,pol, tat and rev.
pKLO1 =for the expression of shRNAs commercially available from OpenBioSystems.
pBabe = for the expression of cDNAs, commercially available from AddGene.
Mammalian cDNAs for the following proteins will be used:
(i) TRIM21, a cytosolic IgG receptor
(ii) TRIM5 and TRIM-Cyp, cytoplasmic restriction factors
(iii) TRIM7, a putative regulator of glycogenin function
(iv) TRIM 20, a gene linked to susceptibility to FMF
(v) TRIM 1&18, genes in which defects lead to the developmental defect Optiz syndrome
(vi) TRIM 19, so-called nuclear-body protein involved in viral restriction and cell cycle.
(vii) TRIM 25, putative restriction factor via interaction with RIG-1.

In addition, siRNAs that selectively repress the expression of each of these proteins will be constructed and expressed.

Evaluation of foreseeable effects

cDNAs and siRNAs will not be expressed in E.coli, because the vectors do not contain a suitable bacterial promoter or translational initiation sequence for these inserts. None of these proteins are known to be toxic or oncogenic, and neither are they likely to change the tissue tropism of the viruses or alter the pathogenicity of the host cells. The siRNAs for repressing the expression of the proteins are also not known to be toxic or oncogenic, and neither will they alter the tissue tropism of the viruses or the pathogenicity of the host cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only GM micro-organisms will be produced in this work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 2 waste will be autoclaved (136°C for 10 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The TRIM family of proteins are found in the cytoplasm where they are of an innate mechanism to prevent the proliferation of viruses and/or bacteria; they are not known to be either toxic or oncogenic and neither will they alter the pathogenicity of the recombinant viruses or the host cells. Cloning will be performed in standard E.coli K12 strains using non-mobilisable plasmids and this aspect of the work is correctly classified as Class 1. Expression of the TRIM proteins and siRNAs will be either from amphotropic retroviruses or lentiviruses; due to the potentially oncogenic nature of the viruses and their ability to infect human cells, gloves must be worn and hence the work is Class 2. Expression may also be performed in mouse cells from ecotropic retroviruses that are incapable of infecting human cells; this work is correctly classified as Class 1.

Project Additional Information

Purposes of the contained use
Mammalian cells regulate the composition of their surface membranes by the processes of exocytosis and endocytosis. Pathogens and viruses gain entry into cell via these pathways. The purpose of this project is to study the molecular mechanisms of these pathways.

Recipient or parental organism
Hosts: E.coli K12 derivatives (e.g. DH5α, MC1061);
Mammalian tissue cell lines (e.g. HEK293, HeLa, Co115).
Retroviral producer cells: HEK293 derived lines, such as Phoenix-ecotropic cells.
Host/vector system

FUW for expression of cDNAs; includes WPRE and geneX
Packaging plasmids pMD2.G, pMDLg/pRRE and pRSV-Rev

Origin & function

Mammalian cDNAs that express proteins involved in endocytosis and exocytosis will be used, including proteins such as intersectin, GRAF, FCHO, synaptotagmins; and receptors and ligands like ephrin receptor and ephrins.

Evaluation of foreseeable effects

cDNAs will not be expressed in E. coli, because the vectors do not contain a suitable bacterial promoter or translational initiation sequence for these inserts. None of these proteins are known to be toxic or oncogenic, and neither are they likely to change the tissue tropism of the viruses or alter the pathogenicity of the host cells.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Project 2009/05 will express proteins involved in endocytosis and exocytosis using VSV-G pseudo-typed lentiviruses in mammalian cells. The mammalian host cells are highly disabled and equivalent to hazard group 1. The E.coli K12 strains used for plasmid production are hazard group 1. The plasmids to be used are all non-mobilisation and will not alter the pathogenicity of the host cells; this aspect of the work is therefore correctly classified as Class 1. The third generation lentiviral system being used will produce non-replicative lentiviruses that are capable of infecting human cells and will express proteins involved in the trafficking of endocytic and exocytotic vesicles. None of the proteins are toxic or oncogenic, and neither will they change the host range of pathogenicity of the lentiviruses. However, the lentiviruses all have a WPRE and a downstream gene X that is potentially oncogenic. Therefore the production and use of recombinant lentiviruses is classified as Class 2.

Growth Rooms
The aim of this project is to improve our understanding of meiotic prophase in mouse oocytes using high resolution live cell confocal microscopy. Homologous pairing, recombination and chiasmata formation occur in oocytes during embryo development. We will use lentiviral and retroviral systems to overexpress meiotic proteins fused to well characterized marker proteins to study their changing distributions during meiosis.

**Hosts:** E. coli K12 derivatives (e.g. XL, DH5α);
Mammalian tissue cell lines (e.g. HEK293, He La, Cos 7, Pnt1A).
Retroviral producer cells: PT67 and HEK293 derived lines, such as Phoenix-ecotropic cells.
Mouse oocytes

**Host/vector system**
Lentiviral system: pLL3.7 for expression of cDNAs; includes WPRE and gene x and the packaging plasmid pCMV delta8.91, with env from pMD.G
Retroviral systems: MMLV-based vectors and the MSCV retroviral expression system

Origin & function

Mammalian cDNAs encoding meiotic proteins will be fused to well characterized marker proteins such as mEGFP, mCherry or PAGFP. The proteins that will be overexpressed are the commonly used markers of different components and structures of a meiotic cell: components of the synaptonemal complex (such as SCP1, SCP2, SCP3), cytoskeletal reporters (such as tubulin, actin and proteins binding to microtubules and F-actin), motor proteins (such as myosins, kinesins), histones (such as TRF1, TRF2, Pot1, Rap1), centrosome components (such as pericentrin, gamma-tubulin), components of the meiotic cohesion complex (such as SMC1/3, SCC1, Rec8, STAG1), nuclear pore complex proteins and other nuclear membrane components including SUN and KASH domain proteins, as well as meiotic proteins involved in chiasma formation and resolution (such as Rad 51, DMC1, MLH1).

Evaluation of foreseeable effects

cDNA's will not be expressed in E.coli, because the vectors do not contain a suitable bacterial promoter or translational initiation sequence for these inserts. None of these proteins are known to be toxic or oncogenic, and neither are they likely to to change the tissue tropism of the viruses or alter the pathogenicity of the host cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Please enter comments on the GM safety committee on the risk assessment
Project 2009/09 aims to study meiotic prophase in mouse oocytes. A variety of proteins that are components of cytoskeleton, nuclear membrane, pore core complex, centromere and telomeres will be over-expressed as GFP fusion proteins and overexpressed in mammalian cells or mouse oocytes by transfection with replication defective lentiviruses and retroviruses. All the proteins to be expressed are non-hazardous and none of them will change the pathogenicity of any of the host cells. Host cells include E.coli K12 strains for the initial cloning and plasmid preparation and the mammalian cells to be transfected; all these host cells are highly disabled and are equivalent to hazard group 1.

Three different forms of recombinant viruses will be used.
1. Recombinant ecotropic retroviruses cannot infect human cells. The proteins to be used will not change the host range or pathogenicity of the virus. This aspect of the work is therefore correctly classified as Class 1.
2. Recombinant amphotropic retroviruses can infect human cells, but cannot replicate due to the segregation of essential genes onto three separate plasmids. The proteins to be used will not change the host range or pathogenicity of the virus and none of the proteins is oncogenic. There is a small but non-negligible risk of insertional mutagenesis, but the risk can be reduced to effectively zero by the wearing of gloves and not using sharps. This aspect of the work is therefore correctly classified as Class 1 (Section 2.11 of the SACGM compendium of guidance).
3. Recombinant lentiviruses are not capable of replication but can infect human cells. The proteins to be used will not change the host range of pathogenicity of the virus and none of the proteins is oncogenic. However, the lentiviral vectors contain the WPRE and downstram X gene, which has the potential to be oncogenic. This aspect of the work is correctly classified as Class 2; gloves will be worn and sharps will not be used.

Historical Date of Additional Info
### Project Additional Information

#### Purposes of the contained use

The aim of the research is to study the biological function and biochemistry of the intramembrane protease rhomboid. From a wide screen of homologous proteins, rhomboid from Providencia stuartii was found most amenable for analysis due to its high expression level and high rate of substrate cleavage. The native substrate is unknown and therefore the function of rhomboid in P. stuartii is to be studied.

#### Host/vector system

| Hosts: E.coli K12 derivatives (e.g. DH5α, XL1); | Providencia stuartii; either wild-type or rhomboid-knockout strain (aarA) |
| Plasmids: pET vectors e.g. pET21a, pET25b+ and the pBR322-based vectors pMAL and pMPM |

#### Origin & function

Plasmids-encoded rhomboid substrates are fusions of the transmembrane domains from Drosophila Gurken and Spitz, E.coli LacY TMD2 or Providencia stuartii TatA fused to maltose-binding protein and thioredoxin. The proposed substrates will be expressed from plasmids in Providencia stuartii and their cleavage monitored by western blotting.

#### Evaluation of foreseeable effects

None of the reporter proteins are known to be toxic or oncogenic, and neither are they likely to alter the pathogenicity of the host cells or their ability to survive in the environment.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only GM micro-organisms will be produced in this work.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Full containment level 2 will be applied.
Containment level 2 waste will be autoclaved (136º for 10 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Project 2010/03 from M F Is to study the rhomboids (intramembrane proteases) and their potential inhibition in the bacterium Providencia stuartii, which is an HG2 organism as it has been implicated in urinary tract infection and perhaps travellers diarrhoea. The bacteria will be transformed with plasmids encoding putative rhomboid substrates whose cleavage can be monitored, and the effects of various rhomboid-inhibitors on this process will be studied. Two strains of P. stuartii will be used, a wild-type strain and an aarA strain that has its native rhomboid knocked out. The expression of rhomboid substrates or the knocking out of the rhomboid gene will neither affect the pathogenicity or the ability of the bacteria to survive in the environment. This work is therefore correctly classified as Class 2 and the work will be performed in the Class 2 pathogen lab in the Containment Suite Note that it is policy in all the Class 2 laboratories for double-gloves to be worn for all work and sharps to be avoided.

Please enter comments on the GM safety committee on the risk assessment

Project Ref 20/10.3

Date Ackn'd 18/03/2010

CU2 Project Title Intracellular immunity in mammalian cells to pathogenic bacteria and viruses

Class CultureVol Class 2 CultureVolume Class 3-4

Class 2 < 1 Litre

Non-GMM Consent Granted

Date Project Ceased

02/03/2022

Page 1184 of 15326
Despite extracellular immune responses, viral and bacterial pathogens are able to infect cells. Infected cells must therefore have mechanisms to neutralise or at least limit the replication of pathogens intracellularly. We would like to investigate how this is accomplished. We aim to identify and characterise restriction factors to determine how they target pathogens and the mechanism by which they neutralise them. This will be performed by infecting mammalian cell lines with human pathogens, either with or without siRNA expression to down regulate intracellular restriction.

**Recipient or parental organism**

**Hosts:** E.coli K12 derivatives (e.g. DH5α, XL1) and mammalian cells e.g. HeLa & HEK293  
Shigella flexneri, wild-type  
Salmonella typhimurium, wild-type and strain 1344  
Cocksackie virus (clone CVB3-GFP)  
Recombinant Sindbis virus and recombinant Adenovirus; both expressing GFP (both CL1, but part of project)

**Host/vector system**

pDsRed2; pUC-based plasmid, ampicillin resistant, expressing a red fluorescent protein. This will be transformed into S. typhimurium, wild-type. S. typhimurium contains GFP integrated into its genome with no associated antibiotic resistance marker. The recombinant sindbis virus and adenovirus are replication defective and both express GFP (assessed as Class 1). The cosackie virus is replication competent and expresses GFP.

**Origin & function**

GFP: Green fluorescent protein from Aequorea victoria  
DsRed2, red fluorescent protein from Discosoma sp. Reef coral  
siRNAs directed towards the repression of genes such as TRIM21, Atg8 (and other autophagy genes), encoding E2 enzymes, TRIM5, TRIM19, TRIM25

**Evaluation of foreseeable effects**

The two strains of S. typhimurium will be expressing fluorescent marker proteins, either dsRed or GFP, that will not alter the pathogenicity of the strains. Whilst no other proteins will be heterologously expressed in S. typhimurium 1344, S.typhimurium (pDsRed2) will also express the antibiotic resistance gene for ampicillin, but it will still be sensitive to quinolone antibiotics if treatment of an infection is ever necessary. The plasmid is based upon pUC and is non-mobilisable. Neither of the reporter proteins are known to be toxic or oncogenic, and neither are they likely to alter the pathogenicity or host range of the non-replicative recombinant sindbis virus, the non-replicative recombinant adenovirus or the replicative cosackie virus.
Expression of siRNAs in mammalian cells will not alter the cells' ability to survive in the environment or their pathogenicity. In addition, during co-infection of mammalian cells with the siRNAs and with either S. flexneri, S. typhimurium, adenovirus, sindbis virus or coxsackie virus, the sRNAs will not alter the pathogenicity, host range or ability to survive in the environment of any of the pathogens.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only GM micro-organisms will be produced in this work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied to all work using S. typhimurium, S. flexneri and cosackie virus

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 2 waste will be autoclaved (136º for 10 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

Is an emergency plan required according to regulation 20?  

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

Mammalian cells will be infected with viruses or bacteria (recombinant Sindbis virus, cosackie virus, recombinant adenovirus, Shigella flexneri, Salmonella typhimurium); studies will then be performed on the effect of knocking-down expression of interferon-upregulated genes by siRNA. pUC-based non-mobilisable plasmids expressing siRNAs will be produced in standard laboratory E.coli K12 strains; the plasmids will neither affect the pathogenicity or survivability of the hosts and Class 1 is appropriate. All mammalian cells are highly disabled and Class 1 is also appropriate. Recombinant Sindbis viruses are replication defective, although they are still able to infect human cells. The viruses will express GFP, which is non-toxic and non-oncogenic and, at worst, upon infection of a worker's cells would result in transient expression of GFP. This aspect of the work is therefore correctly classified as class 1. Similarly, recombinant adenovirus is also replication incompetent and GFP will not affect the virus’ host range or pathogenicity; Class 1 is therefore appropriate. The recombinant cosackie virus expressing GFP is fully replication competent. Cosackie virus is a HG2 pathogen with high-infectivity via aerosols or by oral transmission, producing symptoms such as fever, headache, sore throat, gastroenteritis and sometimes chest and muscle pains. GFP will not alter its pathogenicity or host range and therefore Class 2 is appropriate. Given the high-infectivity via aerosols, all work is to be performed in a Class 1 or 2 Microbiological Safety Cabinet and procedures likely to cause aerosols (particularly centrifugation in a microfuge) must be further risk assessed. Shigella flexneri and Salmonella typhimurium will be resistant to beta-lactams, but will still be sensitive to quinolones in the case of a worker infected. Work with recombinant S. typhimurium and S. flexneri is therefore appropriately classified as Class 2.

02/03/2022
The aim is to study the effect of mutations on the propensity of aggregation for aggregation-prone proteins, such as huntingtin derivatives, superoxide dismutase 1, APP derivatives, synuclein derivatives. In addition, factors that affect the aggregation will be studied. The research will involve the expression of aggregation-prone proteins from replication-incompetent lentiviruses and the modulation of the proteins’ aggregation will be studied by co-expressing shRNAs and a mammalian cDNA library.

Recipient or parental organism

Hosts: E.coli K12 derivatives (e.g. DH5α, XL1, MC1061, Stbl3) and mammalian cells e.g. AR42J, Min6 & HEK293 and primary mouse cell lines (embryonic fibroblasts and neurons)

Host/vector system

The pLenti system from Invitrogen will be used to produce replication-incompetent lentiviruses; this uses the four plasmids pLenti derivatives, pLP1 (expresses HIV-1 gag/pol and contains the HIV-1 RRE), pLP2 (expresses HIV-1 Rev) and pLP/VSIG (expresses the VSV G glycoprotein)

Origin & function

Mammalian (e.g. mouse, human) huntingtin derivatives, insulin mutants, superoxide dismutase 1, APP derivatives, synuclein derivatives. GFP fusions will be made to these proteins as well.
shRNAs directed towards the repression of genes such as mammalian huntingtin derivatives, superoxide dismutase 1, APP derivatives, synuclein derivatives etc.

A mammalian cDNA library

Evaluation of foreseeable effects

All the aggregation proteins and GFP fusions to be expressed are neither toxic nor oncogenic. Note that prions are specifically excluded from this work. The proteins will neither alter the pathogenicity or the host range or the recombinant lentiviruses. In addition, the recombinant lentiviruses will not alter the host cells pathogenicity or their ability to survive in the environment.

Expression of shRNAs from recombinant lentiviruses that are directed towards the down-regulation of the aggregation proteins in mammalin cells will not alter the pathogenicity or host range of the recombinant lentiviruses.

Expression of a mammalian cDNA library from a nonreplicative lentivirus is unlikely to affect the pathogenicity of the host cells or the recombinant virus, or their ability to survive in the environment.

The plasmids used to produce the recombinant viruses will not have any affect on the pathogenicity or ability to survive in the environment of the E. coli host clls used for their production.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only GM micro-organisms will be produced in this work

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied to all work using the nonreplicative recombinant lentiviruses

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 2 waste will be autoclaved (136°C for 10 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The aim of project 2010/6 is to study protein aggregation in standard human cell lines and isolated primary mouse cells. Proteins that are known to aggregate, such as mutants of insulin, huntingtin and superoxide dismutase, will be expressed using recombinant lentiviruses. All of the proteins to be expressed are neither toxic nor oncogenic. Tissue culture cells and mouse explants are highly disabled and are therefore considered to be equivalent to ACDP hazard group 1. Plasmids will be produced in laboratory E. coli K12 strains that are non-colonising and are HG1. The plasmids used the pLenti expression system are pUC-based non-mobilisable plasmids that will neither alter the pathogenicity or ability of the E. coli host cells to survive in the environment, and therefore plasmid production is correctly classified as Class 1. VSV-G pseudotyped lentiviruses have a broad host range and can infect human cells. The recombinant lentiviruses are replication-incompetent and are made by co-transfection of HEK293 cells with 3 helper plasmids. The lack of homology between the plasmids reduces the risk of any recombination event and therefore the likelihood of regenerating a replication incompetent virus is negligible and the testing for such RCVs is considered unnecessary. The one non-negligible hazard associated with the expression systems it contains the WPRE and downstream X gene fragment that is considered to have oncogenic potential. Thus the production and use of the recombinant lentiviruses are correctly assessed as Class 2. Oncogenic DNA will be handled and disposed of appropriately. Obtaining the mouse tissues for this work is covered by project license PPL 80/2035. The Code of Practice for the Containment Suite where this work will be performed dictates the avoidance of all sharps and the wearing of two pairs of gloves.

The aim of project 2010/05 is to study circadian rhythms in isolated primary mouse neurons and brain slices. Standard reporter proteins and proteins that are likely to affect circadian rhythms, such as period proteins, will be expressed using recombinant lentiviruses and recombinant adeno-associated viruses (AAVs). The proteins to be expressed are neither toxic nor oncogenic. Tissue culture cells and mouse explants are highly disabled and are therefore considered to be equivalent to ACDP hazard group 1. Plasmids will be produced in laboratory E. coli K12 non-mobilisable plasmids that will neither alter the pathogenicity nor the ability of the E. coli host cells to survive in the environment, and therefore plasmid production is correctly classified as Class 1. Both lentiviruses and AAVs have a broad host range and can infect human cells. The recombinant systems both produce replication-incompetent viruses by co-transfection of HEK293 cells with either 3 helper plasmids for the lentiviral system or 2 helper plasmids with the AAV system. The lack of homology between the plasmids reduces the risk of any recombination event and therefore the likelihood of regenerating a replication competent virus is negligible and the testing for such RCVs is considered unnecessary. The one non-negligible hazard associated with the expression systems is that they both contain the WPRE and downstream X gene fragment that is considered to have oncogenic potential. Thus the production and use of the recombinant lentiviruses and AAVs are both correctly assessed as Class 2. Oncogenic DNA will be handled and disposed of appropriately. Obtaining the mouse tissues for this work is covered by project license PPL 80/2310. The Code of Practice for the Containment Suite where this work will be performed dictates the avoidance of all sharps and the wearing of two pair of gloves.
### Purposes of the contained use

SOX2 has been identified as the most likely candidate oncogene within the distal segment of chromosome 3q that is amplified in lung cancer. There are other non-coding RNAs (ncRNAs) (e.g. SOX2OT) and genes (PIK3CA) that may well play a synergistic role. We propose to investigate the role of these and other loci known to be dysregulated or mutated in epithelial carcinogenesis by using mammalian cell lines and primary cells as in vitro model systems.

### Host/vector system

Non-replicative lentiviruses will be constructed using a co-infection of HEK293 cells with the plasmids pLL3.7 or pLVTHM (contains inserts and WPRE), pCMV Δ8.91, psPAX2 or pCMV-R8.74 (gag/pol expression), pMD.G or pMD.2G (VSV-g expression). Non-replicative amphotropic retrovirus production will be performed by co-infection of HEK293T cells with plasmids pSuper retro, and plasmids pCMV Δ8.91 (gag/pol expression) and pMD.G (VSV-G expression).

### Origin & function

Inserts carried by the retroviruses and lentiviruses will express shRNA or mir30-based shRNA-mirs targeted for SOX2, SOX2OT and related genes, non-coding RNA e.g. SOX2OT and cDNA versions of SOX2 and related proteins and their putative substrates controlling, for example, the TGFbeta and SMAD pathways.

### Evaluation of foreseeable effects

SOX2 overexpression is potentially oncogenic and there is a likelihood that overexpression of other components within the pathway could be oncogenic. Similarly, there is a possibility that some of these genes are tumour suppressors, so down regulation by shRNA expression could be potentially oncogenic. The inserts to be expressed are not toxic and neither will they alter the pathogenicity of host range of the lentiviruses or retroviruses.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only GM micro-organisms will be produced in this work.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Containment level 2 waste will be autoclaved (136°C for 10 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing

Project 2010/11 aims to study the role of SOX2 amplification and associated genes in squamous epithelial carcinogenesis. Proteins and RNAs will be expressed in recombinant lentiviruses and amphotropic retroviruses. Proteins to be expressed include SOX2 and related proteins and components of the SOX2-controlled pathways. shRNA or mir30-based shRNA-mirs targeted for SOX2 will also be expressed. SOX2 overexpression is potentially oncogenic and there is a reasonable likelihood that overexpression of other components may also be oncogenic. Host cells include E. coli K12 strains for the initial cloning and plasmid preparation and the mammalian cells to be transfected; all these host cells are highly disabled and are equivalent to hazard group 1. Two different forms of recombinant viruses will be generated.  
1. Recombinant amphotropic retroviruses can infect human cells. The proteins to be used will not change the host range or pathogenicity of the virus and the proteins/RNAs to be expressed are potentially oncogenic. This aspect of the work is therefore correctly classified as Class 2.
2. Recombinant lentiviruses are not capable of replication but can infect human cells. The proteins to be used will not change the host range or pathogenicity of the virus and the proteins/RNAs are potentially oncogenic. The lentiviral vectors also contain the WPRE and downstream X gene, which also have the potential to be oncogenic. This aspect of the work is therefore correctly classified as Class 2.

The Code of Practice for the Containment Suite where this work will be performed dictates the avoidance of all sharps and the wearing of two pair of gloves

## Project Additional Information

### Purposes of the contained use

We propose to develop a new system for the expression of proteins in neurons that will allow the labelling of the proteins at specific sites with unnatural amino acids using amber suppression. This will be used to study the role of kinases in signal transduction and in the control of circadian rhythms.

### Recipient or parental organism

Hosts: E. coli K12 derivatives (for example DH5a, MC1061, XI1blue, XL10 gold, TOP10); mammalian cell lines (for example HeLa, HEK293T); primary mouse cells.

### Host/vector system

Non-replicative lentiviruses will be constructed using co-infection of HEK293 cells with the plasmids pCCLsin.PPT.hPGK.EGFP.Wpre (contains inserts and WPRE), pRSV.Rev, pMDLg/pRRE (gag/pol expression), pMD2-G (VSV-G expression)

### Origin & function

Inserts carried by lentivirus will express tRNA synthetase and the corresponding tRNA, a reporter gene (eGFP), and a variety of mammalian kinases

### Evaluation of foreseeable effects

Overexpression of mammalian kinases is potentially oncogenic. The tRNAs, tRNA synthetases and GFP homologues to be expressed are not toxic and neither will they alter the pathogenicity of host range of the lentiviruses. All the lentiviruses contain a WPRE which is potentially oncogenic; it is acknowledged that the start codon is mutated, but this is considered insufficient to prevent the possibility of mutation and Gene X expression.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only GM micro-organisms will be produced in this work

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Containment level 2 waste will be autoclaved (136°C for 10 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

Project 2012/02 wishes to develop an amber suppressor system in mouse neurons. This will initially involve the expression of tRNA synthetases and tRNAs in conjunction with a fluorescent reporter gene such as GFP. Once the system has been developed, the aim will be to use it for the study of mammalian kinases. All the proteins and tRNAs are non-toxic, although the kinases have oncogenic potential or, at worst, are known to be oncogenic. E. coli and mammalin cells are all ACDP hazard group 1. Plasmids are all mobilisation defective or, at worst, mobilisation deficient. Amplification in E.coli of plasmids containing the target proteins/tRNAs will not alter their pathogenicity or their ability to survive in the environment, and this aspect of the work is therefore correctly classified as Class 1. The non-replicative VSV-G pseudo-typed recombinant lentiviruses expressing the target proteins and tRNAs will be able to infect human cells, but the viral tropism and their ability to survive in the environment is unchanged by their inserts. Due to the presence of a WPRE in the lentiviral vectors and its potential oncogenic nature, coupled to the ability of the lentiviruses to potentially infect human cells, all work in lentivirus production and their usage is Class 2, regardless of the insert used.

The Code of Practice for the Containment Suite where this work will be performed dictates the avoidance of all sharps and the wearing of two pairs of gloves.

**Project Additional Information**

**Purposes of the contained use**

Our goal is to understand the molecular basis for synaptic transmission, using the paradigm of the visual systems in mammals and fish. This research requires the use of recombinant lentiviruses and adeno-associated viruses for the expression or down-regulation of specific proteins involved in synaptic transmission and also a series of reporter proteins that either report on intracellular levels of calcium ions, sodium ions or pH, or directly alter their levels through light-activated channels (optogenetics).

**Recipient or parental organism**

Hosts: E.coli K12 derivatives (for example DH5a, MC1061, X11blue, Top10); mammalian cell lines (for example HeLa, HEK293T); primary mouse cells, mouse brain slices, isolated retinas or zebra fish.

**Host/vector system**

Non-replicative lentiviruses will be constructed using co-infection of HEK293 cells with plasmids pCCLsin.PPT.hPGK.EGFP.Wpre (contains inserts and WPRE), pRSV.Rev, pMDLg/pRRE (gag/pol expression), pMD2-G (VSV-G expression).

Non-replicative adeno-associated viruses (AAVs) will be constructed in HEK293 cells by co-infection of plasmid pAAV-6P-SEWB (included WPRE) and the helper plasmids pDP1 and pDP2 (encode rep, cap, E2A, E3, E4 and VA).

**Origin & function**

Inserts carried by the recombinant lentiviruses and AAVs will include proteins expressed at the synapse (such as synaptophysin, ribeye and PSD95, and mutants of them), shRNAi molecules to knockdown the expression of endogenous synaptic proteins (such as ribeye, clathrin, synaptophysin etc), cDNAs encoding fluorescent reporters of cellular activity (such as GFP derivatives that sense calcium ions, sodium ions or pH), fluorescent reporters (gfp or luciferase fusions of synaptic proteins) and optogenetic factors (such as channel rhodopsin and light-regulated adenyl cyclase).

**Evaluation of foreseeable effects**

All the synaptic proteins, their mutants and gene fusions, shRNAi and reporter proteins and optogenetic factors to be expressed are not toxic and neither will they alter the pathogenicity or host range of the lentiviruses or AAVs. All the lentiviruses and AAVs contain a WPRE which is potentially oncogenic; it is acknowledged that the start codon is mutated, but this is considered insufficient to prevent the possibility of mutation and gene X expression.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Only GM micro-organisms will be produced in this work.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

02/03/2022

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The project aims to study synaptic transmission and signal transduction in primary cells, brain slices or in vivo in zebrafish (Danio). Standard reporter proteins and proteins and siRNAs that are likely to affect synaptic transmission, such as synaptophysin, ribeye, PSD95 etc, will be expressed using recombinant lentiviruses and recombinant adeno-associated viruses (AAVs). All of the proteins and siRNAs to be expressed are neither toxic nor oncogenic. Tissue culture cells, mouse explants and Danio are highly disabled and are therefore considered to be equivalent to ACDP hazard group 1. Plasmids will be produced in laboratory E. coli K12 strains that are non-colonising and are HG1. The plasmids used in both expression systems are pUC-based non-mobilisable plasmids that will neither alter the pathogenicity or ability of the E. coli host cells to survive in the environment, and therefore plasmid production is correctly classified as Class 1. Both lentiviruses and AAVs have a broad host range and can infect human cells. The recombinant systems both produce replication-incompetent viruses by co-transfection of HEK293 cells with either 3 helper plasmids for the lentiviral system and 2 helper plasmids with the AAV system. The lack of homology between the plasmids reduces the risk of any recombination event and therefore the likelihood of regenerating a replication competent virus is negligible and the testing for such RCVs is considered unnecessary. The one non-negligible hazard associated with the expression systems is that they both contain the WPRE and downstream X gene fragment that is considered to have oncogenic potential. Thus the production and use of the recombinant lentiviruses and AAVs are both correctly assessed as Class 2. Oncogenic DNA will be handled and disposed of appropriately.

The Code of Practice for the Containment Suite where this work will be performed dictates the avoidance of all sharps and the wearing of two pairs of gloves.

Project Ref 20/13.1
To fully understand the mechanism of T-cell activation, we need to elucidate its underlying principles at the molecular level. To achieve this, the minimal set of components required to recapitulate the initial triggering steps of the pathway have to be reconstituted. This requires using lentiviral transduction technology to stably express multiple gene products in mammalian cell lines.

Hosts: E. coli K12 derivatives (for example DH5a, MC1061, Xl1blue, Top10); mammalian cell lines (for example NIH3T3, HEK293T)

Recipient or parental organism

Non-replicative lentiviruses will be constructed using co-infection of HEK293 cells with the plasmids pHRSIN-CSGW (contains inserts and WPRE), pCMVd8.91 (gag/pol; expression), pMD2.G (VSV-G expression).

Origin & function

Human cDNAs encoding the following will be used: membrane receptors such as the whole T-cell receptor complex, CD4, CD8 and CD28, as well as mutants and chimeras of them; tyrosine kinases such as Lck, Fyn, ZAP70 and CSK, and mutants and truncations of them; phosphatases such as CD45 (ptprc), shp1, cd148; Adapters such as CBP?PAG, LAT, SLP76, GRb2, GADS; Dimerisation domains such as FKBP/FRB and LOV2 or PhyB. In addition fluorescent reporters such as GFP and its analogous will be used.

Evaluation of foreseeable effects

None of the inserts will affect the pathogenicity or survivability of the host cells (E. coli or mammalian cells). None of the inserts will affect the host range, pathogenicity or ability to survive in the environment of the recombinant lentiviruses. None of the inserts are toxic and none of them are oncogenic, except for Lck and Syk. All the lentiviruses contain a WPRE which is potentially oncogenic.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Only GM micro-organisms will be produced in this work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 2 waste will be autoclaved (136° for 20 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

Despite extracellular immune responses, viral and bacterial pathogens are able to infect cells. Infected cells must therefore have mechanisms to neutralise or at least limit the replication of pathogens intracellularly. We would like to investigate how this is accomplished when cells are infected with respiratory syncytial virus. We aim to identify and characterise restriction factors that target respiratory syncytial virus and the mechanism by which the virus is neutralised.

**Hosts:** mammalian cell lines (for example HeLa, HEK293T)

**Recipient or parental organism**

**Replication-vector system**

Recombinant respiratory syncytial will express fluorescent reporter proteins, either GFP (rgRSV-RW30) or DsRed (rrRSV-BN1). The genes are cloned into the L-gene terminus (3' end of the positive sense transcript) and described in Hallak et al. (J Virol 74:10508, 2000). A control recombinant RSV (rRSV) with no insert will also be used.

**Origin & function**

Recombinant respiratory syncytial will express fluorescent reporter proteins. GFP and DsRed fluorescent reporter proteins are not toxic and neither will they alter the pathogenicity or host range of the RSVs.

**Evaluation of foreseeable effects**

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Only GM micro-organisms will be produced in this work.
Full containment level 2 will be applied.

Project 2012/12 is to study the role of Trim21 in the intracellular immunity to Respiratory Syncytial Virus (RSV). RSV is a (-)ssRNA virus belonging to the Paramyxoviridae family that causes respiratory tract infections. In young children (less than 2 years old) infection can lead to hospitalisation, but in healthy adults the symptoms are like a mild cold, but immunosuppressed adults could be affected more severely. There is near ubiquitous seropositivity for RSV in adults. The virus is highly infectious from aerosols and is a robust virus probably capable of surviving for hours on a contaminated surface. RSV is classified as a HAZARD Group 2 pathogen. Recombinant virus expressing either GFP (rgESV-RW30), dsRed (rrRSV-BN1) or no colour protein (rRSV) will be obtained from Prof. M Peeples (Hallak et al. J Virol 74:10508, 2000). The recombinant viruses are all replication competent. Expression of GFP or dsRed will not alter the pathogenicity, host range or survivability of the virus in the environment. Class 2 is therefore appropriate for this work. Given the ease of infection by aerosols, all work must be performed in a Class ll MSC and processes that generate aerosols e.g. sonication will need further risk assessment if required. Centrifugation of viral supernatants must be performed in screw-capped tubes, not snap-capped eppendorfs. The Code of Practice for the Containment Suite where this work will be performed dictates the avoidance of all sharps and the wearing of two pair of gloves.

Expression of mammalian proteins, siRNAs and reporters in eukaryotic cells using viral delivery systems

A fundamental tenet of understanding biological systems is the ability to formulate and test hypotheses on the function of proteins within a cellular context. This entails altering the expression levels of proteins in vivo, either through the overexpression of the native protein or decreasing expression through RNA silencing. All these manipulations are facilitated through the use of recombinant non-replicative viruses.

Hosts: E. coli K12 derivatives (for example DH5a, MC1061, Xl1blue, Top10); mammalian cell lines (for example HeLa, CHO, HEK293T); primary cell lines from e.g. mouse

Host/vector system

(1) HIV-based non-replicative recombinant lentiviruses e.g. based on pCCLsin.PPT.hPGK.EGFP.Wpre or pLKO1;
(2) MLV-based non-replicative recombinant retroviruses e.g. based on pCL-10A1 and VSV-G pseudo-typed
(3) AAV-based non-replicative recombinant adeno-associated virus e.g. based on pAAV-6P-SEWB
(4) deltaGp-RV non-replicative recombinant Glycoprotein-deleted rabies virus e.g. based on pSADdeltaG-F2

All the above require helper plasmids for the generation of viral particles upon cotransfection in mammalian cells.

Origin & function

Mammalian proteins to be expressed fall into all major classes of proteins found in the cell and secreted from the cell and fall into the following classes: (A) Intracellular proteins such as: DNA modifying and repair proteins, post-translational modifying systems (such as phosphorylation, ubiquitination, SUMOylation) metabolic enzymes, proteases, cytoskeletal proteins, motor proteins, nucleoproteins, membrane-binding proteins. (B) Secreted proteins (c) Integral membrane proteins such as transporters, ion channels, receptors, enzymes, structural proteins, molecular chaperones, apoptosis regulators. Specific exclusions include prion agents known or suspected to cause neurological disorders and any biological toxin.

RNAs to be expressed fall into all major classes of RNA found in the cell and also RNAs specifically designed for the modulation of expression levels of native RNAs: (A) Anti-sense RNAs, siRNAs or shRNAs designed to decrease levels of endogenous mRNAs encoding proteins described above. (B) NON-coding RNAs that modulate cellular activities. (c) Structural RNAs

Specific exclusions include any agent that may include the expression of prion agents.
Reported proteins to be expressed include a variety of natural and engineered proteins from bacteria, insects and jellyfish such as GFP derivatives, luciferases, channelrhodopsins, light regulated adenyl cyclase, GFP based calcium sensors such as GCaMP5/6, R-GECo1, pH-sensors or sodium sensors.

Evaluation of foreseeable effects

None of the inserts will affect the pathogenicity or survivability of the host cells (E. coli or mammalian cells). None of the inserts will affect the host range, pathogenicity or ability to survive in the environment of the recombinant lentiviruses. None of the inserts are toxic. Some of the proteins are oncogenic and some of the lentiviral vectors and AAV vectors contain a WPRE which is also potentially oncogenic.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only GM micro-organisms will be produced in this work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied where the risk assessment identifies Class 2 as the appropriate classification.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Contaminated level 2 waste will be autoclaved (136°C for 20 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

The comments are too long to insert in the space given, so please see the attached Risk Assessment for the full comments. In brief:

Lentiviral vectors containing WPRE, regardless of insert: Class 2
pLKO1 lentiviral vectors for RNA expression, Class 1, unless the insert is oncogenic, then Class 2 AAV vectors containing a WPRE, regardless of insert: Class 2
DeltaGp-rabies virus vectors, class 1, unless the insert is oncogenic, then Class 2

Note that inserts that encode prions or biological toxins are specifically excluded from this risk assessment.

Oncogenic DNA will be handled and disposed of appropriately.

The Code of Practice for the Containment Suite where this work will be performed dictates the avoidance of all sharps and the wearing of two pair of gloves.

Waste generated in this project will be effectively inactivated by using the approved disinfectants in the LMB as described in the Safety Handbook. The environmental impact will therefore be negligible.

Project Containment
### Project Additional Information

**Purposes of the contained use**

We wish to produce virus-like particles and replication-incompetent viruses in order to study the dynamics and physiochemical requirements of the membrane fusion event that delivers the viral genome into the cytoplasm during infection. We plan to determine the structures of these viruses or virus-like particles, and their membrane fusion intermediates, by electron microscopy. We also plan to image virus-like particles and replication incompetent viruses by light microscopy as they fuse with synthetic lipid membranes of live cells in culture.

**Recipient or parental organism**

Hosts: E. coli K12 derivatives (for example DH5α, X11blue, Top10); mammalian cell lines (for example HeLa, Vero, CHO, HEK293, BHK)

**Host/vector system**

Production of non-replicative virus like particles for (i) closely related flaviviruses (such as dengue virus, West Nile virus, Japanese encephalitis virus), (ii) closely related phleboviruses such as Rift Valley fever virus, (iii) ΔG vesicular stomatitis virus (VSV) for pseudotyping with viral envelope proteins from other viruses, (iv) Putative endogenous retroviruses from C. elegans and other nematodes.
Genes encoding structural proteins of the relevant viruses will be used to make recombinant non-replicative viruses for dengue virus, West Nile virus and Japanese encephalitis virus and other closely related viruses from the flavivirus genus; West Nile virus; Rift Valley fever virus and other closely related viruses from the phlebovirus genus; yellow fever virus; Hepatitis C virus; HIV-1 ΔG vesicular stomatitis virus; endogenous retroviruses from C. elegans and other nematodes.

Proteins to be expressed in the lentivirus system also include (i) envelope glycoproteins from flaviviruses (E), hepaciviruses (E1/E2) or bunyaviruses (Gn/Gn), (ii) Eukaryotic protein sequences bearing sequence homology to the ectodomains of viral envelope proteins (e.g. from C. elegans and Ancylostoma ceylanicum), (iii) Toll-like receptors 7, 8 and 9 from mammals e.g. mouse, human etc.

Evaluation of foreseeable effects

None of the inserts will affect the pathogenicity of survivability of the host cells (E. coli or mammalian cells). None of the inserts will affect the host range, pathogenicity or ability to survive in the environment of the recombinant lentiviruses. None of the inserts are toxic and none of them are oncogenic. All the lentiviruses contain a WPRE which is potentially oncogenic and therefore Class 2 is appropriate.

All the virus-like particles cannot replicate and therefore Class 1 is appropriate for all the work.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only GM micro-organisms will be produced in this work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied where the risk assessment classes the activities as Class 2.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 2 waste will be autoclaved (136°C for 20 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Lentiviral expression will also be used for the expression of a number of receptors for structural studies, such as RIG-I like receptors and Toll-like receptors, and because this lentiviral system contains a WPRE and X gene, this is correctly classified as Class 2. To facilitate pseudo typing with viral envelope proteins from hepaciviruses, deltaG VSV will be generated using vaccinia strain vB18R-T7 (an attenuated strain) and co-transfection of 5 plasmids. The HCVpp-pseudotyped delta G VSV will only be able to infect hepatic cells, but since the vaccinia strain is not fully attenuated, Class 2 is appropriate.

The Code of Practice for the Containment Suite where this work will be performed dictates the avoidance of all sharps and the wearing of two pair of gloves.

Project Additional Information

Purposes of the contained use
We seek to understand the host & pathogen interactions that occur during tuberculosis (TB), by using a model system where zebrafish (Dania rerio) are infected with Mycobacterium marinum. In addition, we will use the zebrafish model to study the mechanism of infection of other pathogenic bacteria, viruses and helminthes.

Recipient or parental organism
Escherichia coli K12, listeria monocytogenes, Mycobacterium abscessus, Mycobacterium avium complex, Mycobacterium bovis (BCG strain), Mycobacterium smegmatis, Mycobacterium marinum, Mycobacterium ulcerans,
| Pseudomonas aeruginosa, Salmonella arizonae, Salmonella typhimurium, Staphylococcus aureus, Streptococcus iniae, and Streptococcus pneumonia, Candida albicans, Candida glabrata, and Cryptococcus neoformans |

### Host/vector system

Expression of fluorescent markers such as GFP will be from pUC-based plasmids which have Ampicilln ChloramPhenicol, Spectinomycin, Kanamycin, and/or Hygromycin resistance markers, not exceeding 2 antibiotic resistance markers per plasmid. Gene products from the host bacteria/yeast that have been deleted, will be expressed from plasmid pCEB3 to check that complementation does occur. Potentially any gene would want to be expressed back into its host cell.

### Origin & function

Antibiotic resistance genes for ampicillin, chloramphenicol, spectinomycin, kanamycin, and/or hygromycin will be used for plasmid selection. Fluorescent markers such as green fluorescent protein are from Aequorea victoria. Other genes identified in bacteria/yeast upon deletion that lead to interesting phenotypes will be re-expressed in the deleted mutant to check the deletion phenotype is reversible. Potentially any gene in the bacterial yeast could be deleted and then re-expressed from a plasmid.

### Evaluation of foreseeable effects

None of the inserts will affect the pathogenicity or survivability of the host cells (bacteria or yeast). None of the inserts will affect the host range, pathogenicity or ability to survive in the environment of the recombinant GMMs. None of the inserts are toxic and none of them are oncogenic.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only GM micro-organisms will be produced in this work.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied where the risk assessment classes the activities as Class 2.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 2 waste will be autoclaved (136°C for 20 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

N
The aim of project 2014110 is to understand host and pathogen interactions that affect the infectivity of a wide range of pathogenic bacteria and yeasts, specifically the ACDP hazard group 2 pathogens Listeria monocytogenes, Mycobacterium abscessus, Mycobacterium avium complex, Mycobacterium bovis (BGG strain), Mycobacterium smegmatis, Mycobacterium marinum, Mycobacterium ulcerans, Pseudomonas aeruginosa, Salmonella arizonae, Salmonella typhimurium, Staphylococcus aureus, Streptococcus iniae, and Streptococcus pneumonia, Candida albicans, Candida glabrata, and Cryptococcus neoformans. Genes will be knocked-out and, if an interesting phenotype is observed, then the gene will be re-introduced to ensure the wild-type phenotype is recoverable. Knocking-out genes from these pathogens is highly unlikely to increase pathogenicity or their ability to survive in the environment. Similarly, re-introduction of these knocked-out genes or expression of fluorescent reporter proteins will neither alter pathogenicity or the survivability of any of the above pathogenic micro-organisms. Therefore all aspects of work involving the above bacteria and yeasts are correctly classified as Class 2. Plasmids will be produced in laboratory E. coli K12 strains that are non-colonising and are HG 1. The plasmids are pUC-based non-mobilisable plasmids that will neither alter the pathogenicity or ability of the E. coli host cells to survive in the environment, and therefore plasmid production is correctly classified as Class 1.

The Code of Practice for the CL2 lab where this work will be performed dictates the avoidance of all sharps and the wearing of two pair of gloves.

**Project Additional Information**

**Purposes of the contained use**

We seek to understand the host & pathogen interactions that occur during tuberculosis (TB), by using a model system where zebrafish (Danio rerio) are infected with Mycobacterium marinum. Validation of the zebrafish biochemical pathways that have been implicated in affecting the infectivity of bacterial or viral pathogens will be tested in human cell lines by either making knock outs or overexpressing the relevant proteins.

**Recipient or parental organism**

Escherichia coli K12, and a range of mammalian cell lines such as HEK293, A549, J774, THP-1, Mono-mac6, U87MG, human bronchial epithelial cell lines, L929, RAVV264.7, J774A.1, COS7, CHO, and fish cell lines (e.g. ZF4, CLC)

**Host/vector system**

The Trans-Ienliviral packaging system from Dharmacon I GE life sciences will be used, which comprises plasmids pTLA1-PAK (gag pro), pTLA1~ENZ (pol), pT~1--NV. (env - VSV-G), pTLA1-TOFF (tet-off), pTLA1-TAT/REV (TAT/REV) and pGIPZ (contains 5' Ilr, 3' self-Inactivating Ilr, and shRNA, WPRE, and marker genes (GFP and puromycin) between the I TRs).

**Origin & function**

The lentiviral expression system will be used to express or knock-out a wide variety of proteins in the human cell lines such as (a) Cytokines, chemokines, and mediators of the immune response and their receptors, scaffold proteoids and effector proteins during signal transduction (TNFa, IL-1b, CCL2, CCR2, TNFRs, RIPKs, MAPKs, aSMase, antimicrobial peptides, etc) (b) Enzymes and enzyme associated proteins related with metabolism of mediators implicated in immune responses (LTA4H, LTD4DH, Alox etc); (c) Effectors and mediators of cell death pathways (Caspases, pro-apoptic factors - BAX, BAK, BID, PUMA-, pro- survival factors -BCL2, MCL etc); (d) Effectors and mediators of cell migration pathways (SAM68, SFK etc); (e) Effectors, mediators and regulators of immune cell functions (efferocytosis, phagocytosis, endocytosis, lysosome function etc); (f) Genes implicated in gene transcription, RNA metabolism and RNA translation (transcription factors, RNA binding protein etc) (g) Effectors related with protein post-translational modifications (kinases, methylases, acetylase etc); (h) Genes linked to epigenetic modifications

Note that there are explicit exclusions from this list, which include any proteins known to act as infectious prions or toxins
None of the inserts will affect the pathogenicity or survivability of the host cells (bacteria or yeast) or the lentiviruses.
None of the inserts will affect the host range, pathogenicity or ability to survive in the environment of the recombinant
GMMs. None of the inserts are toxic or function as prions. Some of the proteins are potentially oncogenic, but this will
not affect the properties of the host virus/cells.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Only GM micro-organisms will be produced in this work.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Full containment level 2 will be applied where the risk assessment classes the activities as Class 2.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Containment level 2 waste will be autoclaved (136°C for 20 min) before subsequent discharge down the drain into
the public sewer or incineration. It is expected that this will give effectively 100% killing.

---

**Evaluation of foreseeable effects**

The aim of project 2014/08 is to study the role of proteins identified as being important in zebrafish for their ability to
affect infectivity of bacterial pathogens in mammalian cell lines. A wide variety of mammalian proteins will be
expressed. some of which may be oncogenic. Expression will be performed using non-replicative recombinant
viruses using HIV-based lentiviruses. All of the proteins and RNAs to be expressed are neither biological toxins nor
prions. Tissue culture cells are highly disabled and are therefore considered to be equivalent to ACDP hazard group
1. Plasmids will be produced in laboratory E. coli K12 strains that are non-colonising and are HG 1. The plasmids are
pUC-based non-mobilisable plasmids that will neither alter the pathogenicity or ability of the E. coli host cells to
survive in the environment, and therefore plasmid production is correctly classified as Class 1. Lentiviruses have a
broad host range and can infect human cells . The recombinant systems produces replication-incompetent viruses by co-transfection of HEK293 cells with between 5
helper plasmids that have been engineered to ensure that there are
no identical regions within the plasmids that would facilitate recombination and therefore the lik.elihood or regenerating a replication competent virus is negligible and the
testing for such RCVs is considered unnecessary. &
The one non-negligible hazard associated with the expression systems is that the lentiviral expression system for
protein expression contains the WPRE and downstream X gene fragment that is considered to have oncogenic
i potential. Thus the production and use of the recombinant lentiviruses is correctly assessed as Class 2, regardless of
the insert to be expressed (provided it is not a biological toxin or a prion). Oncogenic DNA will be handled and disposed of appropriately.
The Code of Practice for the CL2 lab where this work. will be performed dictates the avoidance of all sharps and the
wearing of two pair of gloves.
The aim is to define the role of factors such as cytokines, receptors, signalling molecules and transcription factors in the development of the immune system and in haematopoesis. We will study this in a variety of model systems such as primary cell lines and established well-characterised eukaryotic cell lines. The methodologies to be used will be CRISPR/Cas9 system, retroviral and lentiviral transductions, and the creation of novel stable cell lines using these technologies.
Hosts: E. coli K12 derivatives (for example DH5a, MC1061, Xl1blue, Top10) and E. coli B cell strains such as BL21 (DE3), C41, Origami); mammalian cell lines (such as HEK293).

### Host/vector system

Production of non-replicative virus like particles for (i) MSCV retroviruses (ecotropic and amphotropic); (ii) pLent6-based lentiviruses; pLKO.1 lentiviruses expressing RNA; lentiviruses expressing human cell directed CRISPR/Cas9 libraries

### Origin & function

The origins of the cDNAs/RNAs to be used will be either murine or human. Strategies will include overexpression of specific cDNAs (e.g. Bcl11 b, GATA3, c-Myb, Nfil3, plzf, Id2, Ets1 etc) and regulatory RNAs (e.g. shRNA to tumour suppressors such as Tcf?, Eomes etc) in mammalian cells. In addition, any gene in the murine or human genome may be knocked-out or knocked-in. In addition, the CRISPR/Cas9 system will be used in either murine retroviruses or lentiviruses to screen knock-outs or knock-ins of cDNA/RNA libraries; there is no intention to make gene drives.

### Evaluation of foreseeable effects

None of the inserts will affect the pathogenicity or survivability of the host cells (E. coli or mammalian cells). None of the inserts will affect the host range, pathogenicity or ability to survive in the environment of the recombinant lentiviruses. None of the inserts are toxic, but many of the cDNAs/RNAs are potentially oncogenic. Class 2 is appropriate for lentiviruses containing a WPRE (expressing any insert) and also for amphotropic murine retroviruses expressing oncogenic cDNA/RNA. Class 1 is only appropriate for lentiviruses and amphotropic murine retroviruses NOT containing a WPRE and NOT expressing an oncogenic cDNA/RNA.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only GM micro-organisms will be produced in this work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied where the risk assessment classes the activities as Class 2.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 2 waste will be autoclaved (136°C for 20 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

Please enter comments on the GM safety committee on the risk assessment

02/03/2022
There is insufficient room for all the comments from the SSC, so please see the attached risk assessment. Verbatim comments for CL2 activities are below, and all other activities were classified as Class 1.

*Lentiviruses and VSV-G pseudo-typed MSCV have a broad host range and can infect human cells. The recombinant systems both produce replication-incompetent viruses by co-transfection of HEK293 cells with between 2-4 helper plasmids that have been engineered to ensure that there are no identical regions within the plasmids that would facilitate recombination and therefore the likelihood or regenerating a replication competent virus is negligible and the testing for such RCVs is considered unnecessary. The one non-negligible hazard associated with the expression systems is that the lentiviral expression system for protein expression sometimes contains a WPRE and downstream X gene fragment that is considered to have oncogenic potential. Production and use of the recombinant lentiviruses containing a WPRE is correctly assessed as Class 2, regardless of the insert to be expressed (provided it is not a biological toxin or a prion). Expression of siRNA from the pLK01 lentiviral expression system, expression of proteins from pLent6 and expression using amphotropic retrovirals do not require a WPRE and therefore class 1 is appropriate for most inserts, unless the inserts' are potentially oncogenic, when Class 2 is the correct classification. Ecotropic retroviruses may be regarded as Class 1, regardless of insert, as they cannot infect human cells. The CRISPR/Cas9 work will be used to make knock-outs or knock-ins in cell lines in tissue culture and there is no intention to make gene drives. Where human lentiviral CRISPR/Cas9 RNA or cDNA libraries are used, this aspect of the work is considered to be Class 2 due to the potential presence of cDNAs that could be oncogenic or iRNAs that could target tumour suppressor genes. The Code of Practice for the Containment Suite where this work will be performed dictates the avoidance of all sharps and the wearing of two pair of gloves."

**Project notified under transitional arrangements**

02/03/2022
### Project Additional Information

**Purposes of the contained use**

The aim of the project is to produce cell lines that are stable knockouts, knock-down or overexpressed proteins of interest involved in the cellular responses to bacterial infection. The cell lines will be made using either CRISPR-Cas9 libraries, specific gene alterations using CRISPR-Cas9 or insertion of the lentiviral genome for protein overexpression.

**Recipient or parental organism**

Hosts: E. coli K12 derivatives (for example Stbl3, DH5a, MC1061, Xl1blue); mammalian cell lines (such as HEK293T), murine primary cell lines.

**Host/vector system**

Production of non-replicative virus-like particles for lentiviruses expressing proteins and RNAs and human cell directed CRISPR-Cas9 libraries.

**Origin & function**

The human proteins/RNAs to be used in the context of the project fall into a number of major categories including autophagy, phagosome maturation, inflammasome components, toll-like receptors etc, but any gene in the genome may be targeted, including tumour-suppressor genes and potential oncogenes.

Specific exclusions include the expression of any agent that may be a prion agent or toxin.

**Evaluation of foreseeable effects**

The lentiviral expression systems used are non-replicative in the absence of specific factors required for virus propagation. The major risk to the user is therefore the expression of elements encoded by the non-replicative virus and the DNA encoding the protein/RNA of interest. Some lentiviruses contain the WPRE that is potentially oncogenic and therefore this is regarded as Class 2. The greatest risk is posed by any of the non-replicative viruses expressing siRNAs that are potentially tumour suppressors, such as critical cell cycle checkpoint regulators (e.g. p53, Rb etc) or DNA repair genes (e.g. MSH2, BRCA1 etc), and proteins that potentially induce oncogenesis upon overexpression, such as tyrosine kinases (e.g. src), transcriptional activators (e.g. myc) or small G protein mutants (e.g. ras). In all these cases, the GMMs are classified as Class 2 and will be handled only in a Class 2 facility in a Class II microbiological safety cabinet. The SOP for this work dictates the use of gloves and the avoidance of sharps to reduce risk of accidental inoculation via a puncture wound to essentially zero.

Specific exclusions include the expression of any agent that may be a prion agent or toxin.

All the expression systems rely on expression of component plasmids in E. coli; none of the inserts will affect the,
pathogenicity or survivability of the host cells. Similarly, none of the inserts will affect the host range, pathogenicity or ability to survive in the environment of the recombinant lentiviruses. CRISPR/Cas9 work explicitly excludes the creation of gene drives, with components either encoded on separate plasmids or purified gRNAs/Cas9 being used.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Only GM micro-organisms will be produced in this work.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Full containment level 2 will be applied where the risk assessment classes the activities as Class 2.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Containment level 2 waste will be autoclaved (136°C for 20 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

There is insufficient room for all the comments from the SSC, so please see the attached risk assessment. Verbatim comments for CL2 activities are paraphrased below, and all other activities were classified as Class 1. *All genes encoding proteins or RNAs in the mammalian cells will be targeted, some of which may be oncogenic or tumour-suppressors. Gene targeting will be performed using non-replicative recombinant viruses, i.e HIV-based lentiviruses. All of the proteins and siRNAs to be expressed/targeted are neither biological toxins nor prions. Non-replicative lentiviruses have a broad host range and can infect human cells. The one non-negligible hazard associated with the expression systems is that the lentiviral expression system for protein expression sometimes contains a WPRE and downstream X gene fragment that is considered to have oncogenic potential. Production and use of the recombinant lentiviruses containing a WPRE is correctly assessed as Class 2, regardless of the insert to be expressed (provided it is not a biological toxin or a prion). Expression of siRNA from the pLK01 lentiviral expression system do not require a WPRE and therefore class 1 is appropriate for most inserts, unless the inserts are potentially oncogenic, when Class 2 is the correct classification. The CRISPR/Cas9 work will be used to make knock-outs, knock-downs or knock-ins in cell lines in tissue culture and there is no intention to make gene drives or use whole animals. Where human lentiviral CRISPR/Cas9 RNA or cDNA libraries are used, this aspect of the work is considered to be Class 2 due to the potential presence of cDNAs that could be oncogenic or iRNAs that could target tumour suppressor genes. The Code of Practice for the Containment Suite where this work will be performed dictates the avoidance of all sharps and the wearing of two pair of gloves.*
**Project Additional Information**

**Purposes of the contained use**

The goal of the project is to identify and characterize proteins involved in initiation of immune responses by dendritic cells (DC). This includes proteins involved in sensing of pathogen and cancer associated signals, antigen processing and presentation, as well as protein trafficking pathways and transcriptional programmes that lead to DC activation and maturation.

**Recipient or parental organism**

Hosts: E. coli K12 derivatives (for example DH5α, MC1 061, XL1 blue, Top10); mammalian cell lines (such as HeLa).
CHO, HEK293, murine primary cell lines.

**Host/vector system**

Production of non-replicative virus-like particles for lentiviruses expressing proteins and RNAs; adeno-associated viruses expressing proteins and RNAs; lentiviruses expressing human cell directed CRISPRiCas9 libraries

**Origin & function**

Cellular proteins to be studied fall into three main classes according to activities: (A) Intracellular proteins such as: DNA modifying and repair proteins, post-translational modifying systems (such as phosphorylation, ubiquitination, SUMOylation) metabolic enzymes, proteases, cytoskeletal proteins, motor proteins, nucleoproteins, membrane-binding proteins. (B) Secreted proteins such as antibodies, hormones, extracellular proteases, molecular chaperones, lipid/metabolite binding proteins. (C) Integral membrane proteins such as transporters, ion channels, receptors, enzymes, structural proteins, molecular chaperones, apoptosis regulators. Specific exclusions include prion agents known or suspected to cause neurological disorders and any biological toxin.

RNAs to be expressed fall into all major classes of RNA found in the cell and also RNAs specifically designed for the modulation of expression levels of native RNAs: (A) Anti-sense RNAs, siRNAs or shRNAs designed to decrease levels of endogenous mRNAs encoding proteins described above. (B) Non-coding RNAs that modulate cellular activities. (C) Structural RNAs

Specific exclusions include any agent that may induce the expression of prion agents.

Reporter proteins to be expressed include a variety of natural and engineered proteins from bacteria, insects and jellyfish such as GFP derivatives, luciferases, channelrhodopsins, light regulated adenylyl cyclase, GFP based calcium sensors such as GCaMP5/6, R-GEC01, pH-sensors or sodium sensors.

In addition, any gene in the murine or human genome may be knocked-out or knocked-in. The CRISPRiCas9 system will be used in either murine retroviruses or lentivirus9s to screen knock-outs or knock-ins of eDNA/RNA libraries; there is no intention to make gene drives.

**Evaluation of foreseeable effects**

Two viral expression systems will be utilised, both of which have the properties of being non-replicative in the absence of specific factors required for virus propagation. The major risk to the user is therefore the expression of elements encoded by the non-replicative virus and the DNA encoding the protein/RNA of interest. Some lentiviruses and AA Vs contain the WPRE that is potentially oncogenic and therefore this is regarded as Class 2. The greatest risk is posed by any of the non-replicative viruses expressing siRNAs that are potentially tumour suppressors, such as critical cell cycle checkpoint regulators (e.g. p53, Rb etc) or DNA repair genes (e.g. MSH2, BRCA1 etc), and proteins that potentially induce oncogenesis upon overexpression, such as tyrosine kinases (e.g. src), transcriptional activators (e.g. myc) or small G protein mutants (e.g. ras). In all the aforementioned cases, the GMMs are classified as Class 2 and will be handled only in a Class 2 facility in a Class II microbiological safety cabinet. The SOP for this work dictates the use of gloves and the avoidance of sharps to reduce risk of accidental inoculation via a puncture wound to essentially zero.

A number of genetic modifications are specifically outside the boundaries of this work. In particular, the following modifications are forbidden: expression of any protein mutant that is suspected of being a prion e.g. PrP(+CJD mutations); expression of biological toxin that are highly toxic to humans e.g. ricin or co-expression of both A and B chains of botulinum toxin.

All the expression systems rely on expression of component plasmids in E. coli; none of the inserts will affect the pathogenicity or survivability of the host cells. Similarly, none of the inserts will affect the host range, pathogenicity or ability to survive in the environment of the recombinant lentiviruses or recombinant AA Vs.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only GM micro-organisms will be produced in this work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied where the risk assessment classes the activities as Class 2.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 2 waste will be autoclaved (136°C for 20 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

There is insufficient room for all the comments from the BSC, so please see the attached risk assessment. Verbatim comments for CL2 activities are below, and all other activities were classified as Class 1.

"A wide variety of proteins will be expressed including standard reporter proteins, mammalian proteins and siRNAs, some of which may be oncogenic. Expression will be performed using non-replicative recombinant viruses, i.e HIV-based lentiviruses and AAVs. All of the proteins and siRNAs to be expressed are neither biological toxins nor prions. Lentiviruses and AAVs have a broad host range and can infect human cells. The recombinant systems both produce replication-incompetent viruses by co-transfection of HEK293 cells with between 2-4 helper plasmids that have been engineered to ensure that there are no identical regions within the plasmids that would facilitate recombination and therefore the likelihood or regenerating a replication competent virus is negligible and the testing for such RCVs is considered unnecessary. The one non-negligible hazard associated with the expression systems is that the lentiviral expression system for protein expression sometimes contains a WPRE and downstream X gene fragment that is considered to have oncogenic potential. Production and use of the recombinant lentiviruses containing a WPRE is correctly assessed as Class 2, regardless of the insert to be expressed (provided it is not a biological toxin or a prion). The CRISPR/Cas9 work will be used to make knock-outs or knock-ins in cell lines in tissue culture and there is no intention to make gene drives. Where human lentiviral CRISPR/Cas9 RNA or cDNA libraries are used, this aspect of the work is considered to be Class 2 due to the potential presence of cDNAs that could be oncogenic or iRNAs that could target tumour suppressor genes. The Code of Practice for the Containment Suite where this work will be performed dictates the avoidance of all sharps and the wearing of two pair of gloves."

02/03/2022
The aim of the project is understand the cellular mechanisms of circadian rhythms. A variety of different report I proteins will be expressed downstream from promoters of genes involved in circadian rhythms ('clock reporters') to monitor effects in different cells and the presence or absence of viruses.

Recipient or parental organism

Hosts: E. coli K12 derivatives (for example DH5alpha, XL 1, Top10); mammalian cell lines (such as human pluripotent stem cell lines, HEK293), murine primary cell lines.

Host/vector system

Production of non-replicative virus-like particles for lentiviruses and Sendai viruses expressing reporter proteins; replicative Herpes Simplex virus (HSV1) expressing reporter proteins and replicative influenza virus PR8 expressing luciferase.
Production of non-replicative virus-like particles for lentiviruses and Sendai viruses expressing reporter proteins; replicative Herpes Simplex virus (HSV1) expressing reporter proteins and replicative influenza virus PR8 expressing luciferase.

**Evaluation of foreseeable effects**

The major risk to the user of the non-replicative lentiviruses is the expression of elements encoded by the lentivirus as they contain a WPRE that is potentially oncogenic and, therefore this is regarded as Class 2. None of the inserts will affect the host range, pathogenicity or ability to survive in the environment of the recombinant lentiviruses. Thus the GMMs are classified as Class 2 and will be handled only in a Class 2 facility in a Class II microbiological safety cabinet. The SOP for this work dictates the use of gloves and the avoidance of sharps to reduce risk of accidental inoculation via a puncture wound to essentially zero.

Influenza strain PR8 is a highly attenuated strain that is unable to infect human cells and the expression of the reporter proteins will not affect its host range, pathogenicity or ability to survive in the environment; Class 1 is therefore appropriate for this work.

Sendai viruses can infect human cells but are non-pathogenic to humans. The recombinant viruses are non-replicative and the expression of the reporter proteins will not affect its host range, pathogenicity or ability to survive in the environment; Class 1 is therefore appropriate for this work.

Herpes simplex virus HSV1 is an ACDP HG2 pathogen that can replicate in humans and cause a variety of diseases. Expression of the reporter proteins will not affect its host range, pathogenicity or ability to survive in the environment; Class 2 is therefore appropriate for this work.

All the expression systems rely on expression of component plasmids in E. coli; none of the inserts will affect the pathogenicity or survivability of the host cells.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Only GM micro-organisms will be produced in this work.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Full containment level 2 will be applied where the risk assessment classes the activities as Class 2.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Containment level 2 waste will be autoclaved (136°C for 20 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

Historical Significant Changes
Project Additional Information

Purposes of the contained use

The goal of the project is to define in high-resolution the architecture of neurotransmitter receptors, their supra-molecular assemblies and, eventually, whole synapses. We aim to link structural work with neuronal physiology, in order to provide fundamental mechanistic insights into the basic biology of neurotransmission.

Recipient or parental organism

Hosts: E. coli K12 derivatives (for example DH5alpha, XL 1 blue, Top10); mammalian cell lines (such as HeLa, CHO, I COS Jurkat, HEK293), murine primary cell lines. II

Host/vector system

Production of non-replicative virus-like particles for lentiviruses and adeno-associated viruses (AAVs) expressing I proteins and RNAs and human cell directed CRISPRCas9 libraries; recombinant replicative baculoviruses expressing oncogenic proteins from a CMV promoter in mammalian cells (BacMam system).

Origin & function

Reporter proteins to be expressed include a variety of natural and engineered proteins from insects and jellyfish such as GFP derivatives and luCiferases, respectively.

The human proteins/RNAs to be used in the context of the project fall into a number of major categories such as structural proteins at the synapse, receptors, G proteins etc, but any gene in the genome may be targeted, including tumour-suppressor genes and potential oncogenes. Specific exclusions include the expression of any agent that may be a prion agent or toxin.

Evaluation of foreseeable effects

The lentiviral and MV expression systems used are non-replicative in the absence of specific factors required for virus propagation. The major risk to the user is therefore the expression of elements encoded by the non-replicative viruses and the DNA encoding the protein/RNA of interest. Some lentiviruses and all the MVs contain the WPRE
that is potentially oncogenic and therefore this is regarded as Class 2. The greatest risk is posed by any of the
non-replicative viruses expressing siRNAs that are potentially tumour suppressors, such as critical cell cycle
checkpoint regulators (e.g. p53, Rb etc) or DNA repair genes (e.g. MSH2, BRCA1 etc), and proteins that potentially
induce oncogenesis upon overexpression, such as tyrosine kinases (e.g. src), transcriptional activators (e.g. myc) or
small G protein mutants (e.g. ras). In all these cases, the GMMs are classified as Class 2 and will be handled only in
a Class 2 facility in a Class II microbiological safety cabinet. Similarly, any expression of potentially oncogenic
proteins using the BacMam baculovirus system in mammalian cells is Class 2. All CRISPR/Cas9 work using human
libraries expressed from lentiviruses also classified s Class 2, due to the high proportion of potential oncogenes and
tumour-suppressors in the human genome. The SOP for all Class 2 work dictates the use of gloves and the
avoidance of sharps to reduce risk of accidental inoculation via a puncture wound to essentially zero.
Specific exclusions include the expression of any agent that may be a prion agent or toxin.
All the expression systems rely on expression of component plasmids in E. coli; none of the inserts will affect the
pathogenicity or survivability of the host cells. Similarly, none of the inserts will affect the host range, pathogenicity or
ability to survive in the environment of the recombinant lentiviruses.
CRISPR/Cas9 work explicitly excludes the creation of gene drives, with components either encoded on separate
plasmids or purified gRNAs/Cas9 being used.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only GM micro-organisms will be produced in this work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied where the risk assessment classes the activities as Class 2.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 2 waste will be autoclaved (136°C for 20 min), before subsequent discharge down the drain into
the public sewer or incineration. It is expected that this will give effectively 100% killing.

Lentiviruses and AAVs have a broad host range and can infect human cells. The recombinant systems both produce replication-incompetent viruses by co-transfection of HEK293 cells with between 2-4 helper plasmids that have been engineered to ensure that there are no identical regions within the plasmids that would facilitate recombination and therefore the likelihood or regenerating a replication competent virus is negligible and the testing for such RCVs is considered unnecessary. The one non-negligible hazard associated with the expression systems is that AAVs and the lentiviral expression system for protein expression sometimes contains a WPRE and downstream X gene fragment that is considered to have oncogenic potential. Production and use of the recombinant AAVs and lentiviruses containing a WPRE is correctly assessed as Class 2, regardless of the insert to be expressed (provided it is not a biological toxin or a prion). Expression of siRNA from the pLK01 lentiviral expression system, expression of proteins from pLenti6 do not require a WPRE and therefore class 1 is appropriate for most inserts, unless the inserts are potentially oncogenic, when Class 2 is the correct classification. The CRISPR/Cas9 work will be used to make knock-outs or knock-ins in cell lines in tissue culture and there is no intention to make gene drives. Where human lentiviral CRISPR/Cas9 RNA or cDNA libraries are used, this aspect of the work is considered to be Class 2 due to the potential presence of cDNAs that could be oncogenic or iRNAs that could target tumour suppressor genes. The SacMam system has a broad host range and can infect human cells and will be used to expressed oncogenic proteins, and therefore this correctly classified as Class 2.

<td>Using fluorescently-labelled UPEC to investigate the role of immune sentinels during infection of the urinary tract</td>
<td>Class 2 ≤ 1 Litre</td>
</tr>
</tbody>
</table>

Non-GMM Consent Granted
The aim is to better understand the pathogenesis of urinary tract infection and chronic pyelonephritis and how this contributes to renal failure by investigating the role of different immune sentinels in the defence of the urinary tract.

Hosts: uropathogenic Escherichia coli (UPEC)

Stable integration of fluorescent reporter proteins into the genome of UPEC

Fluorescent proteins such as GFP, mCherry and all their derivatives

Expression of fluorescent reporters such as GFP or mCherry (and any of their derivatives) will not affect the pathogenicity or the ability of the UPEC to survive in the environment. The GM UPEC will therefore have the same properties as the wild type UPEC and therefore will zero environmental impact and no effect on human health.

Only GM micro-organisms will be produced in this work.

Full containment level 2 will be applied where the risk assessment classes the activities as Class 2.

Containment level 2 waste will be autoclaved (136°C for 20 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.
Project 2018/08 is study the process of infection of uropathogenic E. coli (UPEC) using fluorescently-tagged bacteria. GFP, mCherry or their derivatives will be expressed in UPEC to make them fluorescent. The bacteria will be introduced into mice via a catheter and the organs then analysed for the present of bacteria. UPEC are categorised as HG2. The fluorescent reporters will not alter the pathogenicity of the bacteria and will not make them more effective at surviving in the environment. Introduction of GM UPEC into mice will be via a catheter and thus avoids the use of a sharp needle. Dissection of potentially UPEC-contaminated tissues using sharps will be performed in a Class III MSC and will use forceps to hold tissues during excision and dicing, reducing risks to the workers of needle stick injuries. The project is therefore correctly classified as Activity Class 2.

### Project Additional Information

#### Purposes of the contained use

The overarching purpose of the work is to understand signal transduction and transport processes in normal and abnormal (diseased) vertebrate cells during cellular activities such as neurotransmission, host pathogen interactions, cell division and cellular repair mechanisms. These integrated mechanisms will be studied at the cellular and molecular levels through either the disruption/activation of pathways by siRNA expression or through the expression of proteins and protein mutants with defined activities.

#### Recipient or parental organism

**Hosts:** E. coli K12 derivatives (for example DH5a, MC1 061, X11 blue, Top10); mammalian cell lines (for example HeLa, CHO, HEK293T); primary cell lines from e.g. mouse and human; tissue explants for e.g. mouse; in vivo work in mice.

#### Host/vector system

1. HIV-based non-replicative recombinant lentiviruses e.g. based on pCCLsin.PPT.hPGK.EGFP.wpre or pLK01;
2. MLV-based non-replicative recombinant retroviruses e.g. based on pCL-10A1 and VSV-G pseudo-typed
3. AAV-based non-replicative recombinant adeno-associated virus e.g. based on pAAV-6P-SEW8
4. deltaGp-RV non-replicative recombinant Glycoprotein-deleted rabies virus e.g. based on pSADdeltaG-F2
5. BacMam replicative baculovirus

#### Origin & function

Cellular proteins involved in signal transduction and transport processes fall into three main classes according to activities: (A) Intracellular proteins such as: DNA modifying and repair proteins, post-translational modifying systems (such as phosphorylation, ubiquitination, SUMOylation) metabolic enzymes, proteases, cytoskeletal proteins, motor proteins, nucleoproteins, membrane-binding proteins. (B) Secreted proteins such as antibodies, hormones, extracellular proteases, molecular chaperones, lipid/metabolite binding proteins. (C) Integral membrane proteins such as transporters, ion channels, receptors, enzymes, structural proteins, molecular chaperones, apoptosis regulators. Specific exclusions include prion agents known or suspected to cause neurological disorders and any biological toxin.

RNAs to be expressed fall into all major classes of RNA found in the cell and also RNAs specifically designed for the modulation of expression levels of native RNAs: (A) Anti-sense RNAs, siRNAs or shRNAs designed to decrease
levels of endogenous mRNAs encoding proteins described above. (8) Non-coding RNAs that modulate cellular activities. (C) Structural RNAs
Specific exclusions include any agent that may result in the expression of TSEs or biological toxins.
Reporter proteins to be expressed include a variety of natural and engineered proteins from bacteria, insects and jellyfish such as GFP derivatives, luciferases, channelrhodopsins, light regulated adenyl cyclase, GFP based calcium sensors such as GCaMP5/6, R-GECo1, pH-sensors or sodium sensors.
The vectors will also be used to screen human CRISPR/Cas9 libraries for either gene knock-out, knock-down or knock-up.

Evaluation of foreseeable effects

LFour mammalian viral expression systems will be utilised, all of them have the properties of being non-replicative in "the absence of specific factors required for virus propagation. The major risk to the user is therefore the expression of "elements encoded by the non-replicative virus and the DNA encoding the protein/RNA of interest. Some lentiviruses and AAVs contain the wild type WPRE that is potentially oncogenic and therefore this is regarded as Activity Class 2. In contrast recombinant MLV, delta Gp rabies virus and some lentiviruses do not contain any potentially oncogenic elements and therefore Activity Class 1 is appropriate. The greatest risk is posed by any of the non-replicative viruses expressing siRNAs that are potentially tumour suppressors, such as critical cell cycle checkpoint regulators (e.g. p53, Rb etc) or DNA repair genes (e.g. MSH2, BRCA1 etc), and proteins that potentially induce oncogenesis upon overexpression, such as tyrosine kinases (e.g. src), transcriptional activators (e.g. myc) or small G protein mutants (e.g. ras). In all the aforementioned cases, the GMMs are classified as Activity Class 2 and will be handled only in a Class 2 facility. The SOP for this work dictates the use of gloves and the avoidance of sharps to reduce the risk of accidental inoculation via a puncture wound to essentially zero. The BacMam expression will also be used, which is based on recombinant replicative baculovirus, that cannot replicate in human cells, but can express proteins under the control of the CMV promoter. Where the insert to be expressed is oncogenic or a tumour suppressor, then this is classified as Activity Class 2 and will be used only in a Class 2 facility wearing gloves and avoiding sharps.

A number of genetic modifications are specifically outside the boundaries of this work. In particular, the following modifications are forbidden: expression of any protein mutant that is suspected of being a prion (e.g. PrP+CJD mutations); expression of biological toxin that are highly toxic to humans (e.g. ricin or co-expression of both A and B chains of botulinum toxin).

All the expression systems rely on expression of component plasmids in E. coli; none of the inserts will affect the pathogenicity or survivability of the host cells. Similarly, none of the inserts will affect the host range, pathogenicity or ability to survive in the environment of the recombinant lentiviruses or recombinant AAVs.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only GM micro-organisms will be produced in this work.
Future work may include the introduction of the AC2 GM vectors (lentiviruses and AAVs) into mice. All mouse work is approved by appropriate Home Office licenses. Where possible, mice will be injected with the use of a stereotactic frame or using suitable restraints. Minimal quantities of the AC2 vectors will be used, typically 10 ul. The work will be performed only by highly experienced personnel and gloves will be worn. After injection, mice will be held in a post-operative recovery cabinet (Hepa filtered air supply) for 24 hours and not handled. Bedding will be treated as CL2 waste (autoclaved followed by incineration) and will be removed after 24 hours within a Class II MSC. After 24 hours the viral load in the mouse will be significantly depleted and so the mice will be transferred to CL 1.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Full containment level 2 will be applied where the risk assessment identifies Class 2 as the appropriate classification.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solids from the Containment level 2 lab (e.g. plasticware) will be autoclaved (136°C for 20 min), before disposal by incineration. It is expected that this will give effectively 100% killing.

All liquids from the Containment Level 2 lab will be inactivated by treatment with RBS50 (minimum final concentration of 1 %) for a minimum of 1 hour before subsequent discharge down the drain into the public sewer.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

The comments are too long to insert in the space given, so please see the attached Risk Assessment for the full comments. In brief:
Lentiviral vectors containing a wild type WPRE, regardless of insert: Class 2
Lentiviral vectors with mutated WPRE (no expression of X gene): Class 1, unless insert is oncogenic, then Class 2
pLK01 lentiviral vectors for RNA expression, Class 1, unless the insert is oncogenic, then Class 2
MV vectors containing a wild type WPRE, regardless of insert: Class 2
MV vectors with a mutated WPRE (no expression of X gene): Class 1, unless insert is oncogenic, then Class 2
DeltaGp-rabies virus vectors, class 1, unless the insert is oncogenic, then Class 2
BacMam expression system, class 1, unless the insert is oncogenic, then Class 2
All human CRISPR/Cas9 libraries in lentiviruses (CasH and gRNAs on same vector): Class 2
Note that inserts that encode prions or potent biological toxins are specifically excluded from this risk assessment. Potentially oncogenic DNA will be handled and disposed of appropriately.
The Code of Practice for the Containment Suite where this work will be performed dictates the avoidance of all sharps and the wearing of two pair of gloves.
Waste generated in this project will be effectively inactivated by using the approved disinfectants in the LMB as described in the Safety Handbook. The environmental impact will therefore be negligible.
This project is an update of previously notified CL2 activities; the list of previously notified activities is in Additional Comments. All of these projects were previously approved by the BSC (comments can be found with Notifications).

Project Additional Information

Purposes of the contained use

The investigation of the cellular genetic requirements for efficient retrotransposition using the technically tractable chicken cell line DT40 and Moloney murine leukaemia virus based vector with amphotropic envelope.

Transgenes will be fluorescent marker proteins and also genes to complement the genetic defects engineered into the host DT40 eg genes involved in DNA damage avoidance and repair.

Recipient or parental organism

Avian cell lines (eg DT 40).
Retroviral producer cells: HEK293 derived lines, such as Phoenix-amphotropic, or VSV-G expressing retroviral producer cells.

Host/vector system

MD

Origin & function

Transgenes will be fluorescent marker proteins and also genes to complement the genetic defects engineered into the host DT40 eg genes involved in DNA damage avoidance and repair.
### Evaluation of foreseeable effects

Inserts carried by retroviruses generally correspond to individual, well characterised cDNAs (e.g. reporter genes such as GFP, genes involved in DNA damage avoidance and repair e.g. RAD18, signalling molecules such as NF-kB) or their derivatives (e.g. truncations, point mutations, or fusions to marker proteins, e.g. GFP). Work also includes the creation of retroviral supernatants which may contain hazardous genes such as proto-oncogenes. All inserts are unlikely to increase the pathogenicity of the tc target cell lines.

A non-negligible hazard arises from the risk of insertional mutagenesis and the potentially oncogenic or cytotoxic nature of some of the inserts. DNA grown up from such clones should be handled as set out in the ACGM Compendium of Guidance, Part 3A, Annex 1m, paras. 8-10, i.e. gloves should be worn, sharps avoided and all wastes be rendered harmless before disposal.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only micro-organisms (including tissue culture cells) are involved in this work.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

For the part of the work classified as class 2, full containment level 2 will be applied.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Containment level 1 waste, generated during the initial steps, will be inactivated by either treatment with 1% v/v Clearsol, before discharge down the drain into the public sewer, or by incineration (in a registered facility). Data have been obtained from the manufacturer to show that the disinfection will achieve >10 (to the power of 5) loss of infectivity in the times used, while incineration will give effectively 100% killing.

Containment level 2 waste will be autoclaved (136 degrees C for 10 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that these will give effectively 100% killing.

---

Please enter comments on the GM safety committee on the risk assessment
This work involves the cloning of fluorescent marker proteins and also genes involved in DNA damage avoidance and repair. The ultimate host in both cases is the chicken cell line DT 40, but initial cloning will be into standard laboratory E. coli K12 strains and also, as the vectors include Moloney murine leukaemia virus, appropriate retroviral packaging cell lines.

The transgenes are already covered for work in E. coli under existing projects, and the new vectors to be included in this project are standard mammalian expression plasmids (eg pCDNA) and also the MMLV-based disabled retroviral vectors. These will be packaged using the Phoenix-amphotropic packaging line, or with VSV-G protein pseudo-typing, to produce disabled retroviral particles, capable of only a single infective passage, but with envelope proteins allowing promiscuous infectivity.

The E. coli work and also that with the pCDNA (or similar vectors is correctly classified as Class 1. With the retroviral vectors, there is no hazard with the marker transgenes, and therefore Class 1 is appropriate. With the genes involved in DNA damage avoidance and repair, which are potentially oncogenic, Class 2 is appropriate, as assessed.

It is noted that the potential hazard from the naked DNA for proto-oncogenes has been considered.

**Project Additional Information**

**Purposes of the contained use**

The aims of the project are to understand how adhesion of bacteria to surfaces, followed by defined cell-cell interactions between bacteria, lead to the formation of macroscopic three-dimensional bacterial communities called biofilms.

**Recipient or parental organism**

| Hazard Group 2 bacteria such as Pseudomonas aeruginosa |
| Hazard group 1 bacteria such as Pseudomonas fluorescens and disabled strains of E. coli (K-12 and B derivatives) |

**Host/vector system**

| E. coli K-12 or B derivatives and non-mobilisable vectors |

**Origin & function**

| Standard reporter genes such as GFP and Luciferase |
| Standard antibiotic resistance genes such as Amp and Kan |
| Over expression or knockdown of genes proposed to be involved in the bacterial adhesion process, such as fimbriae genes, Ag43, Pel and Psl. |
| Over expression or knockdown of genes identified from bacterial samples from Cystic fibrosis patients to be involved in biofilm formation. |

**Evaluation of foreseeable effects**

Addition of standard reporter genes has a history of safe use and is not expected to alter the pathogenicity of the host. Standard antibiotic resistance genes are not used to treat the disease and therefore will not alter the ability to treat infections. Over expression of proteins in disabled E. coli K-12 or B derivatives to enable production of proteins for study is not expected to overcome the disabled nature of the strains. Overexpression of genes involved in biofilm formation in P. aeruginosa is not expected to increase virulence. Where there may be potential for affecting virulence the work will be done in strains which are Type IV pili negative. Deletion mutants are likely to have a reduced ability to form biofilms and consequently are less likely to cause infection. Parallel work in P. fluorescens and E. coli will be done to the same standards as P. aeruginosa to ensure consistency.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - sharps are not required for this project.

Degree of kill:
- Autoclaving, effectively 100% kill (annual validation)
- Incineration, effectively 100% kill (licensed incinerator)
- Chemical, effectively 100% kill (following manufacturers guidelines)

### Project Additional Information

#### Purposes of the contained use

The project aims to understand how non-tuberculous mycobacteria (NTM), specific types of gram negative bacteria (E. coli (non-verotoxigenic strains isolated from sputum), P. aeruginosa) and gram positive bacteria (S. pneumoniae, S. aureus) interact with macrophages to avoid intracellular killing and how pharmacological manipulation of cellular processes (such as the phagosomal ionic environment and macro-autophagy) might enhance intracellular bacterial killing and/or modulate release of inflammatory mediators.

#### Recipient or parental organism

NTM (excepting M. bovis BCG) are ubiquitous organisms occurring naturally in the environment (in domestic water, soil and houses). While they can cause lung infections in people with pre-existing structural lung disease (such as Cystic Fibrosis and Chronic Obstructive Pulmonary Disease), they are not pathogenic in healthy people and are not transmissible from person to person. Untransfected, it is usually handled in CL2 areas.

M. bovis BCG is still in current world-wide use as a live vaccine against M. tuberculosis and is not pathogenic in healthy people.

#### Host/vector system

pSMT1 plasmid carrying the luxAB genes from Vibrio harveyi and green fluorescent protein (GFP), Cyan FP, Yellow FP or Red FP; under the control of the constitutively active mycobacterial GroEL (hsp60) promoter; mycobacterial and E. coli origins of replication and a hygromycin resistance cassette. The vectors will not be translated by eukaryotic cells.

#### Origin & function

pSMT1 plasmid carrying the luxAB genes from Vibrio harveyi and green fluorescent protein (GFP), Cyan FP, Yellow FP or Red FP; under the control of the constitutively active mycobacterial GroEL (hsp60) promoter; mycobacterial and E. coli origins of replication and a hygromycin resistance cassette.

LuxAB genes from Vibrio harveyi and green fluorescent protein (GFP) purchased from Clontech

Episomal insertion of plasmid DNA will result in generation of cytoplasmic green fluorescent protein (GFP) and luciferase (lux) as previously utilised in M. bovis and M. tuberculosis (Kampmann et al 2000). No selection advantage is anticipated for LUX-tagged or GFP tagged mycobacteria or bacteria.

**Evaluation of foreseeable effects**

NTM (excepting M. bovis BCG) are ubiquitous organisms occurring naturally in the environment (in domestic water, soil and houses). While they can cause lung infections in people with pre-existing structural lung disease (such as Cystic Fibrosis and Chronic Obstructive Pulmonary Disease), they are not pathogenic in healthy people and are not transmissible from person to person. Untransfected, it is usually handled in CL2 areas.

M. bovis BCG is still in current world-wide use as a live vaccine against M. tuberculosis and is not pathogenic in healthy people. Untransfected and luminescently tagged M. bovis BCG are currently handled in CL2 facilities.

Untransfected and luminescently tagged S. pneumoniae, S aureus, P aeruginosa and E. coli are currently handled in CL2 facilities. While all can cause infections in man, the risk to healthy laboratory staff of these bacteria is extremely low. They will be handled in the tissue culture hoods and no procedures have the potential to generate aerosolised bacteria. The risk of inhalation therefore is extremely low.

**ii) the inserted genetic material**

The inserted plasmid has no eukaryotic promoter, encodes a luciferase gene and green fluorescent protein, which, in all mycobacteria examined to date, is retained intracellularly. The encoded proteins, lux and fluorescent proteins, have benign metabolic type activities (light production, fluorescence) which would have no significant effect on bacterial or cellular gene expression, though products may be toxic to cells expressing high levels. Extracellularly they have no signalling effects and are of very low toxicity. There is no effective way to deliver genetic material to human cells in these conditions.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Bench tops and spills will be wiped with a disinfectant (1% sodium hypochlorite, or 70% alcohol). Spills will be covered with disinfectant soaked towels for at least 15 min and then wiped. GMM will be killed by addition to 1% sodium hypochlorite for at least 15 min.

(As recommended in ‘Standard safety practices in the microbiology laboratory: www.cdc.gov’).

Liquid and solid waste will be double bagged, autoclaved and then incinerated.

## Project Additional Information

### Purposes of the contained use

To study the effects of potential cancer causing genes (oncogenes) on cell growth, we need to infect primary cells with these oncogenes. To do this efficiently, we use HIV-1 viruses to carry the oncogene of interest into the primary human cells. These HIV viruses are made incompetent, meaning they can only infect the cells of interest and no new HIV viruses are then produced that are able to infect new cells. The HIV viruses can therefore not replicate.

### Recipient or parental organism

The gene delivery system involves 3 plasmids that are transfected into virus producing cells, the 293T cell line. The lentiviral system is secured by gene removal such that no new particles can be produced from infected cells. This system functions as the 293t cells express:

- a. The viral envelope protein (VSV-G envelope) from a plasmid called p-VSVG.
- b. The modified HIV-1 genome with the transgene (modified HIV-1 called pHR with deleted envelope and accessory genes like tat, nef and vpr)
- c. The HIV-1 accessory genes, including the reverse transcriptase and the other viral genes involved in replication (from pCMV8.9 plasmid)

The vector can stably integrate into DNA for sustained long-term expression of the transgene. The vector has the ability to infect primary human cells, with subsequent expression of the foreign gene and GFP in these cells. All progeny cells will also express the foreign genes, but no new HIV-1 virions can be produced from the infected cells (replication defective). Because the HIV-1 envelope, that usually binds CD4 and chemokine receptors, has been replaced by the vesicular stomatitis virus envelope (VSV-G), this vector can infect many different cell types in vitro and possibly in vivo. VSG envelope allows entry of virus into cells by way of binding non-specifically to membrane phospholipid of target cells, rather than relying on specific receptor binding.

### Host/vector system

We are testing the functional role of different proteins encoded by Kaposi's sarcoma-associated herpesvirus (KSHV) and by human T-cell leukaemia virus-1 (HTLV-1). These include a viral cyclin homologue (v-cyclin), a latent membrane protein (K15), a latent nuclear antigen (LANA), anti-apoptotic proteins called K7 and a FLIP (FLICE inhibitor protein) homologue (vFLIP) and a membrane protein (K8.1), all encoded by KSHV. The viral cyclin, LANA and K15 are potential oncogenic proteins. We are also testing the mechanisms of transformation by the oncogenic Tax protein encoded by HTLV-1.

### Origin & function

To transduce (infect) primary human cells with these different viral genes, we will clone them into a lentiviral vector. The lentiviral vector is based on HIV-1 pseudotyped with a vesicular stomatitis viral (VSV) envelope, allowing infection into a broad range of cell types. The HIV-1 vector can infect cells but not replicate ("one shot" or "self-inactivating"). In addition, this lentiviral system incorporates a green fluorescent protein (GFP) from a bicistronic transcript allowing the identification of infected cells by immunofluorescence. The transduced cells will include primary human haematopoietic cells, endothelial cells and human stem cells.

### Evaluation of foreseeable effects

1. The transduced cells can only survive in tissue culture at 37°C.
2. The modified lentivirus cannot survive outside cells (dependent on cells for DNA integration), and is replicative incompetent: thus the lentivirus cannot propagate to infect new cells and pose a negligible risk to the environment.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virkon (a peroxygen compound) used at a concentration of 1% is known to have a wide range of microbial activity and is bacteriocidal against many human viruses, including HIV. All tissue culture material and disposable plasticware will be soaked for a minimum of 18-24 hours in a freshly prepared 1% Virkon solution. The fluid is then disposed of down a laboratory sink with excess water. Solid waste is then double bagged in biohazard bags and autoclaved at 134C for 20 minutes at 3.2 bar pressure. Validation of this method will be by independant thermocouples placed in the centre of the load. Verification that the correct conditions have been reached will be obtained by checking the chart recorder printout. The autoclave undergoes a planned preventative maintenance inspection every 3 months. All inactivated waste is then treated as "clinical waste" and removed from site by a UCL contractor.

Please enter comments on the GM safety committee on the risk assessment

In view of the disabled nature of the HIV, the GM Safety Committee accepted the containment level proposed by the investigator subject to the vigorous application of the risk control measures identified as required by the assessment. The room in which the work will be undertaken was last inspected in June 2001 and was found to be in good order. It is due a revisit in January 2002.

### Project Additional Information

#### Purposes of the contained use

The purpose of the activity is to understand which genes control polymorphism in Candida albicans.

#### Recipient or parental organism

Candida albicans is a yeast. It is a commensal residing mostly in the anal cavity as well as the gut of individuals. In humans with severe immunosuppression it can cause anal "thrush". In hospital settings such as intensive care units invasive infections have been reported. Candida albicans is a typical "opportunistic" pathogen.

#### Host/vector system

Candida albicans and Escherichia coli.

#### Origin & function

The genetic material will origin from C. albicans on C dubliniensis.

It is intended to use the material, propagate it in E. coli in specific (standard vectors such as pBlusknip) and construct "disruption cassettes" to delete genes involved in the regulation of polymorphism.

See the detailed project description.

#### Evaluation of foreseeable effects

In this study we intend to identify genes of Candida albicans and Candida dubliniensis that are involved in the control of dimorphism. We intend to delete these genes in C. albicans and C. dubliniensis. It is expected that the resulting deletion mutants will be less capable to filament/replicate and thus be severely compromised in their ability to cause disease. It is not expected that amplification of these genes in E. coli will confer novel properties on the latter making it more virulent. Indeed E. coli will only be used as a host to amplify genetic material from C albicans or C dubliniensis. We do not foresee risks to human health on the environments involved in this study. Specifically we do not intend to release any of our studies into the environment.

See risk assessment form and project description.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All of the waste involving class 2 organisms is collected in dedicated biohazard bags as well as containers. All of the waste containers are sealed and then autoclaved. The autoclaving process is monitored with each lot.

A dedicated servicing contract assures proper monitoring and functioning of our autoclave facilities.

Project Additional Information
# Purposes of the contained use

The research described in this proposal is designed to elucidate the molecular mechanisms of influenza virus assembly and budding as mediated by the M2 protein. To better elucidate the functions of the M2 cytoplasmic tail, mutations will be made throughout the region and incorporated into recombinant viruses which will then be tested for activity.

## Recipient or parental organism

- **Influenza A virus**
- Mammalian and insect tissue culture cell lines.

## Host/vector system

- E. coli and baculovirus

## Origin & function

Individual influenza virus genes will be incorporated into plasmids for growth in E. coli for ultimate expression in mammalian tissue culture cells. Individual influenza genes will also be incorporated into plasmids for growth in E. coli where they will be mutated for subsequent reintroduction into recombinant influenza viruses. Additionally, influenza genes will be incorporated into baculovirus vectors for introduction into insect tissue culture cell lines to allow for influenza virus protein expression and purification. The function of these experiments is to determine the role of influenza virus proteins in the assembly and budding of the virus.

## Evaluation of foreseeable effects

The construction of the GMOs should inform as to the functions of influenza virus proteins in viral budding. The construction of the tissue culture and vector GMOs will not have any adverse effects and has no foreseeable adverse effects. The construction of the GMO influenza viruses will not add any measures of virulence or pathogenicity and will likely attenuate virulence. Thus, there are not foreseeable adverse effects.

## Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

## For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

## Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

This project will generate liquid waste from tissue culture media and virus growth and solid (typically plasticware) waste. Liquid waste will be sterilized via treatment with 30% NaClO for 30 min to give 10% kill. 100% kill will be assessed via testing for viral growth on fresh tissue culture cells every 6 months. After sterilization, waste will be diluted with water and disposed of as non-toxic liquid waste. All solid waste will be subjected to heat inactivation (via autoclave) to give 100% kill. Sterilization will be confirmed via autoclave indicator tape that will be processed with all waste. Sterilized waste will then be disposed of via university services.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
It is the opinion of the GMSC that, as the project will not introduce new genes into the organism, but rather mutate native genes, it is highly likely that there will be either no change or an attenuation of the virulence of the organism. Moreover, the committee felt that performing the work at containment level 2 would result in the GMMs posing low risk of infection. The committee agrees with and supports the categorisation of this project as class 2.

Project Additional Information

Purposes of the contained use

The main goal is to provide a greater understanding of how Uropathogenic E. coli strains are adapted for survival during infection. In particular, the importance of mechanisms involved in nitric oxide tolerance and the export of glutathione will be investigated. The aim is to measure the contribution of specific genes to the tolerance of...
stresses encountered during infection. This work will be extended to clinical bacteraemia-causing E. coli isolates from collaborative work with Prof. F M (East Kent Hospitals University NHS Foundation)

Recipient or parental organism

Uropathogenic E. coli strains
Clinical bacteraemia-causing E. coli isolates

Host/vector system

Mutations will be introduced via transformation of linear DNA fragments. Complementation vectors are conventional expression plasmids with a safe history of use:
pWSK29 (Gene 100, 195-199)
pSU2718(Gene 68, 159-162)

Origin & function

E. coli will be constructed with deletions in genes involved in NO-detoxification, respiratory components, ABC transporters etc. The native genes will be re-introduced on a complementation vector with a safe history of use. Genetic manipulation of E. coli strains involves insertion of antibiotic resistance cassettes. However, these are standard antibiotics for lab use (e.g. kanamycin, chloramphenicol, ampicillin, gentamycin) that are not used in clinical treatments of infections caused by pathogenic E. coli.

Evaluation of foreseeable effects

The proposed modifications to the E. coli strains are predicted to make the recipient bacterium less viable.

There are naturally-occurring strains of Uropathogenic E. coli and bacteraemia-causing E. coli that possess resistance to all the antibiotics intended for use, so there is no danger of engineering E. coli strains with unprecedented combinations of antibiotic resistance. The introduced antibiotic cassettes are standard (ampicillin, kanamycin, chloramphenicol, gentamycin), and are introduced to the GMM via linear transformation and lambda-red mediated recombination, so there is a low risk of the genetic manipulation technique contributing to gene spread.

Other gastrointestinal bacteria, such as Shigella, are potential targets for gene transfer events with E. coli, although this would require an unlikely breach to take place. Furthermore, the antibiotic resistance genes intended for use are already widely disseminated, so such a breach would pose only a small contribution to the spread of antibiotic resistance throughout gastrointestinal flora. The likelihood of worker infection is very low, given that the work will be performed in a level 2 facility by trained individuals using correct technique.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GMM waste will be autoclaved (plates) or treated with Bleach/Virkon (liquid cultures). Bleach.Virkon is the industry standard for killing E.coli.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
The committee noted that the proposed genetic modifications would result in the mutation of native genes that are well characterised as involved in virulence and would therefore be expected to decrease virulence. One concern was that antibiotic resistance could arise. However, the antibiotics to be used are not used clinically and in any case are widely used on class 1 E. coli strains. Uropathogenic E. coli (UPEC) strains are common in the wild and likely to be encountered naturally by the general population. However, as they are capable of causing human disease it was considered that class 2 was the most appropriate designation for this work.

Project Ref 22/12.3

Date Ackn’d 16/07/2012
Date Project Ceased

CU2 Project Title Bioengineering and elucidation of modified tetrapyrroles metabolic pathways

Class 2
CultureVol 1-50 Litres
Non-GMM Consent Granted

Project notified under transitional arrangements N
### Purposes of the contained use

This project is aimed at increasing our understanding of how biochemical pathways operate, how they are controlled and how they can be engineered to enhance the metabolic ability of the host cell:

- by studying in molecular details the step-by-step synthesis of hemes along a novel pathway going via siroheme.
- by investigating unstable metabolite intermediate channelling along the complex vitamin B12 pathway.
- by transferring the genetic software that allows bacteria to make vitamin B12, into E. coli, Lactobacillus, yeast and a higher plant that are unable to make it, and therefore conferring upon these host organisms the ability to make this essential nutrient

### Recipient or parental organism

The recipient microorganisms used for these studies are mainly Escherichia coli K12 and E.coli B (BL21 (DE3) strains). It can also be Bacillus megaterium. Lactococcus lactus, Lactobacillus reteri, Salmonella enterica serovar Typhimurium, Saccharomyces cerevisiae.

### Host/vector system

All vectors used were originally commercial vectors, known to have a safe history of use and are non-mobilised. For example: pET vectors (Novagen), pKK223.3, pGEM (Promega), pACYC vectors, pMal Vectors, pGEX vectors, pRS yeast vectors, pNZ vectors (NICE).

### Origin & function

The inserted genes used from Brucella melitensis, Staphylococcus aureus and Pseudomonas aeruginosa are only orthologous genes of known vitamin B12 biosynthetic genes. The human aminolevulinic acid synthase was subcloned from a plasmid harbouring its cDNA. The source of genes used for this project can also be from Bacillus megaterium, Rhodobacter capsulatus, Rhodobacter sphaeroides, Escherichia coli K12, Desulfovibrio vulgaris, Desulfovibrio desulfuricans, Geobacillus thermoglucosidasius, Anoxybacillus flavithermus, Synechocystis sp., Paracoccus pantotrophus, Synechococcus elongatus, Thermosynechococcus elongatus, Methanosarcins barkeri, Methanobacterium thermoautotrophicum, and ortholog genes from other Archaea will also be used. Also B12 genes from Mycobacterium tuberculosis, B12 biosynthetic genes from different species are cloned in plasmids harbouring standard antibiotic resistances (ampicillin, chloramphenicol and tetracycline) and used in cross-species complementation studies.

### Evaluation of foreseeable effects

All genetic modifications are not expected to alter the pathogenicity of the host organisms. All vectors used in this study have a safe history of use and are non-mobilised.

The work involves a class 2 recipient micro-organism, Salmonella enterica serovar Typhimurium. Salmonella enterica serovar Typhimurium is a pathogenic Gram-negative bacterium predominantly found in the intestinal lumen and can cause gastroenteritis in humans. Salmonella B12 mutant strains are only used in cross-species complementation studies to restore the B12 phenotype. These GMO strains will not gain novel or harmful properties. Only B12 biosynthetic genes form different species that are cloned in plasmids harbouring standard antibiotic resistances (ampicillin, chloramphenicol and tetracycline) and used to transform Salmonella. No gene with a potentially harmful biological activity will be introduced. There is a negligible chance of transfer to other micro-organisms. GMO work will not increase the pathogenicity of this strain.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GMM waste will be autoclaved (plates) in a validated facility or treated with Bleach/Virkon (liquid cultures).
The committee noted that the proposed genetic modifications would simply restore vitamin B12 synthesis in the Salmonella strain. As B12 is a significant factor in the host-pathogen relationship this will restore the pathogenicity of Salmonella B12 mutant strains and could, if higher than normal production of B12 is achieved, potentially increase virulence. However, treatment for Salmonella infections is readily available and combined with the minimal likelihood of increased virulence occurring, means that class 2 containment is suitable and sufficient for this work.

Purposes of the contained use

The main goal is to understand and unravel patterns and evolutionary mechanisms that shaped the genomic, proteomic, cellular and biochemical adaptations of the many independent lineages of eukaryotic parasites. Specifically the protein composition of their mitochondrial-related organelles will be investigated using proteomic and transcriptomic analyses under different environmental conditions. In addition, knock-down and/or knock out parasite strains will be developed to investigate the requirement for individual mitochondrial proteins and pathways for the lifestyle of the different organisms. As part of this approach homologous genes will be transfected into knockdown strains in order to examine the conservation of protein function across parasitic eukaryotes.

Recipient or parental organism

- Acanthamoeba castellanii
- Blastocystis hominis
- Cryptosporidium hominis
- Cryptosporidium parvum
- Entamoeba histolytica
- Giardia lamblia
- Plasmodium yoelii
- Trichomonas vaginalis

Host/vector system

Cloning and evaluation of the corresponding genes will take place using the pGEM-T Escherichia coli system

Origin & function

Individual genes encoding components of different mitochondrial pathways - Fe-S cluster biosynthesis, pyruvate decarboxylation, protein translocation, folding and degradation, metabolic exchange, oxidative phosphorylation, mitochondrial morphology and apoptosis - from all the eukaryotic parasites listed above will be incorporated into plasmids for developing knock-down strains and/or consequently for heterologous expression of the corresponding gene. For complement experiments the T7/TetR system will be employed using p2T7-177 vector for knocking down corresponding gene and pABPURO, PCF4 (for Acanthamoeba, Blastocystis, Cryptosporidium), tag Vag 2 Trichomonas vaginalis), pEi-ck-Myc (for Entamoeba), pL0016 (for Plasmodium) and pRANneo or 5'Δ5N-Pac (for Giardia) vectors for the expression of corresponding proteins.

Evaluation of foreseeable effects

The GMOs constructed during this work are either knock downs of mitochondrial genes or knock downs complemented by homologous genes from the host itself or other species or microbial eukaryotic parasite. The knock downs will be attenuated in comparison to the native organism and this is also likely to be true for the complementation strains. As the genes targetted for knock down and replacement are house-keeping genes, even in the most effective cases the complementation strains are only likely to be as infectious as the original native organism. The most construction of the GMO strains will not add any measure of virulence or pathogenicity and no foreseeable adverse effects are envisioned.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

This project will generate liquid waste from culture media and solid (typically plasticware) waste. Liquid waste will be sterilized via treatment with bleach Virkon and subsequently autoclaved. All solid waste will be sterilised by autoclaving. Spills or potentially contaminated work surfaces will be disinfected as outlined below.

Please enter comments on the GM safety committee on the risk assessment

It is the opinion of the GMSC that, as the project will not introduce new genes into the organism, but simply mutate native genes and replace them with homologous genes from other eukaryotic parasites, it is highly likely that there will be an attenuation of the virulence of the organisms in question and at the most native virulence will be regained.

Moreover, the committee felt that strict adherence to standards of laboratory practice applicable to work at containment level 2 would result in the GMM's posing a low risk of infection. The committee agrees with and supports the categorisation of this project as class 2

**Project Additional Information**

**Purposes of the contained use**

The overall goal is to understand the mechanisms of chromatin regulation in C. albicans. Specific goals are to characterise:

a) The pathways responsible for centromere establishment and maintenance.
b) Regulation of gene expression by the RNAi machinery.
c) The Biology of DNA repeats

**Recipient or parental organism**

C. albicans strains: CA14, ura3: CA18, ura3, ade2: RM1000, his1, ura3; BWP17, his1, ura3, arg4 and derivatives of these strains carrying further disabling markers

**Host/vector system**

Vector system:
1. Non-mobilisable E. coli vectors (including pUC18/19, pBluescript, pGEM-T; lac-based expression plasmids such as pET vectors).
2. Specific non-mobilisable C. albicans vectors (low copy replicating and integrating vectors [YPB1, Clp10, Clp20, Clp30]: low copy replicating and integrating vectors for ectopic expression [YPB-ADHpt, pACT1]; integrating expression vectors regulated by methionine [MET3 promoter], maltose [MAL2 promoter], glucose [PCK1 promoter], or doxycycline [tet ON promoter and tet OFF promote].

These vectors will be prepared from E. coli cultures. We will always use non-pathogenic E. coli strains such as the multiple disabled K12 derivatives, and the rec deficient BLR strain. The E. coli strain BLR is a disabled (recombination deficient) derivative of the strain BL21

**Origin & function**

We are planning to generate null mutants in genes involved in:
1 Centromere assembly and propagation. Null mutants will be expected to compromise centromere function resulting in lethality.
2. RNAi Null mutant will be expected to impair siRNA production of specific chromosomal loci.
3. Histone modifications. Null Mutants will be expected to alter the chromatin structures of specific chromosomal loci. In some experiments, we will express specific genes in C. albicans ectopically using a MET3, MAL or tet promoter

**Evaluation of foreseeable effects**

Transformations will be performed in multiple disabled C. albicans strains (ura3, ade2, arg4, or his1) to ensure that all transformants are avirulent. In none of the cases this is likely to increase virulence; instead transformants will always carry a disabling mutation, thereby rendering them completely avirulent. No null mutations have been described that increase the virulence of C. albicans.

In some experiments, the CA14 strain will be transformed with URA3 plasmids. Insertion of the URA3 marker gene will partially restore the virulence of CA14, but this restoration is not complete because the genes neighbouring URA3 remain inactivated. This is enough to attenuate virulence partially.

In some experiments, we will express specific genes in C. albicans ectopically using a MET3, MAL or tet promoter. In these experiments, the expression level is not maximised. Their ectopic expression levels will be <1% of total cell protein. The ectopic expression of most specific genes is unlikely to affect virulence at all, and in some cases it will be expected to reduce C. albicans virulence by adversely affecting growth. In experiments where we over-express genes, expression levels will be carefully regulated by addition of doxycycline; without doxycycline protein levels will be at or below wild type levels. The key point is that the probability of increasing virulence by ectopic expression of a single gene is very low, because pathogenicity is complex and polygenic trait requiring a high level of fitness of the C. albicans cell (Odds [1994] ASM News, 60, 313). Indeed there is evidence that ectopic expression of factors involved in virulence traits does not increase virulence (Bailey [1997] PhD thesis, University of Aberdeen; Leng [1999] PhD thesis, University of Aberdeen; Rodaki et al. [2006]).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All yeasts will be killed by either heat treatment or addition of appropriate levels of bleach (10% for 30 min) in accordance with standard lab procedures post experimentation

The applicant proposes that the work be subject to class 2 restrictions. The mutations that the applicant proposes to engineer can in no way be expected to increase either the pathogenicity or augment any potential environmental effect.

The committee is therefore satisfied that class 2 is an appropriate level of containment using the measures proposed.

02/03/2022
The research described in this proposal is designed to elucidate the molecular mechanisms of species-specific Ebola virus replication, assembly and budding. At present, the published VLP system expresses proteins from the Zaire species of Ebola virus. To better elucidate the functions of each Ebola virus protein, we will engineer the VLP system to express the proteins from other (lower pathogenicity) virus species (Reston, Sudan, Bundibugyo and TaJ Forest). This will create a variant VLP system reflecting the other Ebola virus species, whilst still retaining the non-infectious nature of the published system. With these systems in place, the activity of the different species proteins can be compared during VLP assembly and budding. Outside of changing the Ebola virus species, no change in the system...
Recipient or parental organism

Plasmids transfected into mammalian tissue culture cell lines

Host/vector system

Mammalian tissue culture cell lines (human, mouse and non-human primate) and E. coli for plasmid growth.

Origin & function

Individual VLP plasmids expressing the Zaire VLP system genes as published will be obtained from Heinz Feldmann at the US National Institutes of Health. Using standard restriction-digest cloning, the Zaire genes in the system will be exchanged for the genes for other Ebola virus species and will then be amplified in E. coli for ultimate expression in mammalian tissue culture cells. Genes to be exchanged include: single protein expression plasmids for the viral proteins NP, L, VP30 and VP35; and a mini-genome expression plasmid containing the genes GP, VP40 and VP24. This exchange will create non-infectious VLP systems for comparative analysis of the assembly and budding of the other Ebola virus species. At no point will the full infectious genome be present for any Ebola virus species and new individual genes will be provided as gene-expression plasmids.

Evaluation of foreseeable effects

The construction of the GMOs (non-infectious plasmid transfected mammalian tissue culture cells) should inform as to the species-specific functions of Ebola virus proteins during viral assembly and budding. The construction of the tissue culture and vector GMOs will not have any adverse effects and has no foreseeable adverse effects. The VLP system has been previously published and widely used worldwide at CL2 containment level. The system is noninfectious and is not capable of producing infectious, replication-competent viruses. The VLP system expresses the viral NP, L, VP30 and VP35 proteins from individual DNA expression plasmids in transfected cells only. When combined with transfection of the negative-sense RNA producing mini-genome expression plasmid, virus-like particles are produced. These VLPs only contain the mini-genome (expressing the genes for GP, VP40 and VP24), thus without the individual DNA expression plasmids, the VLPs are non-infectious, non-replicating and non-hazardous. Thus, the system remains biologically-contained and there is no possibility of producing any infectious replication-competent viruses or particles and as a result there are not foreseeable adverse effects. In addition, because the NP, L, VP30 and VP35 genes are present only as individual DNA gene expression plasmids, the full Ebolavirus genome will never be present, as only the mini-genome is capable of producing the necessary negative sense RNA and this is only for the genes GP, VP40 and VP24, which are not sufficient to produce an infectious virus particle. For added precaution, all work will be performed in a certified category II biological safety tissue culture hood with a users properly trained and wearing laboratory coats and gloves. No sharps will be used during these protocols.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

No infectious replication-competent organisms will be generated or used in this project. This project will generate
liquid waste from tissue culture media and solid (typically plasticware) waste. Liquid waste will be sterilized via treatment with 30% NaClO for 30min (this has been proven to give 100% kill of enveloped viruses such as influenza virus). After sterilization, waste will be diluted with water and disposed of as non-toxic liquid waste. All solid waste will be subjected to heat inactivation (via autoclave) to give 100% kill. Autoclave tape will be utilized on all autoclave sterilization procedures, however, the sterilization will be validated once a month while GMO contained use procedures are being performed. Validation will be though the use of 3M Comply™ (Thermalog™) Steam Chemical Integrators, used as per the manufacturer's directions. Sterilized waste will then be disposed of via University services.

This project utilises a transcription and replication competent virus-like particle (trVLP) system that essentially splits the Ebola viral genome into two: the 4 genes required for viral genome replication and transcription are supplied by a corresponding number of DNA expression plasmids, the 3 structural genes (together with a reporter gene) are provided by a monocistronic negative sense RNA minigenome. When all components are co-expressed, virus-like particles containing the minigenome are produced. These trVLPs have the ability to enter all cells but minigenome replication and transcription and formation of a new generation of trVLPs can only occur in specific target cells that have been pre-transfected with the 4 replication / transcription gene expression plasmids. For all intents and purposes the trVLPs can be considered non-infectious to anything other than these target cells.

In addition, the provision of the two components of this system in different nucleic acids systems, together with the fact that the expression plasmids used do not share any homologous sequence with the minigenome means that there is no potential for recombination to occur. Supporting this, the authors of the paper describing this system state that no recombination events has ever been observed in filoviruses.

Finally, it is important to note that all other viral genes that will be used in this study are being provided as individual clones and no complete viral genomes will be present on site at any time. For these reasons the committee supports the designation of this project as containment level 2.

Project Additional Information

Purposes of the contained use

The aim of this project is to express proteins in human cancer and other standard laboratory cell lines using adenoviral vectors. This includes, but it not limited to, proteins involved in the regulation of growth factor signalling such as proteins of the MAPK (Mitogen Activated Protein Kinase) pathway. Human cancer cell lines that have been genetically modified (GM) with Adenoviral viral vectors will be assayed to identify changes in several cancer related phenotypes such as the response to anti-cancer drugs.

Recipient or parental organism

Human cancer cells lines such as the ovarian cell lines A2780, PEO1, PEO4, EFO-27 and OVCAR3, breast cancer cell lines HCC38, MDA-MB468 and T47D, and colon cancer cell lines HT29, SW620, HCT116. In addition standard laboratory culture cell lines such as CHO may be used.

Host/vector system

Human Adenovirus serotype 5. The Adenoviral viral vectors in this project have the E1 and E3 regions of their genome deleted rendering them replication deficient, minimizing the hazards posed to human health and the environment.

Origin & function

Human genes encoding proteins involved in the regulation of growth factor signalling such as proteins of the MAPK (Mitogen Activated Protein Kinase) pathway. Most of the proteins expressed within this project will also be tagged to validate their expression (e.g. Myc-tag) or visualise their localisation within the cell (e.g. Green Fluorescent Protein).
Human Adenovirus serotype 5 is not a recognised animal pathogen. The inserted genetic material will be of human origin and is therefore unlikely to be able to impact the fitness/infectivity of the Adenovirus or cause alterations in its existing pathogenic traits. Horizontal gene transfer is not known to take place between Adenoviruses, other members of the Adenoviridae family or any other related micro-organisms. In addition, any transfer of genetic material would require the infection and subsequent viral replication inside host cells. The Adenoviral viral vectors being used are missing the E1 region of their genome rendering them replication deficient.

It is possible that loss of containment could result in exposure to human populations. However, any work that carries the risk of generating aerosols will be undertaken in a biological safety cabinet. In addition, wild-type Adenovirus causes self-limiting infections of the upper respiratory tract and the common cold, which usually do not require any treatment. GM Adenovirus may mimic some the characteristics of wild-type Adenovirus but is far less pathogenic due to the E1 and E3 deletions which render the virus replication deficient. Upon culture in a helper cell line, such as HEK293 cells, a replication competent virus has the potential to be produced. However, this is very unlikely as the E1 sequences in HEK293 cells do not overlap with the deleted E1 region. Therefore, two non-homologous recombination events would have to occur to produce a replication competent Adenovirus. Any replication competent virus generated would still be lacking the E3 gene (HEK293 cells do not contain E3) and would therefore have reduced fitness as an infective agent (E3 counteracts host defence mechanisms). In addition, human adenoviral infection is very common; most adults have been infected and have immunity. Taken together the risk from infection by an Adenoviral viral vector is low.

Some GM Adenoviruses generated as part of this project could contain inserted genes that are oncogenes, and therefore could pose a hazard to human health. The risk is mitigated by using a replication deficient Adenovirus (as discussed previously), and that during the Adenoviral life cycle its genome does not insert into the host genome. Expression of an inserted oncogene would therefore be transient and pose little hazard to human health.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Contaminated liquid waste will be treated with a 1% w/v Virkon® S solution for ≥5 minutes. McCormick and Maheshwari (Inactivation of adenovirus types 5 and 6 by Virkon S. Antiviral Res. 64(1):27-33. 2004) showed that a 5 min exposure to ≥0.9% w/v Virkon® S is sufficient to inactivate the crude virus (in the supernatant/cell lysate of HEK293 cells) of Adenovirus type 5. This comparable to the conditions that will be present in our experiments.

Treated waste will subsequently be autoclaved in-house at 126°C for 10 mins, 2.5 bar pressure, prior to disposal down the sink.

Contaminated solid waste, such as tissue culture plastics, is to be double-bagged and autoclaved in-house at 126°C for 10 mins, 2.5 bar pressure, prior to disposal by the waste contractor Viridor. Any work using sharps will be disposed of in the same manner.

Autoclaves are serviced every quarter and undergo an annual thermocouple test by BMM Western Ltd, Kent, UK (http://bmmweston.com/infection-control/).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
This risk assessment clearly outlines the low risk of hazards to human health and the environment. Due consideration has been given to the contingencies that are built in that preclude serious disease or persistence in the environment in the unlikely event of a breach. The viral pathogen has a safe history of use and the suggested laboratory containment level (2) is appropriate. Sufficient control measures are in place for nature of work to be undertaken and the outlined procedures for waste management are appropriate for such a project.

**Date Ackn'd**: 13/12/2019

**CU2 Project Title**: Synthetic biology approaches to compartmentalisation in bacteria and the construction of novel bioreactors

**Class**: Class 2

**Culture Vol**: < 1 Litre

**Non-GMM**: Consent Granted

- **Project notified under transitional arrangements**: N

- **Historical Significant Changes**: Withdrawn

- **Historical Date of Additional Info**: Tick if notifying a connected programme of work

**Project Additional Information**
Purposes of the contained use

This project investigates how proteins are targeted and incorporated into bacterial microcompartments. The aim is to direct specific enzymes to the bacterial microcompartments in order to make bespoke bioreactors. The development of these bioreactors in compartments within the cell would allow for greater control and regulation of the process, detaching the encased process from any negative influences within cellular metabolism.

Recipient or parental organism

Pseudomonas aeruginosa and Listeria monocytogenes

Host/vector system

All vectors used were originally commercial vectors, known to have a safe history of use and are non-mobilised. For example: pET vectors (Novagen), pGEM (Promega), pACYC vectors

Origin & function

Pseudomonas aeruginosa will be transformed with plasmids harbouring only Pseudomonas genes in order to overexpress proteins. The genes of interest, NCBI-GeneID: 878574 and 881385, are predicted to be part of the LemA family of membrane restructuring proteins that when overexpressed in E.coli produce intracellular membranous structures with bioengineering applications. These experiments are aimed at recreating these structures in Pseudomonas.

Listeria monocytogenes strains in which genes had been deleted from the ethanolamine (eut) operon (eutB and eutM) will be transformed with stable chromosomal integrative plasmids harbouring the original genes in order to restore the original function (vitamin B12 dependent).

Evaluation of foreseeable effects

This GMO work will not increase the pathogenicity of recipient organismsthis strain. Pseudomonas aeruginosa is known to cause infections in both humans and animals. However, severe infections in humans usually occur in a nosocomial setting in immunocompromised patients. In animals, Pseudomonas can cause otitis and urinary tract infections in dogs, mastitis in dairy cows and endometritis in horses. Overexpression of the native LemA protein family genes in this organism is not expected to affect the pathogenicity or fitness of Pseudomonas in the host or the wider environment.

Listeria monocytogenes is a causative agent of listeriosis in animals and humans. The deletion of eut genes from Listeria monocytogenes are not expected to confer any advantageous effect on its fitness neither in the host nor the wider environment. In fact, by deleting genes that belong to a pathway that is suspected to help the bacteria grow in specific conditions, the modifications are expected to make these Listeria strains less likely to cause infection and compete in the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
GMM solid waste (plates) will either be autoclaved and disposed in nonmal waste or will be handed to a registered waste disposal company for incineration.
GMM liquid waste will be treated with BleachNirkon. Virkon will be used at 1% solution as recommended by manufacturer. After an overnight treatment in 1% virkon, the liquid waste will be disposed of via the laboratory sink. Virkon is commonly used as a laboratory disinfectant to kill a wide range of micro-organisms from E. coli to MRSA.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
This seems a pretty straightforward Class II project given that they are only planning to express native genes in Listeria and Pseudomonas with no change in potential risk. Moreover the antibiotics utilised for selection are commonly used laboratory antibiotics not used in the treatment of infections by these organisms, there is no known mechanisms of sequence transfer within these orgnaism or between them and other species, and the work in Listeria uses vectors that result in highly stable genome integrations.
Overall we support the classification of this project as Class II.

## Purposes of the contained use

To express cDNAs encoding Entamoeba cytoskeletal and signalling proteins in both Entamoeba and Dictyostelium cells.

## Recipient or parental organism

<table>
<thead>
<tr>
<th>Hosts</th>
<th>E. coli XL1-blue - disabled and slow growing;</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>DH5 - as XL-blue.</td>
</tr>
</tbody>
</table>

## Host/vector system

| Vector | pUC18 - standard molecular biological plasmid vector. |

## Origin & function

### Origin of genetic material

- **Dictyostelium strain AX3** - a free living non-pathogenic soil amoeba which grows at 22 degrees centigrade and is harmless to crops and agriculture.

- **Antamoeba histolytica strain HM-1:IMSS** -- standard laboratory strain. Cysts are the only infectious stage of this parasite and these cannot develop or form in standard lab cultures, hence the parasite is not transmissible to humans in this setting. The cultured form, ie the trophozoite, is very fragile and susceptible to desiccation and detergents. As they are unable to persist in the environment the chance of environmental damage is remote.

### Genetic material

- Full length cDNAs encoding Entamoeba Arp2 and Arp3 - major skeletal proteins involved in movement and cell shape. Selectable markers conferring G418 resistance.

## Evaluation of foreseeable effects

### Effects on human health:

- **Dictyostelium** - None. It is a non-pathogenic soil amoeba, unable to grow at human body temperature and is harmless to crops and agriculture.

- **Antamoeba histolytica** - No likely risks. It is a parasitic enteric protozoan that is responsible for amoebiasis in humans. The disease is characterised by diarrhoea/dystentery, intestinal tissue invasion and potential liver access formation. Epidemiology, the organism is ubiquitous and has a worldwide distribution, although prevalence is much higher in developing, disadvantaged countries and tropical regions. In contrast, rates of infection are low in the developed world, with the majority of these infections being found in specific groups (eg travellers from developing or high incidence areas). Symptomatic invasive amoebiasis only develops in 10% of individuals harbouring the parasite. The organism can exist as both cysts and trophozoites. Transmission is feco-oral and results from ingestion of viable cysts in contaminated food or water. Cysts can remain viable for a long time depending on environmental conditions but are extremely sensitive to desiccation. Trophozoites on the other hand are more fragile and degenerate rapidly in the external environment as well as being easily destroyed by acidic pH (eg stomach acid).

As the only infectious stage of the parasite, the cyst, does not form in standard laboratory cultures the parasite is not transmissible to humans in this setting. Accidental infections have never been reported, but effective drug treatments are available should this happen.

### Environmental hazards:

- **Dictyostelium** - negligible hazard. The strains used are very weak due to multiple mutations and would not compete with local Dictyostelium species.

- **Entamoeba** - The organisms are very sensitive to desiccation and detergents and are not free living. As they are unable to persist in the environment the chances of environmental damage are remote.

The work will be carried out at CL2 and the likelihood of accidental release is very low.
E. coli XL-blue/DH5 - non-colonising, disabled lab strains, no risk to human health or the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation applied for CL2 applied. The laboratory set aside for this work is a relatively new facility and is currently being fitted with a hand wash basin.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Dictyostelium - to kill spent cultures: 1% chlorine bleach.
Entamoeba - Tubes containing liquid cultures and contaminated disposables will be placed in autoclave bags and autoclaved at 121 degrees for 50 minutes and discarded as "clinical waste" (incineration).
Agar plates, loops, tips etc will all be autoclaved. 100% kill.

All methods are more than sufficient to kill Dictyostelium which are fragile, as well as Entamoeba which are sensitive to desiccation and detergents and are not free-living.

Bacterial cultures will be killed with Virkon at the recommended dilution (1:100)

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

02/03/2022
I feel information on human health should be transferred to the relevant section; the nature of the "normal laboratory clothing and protective equipment" should be defined; the autoclave used for disposal of cat 2 waste should be monitored (it is anyway, why not say so for completion?); and the disinfection regimen should be defined, i.e., is 1% chlorine bleach 1% available chlorine, and what is the actual dilution of Virkon used?

**POINTS ADDRESSED IN ASSESSMENT**
- There is no mention of any possible alteration in phenotype resulting from the introduction of cytoskeleton and signalling proteins in Entamoeba and Dictyostelium. I assume they will not become (more) pathogenic but perhaps this could be addressed.

- No increase in virulence/pathogenic capacity is expected. As mentioned in the application, Dictyostelium are free-living non-pathogenic soil amoebae which grow at 22 degrees and therefore do not pose a threat to humans. Likewise Entamoeba does not pose a risk to humans in this/our setting because the cyst, which is the only infectious stage of the parasite, can/do not develop or form in standard laboratory cultures, hence the parasite is not transmissible to humans.

The GMSC also asked whether the Class 1 and Class 2 work should be split into two separate proposals. The investigator felt this was not necessary and not desirable because the work is one experiment, in which cDNAs encoding Entamoeba cytoskeletal and signalling proteins will be expressed in both Entamoeba and Dictyostelium cells.

The GMSC has approved this assessment.

The aim of this project is to develop human cell lines expressing oncogenic components of the growth factor-Ras signal transduction pathway. The modified cells will be used to investigate the changes in gene expression which underlie growth factor regulation of invasion and cell cycle control. The long term aim is to use this system to identify new targets for the diagnosis and treatment of cancer.

The cells to be used will be immortalised human foreskin fibroblasts (iHFFs) and human epidermal keratinocytes (iHEKs). DNA transfection is inefficient in these cells, therefore replication defective murine retroviruses will be used for gene transfer. Human cells in culture are not considered to pose any inherent hazard to human health, nor do they have any capacity to survive autonomously outside of the laboratory. It is not anticipated that the proposed modification will alter these properties. The final GMO cell lines will therefore not exert any foreseeable effects on either human health or the environment.

Replication defective murine retroviruses will be generated and used to transfer oncogenes into the iHFFs and iHEKs cell lines. Such viruses have the potential to infect but not to replicate in human cells. It is unlikely that replication defective retroviruses encoding single oncogenes would be effective carcinogens in humans in the short term. However, retroviral infection and oncogene expression in human stem cells could reduce the number of additional genetic changes required for malignant conversion and thus could conceivably increase the probability of cancer occurring in an infected individual in the long term. ACGM level 2 containment is therefore indicated to prevent exposure to infectious amphotropic virus. This, combined with rigorous waste inactivation procedure and the inherent fragility of retroviruses mean that the risk to the environment is negligible.

The genetic material to be introduced into the iHFF and iHEK cell lines consists of genes which are frequently mutated in human cancers and which are known to comprise components of the growth factor-Ras signal transduction pathway. It is anticipated that studies of the modified cell lines will lead to a better understanding of how these oncogenes cause cancer.

The final GMO human cell lines will contain stably integrated DNA copies of the retroviral vectors encoding the transferred genes but will be free of infectious retrovirus. As a result, they will pose no hazard to human health or to the environment, since they are unable to colonise humans or survive outside of laboratory culture. It will however be important to prevent human exposure or environmental release of the replication defective retroviruses which are used transiently to effect gene transfer. This will be achieved through the use of appropriate physical containment and inactivation procedures.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

To minimise the risk to human health it will be essential to prevent exposure to infectious amphotropic virus. To this end the retroviral regeneration and target cell infection manipulations will carried out in Class II biological safety cabinets in the Class 2 containment laboratory. All viral supernatants and spent medium inactivated using precept tablets before removal from the Class 2 laboratory for autoclaving and final disposal. Solid waste will be double-bagged in biohazard bags prior to removal from the Class 2 laboratory and autoclaved prior to final disposal by incineration. These procedures will result in 100% inactivation of infectious retrovirus.

Infected target cells will be cultured under the above regime until medium supernatants have been shown to be free of replication competent virus as judged by both infection of appropriate indicator cells and assays of reverse transcriptase activity. Once these criteria have been met the infected target cells will be removed from Class 2 containment and handled using standard tissue culture procedures. All cell cultures and spent medium will be autoclaved prior to disposal by incineration. This will achieve 100% killing of GMO cell lines finally used in experimental procedures.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

The Risk Assessment pertaining to this notification was discussed in detail at a meeting of the CRC Beatson Laboratories Safety Committee held on Mon 11 December and approved with minor modification. The Safety Committee requested to be informed when the final GMO cell lines were shown to be free of replicating retrovirus and released from Class 2 containment.

02/03/2022
INTRODUCTION OF Dyrk Family Genes INTO PC12 AND OTHER NEURONAL DERIVED CELL LINES USING AN ADENOVIRUS TYPE 5 DERIVED SHUTTLE VECTOR

One of the fundamental goals of developmental biology is to understand how neuronal stem cell populations are instructed to proliferate in order to produce the correct number and kind of neuronal progeny, and subsequently directed to withdraw from the cell cycle, terminally differentiate and selectively express neuronal cell-specific genes. Rat pheochromocytoma (PC12) cells provide one of the few available tissue culture-based model systems with which to study neuronal growth, differentiation and survival. In PC12 cells, treatment with epidermal growth factor (EGF) induces a mitogenic response while treatment with nerve growth factor (NGF) results in cessation of cell proliferation and terminal differentiation. Therefore, like neuronal stem cells, PC12 cells can exit the cell cycle and terminally differentiate or continue to divide in an undifferentiated state.

We have identified Dyrk2 as a gene which is expressed in a differentiation specific manner in PC12 cells and wish to understand its role. Analysis of Dyrk-family members has the potential to address such issues as developmental neurogenesis, neuronal-based cancers, and neuronal regeneration.

Recipient or parental organism

The cell lines used to propagate the adenoviral GMM (HEK293 or GH329) and the cells to be infected with the GMM (rat pheochromocytoma [PC12] cells and oligodendrocyte-type2 astrocyte progenitor [0-2A] cells) do not pose any inherent risk to human health and cannot survive outside laboratory tissue culture conditions. As DNA transfection is inefficient in these neuronal cells, Dyrk-related genes will be introduced into PC12 and other neuronal derived cell lines using the Adenovator vector system. The system is based on the wild type Ad5 virus which is a normal human pathogen. Approximately 80% of the population express antibodies to this virus indicating prior exposure. Ad5 has been extensively studied in numerous laboratories for well over 30 years with no indication of serious harm to humans. AdenoVator was constructed by deleting sequences from the viral genome making it replication-deficient, preventing the GMM from propagating itself.

Host/vector system

The AdenoVator vectors have E1 deleted (Ad5 nucleotides 1-3533) to remove potential oncogenic sequences and to block viral gene expression, and the E3 region deleted...
(Ad5 nucleotides 28130-30820), which encodes proteins that modulate the host's immune response and are not essential for growth in tissue culture. Such vectors must be grown in E1 expressing cell-lines, such as HEK293 cells or GH329, and consequently the spread of virus outside these cell-lines is prevented because the viruses produced are non-replicative. Deletion of E3 is expected to result in greater presentation of viral antigens to the immune system than in a normal adenoviral infection, resulting in a greater inflammatory response (which might, however, accelerate the clearance of the infected cells). Virus stocks will be stored in aliquots at -20°C, with secondary containment and clearly labelled.

**Origin & function**

Apart from the Dyrk-related genes, no new sequences are present for transfer to related micro-organisms. Dyrk-related sequences have not been reported in any micro-organism and should these sequences be incorporated they are highly unlikely to confer any advantage to the organism or to pose a threat to human health. In vertebrates, Dyrk genes encode a serine/threonine-tyrosine dual-specificity kinase and are associated with brain development. In yeast, the Dyrk homolog has been characterised as an antagonist of the RAS/protein kinase-A pathway and a negative regulator of growth. There is no indication that any Dyrk family member is either oncogenic or toxic.

**Evaluation of foreseeable effects**

Human exposure to either the GMM replication-deficient vector virus or the Dyrk-containing version of the virus will be prevented by appropriate physical containment rigorous inactivation procedures. Furthermore it is highly unlikely that a human would encounter levels of these adenoviruses to trigger a harmful immune response. In addition, the replication deficiencies introduced into the virus make it highly unlikely that exposure would result in a productive infection. Addition of the Dyrk gene should not increase the threat of harm to humans.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

n/a

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

none

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All stocks of virus, whether during production or infection of cell lines, will be handled safely in Class II biological safety cabinets, avoiding the production of aerosols and the use of sharps. Recombinant plasmids containing Dyrk family genes and derived from pAdenoVatorCMV5-IRE5-GFP/pAdEasy-1 will be transferred into HEK293 or GH329 cells by lipofection. Transfection and viral production will be monitored by GFP expression. Viral supernatant will be recovered by freeze-thawing HEK293 or GH329 cells. (Most virus remains cell-associated, only being released into the culture medium if the cell is disrupted.) These supernatants will be amplified by further rounds of infection of HEK293 or GH329 cells. Supernatants will be applied to neuronal cell lines PC12 or 0-2A. Before removal from the Class II facilities, all infectious cells or viral supernatents will be inactivated with precept tablets prior to being double bagged, autoclaved and incinerated. Solid waste materials will also be double bagged autoclaved and incinerated. Hence 100% killing of GM virus and cell lines will be achieved.

**Is an emergency plan required according to regulation 20?** N

### Project Additional Information

**Purposes of the contained use**

The aim of this project is to generate replication-defective adenoviruses that express the cell death inducing molecules p53, E2F and Ask1 including mutations, truncations and fusion protein thereof. This will enable the expression of these in whole cell populations and tumours which will aid investigations in to the way in which these proteins cause tumour cell death. The ultimate goal of the project is to identify factors regulating cell death that may well prove to be novel targets for therapeutic intervention.
The cells to be used will be a range of human and mouse cultures including established and primary cells. In addition, experimental tumours generated in nude mice will also be used. The analysis of cell death in whole cell populations is important, but doing this using standard transfection methods is impossible due to the death of cells before a uniform population is established. As a result, an adenoviral expression system will be employed enabling widespread expression both in vitro and in vivo. The target cells in culture or mice are not considered to pose any inherent hazard to human health, nor do they have the capacity to survive outside the laboratory. The adenoviral infection is only transient and the target cells or mice will not be able to produce infective virus. The cells or mice will therefore not exert any foreseeable effects on either human health or the environment.

Host/vector system

The system to be used to transfer genes known to cause cell death involves disabled replication-defective adenoviruses. These viruses only have the potential to infect human cells when they have been packaged in appropriately engineered packaging cells. Once packaged these infective viruses are extremely labile and do not have the capability to replicate or produce infective virus in other non-engineered cells or mice. In addition to lacking components required for replication, the adenoviruses also lack factors found in wild-type adenoviruses which are involved in evading an immune response. As a result of these safeguards, these viruses cannot exist outside of the laboratory and are incapable of widespread infection. As a result they do not pose a risk to human health or the environment. A risk of minor localised infection does exist when handling the packaged infectious virus, but this is prevented by using the appropriate level of containment and inactivation procedures - hazard containment 2 is therefore recommended and all work will be carried out in Class II biological safety cabinets.

Origin & function

The genetic material to be introduced via the adenoviral system consists of genes (p53, E2F and Ask1) which are known to cause programmed cell death. The activity of these genes is often perturbed during the formation of many cancers causing the tumours to become resistant to the effects of many chemotherapeutic drugs. It is anticipated that by studying the way these factors induce programmed cell death will lead to a better understanding of chemosensitivity and hopefully lead to the identification of novel targets of therapeutic intervention.

Evaluation of foreseeable effects

Disabled replication-defective adenoviruses are labile at 37. In addition, the final GMO cell lines or mice do not contain the necessary components to compliment the disabled virus in order to make an infectious viral particle. Therefore, the final GMO cells or mice will be free of infectious adenovirus. In addition, since the cells or mice are unable to survive outside of the laboratory, it is not foreseeable they will pose any hazard to human health or to the environment. It will, however, be important to prevent human exposure or environmental release when dealing with the infective viral cultures when being transferred from the viral packaging cells to the final target cells or mice. Although unlikely, it is possible that these agents at this stage may cause localised cell killing upon exposure to an infectable organism. The risk though will be nullified by the use of the appropriate level of physical containment and inactivation procedures. Hazard containment 2 is therefore recommended and all work will be carried out in Class II biological safety cabinets.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

To minimise the risk to human health it will be essential to prevent exposure to infectious adenoviral particles. All work will therefore be carried out under Class 2 containment conditions. Following procedures, all viral supernatants and spent medium will be inactivated using precept tablets before removal from the Class II laboratory and autoclaved prior to final disposal by incineration. Solid waste will be double-bagged in biohazard bags prior to removal and autoclaved prior to final disposal by incineration. These procedures will result in 100% inactivation of infectious adenovirus. Target cells will be infected with adenovirus by incubation with medium containing the virus. After three hours this medium will be removed and replaced by non-infective
medium. Being as the replication-defective virus is labile at 37, it is considered that after 24 hour, the culture dish containing the target cells will now be non-infectious. Even though, all cells and medium from these manipulations will be treated with precept tablets before removal from the Class II laboratory and autoclaved prior to final disposal by incineration. Should it be required that target cells are removed from the Class II laboratory then their infectivity will be tested by testing cell supernatant from these for its potential to infect new target cells. Only when the cells have been shown to be non-infective will they be removed from the Class II containment laboratory. Gene transfer using the adenoviral vectors in mice will be by intra-tumoural injection. Procedures will be carried out in a Class II biological safety cabinet in a designated containment laboratory. Animals will be maintained in this laboratory, separate from other animals and any potentially contaminated material including laboratory materials, bedding and killed animals which have previously been injected will be autoclaved together with the cage in the facility prior to incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The risk assessment was discussed in detail at the Cancer Research UK Beatson Laboratories Safety Committee held on Monday 7th April 2003 and approved with minor modification.

### Project Additional Information

#### Purposes of the contained use

The aim of this project is to generate replication-defective adenoviruses that express the cell death modulating molecules p53, p63, p73, p73 na, p73 nB, p73TAa, mdm2, ARF, L11, Puma, Java, ASPP, iASPP, ASPP1, ASPP2, and cyclin G1 including mutations, truncations and fusion protein thereof. This will enable the expression of these in whole cell populations which will aid investigations into the way in which these proteins cause tumour cell death. The ultimate goal of the project is to identify factors regulating cell death that may regulate novel targets for therapeutic intervention.

#### Recipient or parental organism

The cells to be used will be a range of human and mouse cultures including established and primary cells. The analysis of cell death in whole cell populations is important, but doing this using standard transfection methods is impossible due to the death of cells before a uniform population can be established. As a result, an adenoviral expression system will be employed enabling widespread expression both in vitro and in vivo. The target cells in culture are not considered to pose any inherent hazard to human health, nor do they have the capacity to survive outside the laboratory. The adenoviral infection is only transient and the target cells will not be able to produce infective virus. The cells will therefore not exert any foreseeable effects on either human health or the environment.

#### Host/vector system

The system to be used to transfer genes known to modulate cell death involves disabled replication-defective adenoviruses. These viruses only have the potential to infect human cells when they have been packaged in appropriately engineered packaging cells. Once packaged these infective viruses are extremel labile and do not have the capability to replicate or produce infective virus in other non-engineered cells or mice. In addition to lacking components required for replication, the adenoviruses also lack factors found in wild-type adenoviruses which are involved in evading an immune response. As a result of these safeguards, these viruses cannot exist outside of the laboratory and are incapable of widespread infection. These procedures will result in 100% inactivation of infectious adenovirus.

Target cells will be infected with adenovirus by incubation with medium containing the virus. After three hours this medium will be removed and replaced by non-infective medium. Because the replication-defective virus is labile at 37 degrees, it is considered that after 24 hr, the culture dish containing the target cells will now be non-infectious. As an extra precaution, all cells and medium from these manipulations will be treated with precept tablets before removal from the Class II laboratory and autoclaved prior to final disposal by incineration. Should it be required that target cells are removed from the Class II laboratory then their infectivity will be tested by testing cell supernatant from these for its potential to infect new target cells. Only when the cells have been shown to be non-infective will they be removed from the Class II containment laboratory.

The knockdown of tumour suppressor and Wnt family gene expression by RNA interference using amphotropic retroviral and lentiviral vectors.

### Project Additional Information

#### Purposes of the contained use

The aim of the project is to generate replication defective amphotropic retroviruses and lentiviruses that express shRNAs against negative regulators of the oncogenic canonical Wnt signalling pathway (Dickkopf genes: DKK-1, -2, -3 and -4, frazzled protein: FZB) and the tumour suppressor gene Wnt-5A.

This will allow the knockdown in expression of these genes using short hairpin RNAs that generate the stable expression of small interfering RNAs (RNAis) within the target cell. This will enable evaluation of the role of the above genes in human keratinocyte senescence.

#### Recipient or parental organism

The cells used will be primary cultures of human epidermal and oral keratinocytes. The target cells in culture are not considered to pose any inherent hazard to human health, nor do they have the capacity to survive outside the laboratory.

Retroviral or lentiviral infection is only transient in the target cell and it will not be able to produce the virus. The cells will therefore not exert any foreseeable effects on either human health or the environment.

#### Host/vector system

The system used to allow expression of small interfering RNAs against genes mediating senescence in human keratinocytes involves replication-defective amphotropic...
The retroviral vector (p RETROSUPER) and lentiviral vector (pLentLox3.7) will be used to transfer the shRNAs into human keratinocytes. The lentiviral vectors have the advantage of being able to infect non-dividing keratinocytes.

These viruses have the potential to infect human cells only when they have been packaged in appropriately engineered packaging cells. Once packaged these infective viruses are extremely labile and do not have the capability to replicate or produce infective virus in other non-engineered cells.

In more detail:
The p RETROSUPER vector is derived from the Murine Embryonic Stem Cell Virus (pMSCV). The vector has a specifically designed 3'LTR that has a deletion in the LTR promoter elements. This deletion results in inactivation of the LTR mediated transcription upon retroviral integration. The p SUPER constructs will be grown in the excision repair-deficient E.coli strain GT116 to avoid removal of the shRNA sequences. The resulting plasmids will then be transfected in Phoenix-E cells to produce ecotropic retrovirus and then into PT67 cells to generate high titre amphotropic retroviruses. Each of these cell lines contains gag, pol and env genes encoded by 2 separate plasmid expression vectors both of which lack the retroviral cis-acting packaging signal to minimise the likelihood of replication competent virus arising through recombination.

The lentiviral vector used is a third generation system (self inactivating vectors) derived from HIV-1 incorporating many safety features. These include deletion in the enhancer region of the 3'U3 of the long terminal repeat which results in self inactivation after transduction of the target cell. Genes encoding the structural and other components are split into four plasmids which are engineered not to contain any regions of homology to prevent any recombination and none contain LTRs or psi packaging sequence. Thus none of the HIV-1 structural genes are present on the packaged viral genome and thus are never expressed in the transduced target cell. Short hairpin RNAs (shRNAs) will be cloned into the pLentLox3.7 (pLL3.7) lentiviral transfer vector and delivered to the cells in the form of an amphotropic lentivirus. The resulting infected cells will then generate a continuous supply of RNAi in the target cells. Infected cells can be identified by the co-expression of the GFP FLAG with the shRNA. The pLL3.7 vector was engineered by introducing the mouse U6 promoter upstream of a CMV-EGFP expression cassette to create a vector that simultaneously produces shRNAs and a reporter gene. To facilitate the introduction of RNAi stem cell loops, a multiple cloning site was placed immediately after the U6 promoter. The pLL3.7 constructs will be grown in either DHs5 alpha or the excision repair-deficient E.coli strain to avoid removal of the shRNA sequences. The resulting plasmids will then be transfected into 293FT cells along with the packaging vectors pMDLg/pRRE (gag/pol elements), pRSV-REV and pMD.G (VSVG envelope glycoprotein vector) to produce high titre amphotropic lentiviruses. These are available commercially from Invitrogen as pLP1, pLP2 and pLP/VSVG vectors. The lentiviruses will then be recovered by ultracentrifugation and resuspended in phosphate-buffered saline before titration on HeLa cells. Concentrated viruses 10 million infectious units per ml will then be used to infect the normal human keratinocytes.

The genetic material to be introduced via the retroviral and lentiviral systems consists of short hairpin RNAs that target a number of genes involved in mediating senescence in human keratinocytes. These include the four Dickopf genes (DKK-1, -2, -3, -4), frazzled related protein (FZB) and the tumour suppressor gene WNT-5A. These genes have been shown to act as negative regulators of the oncogenic canonical Wnt signalling pathway. Wnt-5A is frequently lost in immortal human keratinocytes and the other genes have been found to be transcriptionally up regulated in senescent human keratinocytes.

It is anticipated that by knocking down the expression of these genes their role in keratinocyte senescence can be further understood.

In addition, the lentiviral vector has been engineered co-express GFP FLAG with the shRNA constructs to act as markers of infected cells.

The final GMO human cells will contain stably integrated DNA copies of the retroviral and lentiviral vectors encoding the transferred shRNAs against the genes listed above. The cells will be free of retrovirus or lentivirus. As a result they will pose no hazard to human health or the environment, since they are unable to colonise humans or survive outside of laboratory culture.
It will however, be important to prevent human exposure or environmental release of the replication defective retroviruses or lentiviruses which are used to transiently effect gene transfer. This will be achieved through the use of appropriate physical containment and inactivation processes.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

To minimize the risk to human health it will be essential to prevent exposure to infectious retroviral or lentiviral particles. All work will therefore be carried out under Class II containment conditions. Following experimental work, all viral supernatants will be autoclaved and spent medium will be inactivated using precept tables (10,000 ppm chlorine) before removal from the Class II laboratory for disposal. Solid waste will be double-bagged in biohazard bags prior to removal from the Class II laboratory and then autoclaved before final consignment of waste to approved contractor. Autoclaves will be validated by annual thermocouple mapping and each run is monitored using Thermalog-S indicator test strips. These processes will result in 100% inactivation of infectious virus.

Infected target cells will be cultured under the above regime until medium supernatants have been shown to be free of replication competent virus as judged by both infection of appropriate indicator cells and assays of reverse transcriptase activity. Once these criteria have been met the infected target cells will be removed from Class II containment and handled using standard tissue culture procedures.

Separate lab coats are worn within the Class II laboratory, gloves will be worn, plastic ware will be used and all use of sharps will be avoided.

Large Scale Activities

Human Clinical Applications

02/03/2022
The aim of this project is to develop replication-defective lentiviral vectors for the transfer of siRNA sequences into human tumor cell lines. Short hairpin RNAs (shRNAs) will be cloned into lentiviral vectors and delivered to the cells in the form of replication incompetent lentivirus. The resulting infected cells will then generate a continuous supply of siRNAs in the target cells. We plan to examine the effect of down regulation of both cell-matrix and cell-cell adhesions on the behaviour of human tumor cells. Cell-cell adhesion proteins (E-cadherin, p120ctn) and cell matrix adhesion proteins (beta 1 integrin, FAK) and other signalling proteins involved in regulation of these adhesions (Src family kinases, Fer and Abl tyrosine kinases, phosphodiesterase type 4 isoforms) will be targeted and effects on tumor cell motility and invasion determined.

The vectors will be supplied by Genscript (pRNAT-U6.1/Lenti and pRNAT in-H1.2/Lenti) and virus will be generated using the invitrogen ViraPower Lentiviral expression system. The virus based on human HIV-1 which has a deletion in the 3'LTR that results in the self-inactivation of the lentivirus after transduction of the target cell.

The recipient cells are human carcinoma derived cell lines: MCF-7 (breast), HT29, H630, KM12C, KM12L4A (colon), A2780 (ovarian), A431 (cervical). These are widely used by research laboratories. Their use has been classified as containment level 1. The target cells in culture are not considered to pose any inherent hazard to human health, nor do they have the capacity to survive outside the laboratory.

The ViasPower Lentiviral expression system is a third generation lentiviral system based on HIV-1 and consists of an expression vector and packaging genes contained on 3 additional plasmids. The expression vector contains the gene of interest. In this case Genescript Vectors pRNAT - U6.1/Lenti and pRNATin-H1.2/Lenti will be used. These commercially available vectors are compatible with the invitrogen ViraPower system. The vectors contains a neomycin resistance gene for establishing a stable cell line.
line and a coral GFP gene for tracking transfection efficiency, which are driven by a CMV promoter and SV40 promoter respectively. H1.2 and U6 promoters are used to drive siRNA expression. The HIV-1 genes env, vif, vpr, vpu and nef have been deleted from the vectors and thus recombination to produce replication competent virus is not possible. The three packaging plasmids pLP1, pLP2 and pLP/VSVG supply the helper function as well as structural and replication proteins in trans for production of Lentivirus. The plasmids have been engineered not to contain any regions of homology with each other to prevent recombination. None of them contains LTRs or the packaging sequence which means none of the HIV-1 structural genes are present in the packaged viral genome.

The 293T producer cell line stably expresses SV40 large T antigen under the control of the CMV promotor. When the expression vector and packaging vectors are co-transfected into 293FT cells, replication incompetent lentivirus is produced which will be used to infect the recipient cells.

These viruses have the potential to infect human cells only when they have been packaged in appropriately engineered packaging cells. Once packaged these infective viruses are extremely labile and do not have the capability to replicate or produce infective virus in other non-engineered cells. They would be unable to spread beyond the infected cell. Mobilisation through interaction of lentivirus with endogenous human retroviruses in the target cells is highly unlikely since the cells are of known origin and clear of HIV.

Origin & function

The genetic material to be introduced via the lentiviral systems consists of short hairpin RNAs that target a number of genes involved in cell-matrix and cell-cell adhesions. Targets include cell-cell adhesion proteins (E-cadherin, p120ctn) and cell matrix adhesion proteins (beta1 integrin, FAK) and other signalling proteins involved in regulation of these adhesions (Src family kinases, Fer and Abl tyrosine Kinases, phosphodiesterase type 4 isoforms) will be targeted and effects on tumor cell motility and invasion determined. Loss of E-cadherin has been casually linked to tumour progression however, there is no evidence that it is a tumour suppressor (Perl et al, Nature 392:190-3, 1998). It is unlikely therefore that its down regulation in human cells would lead to enhanced susceptibility to malignancy. Beta1 integrin and FAK protein levels regulate cell survival during matrix detachment (anoikis) (Xu et al Cell Growth Diff.7:413-418, 1996) and down regulation of these proteins may render the recipient cells more susceptible to anoikis. It is not known what the effect on normal cells would be.

Evaluation of foreseeable effects

The replication defective lentiviral vectors containing the siRNAs described above are unlikely to be hazardous to humans. RNAi sequences that target tumour suppressor genes could act in a similar way to oncogenes however, it is unlikely that replication defective lentiviruses would be effective carcinogens in humans in the short term. It will however, be important to prevent human exposure or environmental release of the replication defective lentiviruses which are used to transiently effect gene transfer. This will be achieved through the use of appropriate physical containment and inactivation processes.

The possibility of exposure to recombinant viruses generated by recombination with wild type virus needs to be considered and may, although unlikely, cause pathological effects in humans. Careful attention will, therefore, be placed on containment and control measures that minimise aerosol production and opportunity for recombination and complementation.

The final GMO human cells will contain stably integrated DNA copies of the lentiviral vectors encoding the transferred siRNAs against the genes listed above. As a result they will pose no hazard to human health or the environment, since they are unable to colonise humans or survive outside of laboratory culture.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
To minimise the risk of human health it will essential to prevent exposure to lentivirus. Virus generation and infection of target cells will be carried out in Class II biological safety cabinets in the Class II containment laboratories, with access restricted to authorised staff. The amount of lentivirus handled will be limited to no more than 25ml of virus stock. The most likely routes through which individuals could be exposed to virus are needle-stick injuries or aerosols generated during experimental procedures. No needles or sharps will be used during virus preparation, whilst the use of the Class II biological safety cabinet will guard against exposure to aerosol. In addition, cell cultures will be contained within clearly labelled boxes during incubation to prevent accidental spillage of medium. All viral supernatants and spent medium will be inactivated using Prespekt tablets (10,000 ppm chlorine) before removal from the Class II laboratories for autoclaving and final disposal. Solid waste will be double-bagged in biohazard bags prior to removal from the Class II laboratories and autoclaved prior to final consignment of waste to approved contractor. Autoclaves will be validated by annual thermocouple mapping and each run is monitored using Thermalog-S indicator test strips. These processes will result in 100% inactivation of infectious virus.

Cells will be cultured using designated bottle of medium that will not be used to passge other cell cultures. Authorised staff will wear dedicated lab coats in the Class II laboratories that are not worn in the general laboratory area. To assess infection efficiencies, the cultures will be sealed and carried in a secondary sealed box and GFP-positive clones identified using the fluorescent microscope situated in the main tissue culture facility. Positive clones will be expanded and checked for virus production before removal from the Category II laboratory. Infected target cells will be cultured under the above regime until medium supernatants have been shown to be free of replication competent virus as judged by infection of appropriate indicator cells. This will be done by treating the parental cell line with culture medium from the derivatised cells and monitoring for GFP production which would indicate the presence of replication competent virus.

**Project Additional Information**

**Purposes of the contained use**

The aim of the project is to test the role of Raf kinase inhibitor protein (RKIP) depletion in a variety of human tumour cell lines (origin of eg, breast, skin, prostate, colon). Down regulation of RKIP will be achieved using DNA vector based siRNA technology. Small DNA inserts encoding short hairpin RNA (shRNA) targeting the gene of interest are cloned into a vector and expressed in the target cell. The shRNA expressed is rapidly processed into siRNA which destroys the cognate RNA. However, in contrast to continuous down regulation, here a tetracycline-regulated expression system is used. This allows for a much more defined approach as the same cell can be examined both in presence and absence of shRNA expression.

**Recipient or parental organism**

The recipient cells would be:
- telomerase immortalised normal human cells (fibroblasts hTERT-BJ1, breast epithelial cells hTERT-HME1)
- human breast tumour cell lines MCF-7, MDA-MB 231, MDA-MB 453, MDA-MB 468, T47D
- human colon tumour cell lines DLD-1, HCT116, HT129, LoVo, SW480
- human melanoma cell lines Mel Im, Mel Ho, Mel Ei, Mel Wei, Mel Ju, Mel Juso
- human prostate tumour cell lines C42, C42B, DU145, LNCaP, PC3
- monkey cell line COS-1 human embryonic kidney cell line HEK293

These are widely used by research laboratories. The target cells in culture are not considered to pose any inherent hazard to human health, nor do they have the capacity to survive outside the laboratory.

**Host/vector system**

The ViraPower™ T-Rex™ Lentiviral Technology allows tetracycline-regulated, in vitro or in vivo delivery of a target gene or RNA to dividing and non-dividing mammalian cells using a replication-incompetent lentivirus. It is based on the lentikat™ system developed by Cell Genesys (Dull et al., J. Virol., 72, 8463-8471, 1998). The lentiviral and packaging vectors supplied in the Block-iT™ Inducible H1 lentiviral RNAi system are third-generation vectors based on lentiviral vectors developed by Dull et al., 1998.

Although the lentiviral vector does have the potential to infect non-dividing human cells, by its design it is unable to spread beyond the infected cell. The likelihood of mobilisation through recombination is highly unlikely. Mobilisation through interaction of lentivirus with endogenous human retroviruses in the target cells is highly unlikely.
since the cells are of known origin and clear of HIV.

The third-generation HIV-1-based lentiviral system includes a significant number of safety features designed to enhance its biosafety and to minimize its relation to the wild-type, human HIV-1 virus. The pLenti4/BLOCK-iT™-DEST and pLent6/TR vectors contain a deletion in the 3' LTR (U3) that does not affect generation of the viral genome in the producer cell line, but results in "self-inactivation" of the lentivirus after transduction of the target cell (Yee et al., 1987; Yu et al., 1986; Zufferey et al., 1998). Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing packageable viral genome.

* The number of genes from HIV-1 that are used in the system has been reduced to three (ie gag, pol, and rev)
* The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 envelope (Burns et al., 1993; Emi et al., 1991; Yee et al., 1994).
* Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids (ie three packaging plasmid and pLenti4/BLOCK-iT™-DEST or pLent6/TR). All four plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus (Dull et al., 1998).
* Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (eg gal, pol, rev, eng) in the 293FT producer cell line, none of them contain LTRs or the packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced.
* The lentiviral particles produced in this system are replication-incompetent and only carry the gene of interest. No other viral species are produced.
* Expression of the gag and pol genes from pLP1 has been rendered Rev dependent by virtue of the HIV-1 RRE in the gag/pol mRNA transcript. Addition of the RRE prevents gag and pol expression in the absence of Rev (Dull et al., 1998).
* A constitutive promoter (RSV promoter) has been placed upstream of the 5' LTR in the pLenti4/BLOCK-iT™-DEST and pLent6/TR vectors to offset the requirement for Tat in the efficient production of viral RNA (Dull et al., 1998).

Origin & function

RKIP is a putative tumour suppressor gene and its loss renders cells metastatic (Chatterjee et al., 2004; Keller, 2004). In contrast, there is no evidence that RKIP plays a direct role in tumourigenesis. However, it cannot be ruled out that amphotropic viruses encoding shRNAs against RKIP might also raise the possibility of tumour formation in addition to their contribution to metastasis.

Literature:

Evaluation of foreseeable effects

The replication defective lentiviral vectors containing the siRNAs described above are unlikely to be hazardous to humans. RNAi sequences that target tumour suppressor genes could act in a similar way to oncogenes however, it is unlikely that replication defective lentiviruses would be effective carcinogens in humans in the short term. The lentiviruses are disabled and cannot replicate unless packaging proteins are supplied, and thus would be unable to spread beyond the infected cell. It will however, be important to prevent human exposure or environmental release of the replication defective lentiviruses which are used to transiently to effect gene transfer. This will be achieved through the use of appropriate physical containment and inactivation processes.

The possibility of exposure to recombinant viruses generated by recombination with wild type virus neeeds to be considered and may, although unlikely, cause pathological effects in humans. Careful attention will, therefore, be placed on containment and control measures that minimise aerosol production and opportunity for recombination and complementation.

The final GMO human cells will contain stably integrated DNA copies of the lentiviral vectors encoding the transferred siRNAs against the genes listed above. As a result they will pose no hazard to human health or the environment, since they are unable to colonise humans or survive outside of laboratory culture.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

To minimise the risk to human health it will be essential to prevent exposure to lentivirus. Virus generated and infection of target cells will be carried out in Class II biological safety cabinets in the Class II containment laboratories, with access restricted to authorised staff. The amount of lentivirus handled will be limited to no more than 25ml of virus stock. The most likely routes through which individuals could be exposed to virus are needle-stick injuries or aerosols generated during experimental procedures. No needles or sharps will be used during virus preparation, whilst the use of the Class II biological safety cabinet will guard against exposure to aerosol. In addition, cell cultures will be contained within clearly labelled boxes during incubation to prevent accidental spillage of medium. All viral supernatants and spent medium be inactivated using Presept tablets (10,000 ppm chlorine) before removal from the Class II laboratories for autoclaving and final disposal. Solid waste will be double-bagged in biohazard bags prior to removal from the Class II laboratories and autoclaved prior to final consignment of waste to approved contractor. Autoclaves will be validated by annual thermocouple mapping and each run is monitored using Thermalog-S indicator test strips. These processes will result in 100% inactivation of infectious virus.

**Date of Significant Change**:  

**Project Additional Information**

**Purposes of the contained use**

The aim of the project is to test the role of a number of genes found to be differentially expressed (or which physically interact with differentially expressed gene products) between Ras or Fos transformed fibroblast cell lines by retroviral infection of the cells with the genes in order to improve the understanding of invasion mechanisms in cancer.

These genes are targets of Ap-1 (AP-1 activity is required by oncogenes that function in the growth factor ras signal transduction pathway) and are involved in cellular invasion; up-regulated genes function as effectors of invasion and down-regulated genes function as suppressors of invasion.

**Recipient or parental organism**

The recipient cells would be:
- Telomerase immortalised (hTERT) human foetal fibroblasts (Tiff cells)
- Tiff cells stably expressing the v-FosFBJ/R gene
- Tiff cells stably expressing the v-Ha-Ras gene
- Rat fibroblasts (208F) cells
- Rat fibroblasts (208F) cells expressing the v-FosFBR gene

The target cells in culture are not considered to pose any inherent hazard to humana health, nor do they have the capacity to survive outside the laboratory. All the mammalian cells to be used have been tested and shown to be free of replicating retrovirus, either in house or others (Curran T, Verma, IM (1984) Virology, 135 p229).

The probability that harmful sequences may be transferred to related viruses is therefore very low.

**Host/vector system**
The retroviral vectors pLNCX, pLHCX and pLPCX (available from Clontech) are based on the Moloney Murine Leukaemia Virus (MOMuLV) and are replication defective since they do not encode the necessary gag, pol and env genes. Transfection into the packaging cell line, Phoenix ampho (Nolan Labs) or RetroPak-PT67 (Clontech), provides these gene products, permitting production of infective virus. Each of these cell lines contains gag, pol and env genes encoded by 2 separate plasmid expression vectors both of which lack the retroviral cis-acting packaging signal to minimise the likelihood of replication competent virus arising through recombination.

Virus produced by the packaging cell line is capable of infecting human cells, however, further production of virus from an infected cell is extremely unlikely, since the virus lacks the gag-pol and env genes. In the packaging cell line these genes are carried in two separate constructs and under the control of non-Moloney promoters, therefore, removing the risk that a single recombination event could result in the virus acquiring the genes necessary to become replication competent. In addition, once packaged these infective viruses are extremely labile. According to the ACGM compendium of guidance part 2B note 15 the appropriate level of containment to control the inherent risk of amphotrophic, replication defective viruses is AGCM Level 1. A risk of minor localised infection does exist when handling the packaged infection virus, but this is prevented by using the appropriate level of containment and inactivation procedures - hazard containment 2 is therefore recommended and all work will be carried out in Class II biological safety cabinets.

The gene sequences are of human origin (with the exception of Qsulf-1 which is of avian origin) and are involved in suppressors of invasion.

- Krp1 - kelch-related protein 1 (Krp1) is necessary for pseudopod elongation.
- Lasp-1 is necessary for cell pseudopod extension and invasion.
- Prex1 - phosphatidylinositol 3, 4, 5-triphosphate-dependent exchanger acts as a guanine nucleotide exchange factor for the RHO family of small GTP-binding proteins (RACs)
- Tiam-1 is a guanine nucleotide exchange factor that activates the RHO family of small GTP binding proteins (RACs) and is known to have oncogenic properties.
- Sulf-1 (human and quail) is a heparan sulfate (HS) 6-0 endosulfatase with preference, in particular, toward trisulfated IdoA2S-GlcNS6S disaccharide units within HS chains. It can function cell autonomously to remodel the sulfation of cell surface HS and promote Wnt signaling when localised either on the cell surface or in the Golgi apparatus.
- Integrin-linked kinase (ILK) is a focal adhesion protein activated by both extracellular matrix and growth factors, is required for the activation of Rac and Cdc42 in epithelial cell. It has known oncogenic activity.
- Integrin linked kinase associated phosphatase (ILKAP) regulates ILK signaling and inhibits anchorage-independent growth. It has known oncogenic activity.
- PINCH1 is a focal adhesion protein that complexes with ILK and is involved in cell spreading and motility. It is proposed to express the above genes and mutated versions which are inactivated or constitutively active. Three of the genes are known oncogenes the others are involved in invasion processes. It is unlikely that amphotropic retroviruses encoding the genes would represent a significant hazard as a localised infection in normal cells. It is proposed to express the above genes and mutated versions which are inactivated or constitutively active.

Evaluation of foreseeable effects

The replication defective retroviral vectors containing the genes described above are unlikely to be hazardous to humans. Some of the gene sequences are oncogenic however, it is unlikely that replication defective retroviruses would be effective carcinogens in humans in the short term. Single oncogenes are not generally considered sufficient to convert primary human cells to full malignancy, and replication defective viruses are not capable of dissemination even in a permissive host, however there is potential for harm to human health in the event of infection. It will however, be important to prevent human exposure or environmental release of the replication defective retroviruses which are used to transiently to effect gene transfer. This will be achieved through the use of appropriate physical containment and inactivation processes.

The possibility of exposure to recombinant viruses generated by recombination with wild type virus needs to be considered and may, although unlikely, cause pathological effects in humans. Careful attention will, therefore, be placed on containment and control measures that minimise aerosol production and opportunity for recombination and complementation.

The final GMO human cells will contain stably integrated DNA copies of the retroviral vectors encoding the transferred genes listed above. As a result they will pose no hazard to human health or the environment, since they are unable to colonise humans or survive outside of laboratory culture.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

To minimise the risk to human health it will be essential to prevent exposure to retrovirus. Virus generation and infection of target cells will be carried out in Class II biological safety cabinets in the Class II containment laboratories, with access restricted to authorised staff. The amount of retrovirus handled will be limited to no more than 25 ml of virus stock. The most likely routes through which individuals could be exposed to virus are needle-stick injuries or aerosols generated during experimental procedures. No needles or sharps will be used during virus preparation, whilst the use of the Class II biological safety cabinet will guard against exposure to aerosol. In addition, cell cultures will be contained within clearly labelled boxes during incubation to prevent accidental spillage of medium. All viral supernatants and spent medium will be inactivated using Presept tablets (10,000 ppm chlorine) before removal from the Class II laboratories for final disposal. Solid waste will be double-bagged in biohazard bags prior to removal from the Class II laboratories and autoclaved prior to final consignment of waste to approved contractor. Autoclaves will be validated by annual thermocouple mapping and each run is monitored using Thermalog-S indicator test strips. These processes will result in 100% inactivation of infectious virus.

Cells will be cultured using designated bottles of medium that will not be used to passage other cell cultures. Authorised staff will wear dedicated lab coats in the Class II laboratories that are not worn in the general laboratory area.

Positive clones will be expanded and checked for virus production before removal from the Category II laboratory. Infected target cells will be cultured under the above regime until medium supernatants have been shown to be free of replication competent virus as judged by infection of appropriate indicator cells or assay or reverse transcriptase activity. Once these criteria are met the infected target cells will be removed from Class II containment and handled using standard tissue culture processes.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

The risk assessment pertaining to this notification was discussed at the CR UK Safety Committee on 24 June 2005 and was approved with minor modification.

02/03/2022
Use of retroviral and lentiviral human siRNA libraries to knock down expression of proteins that interact with known target genes by measuring GFP activity, in order to investigate the events that are required for a tumorigenic phenotype.

The aim of this project is to generate replication-defective retroviruses and lentiviruses that express shRNAs from RNA interference libraries. This will enable the expression of siRNAs in a target cell population which will allow for their selection and identification based on a target gene/reporter construct. The ultimate goal of the project to identify factors regulating cellular processes that may offer novel targets for therapeutic intervention.

The cells to be used in the first instance, will be the human RPE-tert cell line (telomerase-expressing human retinal pigment epithelial cells) These have been modified by transfecting and selecting for a target gene. PUMA, a propapoptotic gene (Nakano, K and Vousden, K.Mol.Cell.7:683-694,2001) linked to a GFP reporter. The RPE-tert cells are not considered to pose any inherent hazard to human health, nor do they have the capacity to survive outside the laboratory. The cells will therefore not exert any foreseeable effects on either human health or the environment.

Other common laboratory cell lines that will be used to complement the GFP reporter construct and subsequent siRNA screening include:
telomerase immortalised normal human cells (fibroblasts hTERT-BJ1, breast epithelial cells hTERT-HME1)
human breast tumour cell lines MCF-7, MDA-MB 231, MDA-MB 453, MDA-MB 468, T47D
human colon tumour cell lines DLD-1, HCT116, HT29, LoVo, SW480
human melanoma cell lines Mel Im, Mel Ho, Mel Ei, Mel Wei, Mel Ju, Mel Juso
human prostate tumour cell lines C42, C42B, DU145, LNCaP, PC3
Burkitt lymphoma EBV negative cell lines CA46, Ramos, BL40, BL41, Bl2
monkey cell line COS-1
Human embryonic kidney HEK293

These are widely used by research laboratories. They are not considered to pose any inherent hazard to human health nor do they have the capacity to survive outside the laboratory and do not harbor any adventitious agents.

### Host/vector system

The system to be used to transfer the retroviral shRNA library involves disabled replication-defective retrovirus pRetroSuper (Brummelkamp, T et al. Cancer Cell 2, 243-7 (2002) or a similar retroviral vector pSM2c (Paddison et al., Nature methods 1:2, 163-7 (2004) available from Open Biosystems Inc. Both these vectors contain the retroviral packaging signal which will only allow them to be packaged when they have been placed in appropriately engineered packaging cells. Once packaged the infective viruses are extremely labile and do not have the capability to replicate or produce infective virus in the other non-engineered cells.

In more detail:

The pRETROSUPER vector and pSM2c vectors are derived from the Murine Embryonic Stem Cell virus (pMSCV). The vectors have a specifically designed 3'LTR that has a deletion in the LTR promoter elements. This deletion results in inactivation of the LTR mediated transcription upon retroviral integration.

The pSM2c cloning vector is roughly equivalent to pSM1 (Paddison et al., methods Mol.Biol.265, 85-100 (2004) with a few notable exceptions. First, the cloning strategy has been changed. Previously "PCR-SHAG" was used to clone hairpins by adding the entire hairpin onto the end of a PCR primer. Now a single oligo is used, containing the hairpin and common 5' and 3' ends, as a PCR template. That is, the oligo is PCR amplified using universal primers that contain XhoI (5' primer) and EcoRI (3' primer). These PCR fragments are then cloned into the hairpin cloning site of pSM2c. The mir30-styled hairpins are expressed from the human U6 promoter. The 5' and 3' flanks are derived from 125 bases surrounding the Human mir30 microRNA.

The pSUPER constructs will be grown in the excision repair-deficient E.coli strain GT116 to avoid removal of the shRNA sequences. The pSM2c constructs will be g rown in E. coli DH10Bpir116 and DH10Bpir116 and DH10BF DOT competent cells. The shRNA plasmids use the pir-dependent R6Ky replication origin. The PirPlus E. coli express the protein (pir gene product), which is essential for cloning, and propagation of the shRNA vectors. The resulting plasmids will then be transfected into the packaging cell lines Phoenix-Ampho (Orbigen Inc) based on 293T (a human embryonic kidney cell line transformed with adenovirus E1a and carrying a temperature sensitive T antigen) or RetroPak-PT67 (BD Biosciences) based on NIH 3T3 to produce amphotropic retrovirus. These helper free cell lines contain gag, pol and env genes encoded by 21 separate plasmid expression vectors both of which lack the retroviral cis-acting packaging signal to minimise the likelihood of replication competent virus arising through a single recombination event.

Transfection into the packaging cell line, Phoenix ampho or RetroPak-PT67, provides these gene products, permitting production of infective virus. At this stage the virus is capable of infecting human cells, however, further production of virus from an infected cell is extremely unlikely, since the virus lacks the gag-pol and env genes. In the packaging cell line these genes are carried in two separate constructs and under the control of non-Moloney promoters, therefore, removing the risk that a single recombination event could result in the virus acquiring the genes necessary to become replication competent.

The vector for the lentiviral shRNA library is a derivative of pLentihair called pLKO.1 (Stewart et al, RNA [2003], 9:493-501) (http://www.addgene.org/pgvec1?f=c&identifier=8453&cmd=findpl). This vector system is based upon HIV-1 lentivirus, although is lacking all HIV-1 genes except gag-pol and env, which are provided in trans by a transient transfection strategy. Also, the virus produced is to be pseudotyped with VSV-G envelope protein rather than HIV-1. The vector requires cotransfection into 293T cells with two other plasmids providing packaging (gag-pol) and envelope (env) functions in trans in order to produce retroviral particles. 293T cells are not employed in this capacity as a packaging cell line, merely as a host for this entirely exogenously introduced viral system. In combination with a self-inactivating LTR on pLKO.1 the transient transfection of a three separate plasmid system effectively eliminates the possibility of recombination to form replication-competent retrovirus. As such the vector system is highly unlikely to cause harm to humans.

### Origin & function
shRNA libraries produce double-stranded RNA identical in sequence to that of the gene of interest that can interfere with its function. Depending on the library to be used the resulting siRNAs can be 21 to 30 nucleotides long.

The lentiviral Expression Arrest-TRC human shRNA library is available commercially from Open Biosystems. This library was designed and developed by the RNAi Consortium (TRC) at the Broad Institute of MIT and Harvard. Currently the human shRNA library (TRC-Hs 1.0) contains over 34,000 shRNA constructs, cloned into lentiviral expression vectors, covering 7300 human genes.

It is anticipated that by knocking down the expression of these genes in relation to a target gene/GFP reporter a link can be made in the target gene pathway/phenotype.

The knock down of genes will involve the tumour supressor gene p53 plus others including, p3000, CBP, retinoblastoma, P16, P27. It is possible that amphotropic viruses encoding shRNAs against tumour suppressor genes might raise the probability of transformation in infected cells.

Other targets are BIK and BAX genes which are pro-apoptotic proteins that when expressed at sufficient levels and in the correct context can induce cell death. Knockdown of these genes in cell lines is predicted to protect them from stimulation induced cell death. BIK has so far been found to be mutated in a few glioma and peripheral B-cell lymphomas and its loss may therefore contribute to oncogenesis. Bax mutations have also been found in colorectal tumours with a microsatellite instability phenotype. Loss of these genes may enable cells to escape specific stimulation induced apoptosis and may therefore contribute to oncogenesis. The frequency of these events in human cancer is low.

Evaluation of foreseeable effects

The final genetically modified cells will contain stably integrated DNA copies of the retroviral or lentiviral vectors encoding the transferred shRNAs. The cells will be free of retrovirus or lentivirus. As a result they will pose no hazard to human health or the environment, since they are unable to colonise humans or survive outside the laboratory culture. It will however, be important to prevent human exposure or environmental release of the replication defective retro- or lentiviruses which are used to transiently effect gene transfer. The worse case scenario in case of infection is the selection of an shRNA that knocks down expression of a gene necessary for tumour suppression. Risk against this will be reduced through the use of appropriate physical containment and inactivation processes. Hazard containment 2 is therefore recommended and all work will be carried out in Class II biological safety cabinets.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The risk assessment pertaining to this notification was discussed at the CR UK Safety Committee of the 21st September 2005 and was approved with minor modification.
**Project Additional Information**

**Purposes of the contained use**

Primary human cells from normal or tumorigenic tissue are to be transfected using amphotropic retroviruses containing human telomerase catalytic component (hTERT) and then analysed for RNA and protein expression, proliferation and other cell culture assays. The function of the expressed hTERT, cDNAs is to immortalise human cells whilst retaining a normal non-neoplastic phenotype. The resulting cells will allow the study of normal and dysplastic human cells in vitro where previously only neoplastic or rodent in vivo models have been available.

**Recipient or parental organism**

The recipient cells would be primary cells that senesce in culture after 3-62 population doublings and will be of the following origins: fibroblasts, keratinocytes, glial, epithelial, striated muscle, kidney etc.

The target cells in culture are not considered to pose any inherent hazard to human health, nor do they have the capacity to survive outside the laboratory. They are derived from patients with no known retroviral disease or Hepatitis.

**Host/vector system**

The retroviral vectors such as pBabe, pRetroSuper, pLNCX, pLHCX and pLPCX are based on the Moloney Murine Leukaemia virus (MMLV) and are replication defective since they do not encode the necessary gag, pol and env proteins. They are available commercially from companies such as BD Biosciences, Invitrogen and Stratagene etc. Phoenix packaging cell lines (Nolan Lab) are second-generation retrovirus producer lines for the generation of helper free retroviruses. The lines are based on the 293T cell line (a human embryonic kidney line transformed with adenovirus Ela and carrying a temperature sensitive T antigen co-selected with neomycin). Transfection of the phoenix E packing cells will produce an ecotropic retrovirus. When this retrovirus is used to infect the Phoenix Amphi packaging cell line, an amphotropic retrovirus is produced which is capable of infecting human cells. However, further production of retrovirus from the infected human cells is extremely unlikely since the virus lacks the gag-pol and env genes.

An alternative packaging cell line is RetroPak-PT67 (BD Biosciences) a mouse fibroblast NIH 3T3-derived cell line designed for the production of infectious, replication-incompetent virus. PT67 contains the Moloney murine leukemia virus (M0MuLV) gag, pol, and env (IOA1-derived) genes. Transfection with a retroviral vector containing the retroviral packaging signal and a target gene allows production of replication-incompetent virus. In the PT67 packaging cell line these genes are carried in two separate constructs and under the control of non-Moloney virus promoters, therefore removing the risk that a single recombination event could result in the virus acquiring the genes necessary to become replication competent.

Virus produced by the packaging cell line is capable of infecting human cells, however, further production of virus from an infected cell is extremely unlikely, since the virus lacks the gag-pol and env genes. In the packaging cell line these genes are carried in two separate constructs and under the control of non-Moloney promoters, therefore,
removing the risk that a single recombination event could result in the virus acquiring the genes necessary to become replication competent. In addition, once packaged these infective viruses are extremely labile. A risk of minor localised infection does exist when handling the packaged infection virus, but this is prevented by using the appropriate level of containment and inactivation procedures — hazard containment 2 is therefore recommended and all work will be carried out in Class II biological safety cabinets.

**Origin & function**

The gene sequences are of human origin: hTERT (Human telomerase reverse transcriptase). It is the catalytic component of telomerase, with similarity to reverse transcriptases; may represent universal subunit for telomerases. Bodnar et al (Science 279:349, 1998) reported bypassing cellular senescence when they transfected human somatic cells lacking telomerase activity with the hTERT gene. Counter et al. (PNAS 95:14723, 1998) reported alteration of the C-terminus of hTERT did not affect enzymatic activity but impeded telomere maintenance, and cells with this mutant telomerase would not immortalize. hTERT has been shown to prolong the lifespan of human cells and has been implicated in the process of epithelial cell immortalisation (Muntoni et al. Oncogene 22, 7804-08 (2003)). It is difficult to envision how the proposed manipulation of the levels of this gene in our cultures could pose a greater risk than the use of existing immortal cancer cell lines in the laboratory. It is therefore unlikely that amphotropic retroviruses encoding these genes would represent a significant hazard as a localised infection of the cells under investigation.

**Evaluation of foreseeable effects**

The replication defective retroviral vectors containing the genes described above are unlikely to be hazardous to humans. hTERT has been shown to prolong the lifespan of human cells and has been implicated in the process of epithelial cell immortalisation. However, it is unlikely that replication defective retroviruses would be effective carcinogens in humans in the short term. Single oncogenes are not generally considered sufficient to convert primary human cells to full malignancy, and replication defective viruses are not capable of dissemination even in a permissive host, however there is potential for harm to human health in the event of infection. It will however, be important to prevent human exposure or environmental release of the replication defective retroviruses which are used to transiently to effect gene transfer. This will be achieved through the use of appropriate physical containment and inactivation processes. The possibility of exposure to recombinant viruses generated by recombination with wild type virus needs to be considered and may, although unlikely, cause pathological effects in humans. Careful attention will, therefore, be placed on containment and control measures that minimise aerosol production and opportunity for recombination and complementation.

The final GM human cells will contain stably integrated DNA copies of the retroviral vectors encoding the transferred genes listed above. As a result they will pose no hazard to human health or the environment, since they are unable to colonise humans or survive outside of laboratory culture.

Project Additional Information

Purposes of the contained use

The aim of this project is to generate replication-defective lentiviruses that express shRNAs against proteins that are important in cancer metastasis and maintenance of cell morphology and signalling. The goal of the project is to test the requirements for specific proteins in various cellular processes such as migration, survival and growth.

Recipient or parental organism

The cells to be used in the first instance, will be the primary and immortalised mouse embryo fibroblast cells (MEF and iMEF). The MEF and iMEF are not considered to pose any inherent hazard to human health, nor do they have the capacity to survive outside the laboratory. The cells will therefore not exert any foreseeable effects on either human health or the environment. These cells are not competent to produce replication defective virus either. Other common laboratory cell lines that will be used include:

- Telomerase immortalised normal human cells (fibroblasts hTERT-BJI, breast epithelial cells hTERT-HMEI)
- Human breast tumour cell lines MCF-7, MDA-MB 231, MDA-MB 453, MDA-MB 468, T47D
- Human colon tumour cell lines DLD-1, HCTI 16, HT29, LoVo, SW480
- Human melanoma cell lines Mel Im, Mel Ho, Mel Ei, Mel Wei, Mel Ju, Mel Juso, A375
- Human prostate tumour cell lines C42, C428, DU145, LNCaP, PC3
- Human squamous cell carcinoma SCC9
- Mouse fibroblast cell lines- NIH3T3, Swiss 3T3
- Mouse myoblast cell line C2C12
- Burkitt lymphoma EBV negative cell lines CA46, Ramos, 8L40, BL41, BL2
- Monkey cell line COS-1
- Human embryonic kidney HEK293

These are widely used by research laboratories. They are not considered to pose any inherent hazard to human health nor do they have the capacity to survive outside the laboratory and do not harbor any adventitious agents.

Host/vector system

Host bacteria for growth of the plasmids are standard disabled laboratory strains of E. Coli such as DH5α and JM109.

The vector systems will be a third generation lentiviral system where all six regulatory/accessory proteins (Rev, Tat, Vif, Vpr, VPu and Nef) are removed, except Rev. Rev acts at the post transcriptional level and is necessary for HIV gag/pol expression. Rev binds to an RNA motif (Rev responsive element RRE) and facilitates the cytoplasmic export of gag/pol messenger. As an extra safety measure Rev is placed on a separate vector (RSV-Rev) from the transfer vector. Only 700bp of the HIV envelope protein are present in the transfer vector, plus RRE and the packaging signal. The packaging construct contains the minimal RRE of 374 bp and the gag/pol genes. Through deletions in both LTR's and the absence of the accessory proteins, including the replication essential Tat, it is highly unlikely that replication of competent virus is produced. However the WPRE could express part of the X protein from the woodchuck hepatitis B virus which may have oncogenic properties. The ACOM advises that vectors containing these sequences are handled at category II or higher.

The vectors to be used in this study are available from Addgene or OpenBiosystems.

The lentiviral packaging cells will be 293T which will be used for the initial rescue of the virus from transfected DNA and for general virus propagation and will also express...
The transfected protein or shRNA of interest.

pWPI from Addgene- vector information available at www.addgene.org

This is the HIV-derived viral transfer vector. The description of the vector is copied from the Trono laboratory website, where we obtained the vector from: “As an analogue of the “self inactivating (sin)” retroviral vectors a sin lentiviral vector was constructed. The standard vector contains the post transcriptional regulatory element of woodchuck hepatitis virus (WPRE, abbreviated in plasmid names) has been inserted to enhance transgene expression as well as a central polypurine tract (cPPT), a cisacting element that improves the efficiency of gene transfer by a few-fold in many targets. All contain a transgene expressed from an elongation factor 1-alfa promoter (or its intron-less version EF1-a short), a robust transcriptional element in most cell types. Unique restriction sites at key positions will allow you to change promoter and transgene. The bicistronic vector allows for simultaneous expression of a transgene and CFP marker to facilitate tracking of transduced cells. Recently, we have developed a series of lentivectors that allows for constitutive or conditional RNA interference. In order to insert your own shRNA a pLVTH vector was designed in a way that Hi Pol III promoter can be easily replaced with Hi-siRNA cassette from pSUPER using EcoRi - Clal (or BamHl - Clai to obtain pLVH version). Alternatively, Hi promoter or tetO-Hi cassette can be substituted by any other siRNA expression cassette (e.g. U6-siRNA etc.).” In third generation lentiviral vectors derived from HIV in general, the total U3 region of the 5’ LTR is replaced by a heterologous Rous Sarcoma Virus (RSV) promoter. The U3 region of the 3’ LTR has a 400 bp deletion encompassing the TATA box. This means that the viral transfer vector has no complete LTR and the LTR’s of the provirus will not lead to transcription after integration into the genome, because of the removal of the U3 promoter. In the other packaging constructs no HIV LTR elements are present, so that it is impossible to get a complete LTR by recombination. The vector contains HIV elements that are necessary for the packaging of the viral RNA, the leader sequence, 360 bp gag, and 700 bp env. The total remaining HIV sequence is 1700 bp, which is 18% of the original viral genome.

pLVTHM from Addgene- vector information available at www.addgene.org

This is a modified version of the pWPI vector, described above, in which the Hi promoter drives expression of shRNA.

pMDLg/pRRE from Addgene- vector information available at www.addgene.org

This is the viral packaging construct. This vector contains 4700 bp HIV sequence: the gag/pol genes, 374 bp of env and the rev responsive element (RRL). Transcription is under control of the CMV promoter for GFP and the U6 promoter for the short oligonucleotides.

pRSV-rev from Addgene- vector information available at www.addgene.org

This vector contains the HIV-rev gene which is under control of the RSV promoter. There will be no translation of HIV gag/pol without expression of Rev, because Rev is necessary for the export of gag/pol messenger from the nucleus to the cytoplasm. This is an additional safety measurement. It is highly unlikely that replication competent virus will be formed from the pMDLg/pRRE vector because this vector will not express gag/pol in the absence of Rev. In the unlikely event that expression were to occur then only very low or undetectable levels are anticipated.

pMD2.g from Addgene- vector information available at www.addgene.org

This is the viral envelope expression vector. Vesicular stomatitis virus glycoprotein expression is under control of the CMV promoter.

pLVTHM- from Addgene- vector information available at www.addgene.org

This is a mammalian expression vector used for cloning the insert into prior to subcloning into pLVCT-TR-KRAB. It is similar to the previous Trono lab pLVTH but it contains a 3bp substitution that generates a unique MluI site for direct cloning of shRNA into MluI-Clal.

pLVCT-TR-KRAB- from Addgene- vector information available at www.addgene.org

This is a mammalian lentiviral expression vector which allows for drug controllable RNA interference using Tet-on shRNA. A vector map is available at the Addgene website.

pMV-CI N-ZEO from http://www.openbiosystems.com

This is a third generation lentiviral vector for the expression of shRNA that may be used as an alternative to pLVTHM, described above, because its microRNA-adapted shRNAmir design may increase levels of gene knockdown and its neomycin selection cassette allows for stable expression. The pCMV-GIN-ZEO characteristics are as follows: CMV promoter driving expression of a GFP marker and an IRES-neomycin selection cassette; a cPPT to help translocation to the nucleus; a WRE to enhance transgene expression ampicillin and zeocin bacterial selectable markers; a 5’ LTR; a pUC origin of replication to promote high copy maintenance in E. coli; a self-inactivating 3’ LTR; a Rev response element; and an RNA polymerase II promoter to drive shRNAmir expression.

Origin & function

Green fluorescent protein

Sequence encodes Green Fluorescent Protein (GFP) which functions as a reporter molecule that fluoresces bright green upon exposure to UV light.

Mouse and human proteins

The cytoskeletal proteins cortactin, HS-1, Scar-i, Scar-2 and Arp are implicated in the regulation of changes in morphology in platelets following stimulation by collagen.
Mutant mouse and human proteins
Point mutants or deletions of N-WASP, Arp2, Scar, Rac, Cdc42, mDia or related cytoskeletal proteins
Short hairpin RNAs corresponding to mouse and human proteins of the actin cytoskeleton
Short oligonucleotide sequences are designed to form short hairpin RNAs which will knock down expression of the above mouse and human genes.
No known hazard could arise from expression of these cDNAs or the short hairpin sequences designed to reduce their expression. All have been widely studied in a similar capacity before (e.g. overexpression by transient or stable transfection or knockdown) by our lab and other labs around the world.

**Evaluation of foreseeable effects**

The final genetically modified cells will contain stably integrated DNA copies of the lentiviral vectors encoding the transferred shRNAs. The cells will be free of lentivirus. As a result they will pose no hazard to human health or the environment, since they are unable to colonise humans or survive outside the laboratory culture, It will however, be important to prevent human exposure or environmental release of the replication defective retro- or lentiviruses which are used to transiently effect gene transfer. The worse case scenario in case of infection is the selection of an shRNA that knocks down expression of a gene necessary for tumour suppression. Risk against this will be reduced through the use of appropriate physical containment and inactivation processes. Hazard containment 2 is therefore recommended and all work will be carried out in Class II biological safety cabinets.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

n/a

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

n/a

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

To minimise the risk to human health it will be essential to prevent exposure to retrovirus. Virus generation and infection of target cells will be carried out in Class II biological safety cabinets in the Class II containment laboratories, with access restricted to authorised staff. The amount of retrovirus or lentivirus handled will be limited to no more than 25m1 of virus stock. The most likely routes through which individuals could be exposed to virus are needle-stick injuries or aerosols generated during experimental procedures. No needles or sharps will be used during virus preparation, whilst the use of the Class II biological safety cabinet will guard against exposure to aerosol. In addition, cell cultures will be contained within clearly labelled boxes during incubation to prevent accidental spillage of medium. All viral supernatants and spent medium will be inactivated using Presept tablets (10,000 ppm chlorine) before removal from the Class II laboratories for final disposal. Solid waste will be double- bagged in biohazard bags prior to removal from the Class II laboratories and autoclaved prior to final consignment of waste to approved contractor. Autoclaves will be validated by annual thermocouple mapping and each run is monitored using Thermalog-S indicator test strips. These processes will result in 100% inactivation of infectious virus.

Cells will be cultured using designated bottles of medium that will not be used to passage other cell cultures. Authorised staff will wear dedicated lab coats in the Class II laboratories that are not worn in the general laboratory area.

Positive clones will be expanded and checked for virus production before removal from the Category II laboratory. Infected target cells will be cultured under the above regime until medium supernatants have been shown to be free of replication competent virus as judged by infection of appropriate indicator cells or assay of reverse transcriptase activity. Once these criteria are met the infected target cells will be removed from Class II containment and handled using standard tissue culture processes.

Project Ref 25/08.1

Date Ackn’d: 11/07/2008

CU2 Project Title: Retroviral infection of mouse or human tissue culture cells to express or knockdown proteins involved in cell signalling, tumourgenesis, cell motility, invasion, metastasis and cell death and survival.

Class: Class 2

Culture Vol: < 1 Litre

Non-GMM: Not Applicable

Consent Granted: Not Applicable

Project notified under transitional arrangements: N

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information
Purposes of the contained use

The ultimate goal of these projects is to identify factors regulating cellular processes that may offer novel targets for therapeutic intervention in human disease. The retroviral vectors, pLNCX or pLPCX or pLHCX, pRetro-X Tet-On Advanced, pRetro-X-Tight-Hyg, pRetro-Tight-Pur (Clontech) and the pSM2 based vectors (LMP, TMP, and derivatives, Open Biosystems and Scott Lowe laboratory) will be introduced, by standard transfection techniques into the viral packaging cell lines, Phoenix-ampho, Phoenix-eco (Orbigen Inc, Nolan Labs), RetroPak PT-67, GP2-293 (Clontech) which will generate amphotrophic or ecotrophic retroviruses. The retroviral vectors will carry either siRNA or microRNA sequences to knock down target protein expression or sequences coding for target proteins that we want to overexpress. We will also express mutated forms of these proteins which are inactivated or constitutively active.

Recipient or parental organism

Host bacteria for growth of the plasmids are standard disabled laboratory strains of E. Coli such as DH5a and JM1 09. The use of E.coli as the recipient micro-organism, has been subject to a risk assessment and designated a Class 1 procedure.

The virus produced by the Phoenix-ampho, RetroPak PT-67, OP2-293 Phoenix-Eco cells will be used to infect human or mouse tissue culture cell lines: Human melanoma: A375, CHL-1, Me1505, Colo-829, A375M2, wm266.4, WM35, Skmel 119, Skmel2, Skmel 147, Skmel 173, RPM18332, Skmel23, BFTC905

Human Breast cancer: TMX2-28, MDA-MB231 and derivatives, MCF1O and derivatives, MCF-7, Hs578t, MDA-MB157, MDA-MB435s, MDA-MB468, MDA-MB8361, BT-549, T47D

Neuroblastoma: SHSY5Y,

Human Osteosarcoma: SAOS-2, U2OS

Human Cervical carcinoma: Hela

Human Keratinocyte cell line: HaCaT

Human head and neck squamous cell carcinoma: SCC9, FaDu, Detroit512, HN5, HN30, H413

Human Vulval 3CC: A431, UMSCV1A, UMSCV1B, LJMSCV6A, UMSCV2, UMSV7

Human T cell lymphoma: Jurkat

Human Burkitts Lymphoma: Ramos, CA46, BL41, BL2, 6L30, L3055, 8L40

Human Ovarian Carcinoma: A2780, JAMA2, 1847, OVCA433, OVCAR3, SKOV3, TR175, 1847, IGROV, QAW42, PA-i

Human Colon carcinoma: HT29, RKO, Colo205, SW620, SW48, 5W480, DLD1, Lovo, Ls174t, SKCO-1, 5W948, HCTI16

Human Prostate tumour: C42, C42B, DU145, LNCaP, PC3 Human Bladder tumour: SW1670, 5637, T24, VMcubl

Human Lung tumour: KNS-62, A549

Human Pancreatic tumour: panc-1, BxPC3, aspc-1, MIA-Paca-2

Human Retinal pigment epithelial cells: RPE

Human telomerase immortalised cell lines: hTERT-BJ1, hTERT-HME1, RPE-tert, Tif-puro

Mouse cell lines: 67NR, 4To7, 4T1, NIH3T3, Swiss 3T3, primary MEFs, immortalised MEFs, MEFs derived from knockout mice, primary mouse T cells, primary mouse melanocytes.

All the mammaliam cell lines are in routine use in many laboratories and have been provided by ATCC. CR UK cell bank, ICR cell bank or from other laboratories and have been tested either in house or at source to be free from replicating retroviruses. The probability that harmful sequences may be transferred from endogenous related viruses is therefore low.

Primary Human Cells: mammary epithelial cells, melanocytes, umbilical vein endothelial cells (HUVECs), fibroblasts, Peripheral blood lymphocytes, tonsillar lymphocytes. These are not considered to pose any inherent hazard to human health. They are derived from patients with no known retrovirial disease or Hepatitis. Derivatives of these cell lines engineered to express the ecotropic retrovirus receptor, the tetracycline transactivator ITA and reporter genes (Luciferase or florescent protein reporters) will also be used. The relevant drug (puromycin, hygromycin or neomycin) will then be used to select cells which have stable expression/knockdown of our gene of interest or appropriate controls.
**Host/vector system**

Host bacteria for growth of the plasmids are standard disabled laboratory strains of E. Coli such as DH5a and JM109. The use of E.coli as the recipient micro-organism, has been subject to a risk assessment and designated a Class 1 procedure. The packaging cells will be Phoenix-ampho, RetroPak PT-67, GP2-293 or Phoenix-Eco cells which will be used for the initial rescue of the virus from transfected DNA and for general virus propagation and will also express the transfected protein or shRNA of interest.

The retroviral vectors pLNCX, pLHCX and pLPCX are based on the Moloney Murine Leukaemia Virus (M0MuLV) and is replication defective since it does not encode the necessary gag, pol and env genes. The pRetroX-Tet-on Advanced and pRetroX-Tight-pur and pRetroX-Tight-hyg vectors are based on mouse sarcoma virus (MSV) sequences and are replication defective. pSM2 is based on the murine stem cell virus and is also replication defective. Transfection into the packaging cell line, Phoenix amphi, Phoenix eco, GP2-293 or RetroPak-PT67, provide these gene products, permitting production of infective virus. At this stage the virus from amphotropic packaging cell lines is capable of infecting human cells, however, further production of virus from an infected cell is extremely unlikely, since the virus lacks the gag-pol and env genes. In the packaging cell line these genes are carried in two separate constructs and under the control of non-Moloney promoters, therefore, removing the risk that a single recombination event could result in the virus acquiring the genes necessary to become replication competent.

**Origin & function**

Some of the genes we wish to express will include known oncogenes (for example Vl2HaRas, V600EBRaf, c-myc) and likewise some of the genes we will knockdown will include known/suspected tumour suppressor genes (for example p53, Dab2). Current knowledge indicates that the de-novo transformation process of human cells requires the peturbation of six-pathways (Rangarajan et al, Cancer Cell, 2004 (2):171-83) and therefore manipulation of individual pathways is not expected to confer a serious cancer risk to normal human cells. Similarly individual expression of activated oncogenes alone results in cellular senescence and/or apoptosis (Wajapeyee et al, Cell 2008 1 32(3):363-74). None of the genes we wish to manipulate encode toxins. Other examples include expression, knockdown and reexpression or mutant constructs for the following: Arp2/3 complex, WASP, N-WASP, Scarl-3, WASH. Cortactin,dynamin, TOCA-1, Rac1, RhoB, RhoF, RhoBTB1,2, Cdc42, IRSp53, MTSS1, ABBA1, Fascin.

**Evaluation of foreseeable effects**

Some of the genes we wish to express will include known oncogenes and likewise some of the genes we will knockdown will include known tumour suppressor genes. Current knowledge indicates that the denovo transformation process of human cells requires the peturbation of six-pathways (Rangarajan et al, Cancer Cell, 2004 (2):171-83) and therefore manipulation of individual pathways is not expected to confer a serious cancer risk to normal human cells. None of the genes we wish to manipulate encode toxins.

Hence, it is unlikely that replication defective retroviruses would be effective carcinogens in humans in the short term. Single oncogenes are not generally considered sufficient to convert primary human cells to full malignancy, and replication defective viruses are not capable of dissemination even in a permissive host, however there is potential for harm to human health in the event of infection. It will however, be important to prevent human exposure or environmental release of the replication defective retroviruses which are used to transiently to effect gene transfer. This will be achieved through the use of appropriate physical containment and inactivation processes. The possibility of exposure to recombinant viruses generated by recombination with wild type virus needs to be considered and may, although unlikely, cause pathological effects in humans. Careful attention will, therefore, be placed on containment and control measures that minimise aerosol production and opportunity for recombination and complementation.

The final GM human cells will contain stably integrated DNA copies of the retroviral vectors encoding the transferred genes listed above. As a result they will pose no hazard to human health or the environment, since they are unable to colonise humans or survive outside of laboratory culture.

Project Ref 25/08.2

Date Ackn'd 26/11/2008  CU2 Project Title Gene transfer using replication defective adenovirus vectors to study the regulation of

Class 2  CultureVolClass2 < 1 Litre  CultureVolumeClass3-4

02/03/2022  Page 1320 of 15326
The aim of the project is to use replication-defective disabled adenovirus vectors expressing GFP and/or full length and mutated forms of transcription factors and their known putative regulators to study transcription and cell proliferation. For example Brf1 will be used for gene transfer into cells such as human diploid fibroblast (IMR90) and mouse embryonic fibroblast (MEF) cell lines, and full length id2 and E47 for gene transfer into cells such as the HeLa cell line. The purpose of the experiments is to study the role of id2, E47 and Brf1 in the regulation of transcription of RNA polymerase III.

The cell lines to be used will be a range of established human and mouse cell lines, for example MEF, IMR90 and HeLa, and pose no significant hazard to human health when used under appropriate containment.

The vectors were originally generated using the commercially available replication-defective disabled adenovirus vector system termed AdEasy, (Quantum Biotechnologies, Montreal, Canada). The vector is based on adenovirus serotype 5 (Ad5). Wild type Ad5 is a human pathogen and classified in hazard group 2. The Adeasy adenovirus vector is deleted for E1 and E3 virus sequences rendering the virus replication defective. The virus s unable to replicate except in a complementing cell lines such as 293 cells (a human embryonic kidney cell line which expresses the left 11% of the Ad5 genome). These viruses have the potential to infect human cells when they have been packaged but are extremely labile and do not have the capability to replicate or produce infective virus. The adenoviruses also lack factors found in wild type adenoviruses which are involved in evading immune response. The replication defective vector can be considered unlikely to cause disease and designated as Class I.

Origin & function

It is not anticipated that the inserted sequences will alter the host range or tissue tropism of the virus. Some of the genes we wish to express may encode oncogenic proteins. Current knowledge indicates that the de-novo transformation process of human cells requires the perturbation of six pathways (Rangarajan et al, Cancer Cell, 2004 (2):171-83) and therefore manipulation of individual pathways is not expected to confer a serious cancer risk to normal human cells. None of the genes we wish to manipulate encode toxins. Hence, it is unlikely that replication defective retroviruses would be effective carcinogens in humans in the short term. **Project Ref** 25/09.1

**Date Ackn'd** 19/03/2009

**CU2 Project Title**

REPORTER ANALYSIS OF CANCER- AND SENESCENCE-ASSOCIATED PROMOTER ACTIVITIES IN CANCER CELL LINES AND PRIMARY CELLS USING LENTIVIRUS CONSTRUCTS.

**Class** Class 2

**Culture Vol Class 2** ≤ 1 L

**Consent Granted** Yes

**Non-GMM**

**Historical Significant Changes**

Withdrawn **N**

**Historical Date of Additional Info**

This project has transferred to GM383

**Date of Significant Change**

02/03/2022

**Project Additional Information**

**Purposes of the contained use**

The aim of this project is to generate replication-defective lentiviruses that express marker genes including firefly or renilla luciferases and/or destabilised variants, GFP and related fluorescent proteins or bacterial nitroreductase under the transcriptional control of various human, viral, or synthetic gene regulatory elements including normal or sitemutated variants of the human telomerase hTR and hTERT promoters, the human p16, p21 and CDK4 promoters and commonly used "constitutive" viral promoters. The constructs will be used to assess basal activity and, through the use of small molecules, siRNA, or transient overexpression of cell signalling genes, regulatory mechanisms of cancer and...
senescence associated gene promoter by reporter assay or cell ablation studies in a variety of cancer and normal cell types including primary haematopoietic and stem or progenitor cells.

**Recipient or parenteral organism**

Recipient cells will include both commonly used normal (untransformed) cell strains such as W138 and MRC5 and common cell lines that are widely used by research laboratories and are not considered to pose any inherent hazard to human health nor have the capacity to survive outside laboratory and do not harbor any adventitious agents.

Examples of cell lines to be used include:

- Additional recipient cells include sub-clones of common cell lines such as 293T, A2780-CP70 and HCT116-p53/- and stably transfected variants such as BJ-hTERT wherein the genetic and epigenetic traits associated with the sub-clone or transgene are not considered to increase the overall inherent hazard to human health of the cell line itself or following transduction with lentivirus.
- Additional recipients are to include normal or transformed primary human cells obtained from donors with appropriate consent such as T-lymphocytes, CD34+ haematopoietic progenitors, mesenchymal stem cells and cells derived from ascitic fluid of patients displaying advanced tumours of the peritoneal cavity. Additional recipients are to include primary cells from animals obtained under appropriate license including rat primary neural cells. All such primary cells will be cultured exclusively under category II containment.

**Host/vector system**

Host Bacteria for growth of the plasmids are standard disabled laboratory strains of E.Coli such as DH5α and JM109 or the Invitrogen proprietary strains Stbl£ (F-mcrB mrr hsdS20(rB-, mB-) recA13 sup E44 ara-14 galK2lacY1 proA2 rpsL20(StrR) xyl-5 - leu mtl-1) or TOP10 (F-mcrA *(mrr-hsdRMS-mcrBC) *80lacZ*M15 *lacX74 recA1 araD139 *(araaleu) 7697 galU galK rpsL (StrR) end A1 napG).

The system to be used for lentivirus construction is the Invitrogen ViraPowere Promoterless Lentiviral Gateway Expression System (www.invitrogen.co, catalogue number K5910-00). The system combines gateway cloning and lentiviral cloning technologies for construction of a 3rd generation lentivirus pseudotyped with the G Glycoprotein gene from vesicular stomatitis virus. The system allows incorporation of any transgene and gene regulatory element in the lentiviral vector. The system comprises:

1. The pENTR 5'-TOPO® TA Cloning Kit for production of a gateway entry clone containing a gene/promoter of interest
2. The vector contains no sequences necessary for virus production.
3. A promoterless pLenti6/R4R2/V5-DEST destination vector into which the promoter and gene of interest are transferred. This expression plasmid contains elements that allow packaging of the construct into virions.
4. Additional packaging plasmids pLP1, pLP2, and pLP/VSVG. And 293FT packaging cells. The packaging cells will be 293FT which will be used for the initial rescue of the virus from transfected DNA and for general virus propagation and will also express the marker genes of interest.

Vector features necessary for viral production:

- pLenti6/R4R2/V5-DEST:
  - Rous Sarcoma Virus (RSV) enhancer/promoter for Tat-independent production of viral mRNA in the producer cell line.
  - Modified HIV-1 5' and 3' Long Terminal Repeats (LTR) for viral packaging and reverse transcription of the viral mRNA (Note: The U3 region of the 3’ LTR is deleted (*U3) and facilitates self inactivation of the 5’ LTR after transduction to enhance the biosafety of the vector.
- HIV-1 psi (*) packaging sequence for viral packaging.
- HIV Rev response element (RRE) for Rev-dependent nuclear export of unspliced viral mRNA.
- pLP1:
  - HIV gag/pol coding sequences encoding genes required for structure and replication of the virus.
- pLP2:
  - HIV Rev OTF under transcriptional control of the RSV promoter encodes the Rev protein, which interacts with the RRE on pLP1 to induce gag and pol expression, and on the pLenti6/V5 expression vector to promote the nuclear export of the unspliced viral RNA for packaging.
- pLP/VSVG:
  - VSVG coding sequence under control of the CMV promoter encodes the envelope G glycoprotein from Vesicular Stomatitis Virus to allow production of a pseudotyped
The system comprises numerous biosafety features designed to produce a self-inactivating, replication defective lentivirus with a negligible risk of homologous recombination between the different plasmid elements. Risk of mobilisation is therefore negligible.

- A deletion in the 3' LTR (*U3) results in "self-inactivation" of the lentivirus after transduction of the target cell.
- The number of genes from HIV-1 that are used in the system has been reduced to three (gag, pol, and rev).
- The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 envelope.
- Genes encoding structural and other components required for packaging are separated onto four plasmids. All four plasmids have been engineered not to contain any regions of homology with each other to prevent recombination events.
- None of the packaging plasmids contain LTRs of the * packaging sequence. Thus, none of the HIV-1 structural genes are present in the packaged viral genome.
- The lentiviral particles produced in this system are replication-incompetent and only carry the gene of interest. No other viral species are produced.
- Expression of the gag and pol genes is prevented in the absence of Rev.
- A constitutive promoter (RSV promoter) has been placed upstream of the 5' LTR in the pLenti6/R4R2/V5-DEST vector to offset the requirement for Tat.

* replaces a symbol as symbols can't be shown

**Origin & function**

No protein is expected to be expressed in bacterial strains used for plasmid propagation. The marker gene products will be expressed in the transfected cells used for virus propagation and in the target cells. All of the protein coding gene sequences to be used in this study have previously been widely used in similar studies and none are considered to present a significant hazard to human health.

Renilla and firefly luciferases derived from commercially available pGL3 or pGL4 (firefly) or phRG orpRL vector families (Promega) encode reporter proteins which catalyse luminescent conversion of the substrates luciferin and coelenterazine.

Nitroreductase (NTR) is an E.Coli derived flavoprotein which catalyses the reduction of a variety of nitroaromatic small molecules such as the nontoxic substrate CB1954, which is converted to a toxic bifunctional alkylating agent in NTR expressing cells. NTR has been used by several laboratories for enzyme/pro-drug gene therapy applications and cell ablation studies and has been safely expressed in human tissues in clinical trials.

Fluorescent proteins such as GFP (green fluorescent protein), or related proteins CFP, RFP, and YFP are used widely as reporter proteins to mark cells in which transgene expression is induced by exposure of transfected cells to appropriate wavelengths of light.

The hTR and hTERT promoter sequences direct expression of the encoded transgenes exclusively in cells with telomerase activity such as cancer cells or some stem cells. Senescence associated gene promoters p16 and p21 are expected to limit transgene expression to cells undergoing senescence. Viral promoters such as SV40 or CMV will be used as positive controls and are expected to direct expression of the encoded transgenes in all cells

**Evaluation of foreseeable effects**

The final genetically modified cells will contain stably integrated DNA copies of the lentiviral vectors encoding the transgene expression cassettes. The cells will be free of lentivirus. As a result they will pose no hazard to human health or the environment, since they are unable to colonise humans or survive outside the laboratory culture. Nevertheless, it will be important to prevent human exposure or environmental release of the replication defective lentiviruses which are used to transiently effect gene transfer. The worse case scenario in case of infection is integration at a site that disrupts expression of a gene necessary for tumour suppression. Risk against this will be reduced through the use of appropriate physical containment and inactivation processes. Hazard containment II is therefore recommended and all work will be carried out in Class II biological safety cabinets.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
To minimise the risk to human health it will be essential to prevent exposure to retrovirus. Virus generation and infection of target cells will be carried out in Class II biological safety cabinets in the Class II containment laboratories, with access restricted to authorised staff. The amount of retrovirus or lentivirus handled will be limited to no more than 25ml of virus stock. The most likely routes through which individuals could be exposed to virus are needle-stick injuries or aerosols generated during experimental procedures. No needles or sharps will be used during virus preparation, whilst the use of Class II biological safety cabinet will guard against exposure to aerosol. In addition, cell cultures will be contained within clearly labelled boxes during incubation to prevent accidental spillage of medium. All viral supernatants and spent medium will be inactivated using Presept tablets (10,000 ppm chlorine) before removal from the Class II laboratories and autoclaved prior to final consignment of waste to approved contractor. Autoclaves will be validated by annual thermocouple mapping and each run is monitored using Thermalog-S indicator test strips. These processes will result in 100% inactivation of infectious virus.

Cells will be cultured using designated bottles of medium that will not be used to passage other cell cultures. Authorised staff will wear dedicated lab coats in the Class II laboratories that are not worn in the general laboratory area.

Positive clones will be expanded and checked for virus production before removal from the category II laboratory. Infected target cells will be cultured under the above regime until medium supernatants have been shown to be free of replication competent virus as judged by infection of appropriate indicator cells or assay of reverse transcriptase activity. Once these criteria are met the infected target cells will be removed from Class II containment and handled using standard tissue culture processes.

The proposal was reviewed and approved as Class II at the Safety Committee Meeting on the 13th May 2008.

</tr>
</tbody>
</table>
Replication deficient retroviral vectors (pLHCX) will be used to deliver tRNA genes to normal and cancer cell lines. This strategy will then be used to analyse the effects of overexpressing tRNA genes on cancer progression and metastasis. Commercially available recipient cell lines will host a helper cell aided retroviral vector (pLHCX) containing an insert with a putative cell proliferation capability.

Recipient or parental organism

Commercially available, authenticated cell lines which are widely used within the international research community and cannot survive outside laboratory culture such as, Telomerase- immortalised fibroblast, Mouse epithelial fibroblasts, Prostate (PC3) and Melanoma-epithelial (WM266.4) cell lines will be used. As a result they are not considered to pose any inherent risk to human health or the environment.

Host/vector system

Replication-incompetent retroviral particles will be produced by transfection of pLHCX (containing our gene of interest) into a commercially available amphotropic ‘Phoenix-ampho’ (helper) cell line.

pLHCX is a replication-incompetent retroviral vector (Clontech used to overexpress genes of interest. It allows transient and stable expression of the gene of interest in selected cell lines, and the production of retroviral particles in retroviral packaging cell lines. pLHCX does not contain the structural gene Gag, Pol and Env necessary for viral particle production. The introduced viral particles cannot therefore replicate within the recipient (e.g. PC3 or WM266.4) cell lines, as the particles do not contain the viral structural genes, gag, pol and env - which remain in the ‘Phoenix’ (helper) cells and prevents the production of replication-competent virus due to recombination events during cell proliferation. As a result they are not considered to pose any inherent risk to human health or the environment.

Origin & function

Overexpression of tRNA imet has been shown to increase cell proliferation in mouse cell lines (MEFs): Cell: 2008 Apr 4;133(1):78-89. This has not been demonstrated in human cell lines.

Evaluation of foreseeable effects

It is not anticipated that the inserted sequence will alter the host-range or tissue tropism of the virus.
Current knowledge indicates that the de-novo transformation process of human cells requires the perturbation of six-pathways (Rangarajan et al, Cancer Cell, 2004 (2):171-83) and therefore manipulation of individual pathways is not expected to confer a serious cancer risk to normal human cells. None of the genes we wish to manipulate encode toxins.

Hence, it is unlikely that replication defective retroviruses would be effective carcinogens in humans in the short term. Single oncogenes are not generally considered sufficient to convert primary human cells to full malignancy, and replication defective viruses are not capable of dissemination even in a permissive host, however there is potential for harm to human health in the event of infection. It will however, be important to prevent human exposure or environmental release of the replication defective retroviral particles which are used transiently to effect gene transfer. This will be achieved through the use of appropriate physical containment and inactivation processes.

The highly unlikely possibility of a recombination event occurring between the created recombinant viral particles with wild type virus needs to be considered and may cause pathological effects in humans. Careful attention will therefore, be placed on containment and control measures that minimise aerosol production and opportunity for recombination and complementation.

The final GM human cells will contain stably integrated DNA copies of the viral vectors encoding the transferred genes listed above. As a result they will pose no hazard to human health or the environment, since they are unable to colonise humans or survive outside of laboratory culture.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Project Additional Information

Purposes of the contained use

The aim of this project is to amplify wild-type and deletion mutant oncolytic adenovirus vectors already produced in the applicant’s previous lab; to evaluate their anti-tumour efficacy in in vitro and in vivo models of human malignancy, particularly ovarian cancer.

Adenovirus serotypes Ad5, Ad11 and Ad35 will be used as reference standards for work performed with Ad5 (mainly E1A) deletion mutants.
Replication competent and replication defective mutants will be constructed using the 'Ad-Easy' system to infect permissive human cell lines. These new mutants may encode transgenes that could induce tumour cell killing alone or enhance the anti-tumour properties of replication-competent deletion mutants. Evaluation of viral efficacy of mutants will be performed on Human and Murine cell lines by a variety of methods. Viral manufacture of replication defective vectors will be performed in HEK293 cell line to provide the E1 'in-trans'.

Concentration of adenoviral constructs from 750ml final cultures will be via Caesium Chloride centrifugation.

Recipient or parental organism

The recipient cell lines HEK293 or A549 will be used. Both are commercially available cell lines which require specific laboratory culture and as such pose negligible risk to humans. HEK 293 is rated Biosafety level 2 because of an E1 fragment of adenovirus embedded in it. It is this fragment that is essential to this series of experiments with E1 deletion adenoviral mutants. Cell line A549 is rated Biosafety level 1.

Host/vector system

One vector system will be oncolytic deletion mutants of Adenovirus. Replication of oncolytic deletion mutants of Adenovirus is attenuated in normal cells/tissue. Multiple mechanisms for this attenuation exist, depending upon the nature of the deletion. Publications attest to the selectivity of replication –between normal human cells compared to a panel of human malignant cells – see Heise et al Nature Med (2000) 6:1134. In addition, multiple phase I and II trials of oncolytic adenovirus have shown no replication in normal tissues.

Wild-type adenoviral vectors, used as reference standards, are replication competent and could infect humans. However, wild-type adenovirus infection in humans with an intact immune system leads to a mild and self-limiting 'flu-like illness.

Origin & function

Mammalian genes are to be inserted into the adenovirus genome and have been chosen to perform their intended function; either to increase tumour-specific killing by the virus (e.g. tumour suppressor or apoptosis-inducing genes), to inhibit the activity of oncogenic pathways or to increase the immunogenicity of infected tumour cells. Documentation exists to indicate that this can be achieved safely. No wild-type oncogenes or direct toxins will be inserted.

The virus will be applied to various established human and murine ovarian carcinoma cell lines; obtained from ATCC and other reputable sources and have consequently been screened for bloodborne viruses. In addition, the human cell lines have also all been previously STR verified and are known to be mycoplasma-free.

Evaluation of foreseeable effects

The deletions induced in adenovirus vectors are designed to narrow the host range, so that there is reduced replication and killing within normal cells, thus increasing the therapeutic index in ovarian cancer cells. Mechanisms to achieve this will include introduction of specific deletions to restrict replication and the use of tumour and tissue-specific promoters.

During process development for clinical grade manufacture of one of the mutants being used, no recombination between vector and HEK293 sequences was detected (limit of detection 1 in 109 genomes) – thus it is believed that the risk of reversion to wild-type virus following amplification in HEK293 cells is extremely low.

Replication-deficient viruses are incapable of replication in cells lacking adenovirus E1 function. Infection of normal human cells as well as malignant cells results in no infectious virion production.

The replication competent adenoviruses used will contain mutations within the viral genome that attenuates replication in normal cells and tissues. The deletions occur in regions of the viral genome that are necessary for replication in normal cells but are complemented by the altered gene expression in cancer cells. Mutants used can only replicate efficiently in cells with deregulated p53 and pRB pathways respectively.
The tumour selective mutants can infect normal cells but the ability to replicate is highly attenuated.

Wild-type adenoviral vectors are replication competent and could infect humans. Wild-type virus infection in humans with an intact immune system leads to a mild and self-limiting 'flu-like illness.

The normal route of adenovirus infection is via aerosol. The use of correctly trained and supervised staff, Class II biological safety cabinets, lab coats and gloves, disinfection and autoclaving of waste will reduce the likelihood of exposure to an extremely low level.

The virus will be applied to various established human and murine ovarian carcinoma cell lines. Because ovarian cancer cells do not contain any adenovirus genomic DNA, there is no risk of recombination of deletion mutants to generate wild-type revertant virus. Thus, generation of adenoviruses and infection of ovarian cancer cells is not considered to pose any inherent hazard to human health. The GM viruses do not have the capacity for survival outside of the laboratory. The recipient cells will therefore not have any foreseeable effect on human health.

E.coli strains are highly attenuated laboratory strains and do not present any hazards to humans.

Human adenoviruses do not replicate in murine tissue - this is true of wild-type, replication-restricted oncolytic viruses and replication-defective E1-deleted vectors.

The only replication following injection into in vivo tissue will be in malignant tumour tissue.

All injections of virus into vivo tissue will be undertaken in class II hoods within the specialist unit, thus minimising the risk of an aerosol-mediated infection during the injection process.

Multiple human studies demonstrate that virus shedding after intraperitoneal, intravenous or intratumoural injection is undetectable. Thus, the risk to humans from murine cell line tissue is negligible as the viruses are replication-deficient or tumour specific and the gene products are not considered harmful to health.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Full containment level 2 will be used, as set out in the Regulations, including appropriate treatments for bulk, contaminated solid waste.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Full containment level 2 will be used, as set out in the Regulations; i.e. Virus generation and infection of target cells will be carried out in Class II biological safety cabinets in the Containment Level II laboratories, with access restricted to authorised staff. Including appropriate treatments for bulk, contaminated solid waste.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All viral supernatants and spent medium will be inactivated using 10,000 ppm free chlorine before removal from the Containment Level II laboratories for final disposal. This process will result in 100% inactivation of infectious virus.

Solid waste will be bagged in biohazard bags prior to removal from the Containment level II lab and then placed in boxes which are sealed prior to removal from the CL2 suites. Boxes remain sealed and are autoclaved before the contents is removed for collection by accredited waste contractors. Autoclaves produce a digital record of load temperature achieved and are validated by annual thermocouple mapping. This process will result in 100% inactivation of infectious virus.

**Project Additional Information**
Purposes of the contained use

To generate cell lines which have had specific genes "knocked out" using LentiCRISPR / CAS9 technology (Clustered Regularly Interspaced Short Palindrome Repeats), by using specific unique guide sequences obtained from the Genome - scale CRISPR Knock - Out (GeCKO) library; which targets 18,080 genes using 64,751 of these guide sequences.

The need for contained use stems from the use of a lentiviral based delivery system of the components which remove target genes. Target genes include those involved in actin binding and regulation, apoptosis, autophagy and lipid metabolism. It is possible, but not an immediate priority that P53 and P53-like genes may be targeted.

The lentiviral based system designed to deliver CAS9 and target guide RNA to recipient cells. The lentiviral vector is LentiCRISPR (Shalem et al Science 343, 84-87 (2014)) and contains a safety modified WPRE component (has been truncated in such a way as to remove the promoter region and any open reading frame for the X protein). The LentiCRISPR used here is based on an pLKO vector backbone. This will be transfected into 293T cells along with PSPAX2 and VSVG packaging vectors to produce lentiviral particles. The guide sequences that will be cloned into LentiCRISPR will target murine and/or human cell lines.

Host/vector system

The "LentiCRISPR" vector systems utilise a replication-incompetent lentiviral vector chosen for expression of CAS9 and guide RNAs (Genome-Scale CRISPR-Cas9 Knockout Screening in Human Cells Shalem et al, Science 343, 84-87 2014). Different versions exist employing different lentiviral backbones.

This lentiviral system allows for the production of viral particles using lentiviral packaging cell lines and includes a number of safety features designed to enhance its biosafety and to minimize its relation to the wild-type, human HIV-1 virus. In doing so, this system, like may others, prevents the generation of recombinant viral particles that possess the required functional Gag-Pol structure for DNA mobilization and the emergence of replication competent lentivirus.

LentiCRISPR contains 2 antibiotic resistance markers, ampicillin as bacterial selection marker and puromycin for mammalian cells.

Although the packaging and envelope plasmids psPAX2 and pVSVG allow expression in trans of genes required to produce (lenti)viral progeny (e.g. gag, pol, rev, tat, env) in the TLA-HEK293T producer cell line, none of them contain LTRs or the Ψ packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell.

The replication-defective viruses are extremely labile and only infective when produced in the appropriate packaging cell line together with the required packaging vectors.

As noted in section 6 (above) the WPRE component has been modified to remove effects from "X protein".

Origin & function

Parental organisms (cell lines) are losing targeted genetic material through these procedures. The targeting of genes (of interest) is accomplished using a technique employing a Genome - scale CRISPR Knock - Out (GeCKO) library which targets 18,080 genes using 64,751 unique guide (RNA) sequences.

The genes removed relate to metabolic pathways associated with cancer (Actin binding and regulation, Apoptosis, Autophagy and lipid metabolism) and could not be foreseen to increase risk. Tumour suppressors such as P53 or P53-like genes (repressors of oncogenic behaviour) may cause oncogenic behaviour limited to the cell lines which are treated.
Evaluation of foreseeable effects

The removal of the genes of interest are not foreseen to increase the risk of an unfavourable event. Removing P53 or P53-like genes (repressors of oncogenic behaviour) may cause oncogenic behaviour in the cell lines which are treated but that will be limited to those cell lines alone.

Hazards arising directly from the inserted gene product:
Guide RNAs will be expressed, and in conjunction with CAS9 will result in deletion of the target genes listed. These target genes have been proposed to play a role in cancer metabolism. Based on current knowledge, deletion of any of these genes is not expected to impart significant hazard.

Hazards arising from the alteration of existing pathogenic traits (e.g. alteration of host range or tissue tropism):
It is not expected that the inserted guide sequences would alter either the host-range or target tropism of the virus.

The possibility of potentially hazardous sequences within the GMM being transferred to related micro-organisms is considered extremely low and would require additional viruses to be present. Both virus-producing and recipient cells are certified virusfree from the supplier.

The genetically modified cells will contain stably integrated DNA copies of the lentiviral vectors encoding the inserts. These cells will not produce lentivirus. Consequently, the cells pose no hazard to human health, since they cannot grow outside of a laboratory environment.

The possibility of plasmid inserts recombining with native lentiviruses could theoretically lead to widespread infection. However, this remains a remote possibility, and even if it were to occur, would be expected to have no detrimental effects due to the nature of the proteins encoded by these inserts, as described above.

To minimise the risk to human health it will be essential to prevent exposure to lentivirus. Careful attention will be placed on containment and control measures that minimise aerosol production and opportunity for recombination and complementation.

Accidental injection, inhalation or ingestion of genetically modified (GM) cells such as these is not considered (in the wider GM community) to pose a threat of actual harm.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virus generation and infection of target cells will be carried out in Class II biological safety cabinets in the Containment Level II suite, with access restricted to authorized and trained staff.

The amount of virus-containing medium handled will be limited to no more than 25ml.

The most likely routes through which individuals could be exposed to virus are needle-stick injures or aerosols generated during experimental procedures. Plastic ware will be used throughout and no needles or sharps will be used during virus preparation.

The use of the Class II biological safety cabinet will guard against exposure to aerosols.

All cell cultures will be contained within clearly labelled boxes during incubation to prevent accidental spillage of medium. All viral supernatants and spent medium will be inactivated using Presept tablets (10,000 ppm free chlorine) before removal from the Containment Level II suite for final disposal.

Page 1335 of 15326
**Project Additional Information**

**Purposes of the contained use**

The purpose of the project is to evaluate the anti-tumour efficacy of oncolytic adenovirus and oncolytic Herpes Simplex Virus, in in-vivo models of human malignancy, particularly ovarian cancer. This will be achieved using Wild-type Ad5, Ad11, Ad35 adenoviral vectors as well as a number of Ad5 deletion mutants. Herpes Simplex Virus vectors are based upon HSV-1 single gene “vector 1716” mutants (neuro-virulence gene ICP34.5) as well as derivatives of this single mutant encoding fluorescent markers. Double deletion mutants (e.g. ICP34.5 and ICP47), with increased selectivity for malignant cells may also be evaluated. Novel derivatives of the adenovirus and HSV vectors (encoding transgenes that could induce tumour cell mortality alone or enhance the anti-tumour properties of replication-competent deletion mutants) will be evaluated.

In some viral treatments, tumour and tissue specific promoters (e.g. CEA, PSA) may be used to drive virus replication (via transcriptional control of E1A transcription) or to drive transgene expression.

**Recipient or parental organism**

Viruses are to be evaluated in various human and murine established carcinoma cell lines growing within subjects (either immunodeficient for human cell lines, or immunocompetent for murine cell lines). These cell lines have been obtained from reputable sources and have consequently been screened for HIV, HepB, HepC and EBV.

Because these tumour cells do not contain any adenovirus or HSV genomic DNA, there is no risk of recombination of deletion mutants to generate wild-type revertant virus. ICP34.5-deleted HSV vectors have been injected into over 200 human patients with advanced malignancy - there are no records of any wild-type reversion in any patient. The recipient cells are not therefore, considered to pose any inherent hazard or foreseeable effect to human health.

**Host/vector system**

Replication of oncolytic deletion mutants is attenuated in normal cells/tissue, depending upon the nature of the deletion and the nature of the vector. Multiple publications from the proposer's lab and others attest to the selectivity of replication – see Heise et al Nature Med (2000) 6:1134. In addition, multiple phase I and II trials of oncolytic adenovirus as well as E1-deleted non-replicating vectors have shown no replication in normal tissues.

Wild-type adenoviral vectors are replication competent and could infect humans. However, wild-type adenovirus infection in humans with an intact immune system leads to a mild and self-limiting 'flu-like' illness.

ICP34.5-deleted HSV is dramatically attenuated in normal non-malignant tissue including neuronal cells, both murine and human. Direct intra-cranial inoculation of 1716 has been demonstrated to be safe in subjects. No wild-type HSV-1 will be used in any experiment.

**Origin & function**

Genes that will be inserted into the adenovirus or HSV genome are designed either to increase tumour-specific mortality by the virus (e.g. tumour suppressor or apoptosis-inducing genes), to inhibit the activity of oncogenic pathways or to increase the immunogenicity of infected tumour cells. There are multiple examples in the
literature where this can be achieved safely. No wild-type oncogenes or direct toxins will be included.

The deletions induced in adenovirus and HSV vectors are designed to narrow the host range, so that there is reduced replication and mortality within normal cells, thus increasing the therapeutic index in ovarian cancer cells. Mechanisms to achieve this will include introduction of specific deletions to restrict replication and the use of tumour and tissue-specific promoters.

During process development for clinical grade manufacture of one of the mutants, no recombination between vector and HEK293 sequences was detected (limit of detection 1 in 109 genomes) – thus it is believed that the risk of reversion to wild-type virus following amplification in HEK293 cells is extremely low. For HSV, there is no evidence from any previous pre-clinical or clinical study that HSV vector 1716 can transfer genetic material to other organisms.

**Evaluation of foreseeable effects**

Replication competent adenoviruses contain mutations within the viral genome that attenuates replication in normal cells and tissues. The deletions occur in regions of the viral genome that are necessary for replication in normal cells but are complemented by the altered gene expression in cancer cells. These mutants can only replicate efficiently in cells with deregulated p53 and pRB pathways. Tumour selective mutants can infect normal cells but the ability to replicate is highly attenuated. Human adenoviruses do not replicate in murine tissue - this is true of wild-type, replication-restricted oncolytic viruses as well as replication-defective E1-deleted vectors. The only replication following injection into tumour-bearing subjects will be in malignant tissue. The normal route of adenovirus infection is via aerosol. 1716 and other ICP34.5-deleted HSV vectors have been administered to over 200 patients with cancer with no significant toxicity. All vectors proposed contain an intact thymidine kinase gene, and thus HSV-infected cells are sensitive to treatment with the anti-viral drugs aciclovir and ganciclovir. All injections of virus will be undertaken in class II hoods within the unit, thus minimising the risk of aerosol-mediated infection during the injection process. Multiple human studies demonstrate that virus shedding after intraperitoneal, intravenous or intratumoural injection is undetectable. Thus, the risk to humans from subjects is negligible as the viruses are replication-deficient or tumour specific and the gene products are not considered harmful to health. In addition, laboratory standard operating procedure in relation to biological agent handling and waste management are such that the likelihood of exposure to a biological agent is reduced to an extremely low level. The risk to human health is low.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Considered and accepted by GMSC

02/03/2022
The aim of this project is to test the differential effect of certain proteins on cell survival, growth and metabolism in relation to the p53 status of cell lines. This will be done by altering the cells using engineered replication-defective lentiviruses that express proteins that are important in the pathways underlying mutant p53 ‘gain-of-function’ in tumours; such as amino acid transporters (such as Slc7a11, Slc3a2), enzymes involved in amino acid metabolism (such as PRODH), and enzymes involved in regulation of bioenergetic pathways.
Recipient or parental organism

The cell line to be used in the first instance will be: MDA-MB-231 a Human breast tumour cell line. MDA-MB-231 is not considered to pose any inherent hazard to human health, nor does the line have the capacity to survive outside the laboratory. The cells will therefore not exert any foreseeable effects on either human health or the environment.

The other cell lines which may be used are of a similar biosafety risk (1) and include:

- Human breast tumour cell lines (MCF-7, MCF10A), Human colon tumour cell lines (HCT116, HT29, SW480, RKO), human ovarian cancer cell lines (A431, PEO1, PEO4, OVCAR3, OVCAR4, CAOV3, COV318), RPE-normal retinal pigment epithelial cells immortalized with h-TERT, Osteosarcoma cell lines (U-2 OS, Saos-2), and a non-small cell lung carcinoma (H1299). All of these cell lines are incapable of producing the replication defective virus used as the vector.

Host/vector system

The ViraPower Lentiviral Expression System (Invitrogen) used is a third generation vector system based upon a HIV-1 lentivirus. It uses a pLenti expression vector that contains many features which prevent the possibility of new replication-competent virus being produced. This includes a non-homologous four plasmid system that allow expression in 'trans' of proteins required to produce viral progeny (e.g. gal, pol, rev, and env) in the 293FT producer cell line. None of the plasmids contain LTRs or the \( \Psi \) packaging sequence, which means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell.

The virus produced uses VSV-G envelope protein rather than that of HIV-1. A deletion in 3’ LTR results in “self-inactivation” of the lentivirus after transduction of the target cells. As a result, once integrated, the lentiviral genome is no longer capable of producing a packageable viral genome.

Origin & function

No protein is expected to be expressed in bacterial strains used for plasmid propagation. The proteins will be expressed in the transfected cells used for virus propagation and in the target cells. Sequences encoding fluorescent proteins (such as enhanced Green Fluorescent Protein (eGFP) and mCherry) may also be inserted. They will function purely as reporter molecules, fluorescing upon exposure to UV light. Human proteins: No known hazard has arisen from expression of the cDNA’s of the tumour suppressor protein p53, the point mutants of p53, the metabolic
genes identified as potential targets of p53 and its mutants [including amino acid transporters (such as Slc7a11, Slc3a2)], enzymes involved in amino acid metabolism (such as PRODH) and enzymes involved in regulation of bioenergetic pathways.

Mutant p53 proteins have been shown to contribute to transformation and should be treated as being as oncogenic as myc and activated Ras proteins. These proteins have been widely studied in a similar capacity (e.g. overexpression by transient or stable transfection) by our lab and others without any reportable hazard. However, to maintain safe working practices, these experiments will be carried out under Containment Level II conditions with appropriate precautions.

**Evaluation of foreseeable effects**

Correct use of the replication defective lentiviral vectors carrying the inserts described above is unlikely to be hazardous to human health. The possibility of widespread infection is very small due to the requirement for 'helper' sequences. There is a minor risk that the virus may integrate at a locus which could be detrimental to health or that the virus could recombine to generate an agent that could cause pathological effects in humans. Careful attention will, therefore, be placed on containment and control measures that minimise aerosol production and opportunity for recombination and complementation. Level 2 containment will be implemented using biological safety cabinets and appropriate procedures.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

To minimise the risk to human health it will be essential to prevent exposure to lentivirus. Virus generation and infection of target cells will be carried out in Class II biological safety cabinets in the Containment Level II tissue culture laboratory, with access restricted to authorised staff. The amount of lentivirus handled will be limited to no more than 25ml of virus stock. The most likely routes through which individuals could be exposed to virus are needle-stick injures or aerosols generated during experimental procedures. Plastic pipettes will be used throughout and no needles or sharps will be used during virus preparation, whilst the use of the Class II biological safety cabinet will guard against exposure to aerosols. In addition, cell cultures will be contained within clearly labelled boxes during incubation to prevent accidental spillage of medium. All viral supernatants and spent medium will be inactivated using Presept tablets (10,000 ppm chlorine) before removal from the Containment Level II laboratory for final disposal. Solid waste will be double bagged in biohazard bags prior to removal from the Containment Level II laboratory and then autoclaved before final consignment of waste to approved contractor. Autoclaves will be validated by annual thermocouple mapping and each run is monitored using Thermalog-S indicator test strips. These processes will result in 100% inactivation of infectious
virus. Cells will be cultured using designated bottles of medium that will not be used to passage other cell cultures. Infected target cells will be cultured under the above regime until medium supernatants have been shown to be free of replication competent virus as judged by infection of appropriate indicator cells and assays of reverse transcriptase activity. Once these criteria have been met the infected target cells will be removed from Containment Level II tissue culture and handled using standard tissue culture procedures. Authorised staff will wear dedicated lab coats in the Containment Level II laboratory that are not worn in the general laboratory area.

Project Ref 25/16.1

Date Ackn'd 06/09/2016

Date Project Ceased

CU2 Project Title Lentivirus mediated overexpression of oncogenes in mouse or human cells to study proteins involved in cell signalling, tumorigenesis, invasion, metastasis, cell death and survival.

Class 2

CultureVolClass2 < 1 Litre

CultureVolumeClass3-4

Consent Granted

Project notified under transitional arrangements N
Replication deficient lentiviral vectors will be used to over express oncogenic moieties such as small GTPases of the RAS superfamily, their regulators, and their interacting and co-operating proteins, and may therefore produce a potentially more hazardous product. Members of the RAS example are known oncogenes and interfering with RAS signalling may offer a potential therapeutic strategy in colorectal cancer.
This over expression will be used to study the survival, apoptosis and invasion of infected cells with the intention of mapping these moieties in these cells.
Viral supernatant may be made in the laboratory or may be purchased as pre made viral supernatants such as those supplied by Genetarget Inc. San Diego. CA

Recipient or parental organism

The lentiviral packaging cells will be HEK293 and derived subtypes which will be used for the initial rescue of the virus from transfected DNA and for general virus propagation and will also express the transfected protein of interest.
Recipient of parental organism

The mouse and human tissue culture cell lines to be used will be well characterised and authenticated cell lines, sourced from reputable suppliers and will pose no inherent risks themselves or risks from adventitious agents.
Human cell lines such as Hela, U20S, MDA-MB 231, MDA-MB 453, HCT116, LNCAP, PC3, MCF-10A, DU145, Calu-3 and the [ATCC CRL-11609] strain of (HPV18- free) RWPE-1.
Mouse cell lines such as 3T3 SA, NIH 3T3, C2C12.
In addition mouse primary cells will be used which will pose no inherent risks themselves or risks from adventitious agents. The cells will therefore not present a hazard to human health.

Host/vector system

Host bacteria for growth of the plasmids are standard disabled laboratory strains of E. Coli such as DH5a, JM109 or Stbl3.
Third generation lentiviral vector systems such as those available from Genetarget Inc will predominantly be used. These contain a reporter gene (GFP or RFP) linked to a target, proprietary CMV promotor (suCMV) and an optional tetracycline inducible CMV promotor. Other third generation lentiviral vector systems to be used include the ViraPower™ Lentiviral Expression System (Invitrogen) which is based on the lentikit™ system developed by Cell Genesys (Dull et al., 1998 J Virol. 1998 Nov. 72(11):8463-71).

A number of features are embedded within these vectors to enhance their biosafety:

• All pathogenic genes have been removed from the wild type HIV-1 genome
• The HIV-1 envelope has been completely removed and replaced (pseudotyped) with the VSV-G gene from Vesicular Stomatitis Virus.
• The packaging genes have been separated from the transfer vector so that the packaged viral genome does not contain any packaging components.
• Sequence homology between the packaging plasmid and transfer plasmid has been reduced to the maximum extent possible to further minimize the risk of plasmid recombination during co-transfection. As a result, packaging genes of these “third generation” lentiviral vectors are non-functional outside of the virus- producing cells.
• A self-inactivating (SIN) transfer vector has been created with a deletion in the 3′-LTR region to ensure it produces only replication-incompetent virus. (Zufferey, R., et al., Self-inactivating lentivirus vector for safe and efficient in vivo gene delivery. J Virol. 72, 9873-80 (1998).)

In some instances it may be necessary to use plKO.1 derivatives vector systems; e.g. pLex and pLix. These systems include similar safety features designed to enhance its biosafety and to minimize its relation to the wild-type, human HIV-1 virus.

• The reverse transcriptase (RT) and integrase (IN) proteins are split from the native Gag-Pol polyprotein and are provided ‘in trans’ on separate plasmids.
Removing the RT & IN components from the packaging construct prevents the lentiviral replication machinery from functioning, thereby rendering these plasmids as inherently replication-deficient. This system prevents the generation of recombinant viral particles that possess the required functional Gag-Pol constructs for DNA mobilisation and the emergence of replicationcompetent lentiviral particles.

• The packaging and envelope plasmids, psPAX2 and pVSV-G, allow expression in trans of genes required to produce viral progeny (e.g. gag, pol, rev, tat, env) in the ‘packaging cells’ (293-FT), none of these contain LTRs or the Ψ packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced cells.
• The parental pLKO plasmid contains the ampicillin-resistance gene for bacterial selection, and the puromycin-resistance gene replaced by alternate mammalian selection markers, e.g. Zeocin, Neomycin, Hygromycin B, or mammalian selection markers, e.g. Zeocin, Neomycin, Hygromycin B, or Blasticidin.
• Other derivatives replace the puromycin gene with a membrane- or nucleus-targeted fluorescent protein.
• Note that these are changes that only affect the selection method in mammalian cells and do not affect any other structural feature of the viral particles, and as such do not exert any foreseeable effects on human health or the environment.
• Details of the parental plasmids:
  o pLEX_301, 302, 303, 304, 305, 306, 307,
  o pLIX_401, 402,
  o pLKO.1 can be found on the Addgene website.

Expression of genes, such as those involved in RAS signalling, are associated with cancer progression and growth, promoting cell survival, growth, and the invasive behaviour of tumour cells. It may prove harmful if such genes were inserted into normal human cells via accidental injury or inhalation.
However, current knowledge indicates that the de-novo transformation process of human cells requires the perturbation of six-pathways (Rangarajan et al, Cancer Cell, 2004 (2):171-83) and therefore manipulation of individual pathways is not expected to confer a serious cancer risk to normal human cells.
Similarly individual expression of activated oncogenes alone results in cellular senescence and / or apoptosis (Wajapeyee et al, Cell 2008 132(3):363-74).

Origin & function

Evaluation of foreseeable effects

Because of the physical segregation of components in 3rd or 4th generation lentiviral constructs, the likelihood of disease propagation beyond the culture dish is very low / negligible. However, lentiviral particles with a VSV-G envelope constitute a minor risk as they are able to infect human cells.
Exposure to most human cells from lentivirus particles is unlikely to cause infection. The likely routes of infection are through aerosol formation and needle sticks where the protective barriers of the body are bypassed.
Therefore there is a small risk to the experimenter of exposure to viral particles, during lentiviral particle delivery phase, via those two routes:
1) Inhalation of aerosol and
2) Inadvertent or accidental needle-stick injury.
There is negligible risk of aerosol inhalation as the amounts of lentiviral particle-containing solutions used during the experiment are tiny and no
In aerosol-producing manipulations (e.g. centrifugation) will be used without suitable containment.

Infection via inhalation or injection of virus would be limited to mucosal cells or cells at the site of injection. (In vivo experiments have shown (Lerchner et al. Gene Therapy (2014) 21 233-241) diffusion of infectious particles no more than millimetres from the injection site. No sharps will be used in the Containment Level II suite.

Assuming a worst case scenario: Even if the infected worker had a preexisting HIV infection, the chances of recombination are extremely small due to the design of the vector.

There is no available evidence for transfer of infectious viral particles to other vulnerable cells via the bloodstream or lymphatic system - except in cases where the intention was to transduce cells of the immune system in the bloodstream / bone marrow.

Viral particles that do not infect cells are estimated to become inactive within hours and no viable virus should remain after 48-72 hours.

It is not anticipated that the inserted sequences will alter the host-range or tissue tropism of the virus.

The probability of harmful sequences being transferred to related viruses is extremely low and would require suitable adventitious agents to be present in the cells being handled. The cells to be used should not pose any inherent risk from adventitious agents.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

To minimize the risk to human health the following safety precautions would be taken.

1. Prevent exposure to lentivirus. Careful attention will be placed on containment and control measures that minimise aerosol production and opportunity for recombination and complementation. Virus infection of target cells will be carried out in Class II biological safety cabinets in the Containment Level II laboratories, with access restricted to authorised staff.

2. Minimize volumes of virus handled. The amount of lentivirus handled will be limited to no more than 25ml of virus stock, and aliquots will be clearly marked.

3. Prevent infection routes. The most likely routes through which individuals could be exposed to virus are needle-stick injuries or aerosols generated during experimental procedures. Plastic ware will be used throughout and no needles or sharps will be used during the procedure, whilst the use of the Class II biological safety cabinet will guard against exposure to aerosols. In addition, cell cultures will be contained within clearly labelled boxes during incubation to prevent accidental spillage of medium.

4. Proper handling of waste.

All viral supernatants and spent medium will be inactivated using Presept tablets (10,000 ppm free...
chlorine) before removal from the Containment Level II laboratories for final disposal. Solid waste will be double bagged in biohazard bags prior to removal from the Containment Level II laboratory and then autoclaved, before final consignment of waste to approved contractor. Autoclaves will be validated by annual thermocouple mapping and each run is monitored using Thermalog-S indicator test strips. These processes will result in 100% inactivation of infectious virus.

5. Usage of designated safety equipment. Cells will be cultured using designated bottles of medium that will not be used to passage other cell cultures. Authorised staff will wear dedicated lab coats in the Containment Level II laboratories that are not worn in the general laboratory area.

6. Follow up on the infected cells. Infected target cells will be cultured under the above regime until medium supernatants have been shown to be free of replication competent virus as judged by infection of appropriate indicator cells and assays of reverse transcriptase activity. Only once these criteria have been met and it has been cleared by the BSO will the infected target cells be permitted to be removed from the Containment Level II laboratory and handled using standard tissue culture procedures.

The purpose of these experiments is to allow us to efficiently and specifically over-express R-spondin 1 in a temporal manner, to investigate the mechanisms of intestinal function in homeostasis and in preclinical cancer models.

Recipient or parental organism

C57Bl6 and mixed background subjects that may be genetically modified are to be used.

Host/vector system

Adeno-associated virus (AAV) vectors using a CMV IE promoter and dimeric hRSP1-hFc fusion will be obtained from overseas collaborators. The virus will be ready to use when arriving at the Institute. The AAV vectors are based on AAV viruses. Our collaborators have experience of using this virus and similar experiments have previously been published (Yan et al., Nature 2017. Non-equivalence of Wnt and R-spondin ligands during Lgr5+ intestinal stemcell self-renewal).

The vector can infect human cells (AAV9 is associated with infection in the intestine as well as CNS, heart, liver, lung and skeletal muscle) but it cannot replicate in them, and it cannot be mobilised. The vectors are regarded as non-pathogenic in humans and not currently known to cause any diseases in humans or animals. The vector capsid can induce a mild localized inflammatory response in humans (Mingozzi et al. Blood 2013).

Origin & function

RSPO-1 is known to modulate Wnt signalling.

The replication defective adenovirus expressing RSPO1 or a control vector
will be used for infection. RSPO-1 is documented as having an ambiguous role as either a mitogen or tumour suppressor. De Cain et al, Oncogene 2017. The purpose of these experiments is to allow us to efficiently and specifically over-express Rspondin 1 in a temporal manner. The AAV vectors contain recombinant transgene sequences flanked by the AAV inverted terminal repeats (ITRs). In dividing cells, AAV DNA is lost through cell division, since the episomal DNA is not replicated along with the host cell DNA this makes it highly unlikely that the AAV could infect a neighbouring cells. The probability of sequences being transferred to other related or unrelated species is extremely low since the virus is replication deficient. It is not anticipated that the inserted sequence will alter the host-range or tissue tropism of the virus. The possibility of transmission of the virus is extremely low since the virus is replication deficient.transfer genetic material to other organisms.

**Evaluation of foreseeable effects**

In the event of exposure it is extremely unlikely that this virus could cause harm to human health. The integration rate of AAV vectors is extremely low if it occurs at all. The risk of human exposure is low, and all appropriate care will be taken to prevent needle stick injury at the time of injection. The method of delivery through intraperitoneal injection as opposed to intravenous injection has been chosen specifically to minimise the risk of needle-stick injury. The protein produced as a result of infection will be an R-Spondin1 protein fused to an Fc domain. It has been widely reported that role of the R-spondin proteins is to potentiate Wnt-signalling in a Wnt-ligand dependent manner, which results in expansion of the Lgr5+ stem cell pool. We (and others) have demonstrated that this expansion of the stem cell pool is a tumour suppressive mechanism in vivo (Huels et al, Nature Communications, 2017; Vermeulen et al, Science, 2013).

Gene fusion events incorporating the RSPO2 or RSPO3 gene loci are found in a proportion of colorectal cancers (Seshagiri et al, Nature, 2012) where it has been postulated that they may potentiate Wnt-signalling in an APC independent fashion. Critically, these fusion proteins are not seen to exist in isolation, and are found associated with strong oncogenic driver mutations such as BRAF or KRAS and are Wnt-ligand dependent. Indeed it has been reported that the RSPO1-Lgr5 signalling axis suppresses tumour progression in colorectal cancer (Zhou et al, Cancer Research 2017). In the unlikely event of user exposure, and of a proliferative response driven by the fusion protein, the use of a non-incorporating AAV delivery system will result in the event being self-limiting.

Project Containment

Project Ref 383/09.1

Date Ackn'd 05/07/2012

Date Project 02/03/2022
Replication-deficient lentiviral vectors (pFG12 vector) will be used to deliver the activated oncogenes RasV12 and BRAFV600E to primary human cell lines to induce senescence. This strategy will be used to further analyze the senescence pathway.

A replication-deficient retroviral vector (pBABE-puro) will also be used to deliver the activated oncogene RasV12 to the human fibroblast cell line IMR-90 (ATCC Number CCL-186) in order to induce senescence. This strategy will be utilized in order to investigate mechanisms of the senescence pathway.

The GMM will be transfected into 293FT cells in order to produce virus and the virus will then be applied to primary human cell lines, such as fibroblasts, melanocytes and keratinocytes, which are widely employed in laboratories and have all been screened for HIV, Hep B, Hep C and EBV. There is no risk from the cells infected. Cells are typically obtained from ATCC.

The GMM (pBABE-puroRasV12) will be transiently transfected into Phoenix cells, a 293T-derived packaging cell line that contains the Gag, Pol and Env viral proteins required for making active virus. Subsequently, viral supernatants produced by Phoenix cells will be used to infect human fibroblasts (IMR-90). Both the Phoenix packaging cell line and IMR-90 fibroblasts are used in extensively in laboratories and have been screened and found to be negative for HIV, Hep B, Hep C and EBV. There is no risk from the infected cells. Cells are obtained from ATCC and have been rigorously characterized.

The ViraPower Lentiviral Expression System (Invitrogen) uses a pLenti expression vector that contains a deletion in the 3’ LTR that results in “self-inactivation” of the lentivirus after transduction of the target cells. When integrated into the target cell the lentiviral genome is therefore no longer capable of producing packagable viral genome. This third generation vector system is based upon a HIV-1 lentivirus, although it is lacking all HIV-1 genes except gag-pol and env, which are provided in trans by a transient transfection strategy. Also, the virus produced is to be pseudotyped with VSV-G envelope protein rather than HIV-1. The vector requires three other packaging plasmids that allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293FT producer cell line. These packaging plasmids separately allow for the expression of gag and pol, a RRE-containing sequence, and the rev protein sequences from HIV-1. None of the packaging plasmids contain LTRs or the Ψ packaging sequence, and therefore, none of the HIV-1 structural genes are actually present in the packaged viral genome so they are never expressed in the transduced target cell. No new replication-competent virus can be produced. (Dull, et al., J. Virology, 8463-8471, 1998).

The pBABE vector system is a retroviral vector construct that has been derived from Moloney murine leukemia virus (MMLV). As with lentiviral constructs, the pBABE retroviral vector also requires three additional packaging plasmids that drive expression in trans of proteins required to produce viral progeny (i.e. gag, pol, rev and env) upon transfection into a producer cell line (Phoenix). The pBABEpuro vector has been designed to avoid homology between the vector and packaging constructs, in order
To decrease the change of homologous recombination in the Phoenix packaging cells.

Origin & function

The Ras and BRAF genes belong to the MAP kinase pathway, which mediates cellular responses to growth signals. When constitutively activated through mutation (RasV12 and BRAFV600E) senescence is conferred through the upregulation of the tumor suppressors p53 and p16INK4a. Activating BRAF mutations are present in up to 80% of melanomas while mutations in the ras gene are very common in adenocarcinomas of the pancreas (90%), the colon (50%), and in myeloid leukemia (30%). Although these gene products are very common in human cancers, additional mutations are required to drive a malignancy. Also, the hazards of the activated oncogene are very minimal due to the inability of the 293FT and Phoenix cells to create a replication-competent virus. In addition to the inserted oncogenes, the carrier plasmid (FG12) contains the woodchuck hepatitis virus posttranscriptional regulatory element (WRE) to increase the level of transcription. Although controversial, WRE may have oncogenic activity but should not pose a hazard due to the safety precautions that are already built in for the activated oncogenes.

Evaluation of foreseeable effects

It is not anticipated that the inserted sequences will alter the host-range or tissue tropism of the virus. Some of the genes we wish to express will oncogenic proteins. Current knowledge indicates that the de-novo transformation process of human cells requires the perturbation of six-pathways (Rangarajan et al, Cancer Cell, 2004 (2):171-83) and therefore manipulation of individual pathways is not expected to confer a serious cancer risk to normal human cells. None of the genes we wish to manipulate encode toxins.

Hence, it is unlikely that replication defective viruses would be effective carcinogens in humans in the short term. Single oncogenes are not generally considered sufficient to convert primary human cells to full malignancy, and replication defective viruses are not capable of dissemination even in a permissive host, however there is potential for harm to human health in the event of infection. It will however, be important to prevent human exposure or environmental release of the replication defective adenoviruses which are used to transiently effect gene transfer. This will be achieved through the use of appropriate physical containment and inactivation processes.

The possibility of exposure to recombinant viruses generated by recombination with wild type virus needs to be considered and may, although unlikely, cause pathological effects in humans. Careful attention will, therefore, be placed on containment and control measures that minimise aerosol production and opportunity for recombination and complementation.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

To minimise the risk to human health it will be essential to prevent exposure to virus. Virus generation and infection of target cells will be carried out in Class II biological safety cabinets in the Containment Level 2 laboratories, with access restricted to authorised staff. The amount of virus handled will be limited to no more than 40ml of virus stock. The most likely routes through which individuals could be exposed to virus are needle-stick injuries or aerosols generated during experimental procedures. No needles or sharps will be used during virus preparation, whilst the use of the Class II biological safety cabinet will guard against exposure to aerosol. In addition, cell cutures will be contained within clearly labelled boxes during incubation to prevent accidental spillage of medium. All viral supernatants and spent medium will be inactivated using Presept tablets (10,000 ppm chlorine) before removal from the Class II laboratories for final disposal. Solid waste will be double-bagged in biohazard bags prior to removal from the Class II laboratories and autoclaved prior to final consignment of waste to approved contractor. Autoclaves will be validated by annual thermocouple mapping and each run is monitored using Thermalog-S indicator test strips. These processes will result in 100% inactivation of infectious virus.

Cells will be cultured using designated bottles of medium that will not be used to passage other cell cultures. Authorised staff will wear dedicated lab coats in the Class II laboratories that are not worn in the general laboratory area.
The project was approved as Class II by the Safety Committee in December 2008

Project Additional Information

Purposes of the contained use

Retroviral vectors will be used to produce retrovirus in order to generate a variety of human and murine, normal and cancer cell lines stably expressing the below proteins. These will be used to study apoptosis, autophagy and mitochondria in relation to cancer development and treatment response.

Recipient or parental organism

Producer cells: Phoenix Ecotropic and Phoenix Amphotropic packaging cells These were obtained from Dr. Gary Nolan, University of Stanford and are extensively used for retroviral generation.

Target cells: Hela, MCF-7, SVEC 4-10, NIH3T3, L929, NIH SA, SV40 transformed murine embryonic fibroblasts, U2OS, HT90, Caco-2, Jurkat. These cell lines are widely used by research laboratories, are well characterized, and have been obtained from either ECACC or ATCC and subsequently been screened for human pathogens including HIV, HBV, HCV and EBV. They do not harbour adventitious agents. They are not considered to pose any inherent hazard to human health nor do they have the capability to survive outside the culturing environment of the laboratory.

Host/vector system

Retroviral vectors: pBabe puro, pBabe hygro, pLZRS ires zeo, PMX ires GFP, pSuper retro

The vectors are again widely used by research laboratories and have been developed to provide the viral package signal, transcription and processing elements, and a target gene. The Packaging cells, into which the vectors are inserted, provide the envelope components.

Origin & function

Inserts:

Apoptosis related: Bcl-XL, Mcl-1, tBid, PUMA, Bax, Bad, Bak, Bfl-1, Mcl-1, Bcl-2, Caspase-3, DD Caspase 3, Caspase-9, Caspase-8, RIP3K, RIP1K, FADD, TNFR-1, Trail, Fas, PGAM5, Drp-1, Cytochrome-c GFP, Smac mCherry, Omi mCherry, caspase activity FRET reporter probe, Parkin, PINK1

Autophagy: mCherry LC3, eGFP LC3, eGFP mCherry LC3, eGFP p62, mCherry p62, Atg7, Atg5, Atg12, DD Atg5

Mitochondrial: mito matrix dsRed, mito matrix YFP, mitochondrial outer membrane targeted GFP, mitochondrial intermembrane space targeted Cre recombinase

Evaluation of foreseeable effects

Hazards associated with target/recipient cell lines

Phoenix Ecotropic or Phoenix Amphotropic cells are extensively used for retroviral generation. The target cells have been sourced from either ECACC or ATCC and subsequently been screened for human pathogens including HIV, HBV, HCV and EBV. They are widely used within and outside the Institute and are unable to survive outside a laboratory environment. Consequently, the cells should not have any foreseeable effects on human health or the environment.

Hazards associated with the vector system and inserted gene products

pBabe puro/pBabe hygro (Addgene), pLZRS zeo (Addgene), PMX ires GFP (Addgene), pSuper Retro (Addgene) are all replication incompetent retroviral vectors that allow production of retroviruses encoding proteins or shRNA targeting proteins of interest. Stable cell lines will be selected with puromycin (pBabe puro/pSuper retro), zeocin (pLZRS zeo), hygromycin (pBabe hygro) or sorted for GFP expression (PMX ires GFP).

Using the Phoenix cells and the above plasmids, viral progeny are only produced following transfection of the plasmid encoding the gene of interest (because this provides
the viral packaging signal in trans). Produced virus are replication incompetent, since they lack various genes essential for viral replication. The genes, including Gag-Pol and Env are provided in trans by the Phoenix packaging cell line.

None of the gene inserts to be used are known oncogenes in themselves. Pro-apoptotic proteins such as Bax and Bak can only kill cells upon massive overexpression, it is not anticipated that retroviral transduction will attain the required levels. Many of the fluorescent fusion proteins are used solely as reporters, with no known toxic or oncogenic properties. None of the gene inserts to be used are expected to alter viral tropism.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virus generation and infection of target cells will be carried out in Class II biological safety cabinets in the Containment Level II laboratories, with access restricted to authorized and trained staff. The amount of retrovirus handled will be limited to no more than 5ml of virus stock. The most likely routes through which individuals could be exposed to virus are needle-stick injuries or aerosols generated during experimental procedures. Plastic ware will be used throughout and no needles or sharps will be used during virus preparation. The use of the Class II biological safety cabinet will guard against exposure to aerosols.

All cell cultures will be contained within clearly labelled boxes during incubation to prevent accidental spillage of medium. All viral supernatants and spent medium will be inactivated using Presept tablets (10,000 ppm free chlorine) before removal from the Containment Level II laboratories for final disposal.

Solid waste will be double bagged in biohazard bags prior to removal from the Containment Level II laboratory and then autoclaved before final consignment of waste to approved contractor. Autoclaves will be validated by annual thermocouple mapping and each run is monitored using Thermalog-S indicator test strips. These processes will result in 100% inactivation of infectious virus.

Cells will be cultured using designated bottles of medium that will not be used to passage other cell cultures. Authorised staff will wear dedicated lab coats in the Containment Level II laboratories that are not worn in the general laboratory area.

Infected target cells will be cultured under the above regime until medium supernatants have been shown to be free of replication competent virus as judged by infection of appropriate indicator cells and assays of reverse transcriptase activity. Only once these criteria have been met will the infected target cells be removed from Containment Level II laboratory and handled using standard tissue culture procedures.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The project was approved as ClassII by the Safety Committee on 12 June 2012.

## Project Additional Information

### Purposes of the contained use

The aim of the activities is to utilise SFV for expressing a variety of foreign proteins that could be of either viral or cellular origin. The foreign proteins could be derived from viruses that are human pathogens such as hepatitis C virus (HCV) or respiratory syncitial virus (RSV). The purpose is to use SFV to express high levels of the proteins in mammalian cells. This permits the study of the properties and functions of individual components of a particular virus in the absence of all other viral components.

### Recipient or parental organism

The vectors used for introduction of foreign sequences into SFV are derived from the SFV viral genome. SFV is a well studied virus which does have a wide natural host range (including birds, rodents and anthropod vectors) but this does not include man.

It is intended eventually to use Sindbis virus also.

### Host/vector system

- **Host system(s):**
  - Bacterial: Disabled E. coli K12-derived strains such as DH5.
Mammalian: a range of tissue culture cell lines of mammalian origin.
Vector system(s):
Mobilisation-defective plasmids pGEM1, pSFV1 and its derivatives. SFV-based expression in animal cells requires in vitro synthesis of recombinant RNA from pSFV1-derived and pSFV3 plasmids.

Origin & function
Hepatitis C virus (HCV), GBV-B and respiratory syncytial virus (RSV)
The system will be used for studying proteins encoded by these viruses.

Evaluation of foreseeable effects
Semliki Forest Virus is being used to study proteins from other viruses in this programme and evaluation of effects has to take into account both it and the other virus species involved. HCV is a natural human pathogen that causes chronic infection. The only documented route of infection is by contact with infected blood. The natural host for GBV-B is unknown, although there are literature reports that it is infectious in tamarins. It is not known whether humans are susceptible to infection. From studies elsewhere on infection of chimpanzees by HCV and GBV-B, infection is only successful using the entire genome. Generation of full-length genomic RNA of HCV in the SFV system is not possible. Furthermore, in the SFV system, there will be no combination of vectors introduced into cells that permits generation of full-length HCV and GBV-B genomes by any recombination mechanism. Hence, infectious HCV cannot be produced. It is not expected that HCV and GBV-B proteins will be toxic to man.

Although wild-type SFV can infect animals, the system produces disabled virus that will give only a single round of infection. The most significant consequence of infection by direct inoculation may be an immune response to SFV proteins and those inserted into the vector. There is a possible risk of infection by either aerosols or direct inoculation. Therefore, any SFV particles produced by the vector system will be handled in a safety cabinet and no sharps will be used.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
none

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

DISINFECTION POLICY
The three methods for disinfection are as follows:
1. Chloros - 1% v/v
2. Virkon - 1% w/v
3. Autoclaving
All of the above methods can be used for herpes, adeno, vaccinia, bunya, respiratory syncitial, measles, chandipura and baculo viruses. Material derived from other viruses must be disinfected by autoclaving and possibly incineration as described in the relevant risk assessment form.
The methods are also suitable for E.coli.
Chloros (outside the laboratory)
For bulk overnight steeping of glassware
Laboratories will be supplied daily with a trolley on which are large round vats for heavy glassware and smaller rectangular vats for light glassware. The appropriate volumes of stock Chloros is pre-dispersed in accompanying plastic bottles.
N.B. With the exception of empty pipette cans and chloros containers, no other items are permitted on this trolley.
Virkon (within the laboratory)
For bulk liquids (e.g. discarded tissue culture media)
Virkon powder* should be added to give a 1% w/v final concentration and the container mixed thoroughly.
For large containers (e.g. burrers, large and medium tissue culture flasks)
Treat with 1% w/v Virkon, either by adding powder and filling with water as above, or by dilution of a fresh concentrate. Stock solutions of Virkon must be dated: they retain efficacy for 1 week. Care should be taken to resuspend any pelleted or clumped material and to completely fill the container, swabbing the threads and then inverting closed flasks and burrers to ensure the neck is treated.

With both of the above methods the treated containers must be soaked for a minimum of 1 hour before disposing liquid down the sink, glassware to normal wash-up and plasticware to normal solid waste (black bags) - laboratory personnel must remove any large bulk waste to cleaning department bins. It is recommended that materials being disinfected are clearly marked. For large glass conical flasks (greater than 1 litre capacity) These should be filled with 1% w/v Virkon and placed on the designated trolleys located on the first and second floors. The washroom staff will empty these trolleys first thing in the morning. These trolleys are for the disposal of large flasks only - other material must not be left on them. For surfaces, equipment and instruments Surfaces should be swabbed with 1% w/v Virkon (less than one week old).

Equipment and instruments can be similarly disinfected but extreme caution should be exercised with electrical equipment. If in doubt see the Technical Services Manager. While Virkon is regarded as an extremely safe compound, care should be taken when dispensing dry powder in bulk. A protective face mask could be used to prevent inhalation.

Autoclaving For small vessels (e.g. petri dishes and small tissue culture flasks) These should be placed in the biological waste discard boxes (lined with clear bags) in each lab. For higher risk organisms (e.g. clinical isolates, hepatitis, HIV) These should be placed in the biological waste discard boxes (lined with biohazard bags) which will be autoclaved prior to incineration of the contents.

For contaminated material (e.g. burrers with fungi or bacteria) These should not be opened but transported and loaded, at the allotted time, into the "dirty" autoclave in the washroom for inclusion in liquid discard cycle. All lids must be loosened at the autoclave when the material is loaded. In the event that the "dirty" autoclave is still running the previous cycle, being serviced or out of order, all discard boxes or other contaminated materials must be returned to their lab of origin. They MUST NOT be left at the autoclave or given to the washroom staff. Other methods - Any other method or disinfecting agent (e.g. sensitivity reactions) must be treated as a separate experimental procedure with its own evaluation of efficacy and risk assessment form. General Aerosols Benchworkers should be wary of all techniques and manipulations which give rise to aerosols when using hazardous materials e.g. filling used burrers contaminated with viruses. Where practicable these procedures should be performed in an appropriate safety cabinet. Biological materials - It is recommended that all vessels used with biological materials be disinfected e.g. burrers used for non infected cell growth be treated with Virkon before discarding to normal waste. WASTE DISPOSAL The disposal of waste chemicals and solvent can often cost more than the original material. It is important, therefore, when orders are placed for chemicals that only sufficient is ordered for your immediate use. Waste disposal must be considered as integral to all laboratory procedures. These notes summarise the principles of waste disposal organisation and describe the approved System of Work for discarding labware. The guidance principle is that scrupulous care must be taken to protect the interest of cleaners, other staff, the public and the environment.

Waste-bag colour code and disposal routes BLACK = Non-hazardous; cleaners may remove RED = These are for material requiring the attention of specialist waste disposal companies and are for compounds (e.g. ethidium bromide) identified in risk assessment forms. See "Waste Chemicals" below. YELLOW = These will not be available to laboratory workers. They are for incineration of autoclaved clinical waste. TRANSPARENT/BIOHAZARD = Microbiological waste for autoclaving. These must be transported in the metal disposal boxes and placed in the "dirty" autoclave in the washroom at the appropriate times. General Waste General waste in the laboratory may be put into the normal disposal containers. However, it is important that broken glass and other hazardous waste is kept separate. Waste solvents are collected in metal drums at the back of the spirit store. Potential hazards exist in mixing different solvents and there are separate drums for each of 3 categories of waste: 1) Flammable, e.g. ether, methanol, acetone. 2) Non-flammable, e.g. DMSO, phenol, chloroform. 3) Oils, e.g. waste from centrifuges, pumps, etc.

The material and amount disposed of in each category must be entered into the appropriate log book provided stating your name and date. Consult The Technical Services Manager if you are in any doubt as to which category your waste belongs. Make sure that there is adequate room left in the drum before starting. There should always be an empty drum below the one in use. If you finish a drum, inform The Technical Services Manager. Absorption granules for soaking up any solvent spillage are available in the solvent store.
From Divisional Safety Committee minute of 22/09/2000

5 Genetic modification proposal: Analysis of GBV-B structural proteins
In discussion there emerged more concern with the introduction of a new virus to the institute than with the proposed GM aspects. It was not known whether the virus is human or tamarin originally. The chief interest was as a model for HCV infection and, in this case, its structural proteins.

5.1 RME noted that there was one report in the literature of VSV glycoproteins being expressed in Semliki Forest Virus.
5.2 There was some concern with the statement "not envisage..... will produce infectious virus" However, part 10 did address concerns.
5.3 It was important to check with the ACDP on the classification GBV. (see 4.2 above)
5.4 The question has to be answered whether it extended previously agreed work, and hence whether a new notification to the HSE was needed.
5.5 It was recommended that the reference to "Experience of expression with HCV...." be moved from part 10 to part 7. Subject to these constraints the proposal was accepted. From the Virology Safety Committee minutes of 07/02/2001

24 Use of Semliki Forest Virus to study RSV proteins
It was noted that the original use of Semliki Forest virus has not constituted genetic modification. A further proposal was now considered to introduce GM of this virus and Notification of a new Activity was indicated. The present proposal represented an additional GM use of SFV.
24.1 The autoclaving of all waste was queried: the normal regime should be adequate (AW to check). Also, the ACGM Guidance Notes provided a model for the environmental risks. (RT to discuss with RS).
24.2 Subject to these changes the proposal was accepted at class 2.

### Project Additional Information

#### Purposes of the contained use
- Study of the structure and function of Norwalk-like viruses, and related viruses of public health significance.

#### Recipient or parental organism
- Human small round structured virus (SRSV)
- Feline calicivirus (FCV)

#### Host/vector system

**Hos system(s)**
1. **Prokaryotic**
   - Plasmid propagation: E.coli TG2, JM101, DH5α, MC1061
   - Expression in E.coli: E. coli BL21, BL21 (DE3)

2. **Eukaryotic**
   - Yeast protein expression system: Pichia pastoris
   - Insect cell lines: Spodoptera frugiperda
   - Mammalian cell lines: MRC5, HeLa, Ohio HeLa, 293, BSC-1, VERO, RD, CHO, BHK

**Vector system(s)**
1. **Prokaryotic**
   - Plasmid propagation: pBR322, pUC, PGM, pJM1, pEMBL, PACYC184, pBLUESCRIPT
   - Protein expression: pGEMEX, pET, pUC119

2. **Eukaryotic**
   - Protein expression in yeast: pPIC9, pPIC3
   - Protein expression in insect cells: Autographa californica baculovirus
   - Protein expression in mammalian cells: pcDNA3, pREP, pTM1 & pTM3 (vaccinia expression), vTF7-3 (vaccinia T7 system), MVA-T7, fowlpox T7, non-cytopathic Sindbis virus replicons
   - Virus expression in eukaryotic cells
FCV full genome and cloned segments of SRSV will be used to study the structure and function of individual proteins and the replication of the virus.

**Origin & function**

The predicted characteristics of the proteins indicate that there will be no toxic effect on humans or the environment. (Those produced in other laboratories have been used to raise antibodies and had no toxic effect).

**Evaluation of foreseeable effects**

Origin & function

The predicted characteristics of the proteins indicate that there will be no toxic effect on humans or the environment. (Those produced in other laboratories have been used to raise antibodies and had no toxic effect).

n/a

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

none

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

**DISINFECTION POLICY**

The three methods for disinfection are as follows:-

1. Chloros - 1% v/v
2. Virkon - 1% w/v
3. Autoclaving

All of the above methods can be used for herpes, adeno, vaccinia, bunya, respiratory syncitial, measles, c handipura and baculo viruses. Material derived from other viruses must be disinfected by autoclaving and possibly incineration as described in the relevant risk assessment form.

The methods are also suitable for E.coli

Chloros (outwith the laboratory)

For bulk overnight steeping of glassware

Laboratories will be supplied daily with a trolley on which are large round vats for heavy glassware and smaller rectangular vats for light glassware. The appropriate volumes of stock Chloros is pre-dispensed in accompanying plastic bottles.

NB  With the exception of empty pipette cans and chloros containers, no other items are permitted on this trolley.

Virkon (within the laboratory)

For bulk liquids (eg. discharged tissue culture media)

Virkon powder *should be added to give a 1% w/v final concentration and the container mixed thoroughly.

For large containers (eg. burrlers, large and medium tissue culture flasks)

Treat with 1% w/v Virkon, either by adding powder and filling with water as above, or by dilution of a fresh concentrate. Stock solutions of Virkon must be dated: they retain
efficacy for 1 week. Care should be taken to resuspend any pelleted or clumped material and to completely fill the container, swabbing the threads and then inverting closed flasks and burrlers to ensure the neck is treated.

With both of the above methods the treated containers must be soaked for a minimum of 1 hour before disposing liquid down the sink, glassware to normal wash-up and plasticware to normal solid waste (black bags) - laboratory personnel must remove any large bulk waste to cleansing department bins. It is recommended that materials being disinfected are clearly marked.

For large glass conical flasks (greater than 1 litre capacity)

These should be filled with 1% w/v Virkon and placed on the designated trolleys located on the first and second floors. The washroom staff will empty these trolleys first thing in the morning. These trolleys are for the disposal of large flasks only - other material must not be left on them.

For surfaces, equipment and instruments

Surfaces should be swabbed with 1% Virkon (less than one week old). Equipment and instruments can be similarly disinfected but extreme caution should be exercised with electrical equipment. If in doubt see the Technical Services Manager.

*While Virkon is regarded as an extremely safe compound, care should be taken when dispensing dry powder in bulk. A protective face mask could be used to prevent inhalation.

Autoclaving

For small vessels (eg petri dishes and small tissue culture flasks)

These should be placed in the biological waste discard boxes (lined with clear bags) in each lab.

For higher risk organisms (eg. clinical isolates, hepatitis, HIV)

These should be placed in the biological waste discard boxes (lined with biohazard bags) which will be autoclaved prior to incineration of the contents.

For contaminated material (eg burrlers with fungi or bacteria)

These should not be opened but transported and loaded, at the allotted time, into the "dirty" autoclave in the washroom for inclusion in liquid discard cycle. All lids must be loosened at the autoclave when the material is loaded.

In the event that the "dirty" autoclave is still running the previous cycle, being serviced or out of order, all discard boxes or other contaminated materials must be returned to their lab of origin. They MUST NOT be left at the autoclave or given to the washroom staff.

Other methods

Any other methods or disinfecting agent (eg. stericol, gluteraldehyde, SDS) required for scientific or personal reasons (eg. sensitivity reactions) must be treated as a separate experimental procedure with its own evaluation of efficacy and risk assessment form.
General

Aerosols

Benchworkers should be wary of all techniques and manipulations which give rise to aerosols when using hazardous materials eg. filling used burrers contaminated with viruses. Where practicable these procedures should be performed in an appropriate safety cabinet.

Biological materials

It is recommended that all vessels used with biological materials be disinfected eg. burrers used for non infected cell growth be treated with Virkon before discarding to normal waste.

WASTE DISPOSAL

The disposal of waste chemicals and solvent can often cost more than the original material. It is important, therefore, when orders are placed for chemicals that only sufficient is ordered for your immediate use. Waste disposal must be considered as integral to all laboratory procedures. These notes summarise the principles of waste disposal organization and describe the approved System of Work for discarding labware.

The guiding principle is that scrupulous care must be taken to protect the interests of cleaners, other staff, the public and the environment.

Waste-bag colour code and disposal routes

BLACK = Non-hazardous; cleaners may remove
RED = These are for material requiring the attention of specialist waste disposal companies and are for compounds (eg. ethidium bromide) identified in risk assessment forms. See "Waste Chemicals" below.
YELLOW = These will not be available to laboratory workers. They are for incineration of autoclaved clinical waste.
TRANSPARENT/BIOHAZARD = Microbiological waste for autoclaving. These must be transported in the metal disposal boxes and placed in the "dirty" autoclave in the washroom at the appropriate times.

General waste

General waste in the laboratory may be put into the normal disposal containers. However, it is important that broken glass and other hazardous waste is kept separate.

Waste solvents

Solvent waste is collected in metal drums at the back of the spirit store. Potential hazards exist in mixing different solvents and there are separate drums for each of three categories of waste:

1. Flammable, eg ether, methanol, acetone.
2. Non-flammable, eg DMSO, phenol, chloroform.
3. Oils, eg waste from centrifuges, pumps, etc.

The material and amount disposed of in each category must be entered into the appropriate log book provided stating your name and date. Consult The Technical Service Manager if you are in any doubt as to which category your waste belongs. Make sure that there is adequate room left in the drum before starting. There should always be an empty drum below the one in use. If you finish a drum, inform The Technical Services Manager. Absorption granules for soaking up any solvent spillage are available in the solvent store.
From the Divisional Safety Committee minute of 03/05/2000

RME spoke to the proposal which, if accepted, would represent a new programme of work requiring notification to the HSE.

9.1 Caliciviruses caused human gastrointestinal disease typified by an acute but usually short-lived episode of severe diarrhoea and vomiting. Currently they were classified at ACDP level 2.

9.2 Growth in tissue culture could not yet be achieved and there was no testing of Virkon effectiveness. It was noted that were a tissue culture system to become available this would materially alter the safety implications (though not a genetic modification issue in itself).

9.3 The project would involve recovery of unmodified virus from cDNA clones. For future modification of clones a further proposal would be brought to the Committee.

9.4 The Committee accepted the proposal. A submission to the ACGM would follow.

Please enter comments on the GM safety committee on the risk assessment

Project Ref 26/01.3

Date Ackn'd: 26/02/2001

CU2 Project Title: GENETIC MODIFICATION OF PARAMYXOVIRUSES

Class: Class 2

CultureVolClass2: < 1 litre

CultureVolumeClass3-4:
Project Additional Information

**Purposes of the contained use**
To study respiratory syncytial virus and related viruses of public health significance.

**Recipient or parental organism**
Respiratory Syncytial Virus (RSV)

**Host/vector system**

1) Propagation of viral cDNA. Standard laboratory hosts.
   - JM109
   - DH5
   - Late6 (a derivative of SURE, developed for maintenance of large, unstable plasmids such as the RSV antigenome).
2) Expression in mammalian cell-lines ie production of infectious virus particles. Established cell lines.
   - HepC
   - BHK
   - Cos-7

**Origin & function**
Isolates of RSV
**RSV is relatively common in the human population. The experiments are designed to study the functions and interactions of the proteins encoded by the RSV genome. It is expected that engineered virus will be no more hazardous than the wild type. Eventually it is hoped to identify viral proteins which are potential targets for antiviral drugs.**

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

| n/a |

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

| none |

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

**DISINFECTION POLICY**

The three methods for disinfection are as follows:

1. Chloros - 1% v/v
2. Virkon - 1? w/v
3. Autoclaving

All of the above methods can be used for herpes, adeno, vaccinia, bunya, respiratory syncitial, measles, chandipura and baculo viruses. Material derived from other viruses must be disinfected by autoclaving and possibly incineration as described in the relevant risk assessment form.

The methods are also suitable for E. coli.

Chloros (outwith the laboratory)

For bulk overnight steeping of glassware

Laboratories will be supplied daily with a trolley on which are large round vats for heavy glassware and smaller rectangular vats for light glassware. The appropriate volumes of stock Chloros is pre-dispensed in accompanying plastic bottles.

NB With the exception of empty pipette cans and chloros containers, no other items are permitted on this trolley.

Virkon (within the laboratory)

For bulk liquids (eg discarded tissue culture media)

Virkon powder *should be added to give a 1% w/v final concentration and the container mixed thoroughly.

For large containers (eg burrlers, large and medium tissue culture glasks)

Treat with 1% w/v Virkon, either by adding powder and filling with water as above, or by dilution of a fresh concentrate. Stock solutions of Virkon must be dated: they retain efficacy for 1 week. Care should be taken to resuspend any pelleted or clumped material and to completely fill the container, swabbing the threads and then inverting closed flasks and burrlers to ensure the neck is treated.
With both of the above methods the treated containers must be soaked for a minimum of 1 hour before disposing liquid down the sink, glassware to normal wash-up and plasticware to normal solid waste (black bags) - laboratory personnel must remove any large bulk waste to cleansing department bins. It is recommended that materials being disinfected are clearly marked.

For large glass conical flasks (greater than 1 litre capacity)

These should be filled with 1% w/v Virkon and placed on the designated trolleys located on the first and second floors. The washroom staff will empty these trolleys first thing in the morning. These trolleys are for the disposal of large flasks only - other material must not be left on them.

For surfaces, equipment and instruments.

Surfaces should be swabbed with 1% w/v Virkon (less than one week old). Equipment and instruments can be similarly disinfected but extreme caution should be exercised with electrical equipment. If in doubt see the Technical Services Manager.

* While Virkon is regarded as an extremely safe compound, care should be taken when dispensing dry powder in bulk. A protective face mask could be used to prevent inhalation.

Autoclaving

For small vessels (eg petri dishes and small tissue culture flasks)

These should be placed in the biological waste discard boxes (lined with clear bags) in each lab.

For higher risk organisms (eg clinical isolates, hepatitis, HIV)

These should be placed in the biological waste discard boxes (lined with biohazard bags) which will be autoclaved prior to incineration of the contents.

For contaminated material (eg burrers with fungi or bacteria).

These should not be opened but transported and loaded, at the allotted time, into the "dirty" autoclave in the washroom for inclusion in liquid discard cycle. All lids must be loosened at the autoclave when the material is loaded.

In the event that the "dirty" autoclave is still running the previous cycle, being services or out of order, all discarded boxes or other contaminated materials must be returned to their lab of origin. They MUST NOT be left at the autoclave or given to the washroom staff.

Other methods

Any other method or disinfecting agent (eg stericol, gluteraldehyde, SDS) required for scientific or personal reasons (eg sensitivity reactions) must be treated as a separate experimental procedure with its own evaluation of efficacy and risk assessment form.

GENERAL

Aerosols
Benchworkers should be wary of all techniques and manipulations which give risk to aerosols when using hazardous materials eg. filling used burrers contaminated with viruses. Where practicable these procedures should be performed in an appropriate safety cabinet.

Biological materials

It is recommended that all vessels used with biological materials be disinfected eg. burrers used for non infected cell growth be treated with Virkon before discarding to normal waste.

WASTE DISPOSAL

The disposal of waste chemicals and solvent can often cost more than the original material. It is important, therefore, when orders are placed for chemicals that only sufficient is ordered for your immediate use. Waste disposal must be considered as integral to all laboratory procedure.s These notes summarise the principles of waste disposal organisation and describe the approved System of Work for discarding labware.

The guiding principle is that scrupulous care must be taken to protect the interests of cleaners, other staff, the public and the environment.

Waste-bag colour code and disposal routes

BLACK = Non-hazardous; cleaners may remove
RED = These are for material requiring the attention of specialist waste disposal companies and are for compounds (eg ethidium bromide) identified in risk assessment forms. See "Waste Chemicals" below.
YELLOW = These will not be available to laboratory workers. They are for incineration of autoclaved clinical waste.
TRANSPARENT/BIOHAZARD = Microbiological waste for autoclaving. These must be transported in the metal disposal boxes and placed in the "dirty" autoclave in the washroom at the appropriate times.

General waste

General waste in the laboratory may be put into the normal containers. However, it is important that broken glass and other hazardous waste is kept separate.

Waste solvents

Solvent waste is collected in metal drums at the back of the spirit store. Potential hazards exist in mixing different solvents and there are separate drums for each of three categories of waste:

1. Flammable, eg ether, methanol, acetone
2. Non-flammable, eg DMSO, phenol, chloroform.
3. Oils, eg waste from centrifuges, pumps, etc.

The material and amount disposed of in each category must be entered into the appropriate log book provided stating your name and date. Consult The Technical Services Manager if you are in any doubt as to which category your waste belongs. Make sure that there is adequate room left in the drum before starting. There should always be an empty drum below the one in use. If you finish a drum, inform The Technical Services Manager. Absorption granules for soaking up any solvent spillage are available in the solvent store.
From Divisional Safety Committee minutes 13/09/2000

10. Genetic modification proposal: Genetic manipulation of respiratory syncytial virus

It was intended to use a commercially available system (from Aviron) which did not need M2. Although the proposer would start using vaccinia strain T7 he would move away from this to a fowlpox or sindbis virus system.

10.01 Fundamentally it would be an RSV rescue system and as such represented a new programme of work. On this basis it was agreed by the Committee at level 1 or (vaccinia) level 2.

10.02 This would be submitted to the HSE as a paramyxovirus programme.

Animal Units | Large Scale Activities | Human Clinical Applications

02/03/2022
### Project Additional Information

**Purposes of the contained use**

To study the proteins of hepatitis C virus.

**Recipient or parental organism**

BVDV

**Host/vector system**

- **Host system(s):** Disabled E. coli K12-derived strains such as DH5
- **Mammalian:** Human hepatocyte derived cell lines (eg Huh-7, HepG2 etc), BHK, MDBK

**Origin & function**

HCV genomic cDNA sequences expressing viral proteins will be used for structure and function analysis.
If successful, the system will generate chimeric pseudotype BVDV particles carrying HCV structural proteins which may change its host and tissue tropism. Furthermore, the pseudotype particles are likely to encapsidate replication competent chimeric cDNA genome carrying HCV structural genes. Therefore, these particles could infect cells and replicate if injected into humans. It is virtually impossible to predict the outcome of accidental infection of humans with the chimeric particles and hence the categorization of the proposed work as class 3 activities.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

DISINFECTION POLICY
The three methods for disinfection are as follows:

1. Chloros - 1% v/v
2. Virkon - 1% w/v
3. Autoclaving.

All of the above methods can be used for herpes, adeno, vaccinia, bunya, respiratory syncitial, measles, chandipura and baculo viruses. Materials derived from other viruses must be disinfected by autoclaving and possibly incineration as described in the relevant risk assessment form.

The methods are also suitable for E. coli.

Chloros (outwith the laboratory)

For bulk overnight steeping of glassware.

Laboratories will be supplied daily with a trolley on which are large round vats for heavy glassware and smaller rectangular vats for light glassware. The appropriate volumes of stock Chloros is pre-dispensed in accompanying plastic bottles.

NB With the exception of empty pipette cans and chloros containers, no other items are permitted on this trolley.

Virkon (within the laboratory)

For bulk liquids (eg discarded tissue culture media)

Virkon powder * should be added to give a 1% w/v final concentration and the container mixed thoroughly.

For large containers (eg burrlers, large and medium tissue culture flasks)

Treat with 1% w/v Virkon, either by adding powder and filing with water as above, or by dilution of a fresh concentrate. Stock solutions of Virkon must be dated: they retain efficacy for 1 week. Care should be taken to resuspend any pelleted or clumped material and to completely fill the container, swapping the threads and then inverting.
closed flasks and burrers to ensure the neck is treated.

With both of the above methods the treated containers must be soaked for a minimum of 1 hour before disposing liquid down the sink, glassware to normal wash-up and plasticware to normal solid waste (black bags) - laboratory personnel must remove any large bulk waste to cleansing department bins. It is recommended that materials being disinfected are clearly marked.

For large glass conical flasks (greater than 1 litre capacity)

These should be filled with 1% w/v Virkon and placed on the designated trolleys located on the first and second floors. The washroom staff will empty these trolleys first thing in the morning. These trolleys are for the disposal of large flasks only - other material must not be left on them.

For surfaces, equipment and instruments.

Surfaces should be swabbed with 1 w/v Virkon (less than one week old). Equipment and instruments can be similarly disinfected but extreme caution should be exercised with electrical equipment. If in doubt see the Technical Services Manager.

* While Virkon is regarded as an extremely safe compound, care should be taken when dispensing dry powder in bulk. A protective face mask could be used to prevent inhalation.

Autoclaving

For small vessels (eg petri dishes and small tissue culture flasks)

These should be placed in the biological waste discard boxes (lined with clear bags) in each lab.

For higher risk organisms (eg clinical isolates, hepatitis, HIV)

These should be placed in the biological waste discard boxes (lined with biohazard bags) which will be autoclaved prior to incineration of the contents.

For contaminated material (eg burrers with fungi or bacteria)

These should not be opened but transported and loaded, at the allotted time, into the "dirty" autoclave in the washroom for inclusion in liquid discard cycle. All lids must be loosened at the autoclave when the material is loaded.

In the event that the "dirty" autoclave is still running the previous cycle, being serviced or out of order, all discard boxes or other contaminated materials must be returned to their lab of origin. They MUST NOT be left at the autoclave or given to the washroom staff.

Other methods.

Any other method or disinfecting agent (eg stericol, gluteraldehyde, SDS) required for scientific or personal reasons (eg sensitivity reactions) must be treated as a separate experimental procedure with its own evaluation of efficacy and risk assessment form.

General
Aerosols
Benchworkers should be wary of all techniques and manipulations which give rise to aerosols when using hazardous materials eg filling used burrers contaminated with viruses. Where practicable these procedures should be performed in an appropriate safety cabinet.

Biological materials
It is recommended that all vessels used with biological materials be disinfected eg burrers used for non infected cell growth be treated with Virkon before discarding to normal waste.

WASTE DISPOSAL
The disposal of waste chemicals and solvent can often cost more than the original material. It is important, therefore, when orders are placed for chemicals that only sufficient is ordered for your immediate use. Waste disposal must be considered as integral to all laboratory procedures. These notes summarise the principles of waste disposal organisation and describe the approved System of Work for discarding labware.

The guiding principle is that scrupulous care must be taken to protect the interests of cleaners, other staff, the public and the environment.

Waste-bag colour code and disposal routes.
BLACK - Non-hazardous; cleaners may remove
RED - These are for material requiring the attention of specialist waste disposal companies and are for compounds (eg ethidium bromide) identified in risk assessment forms. See "Waste Chemicals" below.
YELLOW - These will not be available to laboratory workers. They are for incineration of autoclaved clinical waste.
TRANSPARENT/BIOHAZARD - Microbiological waste for autoclaving. These must be transported in the metal disposal boxes and placed in the "dirty" autoclave in the washroom at the appropriate times.

General waste
General waste in the laboratory may be put into the normal disposal containers. However, it is important that broken glass and other hazardous waste is kept separate.

Waste solvents
Solvent waste is collected in metal drums at the back of the spirit store. Potential hazards exist in mixing different solvents and there are separate drums for each of three categories of waste:
1. Flammable, eg ether, methanol, acetone.
2. Non-flammable, eg DMSO, phenol, chloroform.
3. Oils, eg waste from centrifuges, pumps, etc.

The material and amount disposed of in each category must be entered into the appropriate log book provided stating your name and date. Consult the Technical Services Manager if you are in any doubt as to which category your waste belongs. Make sure that there is adequate room left in the drum before starting. There should always be an empty drum below the one in use. If you finish a drum, inform the Technical Services Manager. Absorption granules for soaking up any solvent spillage are available in the solvent store.
From the local Committee minute of 01/05/2002:

It was noted that all relevant staff were CL3 trained.

6.1 In discussion no major problems were identified but it was noted that, with BVDV being modified, HSE approval of a new GM Activity would be required.

6.2 It was noted that RME and others had used a similar HCV protease-dependent system.

6.3 Some textual revisions were required, to strengthen the proposal. The introduction should state that BVDV is not a Specified Animal Pathogen. Also, a few more papers on existing recombinants should be cited since there are more recent papers on recombination in vitro (RME to advise). Section 6 should mention that some recombinants will have both BVDV glycoproteins and HCV proteins.

6.4 Subject to these changes, the proposal was agreed for presentation to the HSE as a new class 3 notification.

Project Ref 26/04.1

Date Ackn’d 07/04/2004
CU2 Project Title USE OF DISABLED ADENOVIRUS VECTORS DESIGNED FOR EXPRESSION OF
Class 2
Culture Vol
Class 2 ≤ 1 litre

02/03/2022
Page 1380 of 15326
This project covers the broad area of the use of disabled adenovirus vectors for the expression of cloned genes of interest in mammalian cells. Several such vector systems are now available, some commercially, and while they vary in detail, they have in common the lack of the essential E1A gene, and therefore they can be propagated only in complementing cell lines. This genetic modification proposal is intended to register the use of adenovirus vectors for gene expression in the Division of Virology. The risk assessment for each such project will be considered on an individual basis as such proposals are made, with specific reference to the vector system and cloned inserts being used. These future proposals will be considered as an amendment to this parent proposal.

Recipient or parental organism

Complementing cell lines 293 and 911, which express the adenovirus E1A protein, will be used to propagate stocks of the recombinant adenoviruses.

Host/vector system

The viruses will be used for experimentation in standard mammalian cultured cell lines such as Hep2, human foetal fibroblasts and Vero cells. The virus vectors are those commercially supplied by BD Biosciences (for full information see http://www.bdbiosciences.com/clontech/techninfo/manuals/index.shtml). These are rountinely used in many laboratories around the world and are accepted as Category 2 pathogens.

The adenovirus vectors to be used are of two types. Firstly those in which constitutive expression of the cloned genes is under the control of the human cytomegalovirus immediate-early promoter region. Secondly, a tri-partite inducible expression system, in which expression of the cloned genes is controlled by an inducible tetracycline responsive promoter, and the tetR-VP16 fusion activator protein provided in trans by a second adenovirus vector (Ad.CMV-rtTA). Thus the recombinant proteins will be expressed only in cells treated with tetracycline derivatives and co-infected with both adenoviruses.

Origin & function

The initial list of the viruses to be utilised is:
- Ad.CMV-null: Adenovirus vector with HCMV IE promoter and no insert.
- Ad.TRE-null: Adenovirus vector with Tet-responsive promoter and no insert.
- Ad.CMV-GFP: Adenovirus vector with HCMV promoter and EGFP insert.
- Ad.TRE-GFP: Adenovirus vector with Tet-responsive promoter and EGFP insert.
- Ad.CMV-PMLwt: Adenovirus vector with HCMV promoter and wt PML insert.
Ad.CMV-rtTA: Adenovirus vector expressing the doxycycline-inducible transactivator of the TRE promoter.
Ad.TRE-PMLwt: Adenovirus vector with Tet-responsive promoter and wt PML insert.
Ad.TRE-ICPO: Adenovirus vector with Tet-responsive promoter and ICPO insert.
Ad.TRE-n212: Adenovirus vector with Tet-responsive promoter and ICPO insert truncated at residues 212.

Abbreviations:
HCMV  Human cytomegalovirus.
TRE  Tetracycline responsive element.
GFP  enhanced green fluorescent protein
PML  Promyelocytic leukaemia protein.
ICPO  Infected cell protein O of HSV-1
HSV-1  herpes simplex virus type 1

Evaluation of foreseeable effects

The adenoviruses to be used are defective for the essential E1A gene products and they are also deleted for the E3 region, so they are unable to replicate and spread in normal human cells. However, the inserted genes are designed to be expressed in mammalian cells, and therefore the project is designated as Level 2. Increased expression of the PML proteins is very unlikely to be harmful since PML is expressed in a wide range of cell types, and high level expression of PML is a normal consequence of interferon treatment of cells. ICPO is very unlikely to be more harmful to man when expressed in the tet inducible vector virus pair than when expressed during the course of a normal HSV-1 infection. Detailed safety guidance concerning these adenovirus vectors, and the protocols approved for their use in the National Institutes of Health, Bethesda USA, is available at: http://www.bdbiosciences.com/clontech/techinfo/manuals/index.shtml

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Extract from the Divisional Safety Handbook.

DISINFECTION POLICY

The three methods for disinfection are as follows:
1. Chloros - 1% v/v
2. Virkon - 1% w/v
3. Autoclaving

All of the above methods can be used for herpes, adeno, vaccinia, bunya, respiratory syncitial, measles, chandipura and bacula viruses. Material derived from other viruses must be disinfected by autoclaving and possibly incineration as described in the relevant risk assessment form.

The methods are also suitable for E. coli.

Chloros (outwith the laboratory)
For bulk overnight steeping of glassware
Laboratories will be supplied daily with a trolley on which are large round vats for heavy glassware and smaller rectangular vats for light glassware. The appropriate volumes of stock Chloros is pre-dispensed in accompanying plastic bottles.

NB With the exception of empty pipette cans and chloros containers, no other items are permitted on this trolley.

Virkon (within the laboratory)

For bulk liquids (eg discarded tissue culture media)
Virkon powder *should be added to give a 1% w/v final concentration and the container mixed thoroughly.

For large containers (eg burriers, large and medium tissue culture flasks)
Treat with 1% w/v Virkon, either by adding powder and filling with water as above, or by dilution of a fresh concentrate. Stock solutions of Virkon must be dated: they retain efficacy for 1 week. Care should be taken to resuspend and pelleted or clumped material and to completely fill the container, swabbing the threads and then inverting closed flasks and burriers to ensure the neck is treated.

With both of the above methods the treated containers must be soaked for a minimum of 1 hour before disposing liquid down the sink, glassware to normal wash-up and plasticware to normal solid waste (black bags) - laboratory personnel must remove any large bulk waste to cleansing department bins. It is recommended that materials being disinfected are clearly marked.

For large glass conical flasks (greater than 1 litre capacity)
These should be filled with 1% w/v Virkon and placed on the designated trolleys located on the first and second floors. The washroom staff will empty these trolleys first thing in the morning. These trolleys are for the disposal of large flasks only - other material must not be left on them.

For surfaces, equipment and instruments
Surfaces should be swabbed with 1% w/v Virkon (less than one week old). Equipment and instruments can be similarly disinfected but extreme caution should be exercised with electrical equipment. If in doubt see the Technical Services Manager.

* While Virkon is regarded as an extremely safe compound, care should be taken when dispensing dry powder in bulk. A protective face mask could be used to prevent inhalation.

Autoclaving
For small vessels (eg petri dishes and small tissue culture flasks)
These should be placed in the biological waste discard boxes (lined with clear bags) in each lab.

For higher risk organisms (eg clinical isolates, hepatitis, HIV)
These should be placed in the biological waste discard boxes (lined with biohazard bags) which will be autoclaved prior to incineration of the contents.

For contaminated material (eg burriers with fungi or bacteria)
These should not be opened but transported and loaded, at the allotted time, into the ‘dirty’ autoclave in the washroom for inclusion in liquid discard cycle. All lids must be loosened at the autoclave when the material is loaded.

In the event that the ‘dirty’ autoclave is still running the previous cycle, being services or out of order, all discard boxes or other contaminated materials must be returned to
their lab of origin. They must not be left at the autoclave or given to the washroom staff.

Other methods
Any other method or disinfecting agent (e.g., stericol, gluteraldehyde, SDS) required for scientific or personal reasons (e.g., sensitivity reactions) must be treated as a separate experimental procedure with its own evaluation of efficacy and risk assessment form.

General

Aerosols
Benchworkers should be wary of all techniques and manipulations which give rise to aerosols when using hazardous materials e.g., filling used burriers contaminated with viruses. Where practicable these procedures should be performed in an appropriate safety cabinet.

Biological materials.
It is recommended that all vessels used with biological materials be disinfected e.g., burriers used for non-infected cell growth be treated with Virkon before discarding to normal waste.

WASTE DISPOSAL
The disposal of waste chemicals and solvent can often cost more than the original material. It is important, therefore, when orders are placed for chemicals that only sufficient is ordered for your immediate use. Waste disposal must be considered as integral to all laboratory procedures. These notes summarise the principles of waste disposal organisation and describe the approved System of Work for discarding labware.

The guiding principle is that scrupulous care must be taken to protect the interests of cleaners, other staff, the public and the environment.

Waste-bag colour code and disposal routes.

BLACK = Non-hazardous; cleaners may remove.
RED = These are for material requiring the attention of specialist waste disposal companies and are for compounds (e.g., ethidium bromide) identified in risk assessment forms. See "Waste Chemicals" below.
YELLOW = These will not be available to laboratory workers. They are for incineration of autoclaved clinical waste.
TRANSPARENT/BIOHAZARD = Microbiological waste for autoclaving. These must be transported in the metal disposal boxes and placed in the "dirty" autoclave in the washroom at the appropriate times.

General waste
General waste in the laboratory must be put into the normal disposal containers. However, it is important that broken glass and other hazardous waste is kept separate.

Waste solvents
Solvent waste is collected in metal drums at the back of the spirit store. Potential hazards exist in mixing different solvents and there are separate drums for each of three categories of waste.

1. Flammable, e.g., ether, methanol, acetone.
2. Non-flammable, e.g., DMSO, phenol, chloroform.
3. Oils, e.g., waste from centrifuges, pumps etc.
The material and amount disposed of in each category must be entered into the appropriate log book provided stating your name and date. Consult the Technical Services Manager if you are in any doubt as to which category your waste belongs. Make sure that there is adequate room left in the drum before starting. There should always be an empty drum below the one in use. If you finish a drum, inform the Technical Services Manager. Absorption granules for soaking up any solvent spillage are available in the solvent store.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Extract from the Minutes of the Divisional Safety Committee meeting of 17.2.2004

The intended work was described. It was noted that the adenovirus technology was a very useful and widely used technique. However on winding up previous GM work involving adenovirus at the time the current Regulations came into force, the Division had formally discontinued GM of adenovirus. Formal Notification of the proposed work was required as a new Activity. The capability to do this work was important. The technique was expected to be useful to a number of teams in the Division.

3.1 A disabled strain of adenovirus would be used. The vectors listed in the proposal would not be the only ones and were specific to the immediate project, so Notification in that sense would be generic. The proposal could appropriately be made more general (Action: RDE).

3.2 No reservations were expressed on safety issues. The project was approved for work at level 2. AW to progress Notification (Action: AW). (The Notification fee was likely to rise from the current 576 as from 1.4.2004, so it should be done then).

Project Ref 26/11.1
Arboviruses are transmitted to susceptible vertebrates by arthropod vectors such as mosquitoes or ticks. Most arboviruses belong the Flaviviridae, Bunyaviridae and Togaviridae families of RNA viruses. While arboviruses can cause disease in vertebrates - ranging from febrile illness to more severe complications, depending on virus and/or host - as well as cell death in infected cultured cells, this appears not to be the case in the arthropods that transmit them. In fact, arbovirus-infected arthropods display few or no signs of disease (Fragkoudis et al., 2009), and this effect can be mimicked in arthropod cell culture.

Infection of mosquito or tick cells usually begins with an acute phase with high titre virus production followed by a persistent infection which, once established can last the life time of the arthropod cell culture. The biological reasons behind persistence are poorly understood and are believed to be linked to innate immune responses of the arthropod host. Research on antiviral immune responses in vector arthropods has only in recent times seen some progress yet this area of research is crucial in understanding this virus/host interaction and develop novel antiviral control strategies targeting the vector. It is now clear, mainly from research on arbovirus-infected mosquitoes, that vectors do not passively replicate arboviruses but that immune responses are activated. These can result in activation of immune signalling pathways (STAT, TOLL, IMD etc.), humoral responses in the arthropod hemocoel and most crucially RNA interference (RNAi) responses. It is not known how immune signalling pathways are activated following infection or how exactly they would mediate antiviral activities, and extracellular responses such as phenoloxidase activities also appear to be involved. The RNAi responses are better understood and form a major antiviral defence. Viral replication induces production of double stranded RNA which serves as a substrate for dicer-type nuclease activities to produce virus-induced small interfering RNAs (also called viRNAs in the context of viral infection) which are integrated into the RNA-induced silencing complex (RISC). The RISC presumably mediates antiviral activities by finding viral RNAs through complementarity with viRNAs and then mediating nucleolytic cleavage of those viral RNAs. Although some steps in this antiviral pathway are known, mechanisms, triggers etc. are poorly understood. In addition, arthropod cells might differentially regulate subsets of their own small RNA repertoire following infection by arboviruses.

In this project, we aim to further analyze:

- The induction, regulation and mechanisms of antiviral signalling pathways such as STAT, TOLL, IMD etc. in arthropod cells such as mosquito and tick cells, as well as mosquitoes and tick organ cultures. This project will look at protein functions and signalling regulation within these pathways.
- The induction, regulation and mechanisms of humoral, extracellular antiviral responses. We will analyse viral triggers and key components that lead to activation of extracellular responses. This project will be carried out in arthropod cells such as those derived from mosquitoes and ticks, but also live mosquitoes, and tick organ culture.
- The induction, regulation and mechanisms of small RNA pathways including antiviral RNAi in arthropod cells such as mosquito and tick cells, as well as live mosquitoes and tick organ cultures. We will analyse the nature and characteristics of small RNAs including those derived from cells as well as the regulation of the RNAi machinery (including that of proteins involved in RNAi).
- The relationship between virus/cell interactions and virus replication and induction of immune responses. Virus replication rates as well as interactions with host proteins are likely key determinants in the outcome of infection and those will be investigated.

To infect arthropod cells, mosquitoes or tick organ cultures, we will use arboviruses that are well understood and for which molecular tools are available. In addition to strains of the viruses, we will use genetically modified viruses as well as replicons derived from these viruses. Replicons are replicating viral RNA elements which lack the components to form virions (packaging signals, structural proteins) but contain RNA elements and proteins sufficient to replicate the replicon RNA. Replicons can either be introduced into cells by transfection, or packaged by co-expression of structural proteins into so-called virus-replicon particles.

Virus models to be studied are viruses of both the Togaviridae (genus Alphavirus) and Flaviviridae (genus Flavivirus) families, and/or derived replicons:

1. As a model for tick-borne arboviruses, we will study infections by Langat virus (LGTv). LGTV is a tick-borne flavivirus of the Flaviviridae family. It was first isolated from Ixodes granulatus ticks in 1956 in Malaysia (Smith, 1956). The natural transmission cycle of the virus is believed to involve rats in areas such as Thailand, Malaysia and Russia. LGTV can cause encephalitis in experimentally infected mice (Webb et al., 1968) but is not very neuroinvasive compared to other more virulent members of the tick-borne flavivirus group (Thind & Price, 1966) and is considered the non-pathogenic member of the Tick-borne encephalitis complex. The naturally attenuated Malaysian strain TP21 (the most common laboratory strain), is not associated with human disease under natural conditions (Rumyantsev et al., 2006) and LGTV has been used as a live attenuated vaccine in humans (Dubov et al., 1972).

A cDNA copy of the LGTV genome (a positive-stranded RNA of approx. 11 kb encoding a polyprotein with structural sequences followed by non-structural sequences) is available, allowing manipulation of the genome (Rumantsyev et al., 2006). This plasmid has been or will be engineered to delete to targets sequences (for example for replicon production), mutate specific sequences or insert genes such as reporter genes (for example fluorescent molecules such YFP, eGFP or various types of luciferase), insect immune response inhibitors or drug resistance genes (to facilitate selection of cells harbouring replicons). Genetic changes that will be introduced into the virus sequences (point mutations, deletions, insertions) will be targeted at disrupting specific functions of virus RNA or virus proteins and can be expected to attenuate virus fitness; such changes are highly unlikely to increase virulence. The viral envelope glycoprotein and capsid protein sequences which are the major determinants of host range and cell tropism will not be changed beyond the addition of marker genes such as GFP (as fusion or cleavable inserts into this coding region); host range and cell tropism are therefore unlikely to be altered. Changes to viral sequences will target disruption of viral protein functions or sequences.

LGTv can be directly used to infect cells. cDNA plasmids with LGTV sequences will be amplified using standard disabled laboratory strains of bacteria (usually strain BD1528 which is routinely used for flavivirus cDNAs). Plasmids or transcribed RNA will be transfected into eukaryotic cells. Depending upon the construct, in eukaryotic cells this may result in replication of virus RNA and production of new virions. Virus or virus replicon particles generated from these plasmids will be used to infect eukaryotic cell and tissue cultures, to investigate virus replication in arthropod cells such as tick cells or tick organ cultures (derived from ticks). The use of LGTV expressing a reporter gene such as GFP or luciferase will allow accurate, rapid, efficient, localised and repetitive monitoring of infection of cells and tissues which is important for immunity studies.

In addition to the use of LGTV, we plan to carry out comparative studies between LGTV replicons and replicons of other arthropod-borne flaviviruses such as tick-borne encephalitis or dengue virus; those replicons are not covered by Schedule 5 and no sequences for complete schedule 5 virus genomes (ie sequences encoding missing structural genes that are required to complement the full set of viral proteins to produce infectious virion) are stored in-house. Those replicon RNAs will not be packaged; only RNA will be introduced into cells to study replication; replicons will not be mixed in the same cells (either by co-transfection/infection or potential superinfection by spreading virus) with sequences of related viruses from within the same genus to avoid recombination events during co-infection (recombination can only occur when viruses replicate in the same cell). Like LGTV-derived replicons, other flavivirus replicons pose no risk to safety to human and animal health as they cannot spread and transfected cells will be eliminated by cell death or the immune system. Experiments with these replicons will be carried out to study host innate immune responses (RNAi, immune signalling) and/or virus-host cell interactions (protein interactions, replication complex localization in cells etc.). These experiments will complement studies carried
out with LGTV and allow us to verify how broadly relevant some findings (those that do not rely on formation of infectious virus or/and virus spread) obtained with a model virus are to other members of the family.

2. As a model for Togaviridae (genus Alphavirus) infection of arthropod cells, we will study infections by Semliki Forest virus (SFV). SFV is naturally found in central and Southern Africa and is transmitted between animals and birds by mosquitoes (mainly Ae. aegypti and africanus). SFV can infect man and is classified as a hazard group 2 pathogen by the ACDP. The alphavirus genome consists of a single strand of positive sense RNA of around 12 kb. This RNA codes for two open reading frames. The first codes for the non-structural viral replicase proteins (nsP1, 2, 3 & 4), the second for the viral structural proteins (C, E1, E2 & E3). Expression of the replicase proteins is under the control of a promoter (P) in the 5’ non-coding region of the virus. Expression of the structural proteins is under the control of a subgenomic promoter (SP) which is activated later in infection and leads to a high level of expression from this second open reading frame.

There are several strains of SFV which have been derived from natural isolates, these include prototype SFV4, L10, A7 and A7(74). Each of these strains has been cloned and sequenced and is available as a series of plasmids which can be amplified in standard bacterial systems. In vitro transcription of the plasmid cDNA can give rise to an RNA which when transfected into cells can give rise to infectious virus; alternatively RNA is transcribed from transfected plasmid under control of eukaryotic promoters such as the CMV promoter. The SFV cDNAs can be engineered to give rise to virus mutants or engineered viruses. The prototype strain SFV4 forms the basis of the SFV vector system which is widely used for eukaryotic gene expression (Smerdou and Liljestrom, 1999). SFV natural isolates, cDNA derived viruses and mutant viruses derived from these cDNA clones have been used extensively by us and others. In mice, different strains show different pathogenicity and these are likely to be due to sequence differences. We will produce and use genetically engineered SFV viruses mutated in viral proteins or sequences expressing additional genes (reporter genes such as luciferase or fluorescent proteins, insect immune response antagonists etc.) as part of the non-structural open reading frame, the structural or from duplicated subgenomic promoters (Siu et al., 2011; Attarzadeh-Yazdi et al., 2009). If the coding sequence for a protein such as a reporter gene would be inserted into the viral structural polyprotein-coding sequence, in the resultant hybrid polyprotein the added protein would be separated from the structural proteins by protease cleavage sites. No changes to the sequence of the structural proteins would ensue so that there would be no changes to virus tropism resulting from changes to the structural proteins. Introduction of additional sequences into SFV is likely to provide no change or to decrease virulence. Changes to viral sequences will target disruption of viral protein functions or sequences.

In addition to infection with SFV, it is possible to use virus-derived replicons. In replicons, the structural genes are replaced by a polylinker which allows insertion of foreign sequences. The system exploits the wide cell tropism of SFV, but has no potential for virulence since genes for the viral structural proteins are deleted. A helper system is also available whereby recombinant RNA can be packaged into infectious virus-replicon particles (VRP); this system is deemed extremely safe (Smerdou and Liljestrom, 1999). Packaging of genomic RNA into new virions is absolutely dependent on a packaging sequence in the replicase gene. Packaged VRPs are made by using cells which also express the viral structural genes (usually by cotransfection of structural gene-encoding mRNA transcripts). In the absence of genes encoding the viral structural proteins in replicons, new infectious virus particles capable of initiating a propagating infection cannot be regenerated in VRP-infected cells; VRPs are thus also referred to as ‘suicide particles’. Replicons can be used to express reporter genes or other genes of interest such as insect RNAi inhibitors.

SFV and engineered variants will be used to infect eukaryotic cell and tissue cultures, as well as arthropods such as mosquitoes. The use of genetically modified marker viruses will allow monitoring of infected cells and tissues, determination of the spread of infection and dissection of specific tissues / areas or even specific cells for further analysis. Again these properties are very useful to study immune responses in arthropod cells and tissues.

In addition to the use of SFV we plan to carry out comparative studies with other arthropod-borne alphavirus replicons such as those derived from chikungunya virus; those replicons are not covered by schedule 5 and no sequences for the complete genome (ie sequences encoding structural genes required to complement the viral protein set to give infectious virions) will be stored in house. Those replicons will not be packaged into VRPs, only RNA will be introduced into cells to study replication; replicons will not be mixed with related viruses from within the same genus in the same cell (either by co-infection/transfection, or potential superinfection by spreading virus) to avoid recombination events during co-infection. Like SFV-derived replicons, other alphavirus-derived replicons pose no risk to safety or human health as they cannot spread and transfected cells will be eliminated by cell death or the immune system. Experiments with these replicons will be carried out to study host innate immune responses (RNAi, immune signalling) and/or virus-host cell interactions (protein interactions, replication complex localization in cells etc.). These experiments will complement studies carried
out with SFV and allow us to verify how broadly relevant some findings (those that do not rely on formation of infectious virus or virus spread) obtained with a model virus are to other members of the family.

References:

Recipient or parental organism

Arboviruses and derived replicons used will be of the Flaviviridae and Togaviridae (genus Alphavirus) virus families.

Togaviridae:
Semliki Forest virus prototype (SFV4), and strains such as A7 and A7(74).
Semliki Forest virus-derived replicons and virus-replicon particles.
Other arthropod-borne alphavirus replicons (for example derived chikungunya virus).

Flaviviridae:
Langat virus (strain TP21, the most commonly used lab strain, or others).
Langat virus-derived replicons.
Other arthropod-borne flavivirus replicons (for example derived from tick-borne encephalitis virus and dengue virus).

Host/vector system

All organisms will be used at containment level 2, which is routine practice.

02/03/2022 Page 1389 of 1532
Plasmid vectors:
Viral sequences (including full length clones or partial sequences of SFV or LGTV) and other genes (cellular, viral or reporter) are available in plasmid-encoded cDNA form. RNAs can be transcribed through bacterial promoters (ie. T7 or SP6) or eukaryotic promoters (CMV, SV40 etc.) Plasmids contain an origin of replication followed by a prokaryotic selectable marker (usually antibiotic resistance against ampicillin or kanamycin) and sometimes a selectable eukaryotic drug resistance marker such as neomycin or puromycin resistance. The bacterial systems are non-mobilisable vectors in a disabled prokaryotic host.

Hosts:

Prokaryotic hosts:
Disabled, commercially available E. coli strains such as Sure, JM109, XL-strains, DH-strains, Rosetta etc. These strains can only survive in a controlled laboratory environment and will be used for propagation of plasmids. Good microbiological practice and sterilisation of all contaminated waste should prevent release of viable organisms. The risk to the environment is therefore effectively zero.

Eukaryotic hosts:
Vertebrate cell lines of various origins (typically mouse, hamster, etc.) and invertebrate cell lines of various origins (mosquito, tick etc.). Mosquitoes, mainly strains of Ae. aegypti (such as the laboratory strain Liverpool red eye). Tick organ cultures from dissected ticks.

In prokaryotic cells, only selectable (eg antibiotic resistance) genes will be translated.

Virus sequences will be under the control of a promoter that will only generate transcripts in eukaryotic cells or in vitro transcription reactions.

In eukaryotic cells, RNA will be translated into the following gene products:

- Arboviral proteins and RNAs (SFV and LGTV, or replicons of related arboviruses): Proteins involved in replication and transcription of viral genetic material and virus structural proteins. Some of these virus proteins will interact with host-cell components and may affect host cell responses to infection; these interactions are not currently known. If all virus sequences are translated new virions may be generated; replicons are non-propagative viral RNAs (capable of replication). Partial RNAs do not give rise to propagating infectious material but can display biological activities (ie. RNAi inhibitory, expression of some viral proteins for example for packaging of replicons).

- Non-arboviral genes: Genes of prokaryotic (eg CAT) or eukaryotic (eg. reporter genes such as luciferases or fluorescent proteins such as GFP; inhibitors of insect immunity ie. RNAI inhibitors, signalling inhibitors, melanization inhibitors etc.) origin. No proteins known to interfere with vertebrate immune responses will be cloned into full length SFV or LGTV. The recombinant foreign proteins to be expressed provide no significant increase in the hazard to human health; none are toxic or likely to produce disease in the quantities that could be produced by accidental exposure to these systems. Non translated RNA sequences have no known toxic effects and pose no risk to human health.

Techniques used to introduce insert or vectors into cells:

Prokaryotic cells: Introduction of DNA into E. coli will be by heat shock/chemical transformation. These techniques have been extensively described and are widely used; they rely on getting DNA very close to the bacterial membrane and introducing the genetic material through pores or membrane fusion.

Eukaryotic cells: Mammalian cells will be transfected using reagents such a lipofectamine or by electroporation. Virus genomes will be introduced into cultured cells or tick organ cultures by infection with virus or virus replicon particles (VRP), using transfection reagents or by electroporation.
Note - location and nature of where experiments are to be carried out:

GM 26 (CVR Church Street):
- Preparation, characterisation and genetic manipulation of viruses and replicons.
- Infection of cell lines and organ cultures, preparation of lysates, extracts and fixed tissues for downstream analysis.

GM223 (CVR Garscube Estate):
- Infection of Ae. aegypti mosquitoes with Semliki Forest virus (SFV) (wild type or genetically modified) or VRPs by bloodmeal.
- Isolation of SFV, or nucleic acids or proteins from Ae. aegypti mosquitoes for downstream analysis (for example real time PCR for quantification of gene expression, reporter gene assays etc.).
- Fixation of mosquito tissues for downstream analysis (immunofluorescence, fluorescent reporter gene expression).

Evaluation of foreseeable effects

Foreseeable effects/risk assessment for human health and safety (also see Risk Assessments):

Plasmid vectors:
Viral sequences (including full length clones or partial sequences of SFV or LGTV) and other genes (cellular, viral or reporter) are available in plasmid-encoded cDNA form. Plasmid vectors are based on bacterial plasmids and contain an origin of replication for prokaryotic cells and selectable antibiotic/drug resistance (pro- or eukaryotic) markers. By themselves these vectors present no risk to human health. Vectors have no selective advantage and would soon be lost from the bacterial population. The bacterial systems are non-mobilisable vectors in a disabled prokaryotic host. Transcription of even complete viral cDNA (SFV or LGTV) will result in no infectious RNA since the promoters are not active in prokaryotic hosts. Systems for prokaryotic gene expression are under control of an inducible prokaryotic promoter. Systems for eukaryotic RNA or protein expression are under the control of promoters of viral (such as CMV or SV40), eukaryotic (eg actin promoter, pathway inducible promoter such as STAT) or prokaryotic (such as T7 or SP6 promoter for in vitro transcription) origin. Plasmids with eukaryotic promoters such as the CMV promoter can be transcribed in human cells. None of the genes used in these studies are oncogenes. The hazard of expressing 'foreign' genes from these eukaryotic promoter plasmids would depend on the expected physiological effects of the foreign gene product and is discussed in more detail below.

SFV:
In Africa, natural infections have been associated with mild febrile illness (Mathiot et al., 1990). Various laboratory strains of SFV including prototype-SFV4, L10, A7 and A7(74) have been used extensively in many laboratories and even (in the past) for student practical classes. There is one report of laboratory based human disease. Death of a laboratory worker in Germany was associated with infection by the Osterrieth strain of SFV (Willems et al., 1979). This (Osterrieth) strain of SFV is no longer used experimentally. Whilst the above case report is noted, it dates back over 30 years and is difficult to reconcile with the extensive use of other strains of SFV with no reported adverse effects over a 50 year period. This case report makes the unpublished observation that antibodies against SFV can be demonstrated in the serum of many laboratory personnel working with it. It is generally considered that the individual who died was probably immunosuppressed and therefore highly susceptible to infection. Anecdotal reports and reported laboratory incidents indicate no human clinical signs after accidental inoculation with various laboratory strains of SFV. The classification into ACDP hazard group 2 indicates current expert opinion that containment level 2 precautions are considered adequate for controlling the risks associated with working with SFV. The viral envelope glycoproteins and capsid protein sequences are the major determinants of host range and cell tropism and will not be changed beyond the addition of marker genes such as GFP (as fusion or cleavable inserts into this coding region) into the structural open reading frame; host range and cell tropism are therefore unlikely to be altered. SFV is classified as ACDP hazard group 2. Personnel working with this virus are expected to inform occupational health should they become pregnant or immunosuppressed.

LGTV:
Under normal conditions, LGTV is only very rarely pathogenic to humans; live virus has been used in vaccine trials in humans (Dubov et al., 1962). Development of this vaccine was stopped in the 1980s because of rare (1 in 20,000) occurrences of post-vaccinal neurological disease (Rumyantsev et al., 2006). Genetic changes that will be introduced into the virus sequences will be targeted at disrupting specific functions of virus RNA or virus proteins and can be expected to attenuate virus fitness; such changes are highly unlikely to increase virus virulence as they modify virus sequences, or change genome length, or lead to expression of additional sequences such as...
reporter genes which confer no advantage to virus replication. As for SFV, the viral envelope glycoproteins and capsid protein sequences which are the major determinants of host range and cell tropism will not be changed beyond the addition of marker genes as fusion or cleavable inserts into the region coding the structural proteins; host range and cell tropism are therefore unlikely to be altered. LGTV is not listed on the ACDP list but should be classified as hazard group 2 (current use in the UK and internationally, see http://www.healthsafe.uab.edu/pages/biosafety/biosafetymanual.pdf).

Personnel virus working with this virus are expected to inform occupational health should they become pregnant or immunosuppressed.

The host/recipient organism:
Prokaryotic organisms: All strains will be disabled, commercially available E. coli derivatives classified as ‘especially disabled hosts’ by ACDP. These strains cannot colonise humans and are known not to cause harm to humans.

Eukaryotic cells and tick organ cultures:
Cell lines to be used would not survive inside the human body (immune rejection) and are not known to carry harmful pathogens. Addition of DNA or RNA will confer no growth or survival advantage in or outside the laboratory to cell lines of vertebrate or arthropod origin. The tick organ cultures are derived from dissected ticks and are immobile culture systems. As with the cell lines they could not survive in humans. Organ cultures are generally derived from ticks sourced from ‘pathogen-free’ colonies; ticks from other sources (for example ‘field ticks’) could carry other pathogens and will not be used in these studies.

Mosquitoes (also see paragraph 8, below): These will be sourced only from ‘pathogen-free’ laboratory colonies (provided by Prof. Eileen Devaney, University of Glasgow). Precautions will be taken to minimise the risk of bites or escapes in strict compliance with standard operating procedures (attached separately). Work with virus replicons and VRPs will be done under the same procedures and containment as work with infectious virus (wild type or genetically modified). Measures to prevent human infection include storage of infected arthropods in sealed containers; work in designated rooms with restricted access; wearing of gloves and cooling of arthropods to slow their movement and facilitate handling. Samples (dead arthropods or material from these) will be transported to our CL2 laboratory according to standard regulations.

The inserted/donated genetic material:
Viral RNA and proteins, cellular proteins: Most individually expressed viral or cellular proteins (for example arthropod immune response inhibitors) are unlikely to have harmful effects in eukaryotic cells, however some could perturb normal arthropod cellular metabolism, predispose or protect against cell death or render cells more or less susceptible to other infections. It is very unlikely that SFV or LGTV (and other alphavirus, flavivirus or insect virus) RNA or proteins would have any harmful toxin-like effect outside cells. RNA containing the complete SFV or LGTV sequence can give rise to infectious virus in eukaryotic cells; alphavirus and flavivirus replicon RNAs are non-propagative and pose no harm (individual infected cells are likely to die or be eliminated by the immune system). Viral non-coding RNA sequences are likely to have minimal effects on virus replication, especially outside arthropod cell systems, and do not encode biologically active molecules that are likely to induce physiological effects in humans. As described under (9), no proteins or sequence which could interfere with immune responses in vertebrates will be cloned into viral genomes.

Reporter genes: Reporter genes of prokaryotic or eukaryotic origin (eg luciferase, fluorescent proteins etc.). No harmful properties have been attributed to these proteins. There would be no altered physiology expected if any of these genes were expressed; eGFP for example is a spontaneously fluorescent protein isolated from Aequorea victoria a coelenterate and has no known detrimental effects. Luciferase is another commonly used reporter gene and is derived from the firefly Phontinus pyralis or the jellyfish Renilla reniformis. It is an enzyme which catalyses production of light from luciferin and ATP; the light produced is used as a measure of gene activity. The enzyme has no other biological function.

Other non-coding RNA sequences: Any effects these elements have on gene expression are likely to be minimal. They may affect gene function or virus replication in individual cells but are unlikely to lead to whole body physiological effects as they do not code for the production of secreted bioactive molecules, and are unlikely to have any biological effects outside arthropod cell systems.

Sequence changes in viral sequences:
Mutation or deletion will target disruption of non-structural protein functions or non-coding viral sequences and are likely to have no or deleterious effects on viral replication, thus not increasing risk or hazards to human health associated by viruses genetically modified in such a way.

Control measures – assign provisional containment level:
GM bacteria transfected with plasmids containing viral sequences - Containment Level 1.
Eukaryotic cells (including tick organ cultures) containing alphavirus or flavivirus sequences unable to form complete infectious virus – Containment Level 1.
Eukaryotic cells (including tick organ cultures) containing full length SFV/LGTV sequences (capable of forming infectious virus, or capable of undergoing recombination or minor mutations to form infectious virus) – Containment Level 2.
Arthropods containing viral sequences unable to form complete infectious virus – Arthropod Containment Level 2.
Arthropods containing full length viral sequences (capable of forming infectious virus, or capable of undergoing recombination or minor mutations to form infectious virus) – Arthropod Containment Level 2
All with Good Microbiological Practice and Good Occupational Safety and Hygiene. Wear laboratory coat and gloves. For work with mosquitoes, wear a white laboratory overall with elastic cuffs, gloves and a mosquito net that covers the head. A microbiological safety cabinet will be used where appropriate.

Foreseeable effect/risk assessment for the environment:

SFV: This virus is not endemic in the UK It is not on the SAPO list. It is not clear whether suitable vertebrate hosts and insect vectors are present to establish an infection in this country. SFV can infect vertebrates (such as rodents) and certain biting insects. It is unclear whether suitable hosts are present. Transmission to vertebrates is by inoculation and to insect is by feeding on blood of an infected vertebrate. SFV is naturally transmitted by mosquitoes such as Aedes aegypti and Aedes africanus. Given the absence of these specific mosquitoes in Scotland and low pathogenicity of strains, the chance of infected laboratory mosquitoes (unlikely to survive for any extended length of time in the local environment) initiating a transmission cycle sustained by local insects is negligible. The modified viruses or replicons or replicons of other arthropod-borne alphaviruses will not have any inserted foreign genes other than non-harmful genes or sequences, or disruptive changes in non-structural genes or non-coding sequences; changes in virus pathogenesis are therefore unlikely other than as described above under the human health and safety section. In the absence of a suitable host or vector these viruses would not survive in the environment and the risk is effectively zero.

LGTV: This virus is not endemic to the UK. It is not on the SAPO list. LGTV is naturally transmitted by ticks; it was originally isolated from Ixodes granulatus ticks in SE Asia. The competence of UK ticks for this virus is unknown. A related virus, Louping-III virus, is found in ticks throughout the British Isles. Given the location of our laboratories, tick populations are unlikely to be very low in the immediate vicinity. Ticks generally acquire infection from a blood meal on vertebrates and as ticks are excluded from our laboratories, and viruses stored in closed containers the chance of accidental tick infection is negligible. Modified viruses or replicons or replicons of other arthropod-borne flaviruses do not contain anything other than non-harmful genes or sequences, or disruptive changes in non-structural genes or non-coding sequences; changes in virus pathogenesis are therefore unlikely other than as described above under the human health and safety section. The likelihood of virus released from our laboratory infecting a local tick is effectively zero (see disinfection and waste disposal procedures).

Hosts:

Prokaryotic organisms: Disabled, commercially available E. coli strains. These strains can only survive in a controlled laboratory environment and will be used for propagation of plasmids. Good microbiological practice and sterilisation of all contaminated waste will prevent release of viable organisms. Acquiring antibiotic resistance (from the plasmid vector) or additional sequences (virus or marker gene sequences) will not give these strains any survival advantage in the environment. The risk to the environment is therefore effectively zero.

Eukaryotic cells: Cell lines (and tick organ cultures) to be used are not viable outside the laboratory and thus pose no threat to the environment. Addition of plasmid vectors or virus will confer no growth or survival advantage in the environment.

Mosquitoes: Arthropods will be contained as described above under ‘risk to human health’ (and as detailed below, section 8). If arthropods carrying infectious material were to escape from our facilities they would have no survival advantage in the environment but could transmit the infection by bite. Whether this would initiate a natural sustainable cycle of SFV infection in Scotland is unlikely given the generally low mosquito activity. Given that escaped uninfected arthropods and natural arthropods will be
rare and that virus samples are in sealed containers and generally used in microbiological safety cabinets, the chances of arthropods becoming infected in the laboratory outside containment are virtually zero.

In summary

i) consequence/severity of effects: Low

ii) likelihood of effects being realised: Negligible

iii) overall risk: Effectively zero

Final classification: GM bacteria transfected with plasmids containing viral or other eukaryotic sequences (unable to cause disease, minimal hazard to health and environment) - Containment Level 1.

Eukaryotic cells (including tick organ cultures) containing viral sequences unable to form complete infectious virus – Containment Level 1.

Eukaryotic cells (including tick organ cultures) containing full length SFV or LGTV sequences (capable of forming infectious virus, or capable undergoing recombination or mutation to form infectious virus) – Containment Level 2.

Arthropods containing viral sequences (full length, partial) – Arthropod Containment Level 2.

All with Good Microbiological Practice and Good Occupational Safety and Hygiene. Wear laboratory coat and gloves. For work with mosquitoes, wear a white laboratory overall with elastic cuffs, gloves and a mosquito net that covers the head. As a routine measure all work will be carried out Containment level 2. A microbiological safety cabinet will be used where appropriate.

References:

Infection of mosquitoes will take place in a dedicated insectary at arthropod containment level 2 (AcCL2). A standard operating procedure (SOP) has been added separately.

Whole mosquitoes will be injected or fed (membrane feeding or capillary tube) with liquid (including blood) containing virus derived material, infectious virus, or a mixture of these. Viruses, RNA and proteins will be isolated from crushed mosquitoes. Virus infected live mosquitoes may be monitored by microscopy. Arthropods will be studied inside closed containers. In addition wingless mosquitoes may be used (wings will be removed from cold immobilised mosquitoes inside containment – glove box; see below.

ArCL2 is suitable for arthropods infected with hazard group 2 pathogens (human or animal) or Class 2 GMOs eg Semliki Forest virus, Langat virus etc.

Containment:

- The ArCL2 room will be arthropod-proof. Entrance door into insectary separated from surrounding facilities by additional door.
• door to facility will have clear signage indicating ‘arthropod containment level 2, no unauthorized entry’;
• any ventilation inlets and outlets of room and incubators will be screened with gauze or similar of pore size small enough to trap the smallest arthropod life cycle stage;
• windows (if present) and doors will be sealed;
• sinks (if present) will have an adequate arthropod-proof trap or be sealed;
• measures will be taken to enable escapees to be easily detected and recaptured or destroyed (white/clear walls);
• solid and liquid waste will be autoclaved (some invertebrates are not killed by chemical disinfectants or fumigants);
• an insecticidal spray will be available for use in an emergency (ONLY) (use of insecticides may render the room unfit for invertebrates for a long period, if not permanently; non-residual type insecticides should be chosen; insecticides do not have an immediate “knock-down” effect on ticks, but could cause long-term damage);
• infected flying insects will be kept in primary and secondary containment (glove box, incubator);
• primary containers for mosquitoes will be either (i) solid material sealed with a tight-fitting (tape secured with an elastic band) net lid or, (ii) a sleeved netting cage;
• secondary containment for mosquitoes will be either: (i) ‘arthropod-proof’ incubator, transparent or with transparent inner door, (ii) large and robust transparent sealed plastic bag with pin-prick air holes, (iii) transparent glove box, (iv) transparent Perspex box sealed (tape or elastic band) with a net cover;
• experimental containers (both primary and secondary) will be labelled to indicate the date, workers initials, arthropod species, number of arthropods and the nature of any infectious agent; the number of arthropods in each standard primary container will be kept to a minimum and for flying arthropods will not exceed numbers that can be easily counted (ie. 20)
• numbers will be adjusted as arthropods are removed (or to record escapees); each arthropod will be accounted for as the work proceeds through to final fixation or disposal;
• all experiments will also be recorded in a log book (species, worker initial, date, number of arthropods, nature of infectious agent;
• flying or crawling arthropods will be handled on white trays to detect escapees;
• infected arthropods will be killed before they are taken out of the containment facility;
• operating protocols designed to minimise escape and bites will be adhered to.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GM26 (CVR Church Street)

Solids from cell culture (eg plasticware such as flasks, tubes, pipettes tips etc.) - soak in 1% Virkon (w/v) for a minimum of 12 hours. Dispose of as normal solid waste (black bag).

Other solids (agar plates, gloves etc.) placed in a metal disposal box (lined with clear bag) and disposed of by autoclaving using a make safe cycle of 1210C for 30 minutes.

Arthropod-derived material such as the remains of mosquitoes or tick organ cultures will be placed in a metal disposal box (lined with clear bag) and disposed of by autoclaving using a make safe cycle of 1210C for 30 minutes.

Liquids (eg samples, culture supernatants, tissue culture media) – add Virkon to final concentration of 1% (w/v) for a minimum of 12 hours, then discharge to drains.

Liquids (E. coli culture medium)- add Virkon to final concentration of 1% (w/v) for a minimum of 12 h, then discharge to drains.

Sharps (in sharps bin, eg needles, syringes, scalpels) - autoclave by using a make safe cycle of 1210C for minutes.

Degree of kill:
Chemical Sterilization by Virkon- effectively 100% kill.
Autoclaving - effectively 100% kill (annual validation).

GM223 (CVR Garscube Estate):

Solids (pipettes tips, gloves etc.)- place in container (lined with sealed bag) and dispose of by autoclaving using a make safe cycle of 121-123°C for 30 minutes.

Arthropod-derived material such as the remains of mosquitoes will be placed in a sealed container (lined with clear bag) and disposed of by autoclaving using a make safe cycle of 121-123°C for 30 minutes.

Liquids (eg. samples) – dispose of by autoclaving using a make safe cycle of either 121-123°C for 30 minutes.

Degree of kill:
Autoclaving - effectively 100% kill (annual validation).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
1. GM 26 committee comments (approval date 25/08/11; see below):

The CVR Church Street GM subcommittee met on 22/08/11 to consider the proposal:

"Arthropod host cell/arbovirus interactions and immune responses induced by virus replication."

Subcommittee members:
R E
J M
A P
F R

The subcommittee members agreed recommendations for modifications to the following topics:

In Section 12 (Describe the waste management measures etc) of the HSE Notification and Section 16 (Proposed experiments etc, sub-heading Waste Disposal) of the Risk Assessment :-

Some of the autoclaving cycles specified were not available on the autoclave at the CVR Church Street site.

Procedures appropriate for clinical waste, incineration and microwaving were either not in use at the CVR Church Street site or would be expensive to implement. They were considered to be unnecessary for this proposal.

The procedure specified placing arthropod derived material into a sealed container for autoclaving. However, autoclaving requires containers be open to allow entry of steam.

No procedures for disinfection of contaminated material were described. All material is to be rendered safe by autoclaving, which would entail contaminated material being stored and transported to the autoclaves. This was considered an unacceptable risk, especially for liquid waste, and requires an effective disinfection procedure to be put in place.

The subcommittee decided that the relevant entries under section 12 in the HSE Notification and section 16 of the Risk Assessment should be replaced with the existing waste disposal and disinfection policies employed at the CVR Church Street site. These are available on the local intranet. Before this can be approved, validation must be obtained regarding the effectiveness of Virkon for inactivating LGTV and SFV.

In Section 6 (Purpose of the contained use), reference is made to subgenomic replicons of other arboviruses (eg chikungunya and dengue) that are not otherwise included in this proposal. A full description of the work to be carried out with these agents, the nature of the hazards and the precautions required should be included in both the HSE Notification and Risk Assessment.

Clarification is required for section 8 (Containment and control measures for GMOs that are not micro-organisms; page 11) of the HSE Notification and for section 11, sub-heading Hosts (page 8) of the Risk Assessment concerning the transport of arthropods. The latter states that; "Samples (dead or non-mobile arthropods (our italics) or material from these) will be transported to our CL2 laboratory according to standard regulations." The subcommittee agreed that no living infected arthropods would be allowed in the CVR Church Street site and that they should only be handled in an insectary.
The reference to; “the city centre location of our laboratories” on page 10 of the Risk Assessment is not appropriate for the CVR Garscube site and should be removed.

Under section 7, sub-heading Control measures (page 8) of the HSE Notification, the use of appropriate PPE (not just gloves) should be specified.

An estimate of virus quantities (eg pfu/ml) should be provided in addition to the culture volumes in the HSE Notification, section 9 (Maximum culture volumes per experiment; page 11) and the RA section 16 (Culture volumes; page 14).

The requested changes were made and on 25/08/11 the revised documents were circulated to and approved by the subcommittee members.

2. GM223 committee comments (approval date 20.10.2011, see below):

"The risk assessment was clear but clarification on local mosquito activity was required; more detail on any full length viruses being held, and careful consideration of any possible recombination events was deemed essential. Risks to immune-suppressed personnel needed to be mentioned.

These points have been addressed in form CU2 and Risk Assessment, and on the 20.10.2011 the revised documents were approved.

Dr. G on behalf of the committee."

The Bunyaviridae is one of the largest taxonomic arbovirus groups (over 300 named isolates). Viruses within the Bunyaviridae are classified into five genera: Orthobunyavirus, Hantavirus, Nairovirus, Phlebovirus and Tospovirus following molecular organization and serotyping [1]. Within a genus, viruses show similar patterns in the sizes of their genome segments and structural proteins, and whether or not non structural proteins are encoded. Bunyaviruses are important examples of emerging viruses, including pathogens of humans and/or animals [2,3]. The bunyavirus genome is a tri-segmented single-stranded RNA genome of negative (or ambi-sense) polarity that encodes four structural proteins. The genome segments are called L (large), M (medium) and S (small). The L RNA encodes the L protein, the M RNA segment Gn and Gc, and the S RNA the N protein. In addition, some viruses encode non-structural proteins called NSm (M segment) and NSs (S segment). The segments are encapsidated by the nucleocapsid (N) protein and interact with the viral RNA dependent RNA polymerase, the L protein, to form ribonucleoprotein complexes (RNP) known as nucleocapsids. During replication, a positive-stranded antigenome is produced which serves as the template for the de novo production of negative-stranded genomes. The polymerase L also transcribes shorter mRNAs which direct synthesis of bunyavirus proteins; interestingly, caps are “snatched” from cellular mRNAs. The bunyavirus terminal 3’ and 5’ sequences are largely complementary and interact to give the genome a characteristic pan-handle structure; these terminal sequences (and other sequence elements adjacent to the protein-coding regions) contain elements regulating transcription and replication of the bunyavirus genome. The RNPs are contained within a lipid envelope into which the two viral glycoproteins Gn and Gc are inserted. Replication occurs in the cytoplasm of infected cells, and viruses mature by budding at Golgi membranes (reviewed in [4]).

Most bunyaviruses are transmitted by arthropod vectors such as mosquitoes or ticks. Infection of arthropod cells is usually not cytopathic while vertebrate cells die following infection. Understanding the molecular basis for the different outcomes of infection in these cells of different origin is of fundamental importance, and may help in the development of new control measures for arboviral diseases. This is likely to imply immune responses (which differ in both hosts) and virus host interactions [5,6]. Research on antiviral immune responses in arthropod vectors has focused on positive-strand RNA viruses. Arthropod vectors activate immune responses upon infection, i.e. immune signalling pathways, humoral responses and most crucially RNA interference (RNAi) responses. Viral replication induces production of double stranded RNA, the RNAi-inducing substrate cleaved by dicer-type nuclease activities to produce virus-induced small interfering RNAs (also called viRNAs in the context of viral infection) which are integrated into the RNA-induced silencing complex (RISC). The RISC mediates nucleolytic cleavage of complementary viral RNAs. In addition, arthropod cells might differentially regulate subsets of their own small RNA repertoire following infection by arboviruses. In vertebrates, it is clear the interferon response is a key factor in limiting bunyavirus replication and this process, as well as bunyavirus antagonism of the interferon (as well as other host antiviral responses such as PKR) is an area which has seen important progress although important questions remain [6].

This project will investigate bunyavirus molecular biology and virus/host interactions, including structure-function analyses of viral proteins and the role of signals within viral RNAs, the interactions of bunyaviruses with host cell components, as well as the role of immune responses in controlling bunyavirus replication.
Two orthobunyaviruses will be at the core of this project. Bunyamwera virus (BUNV) is the prototype virus of the family [7]. Originally isolated in Uganda from infected mosquitoes, most of our understanding of bunyavirus biology is due to studies on this model bunyavirus. We will also study Schmallenberg virus (SBV), which was recently isolated from cattle in Germany and leads to disease (fever, diarrhoea, malformations, abortion) in cattle and sheep [8,9]. Non-hazardous minigenome systems (see below) of bunyaviruses of higher containment levels such as Rift Valley fever virus (RVFV) [10] may also be studied.

A reverse genetics systems that allows manipulation of the BUNV genome is available [11,12]. Cultured cells constitutively expressing bacteriophage T7 RNA polymerase are transfected with a mixture of 3 plasmids, each containing a full-length cDNA copy of one of the bunyavirus genome segments under control of T7 promoter and terminator sequences, and a hepatitis delta ribozyme sequence. Intracellular transcription produces exact copy RNA transcripts that act as viral mRNAs and templates for viral RNA synthesis that result in production of infectious virus. The system was initially established with BUNV and was subsequently adopted by other bunyaviruses such as the orthobunyavirus LaCrosse [13,14]. A reverse genetics system allows us to introduce mutations into the orthobunyavirus genome, as well as to introduce new sequences (such as reporter genes) or change or delete sequences [15,16,17]. Similarly, minigenome systems can be constructed in which only the coding sequences between the terminal orthobunyavirus sequences (either genomic or antigenomic) are replaced with a reporter gene such as Renilla luciferase (RLuc) or eGFP. A minigenome will be transcribed if N and L proteins are co-expressed from expression plasmids, which is useful to study the role of sequences and proteins in replication and in packaging as minigenome RNPs can be introduced into virions following superinfection with BUNV for example [18,19] and potentially also virus replicon particles (VRPs) by co-expression of glycoproteins. Minigenomes are on their own non-propagating and are used to mimik virus replication, and thus are a safe alternative to study for example replication of high-containment bunyaviruses.

In this project, we aim to work on the following topics as listed below. Eukaryotic host systems will be cells of vertebrate or invertebrate origin.

1) Development and use of reverse genetics systems for BUNV and SBV. Such a system is already in use for BUNV, and the SBV system will be designed along the same principles as the BUNV system. Similar systems for other bunyaviruses of the same hazardgroup may be considered for comparative studies.

Reverse genetics systems will be used to:
- Introduce mutations into the bunyavirus sequences. These can target coding or non-coding sequences although amino acid sequences of the glycoproteins will not be changed, to avoid alterations of host cell tropism.
- Introduce deletions and insertions into bunyavirus sequences, targeting coding or non-coding sequences. Deletions can for example target parts of non-coding regions, insertions can be reporter genes, bunyavirus genes may be completely replaced with other sequences.
- Exchange sequences between bunyavirus segments and within segments. Sequences from within bunyavirus segments will be transferred to other segments or transferred to other regions of the same segment.

Recombinant and wild type bunyaviruses will be used to:
- Study viral growth, gene expression, replication and packaging mechanisms in host cells.
- Study interactions with the host cell (replication, interaction with host cell factors, immunity).

2) Development and use of bunyavirus minigenome systems
- A BUNV minigenome is already in use and similar system will be developed for SBV. Minigenome systems will be used (as read-outs) in studies on protein functions (cellular, viral), sequence function, segment packaging (packaging by glycoproteins co-expression, or following co-infection) and complementation studies (ie. BUNV N in SBV minigenome).
- Minigenome systems of others bunyaviruses will be developed or obtained for studies on replication and packaging (Rift Valley fever virus etc).

3) Functional studies and expression of bunyavirus proteins.
- Manipulation of protein sequences by introduction of point mutations, deletions, insertions, fusion to others sequences such as reporter genes, tags etc.
- Expression of bunyavirus protein to study interactions with host cell components and cellular localisation.
- Expression of bunyavirus proteins by prokaryotic expression systems, for example for protein purification.
- Expression of bunyavirus proteins by eukaryotic expression systems (plasmid, retroviral expression), for example to produce packaging cell lines, cell lines expressing virus-like particles, or cell lines to study protein function.
- Expression of bunyavirus proteins by eukaryotic expression systems (plasmid, retroviral expression), to produce packaging cell lines for bunyavirus sequences (segments or minigenomes; production of single round infectious particles) and cell lines expressing virus-like particles.
- Silencing of bunyavirus gene expression or host genes involved in bunyavirus replication by RNA interference.

4) Studies on host immunity.

- Interactions of bunyaviruses (wild type, recombinant, minigenome) with vertebrate host responses, and counteraction of host responses (for example by NSs proteins) will be investigated. Immune signalling/antiviral responses (including activation mechanisms), and viral interference therewith, will be analysed. This will involve studies of extra- and intra-cellular host molecules. Role of immunity in host cell tropism (infections of cells from different species) will also be investigated. These studies will also use reporter genes inducible upon activation of a given pathway. Vertebrate-origin cell culture models are available.
- Interactions of bunyaviruses (wild type, recombinant, minigenome) with arthropod host responses, and counteraction of host responses will be analysed. Studies of the RNA interference response (host proteins regulating this mechanisms, identification and role of cellular and viral small RNAs, role of bunyavirus sequences in countering host responses) as well the role of immune signalling pathways and antiviral responses (including activation mechanisms) will be investigated. This will involve extra- and intra-cellular pathways (for example extracellular melanisation pathways). These studies will also use reporter genes inducible upon activation of a given pathway. Arthropod-origin cell culture models are available.
- The roles of bunyavirus RNAs in activitating or inhibiting vertebrate or arthropod immune responses will be investigated (expressed in viral systems such as Semliki Forest virus or plasmid-based expression).

References:

Recipient or parental organism

Viruses and derived replicons to be used will be of the Bunyaviridae family:
- Schmallenberg virus (SBV) (Orthobunyavirus).
- Bunyamwera virus (BUNV) (Orthobunyavirus).
- Recombinant viruses derived from BUNV and SBV.
- Minigenome systems derived from BUNV, SBV, and other bunyaviruses (Rift Valley fever virus etc.).

Other containment level 2 bunyaviruses (Guaroa virus, Maguari virus, Toscana and Sandfly fever phleboviruses etc.) may be considered as required.

No infectious containment level 3 or 4 viruses will be used.

Host/vector system

All organisms will be used at containment level 2, which is routine practice.

Plasmid vectors:
Viral sequences (full length clones of BUNV or SBV; partial sequences of these and other bunyaviruses) and other genes (cellular, viral, reporter) are available in plasmid-encoded cDNA form. RNAs can be transcribed from bacterial promoters (ie. T7 or SP6 by in vitro transcription or plasmid-expressed RNA polymerase in cells) or eukaryotic promoters (CMV, SV40, cellular promoter, baculovirus promoters etc.). Plasmids for expression of bunyavirus sequences (virus rescue or minigenome) contain a T7 RNA polymerase promoter, T7 terminator and a hepatitis delta-derived ribozyme sequence. Plasmids contain an origin of replication followed by a prokaryotic selectable marker (usually antibiotic resistance against ampicillin or kanamycin) and sometimes a selectable eukaryotic drug resistance marker such as neomycin or puromycin resistance. The bacterial systems are non-mobilisable vectors in a disabled prokaryotic host.

Lentiviral expression vectors: only at GM Centre 26; use is covered in CVR GM form 41 and amendments.

Hosts:

Prokaryotic hosts:
Disabled, commercially available E. coli strains such as Sure, JM109, XL-strains, DH-strains, Rosetta etc. These strains can only survive in a controlled laboratory environment and will be used for propagation of plasmids. Good microbiological practice and sterilisation of all contaminated waste should prevent release of viable organisms. The risk to the environment is therefore effectively zero.
Eukaryotic hosts:
Vertebrate cell lines of various origins (typically human, mouse, hamster, bovine etc.) and invertebrate cell lines of various origins (mosquito, culicoides, tick etc.). The vertebrate BSR-T7/5 cell line (derived from BSR, a clone of BHK) (Buchholz et al., 1999) expresses T7 RNA polymerase and will be used for minigenome assays and virus rescue, as may similar cell line expressing T7 RNA polymerase.

In prokaryotic cells, only selectable (eg antibiotic resistance) genes will be translated; prokaryotic cells may also be used for protein expression and subsequent purification.

In eukaryotic cells, the following RNAs will be produced which may be translated into the following gene products:

- Bunyavirus proteins and RNAs (BUNV and SBV, or minigenomes): Proteins involved in replication and transcription of viral genetic material and virus structural proteins. Some of these virus proteins will interact with host-cell components and may affect host cell responses to infection; few of these interactions are currently known. If all virus sequences are translated new virions may be generated; minigenomes are non-propagative viral RNAs (capable of replication). Partial RNAs do not give rise to propagating infectious material but may display biological activities (ie. RNAi inhibitory).

- Non-bunyavirus genes or sequences: Genes of prokaryotic (bacteriophage polymerases) or eukaryotic (eg. reporter genes such as luciferases or fluorescent proteins such as GFP; inhibitors of arthropod innate immunity, vertebrate or arthropod host genes etc.) origin. Reporter gene sequences will also be present in bunyavirus minigenome RNA. The recombinant foreign proteins to be expressed provide no significant increase in the hazard to human health; none are toxic or likely to produce disease in the quantities that could be produced by accidental exposure to these systems. Non translated RNA sequences (including T7 terminator and hepatitis delta ribozyme in plasmids used for virus rescue or minigenomes) have no known toxic effects and pose no risk to human health.

Techniques used to introduce insert or vectors into cells:

Prokaryotic cells: Introduction of DNA into E. coli will be by heat shock/chemical transformation. These techniques have been extensively described and are widely used; they rely on getting DNA very close to the bacterial membrane and introducing the genetic material through pores or membrane fusion.

Eukaryotic cells: Cells will be transfected using transfection reagents such a lipofectamine or by electroporation. Virus genomes or sequences will be introduced into cultured cells by infection with virus or virus replicon particles (VRP). Lentiviruses will be packaged and used to infect target cells.

Note- Nature of experiments are to be carried out at Church Street and Garscube Estate:

GM 26 (CVR Church Street):
- Preparation, characterisation and genetic manipulation of bunyaviruses and bunyavirus minigenomes.
- Protein expression and purification (prokaryotic cells), protein expression and purification (eukaryotic cells including lentiviral expression), protein interaction and modification studies.
- Infection/transfection of cell lines, preparation of lysates for downstream applications (including sequencing).
- Reporter gene assays, immunofluorescence studies.

GM223 (CVR Garscube Estate):
- As above; exception: separate GM notification for lentiviral/retroviral expression required.
Foreseeable effects/risk assessment for human health and safety (also see Risk Assessments):

Plasmid vectors:
Viral sequences (including full length clones or partial sequences of SBV or BUNV or other bunyaviruses) and other genes (cellular, viral or reporter) are available in plasmid-encoded cDNA form. Plasmid vectors are based on bacterial plasmids and contain an origin of replication for prokaryotic cells and selectable antibiotic/drug resistance (pro- or eukaryotic) markers. By themselves these vectors present no risk to human health. Vectors have no selective advantage and would soon be lost from the bacterial population. The bacterial systems are non-mobilisable vectors in a disabled prokaryotic host. Transcription of even complete viral cDNA (SBV or BUNV) will result in no infectious RNA since the promoters are not active in prokaryotic hosts. Systems for prokaryotic gene expression are under control of an inducible prokaryotic promoter. Systems for eukaryotic RNA or protein expression are under the control of promoters of viral (such as CMV or SV40), eukaryotic (eg actin promoter, pathway inducible promoter such as STAT, interferon etc.) or prokaryotic (such as T7 or SP6 promoter for in vitro transcription) origin. Plasmids with eukaryotic promoters such as the CMV promoter can be transcribed in human cells. None of the genes used in these studies are oncogenes. The hazard of expressing ‘foreign’ genes from these eukaryotic promoter plasmids would depend on the expected physiological effects of the foreign gene product and is discussed in more detail below.

BUNV:
Infection with this virus can cause a febrile illness with headache, arthralgias, rash and infrequent central nervous system involvement (Gonzalez and Georges, 1988). The classification into ACDP hazard group 2 indicates current expert opinion that containment level 2 precautions are considered adequate for controlling the risks associated with working with BUNV. The viral glycoprotein amino acid sequences are the major determinants of host range and cell tropism and will not be changed beyond the addition of marker genes as fusion or cleavable markers into the structural open reading frame. Genetic changes that will be introduced into the virus sequences will be targeted at disrupting or changing specific functions of virus RNA or virus proteins and can be expected to attenuate virus fitness; such changes are highly unlikely to increase virulence as they modify virus sequences, or change genome length, or lead to expression of additional sequences such as reporter genes which confer no advantage to virus replication.

SBV:
This an animal pathogen, and not likely to be a risk to human health by current guidelines (http://ecdc.europa.eu/en/publications/Publications/Forms/ECDC_DispForm.aspx?ID=795). Genetic changes that will be introduced into the virus sequences will be targeted at disrupting or changing specific functions of virus RNA or virus proteins and can be expected to attenuate virus fitness; such changes are highly unlikely to increase virus virulence as they modify virus sequences, or change genome length, or lead to expression of additional sequences such as reporter genes which confer no advantage to virus replication. As for BUNV, the viral glycoprotein amino acid sequences which are the major determinants of host range and cell tropism will not be changed beyond the addition of marker genes as fusion or cleavable markers. SBV is not listed on the ACDP or SAPO list but is recommended to be classified as hazard group animal pathogen 2 (see attached recommendation). We propose to treat SBV like BUNV in terms of risk for human infections and health unless other regulation is in place for a particular pathogen. In addition, personnel working with SBV should not be in contact with susceptible animals or visit farms/zoos where they could potentially come into contact with susceptible species for a period of 48 hours. A form outlining that they have understood their responsibility with regards to minimising the risks to the environment associated with this virus will be signed by personnel working on SBV.

Personnel working with these viruses are expected to inform occupational health should they become pregnant or immunosuppressed, and if planning pregnancy inform the PI so that precautionary measures can be introduced following advice from occupational health.

Bunyavirus minigenomes:
Minigenomes pose no risk to human health, including those derived from pathogenic bunyaviruses such as Rift Valley fever virus. They cannot propagate on their own, replication requires co-expression of L and N proteins. Even if packaged by co-expression of glycoproteins and thus used to infect cells, their own transcriptional activity would be minimal. If packaged into virions, the associated risk is that of the virus itself as reporter genes in minigenomes are not reported to be toxic.

Note 1: Should material such as minigenomes or other sequences be obtained for bunyaviruses listed under schedule 5 regulations, no additional sequences that could potentially be used to assemble the full length genome of a schedule 5 pathogen will be stored in locations that do not have required licenses.
Note 2: No reassortment experiments between BUNV, SBV or closely related orthobunyaviruses will be carried out as class 2 activity, to eliminate the possibility of creating viruses with enhanced pathogenicity such as Ngari (Gerrard et al., 2004). No work with two or more viruses of different bunyavirus species will be carried out in parallel in the same microbiological safety cabinet. Microbiological safety cabinets are decontaminated between experiments (UV and/or alcohol). The risk of accidental co-infection is effectively zero.

The host/recipient organism:
Prokaryotic organisms: All strains will be disabled, commercially available E. coli derivatives classified as ‘especially disabled hosts’ by ACDP. These strains cannot colonise humans and are known not to cause harm to humans.

Eukaryotic cells:
Cell lines to be used would not survive inside the human body (immune rejection) and are not known to carry harmful pathogens. Addition of DNA or RNA or infection will confer no growth or survival advantage in or outside the laboratory to cell lines of vertebrate or arthropod origin.

The inserted/donated genetic material:
Viral RNA and proteins, cellular proteins: Most such bunyavirus-expressed viral (such as inhibitors of insect immunity; where tested in vivo this has led to more rapid death of arthropod vectors) or cellular proteins are unlikely to have harmful effects in eukaryotic cells, however some could perturb normal cellular metabolism, predispose or protect against cell death or render cells more or less susceptible to other infections if overexpressed or silenced. It is very unlikely that BUNV or SBV (and hazard group 2 bunyaviruses) RNA or proteins would have any harmful toxin-like effect outside cells. Only antigenomic RNA containing a bunyavirus sequence can be translated or give rise to infectious virus (if all necessary genomic information is provided) in eukaryotic cells; minigenome RNAs are non propagative and pose no harm (individual cells replicating minigenome are likely to die or be eliminated by the immune system). Viral non-coding RNA sequences are important in bunyavirus replication but do not encode biologically active molecules that are likely to induce physiological effects in humans on their own.

No proteins that are known to interfere with immune or host responses in vertebrates will be cloned into bunyavirus genomes for the purpose of virus rescue under containment level 2 conditions, to avoid producing potentially highly pathogenic bunyaviruses by adding a more potent host response antagonist that those already present in bunyavirus genomes.

Reporter genes: Reporter genes of prokaryotic or eukaryotic origin (eg luciferase, fluorescent proteins etc.). No harmful properties have been attributed to these proteins. There would be no altered physiology expected if any of these genes were expressed; eGFP for example is a spontaneously fluorescent protein isolated from Aequorea victoria a coelenterate and has no known detrimental effects. Luciferase is another commonly used reporter gene and is derived from the firefly Photinus pyralis or the jellyfish Renilla reniformis. It is an enzyme which catalyses production of light from luciferin and ATP; the light produced is used as a measure of gene activity. The enzyme has no other biological function. Introduction of these reporter genes is unlikely to increase the risk associated with these viruses.

Other non coding RNA sequences (siRNAs, dsRNAs, other RNAs): Any effects these elements have on overall gene expression are likely to be minimal. They may affect gene function or virus replication in individual cells but are unlikely to lead to whole body physiological effects as they do not code for the production of secreted bioactive molecules.

Other sequence changes in viral sequences:
Mutation or deletion will target disruption of non-structural protein functions or non-coding viral sequences and are likely to have no or deleterious effects on viral replication, thus not increasing risk or hazards to human health associated by viruses genetically modified in such a way. No changes will be introduced that will change the amino acid sequence of the glycoproteins Gn and Gc (with the exception of in-frame fusion to reporter genes) so viral tropism is not affected.
Summary:
Genetic changes that will be introduced into the BUNV or SBV sequences as described above can be expected to attenuate virus fitness (with the exception of insect immunity inhibitors, but this does not concern human health); such changes are highly unlikely to increase virus virulence as they modify virus sequences (which are optimized for replication), or change genome length, or lead to expression of additional sequences such as reporter genes which confer no advantage to virus replication or have no effects outside the infected cell. Therefore we do not expect increased risk or hazards associated with viruses modified in such a way.

Control measures – assign provisional containment level:
GM bacteria transformed with plasmids containing viral sequences, reporter genes, other eukaryotic/prokaryotic genes or non-coding sequences - Containment Level 1.
Eukaryotic cells containing bunyaviral sequences unable to form complete infectious virus, or plasmids expressing reporter genes, other eukaryotic/prokaryotic genes or non-coding sequences – Containment Level 1.
Eukaryotic cells containing hazard group 2 bunyavirus sequences (capable of forming infectious virus, or capable of undergoing recombination or minor mutations to form infectious virus) – Containment Level 2.

All with Good Microbiological Practice and Good Occupational Safety and Hygiene. Wear laboratory coat and gloves. A microbiological safety cabinet will be used where appropriate (see below). Work with infectious bunyaviruses should take place in a microbiological safety cabinet. Spray gloves with alcohol when working outside the hood or before disposing.

Foreseeable effect/risk assessment for the environment:
BUNV: This virus is not endemic in the UK, and it is not on the SAPO list. It is not clear whether suitable vertebrate hosts and insect vectors are present to establish an infection in this country. BUNV can infect vertebrates (such as rodents) and certain biting insects. Transmission to vertebrates is by inoculation and to insect is by feeding on blood of an infected vertebrate. BUNV was isolated from mosquitoes in Uganda. Given the absence of these specific mosquitoes in Scotland and low pathogenicity of virus strains, the chance of accidentally infected arthropods initiating a transmission cycle sustained by local insects is negligible. The modified viruses will not have any inserted foreign genes other than non-harmful genes or sequences (with exception of inserted insect immunity inhibitors, which may lead to rapid death of infected arthropods), or (usually disruptive) changes in viral genes (with the exception of glycoproteins, whose amino acid sequences will not be changed) or non-coding sequences; changes in virus pathogenesis are therefore unlikely other than as described above under the human health and safety section. In the absence of a suitable host or vector these viruses would not survive in the environment and the risk is effectively zero. Arthropods are kept out of labs and the risk of accidental infection of insects by ingestion of contaminated material is also effectively zero for BUNV.

SBV: This virus has now been detected in the UK, and infections are most likely the result of midges carried from mainland Europe to the UK (Veterinary Record, News & Reports- see reference below). However other blood-feeding arthropods cannot be ruled out and vector competence studies are required. It is not yet on SAPO or ACDP lists and the recommendation (including for infection of insects) from Scottish Government (Rural and Environmental directorate) is to handle this pathogen as a category 2 animal pathogen (see attached recommendation). We propose, until further notification, to work with SBV at containment level 2 similarly to BUNV. The modified viruses do not contain anything other than non-harmful genes or sequences (with the exception of inserted insect immunity inhibitors, which may lead to rapid death of infected arthropods), or disruptive changes in genes (with the exception of glycoproteins, whose amino acid sequences will not be changed) or non-coding sequences; changes in virus pathogenesis are therefore unlikely other than as described above under the human health and safety section. If SBV was to escape the lab and infect local midges (or possibly other arthropods), there is a significant risk it could initiate a transmission cycle although this virus might arrive here by natural means (competence of local midges for SBV is not known but there is a significant risk they may be able to act as vectors). However arthropods are kept out of labs and the risk of infection of arthropods by ingestion of contaminated material is low and the likelihood of virus released from our laboratory infecting local vectors is effectively zero (see disinfection and waste disposal procedures). In addition, advice will be given to lab personnel that they should not be in contact with susceptible animals or visit farms/zoo where they could potentially come into contact with susceptible species for a period of 48 hours following work with SBV. A form outlining that they have understood their responsibility with regards to minimising the risks to the environment associated with this virus will be signed by personnel working on SBV.
Note: No proteins which could interfere with immune or host responses in vertebrates will be cloned into bunyavirus genomes for the purpose of virus rescue under containment level 2 conditions, to avoid producing potentially highly pathogenic bunyaviruses by adding a more potent host response antagonist that those already present in bunyavirus genomes.

We propose to use containment group 2 bunyaviruses (see point 7) similar to BUNV unless other regulations are in place for a particular pathogen.

Minigenomes: These systems derived from BUNV, SBV or other bunyaviruses are non-propagative and even if packaged, pose no or no additional hazard.

Hosts:

Prokaryotic organisms: Disabled, commercially available E. coli strains. These strains can only survive in a controlled laboratory environment and will be used for propagation of plasmids. Good microbiological practice and sterilisation of all contaminated waste will prevent release of viable organisms. Acquiring antibiotic resistance (from the plasmid vector) or additional sequences (virus or marker gene sequences) will not give these strains any survival advantage in the environment. The risk to the environment is therefore effectively zero.

Eukaryotic cells: Cell lines to be used are not viable outside the laboratory and thus pose no threat to the environment. Addition of plasmid vectors or virus or minigenomes will confer no growth or survival advantage in the environment.

In summary

i) consequence/severity of effects: Severe

ii) likelihood of effects being realised: Low

iii) overall risk: Low

Final classification: GM bacteria transformed with plasmids containing viral sequences, reporter genes, other eukaryotic/prokaryotic genes or non-coding sequences (unable to cause disease, minimal hazard to health and environment) - Containment Level 1.

Eukaryotic cells containing bunyaviral sequences unable to form complete infectious virus, or plasmids expressing reporter genes, other eukaryotic/prokaryotic genes or non-coding sequences – Containment Level 1.

Eukaryotic cells containing bunyavirus sequences capable of forming infectious virus, or capable undergoing recombination or mutation to form infectious virus – Containment Level 2.

All with Good Microbiological Practice and Good Occupational Safety and Hygiene. Wear laboratory coat and gloves. As a routine measure all work will be carried out at Containment level 2. A microbiological safety cabinet will be used where appropriate. Work with infectious bunyaviruses should take place in a microbiological safety cabinet. This additional layer of security also is to prevent accidental contamination of any arthropods (thus reducing risk to the environment). Spray gloves with alcohol when working outside the hood or before disposing. Traps to catch arthropods will be present in labs were work with live infectious bunyaviruses is carried out.

**GM26 (CVR Church Street):**

Solids from cell culture (eg plasticware such as flasks, tubes, pipette tips etc.) - soak in 1% Virkon (w/v) for a minimum of 12 hours. Dispose of as normal solid waste (black bag).

Other solids (agar plates, gloves etc. )- placed in a metal disposal box (lined with clear bag) and disposed of by autoclaving using a make safe cycle of 121°C for 30 minutes. Gloves used for bunyavirus work should be disinfected with alcohol before putting in containers.

Liquids (eg samples, culture supernatants, tissue culture media) – add Virkon to final concentration of 1% (w/v) for a minimum of 12 hours, then discharge to drains.

Liquids (E. coli culture medium)- add Virkon to final concentration of 1% (w/v) for a minimum of 12 hours, then discharge to drains.

Sharps (in sharps bin, eg needles, syringes, scalpels) - autoclave by using a make safe cycle of 121°C for 30 minutes.

**Degree of kill:**
- Chemical Sterilization by Virkon- effectively 100% kill.
- Autoclaving - effectively 100% kill (annual validation).

**GM223 (CVR Garscube Estate):**

Disposable solids (eg plasticware such as flasks, tubes, pipette tips etc.): soak in 1% Virkon (w/v) for a minimum of 12 hours. Transfer solid contents to clear autoclave bags and autoclave at 121°C for a minimum of 20 minutes prior to final disposal by district council to land fill, remaining liquid to be discharged to drain.

Other solids (agar plates, gloves etc.): placed in a marked box lined with a clear autoclave bag, and disposed of by autoclaving using a make safe cycle of 121°C for at least 20 minutes. Seal contaminated plates (with for example bacterial GMOs) before placing in bag, to avoid lid falling off. Gloves used for bunyavirus work should be disinfected with alcohol before putting in containers.

Liquids (eg. samples, bacterial culture media, tissue culture media) - add Virkon to final concentration of 1% (w/v) for a minimum of 12 hours, then discharge to drains.

Sharps (in sharps bin, eg needles, syringes, scalpels) - autoclave by using a make safe cycle of 121°C for at least 20 minutes, then incinerated.

**Degree of kill:**
- Chemical Sterilization by Virkon- effectively 100% kill.
- Autoclaving - effectively 100% kill (annual validation).
1. GM 26 committee comments:

The CVR Church Street GM subcommittee met on 22/08/11 to consider the proposal:
"Bunyavirus molecular biology and virus/host interactions."

Present:
*********** personal details removed

The following topics were discussed:

The committee members had no concerns regarding the overall aims of the proposed experiments. Overall the work with Bunyamwera virus (BUNV) was approved for handling under normal class 2 conditions. Questions were raised over some aspects of the work with Schmallenberg virus (SBV). Additional questions on risk to the environment and containment were also discussed.

This points have been addressed in form CU2 and the Risk assessment, and on the 15.03.2012 the documents were approved.
On behalf of the CVR Church Street subcommittee, Dr. P"

2. GM223 committee comments:

"The risk assessment was clear and comprehensive but a number of clarifications in particular on risk to the environment by SBV (vectors, accidental contamination of local arthropods) were required.

These points have been addressed in form CU2 and Risk Assessment, and on the 15.03.2012 the revised documents were approved.

Dr. G on behalf of the committee."

Drosophila C virus (DCV) belongs to the genus Cripavirus now classed within the Dicistroviridae family (previously Picornaviridae) within the order Picornavirales. It is a single stranded, positive-stranded RNA virus with a genome length of approximately 9300 bases. Unlike picornaviruses, the genome encodes two open reading frames (ORF) which encode (towards the 5’ end) an open ORF coding for non-structural proteins and (towards the 3’ end) an ORF coding structural proteins. The non-structural ORF encodes proteins involved in virus replication (including the RNA interference inhibitor 1A), while the structural ORF encodes viral envelope proteins. Both open reading frames are translated via separate internal ribosome entry sites in the genome. A Vpg protein is attached to the 5’ end the 3’ end contains a poly A sequence. These viruses are non-enveloped (1).

DCV has a worldwide distribution (including UK) and is also found in laboratory strains of Drosophila melanogaster and cultured cells (D. Obbard, University of Edinburgh, personal communication); it can also infect a variety of drosophila species (6). Infection leads to more rapid development, females are heavier and lay more eggs. Infection occurs by ingestion and infection is not pathogenic, although this may vary between flies. Interestingly, infection by injection leads to rapid death of flies (4). DCV is not a SAPO or ACDP pathogen; it does not infect vertebrate cells.

The genetic and molecular tools available for D. melanogaster make it a very useful model to study virus-host interactions and virus pathogenesis in an easily grown and genetically manipulated host. DCV has been particularly used in studies on antiviral immune signalling and RNA interference responses in drosophila (7); this research has led the insect virology field for many years. The DCV 1A protein acts as a viral suppressor of RNA interference (10), yet the virology of these virus/drosophila interactions is overall poorly understood in contrast to the extensive knowledge we have of drosophila genes and physiology. DCV is also inhibited by endosymbiotic Wolbachia bacteria in drosophila (9). This is similar other RNA viruses such as arboviruses in mosquitoes (which may be a useful control measure in public health strategies) yet it is not known...
how inhibition by the endosymbiont is mediated and powerful drosophila genetics may be required to solve this question and improve the uses of Wolbachia endosymbionts (5).

Despite the strength of D. melanogaster genetics, a major drawback of drosophila immunity research is that no reverse genetics system is available to manipulate and study the genome of DCV. This project aims to develop an infectious DCV clone to apply reverse genetics technology to this virus. A dicistrovirus infectious clone has so far only been described for Rhopalosiphum padi dicistrovirus (RhPV) (2, 8). This clone is not very efficient and one of the major drawbacks is that the length of the 3’ poly A tail is not known for these viruses; it is likely to be similar to picornaviruses and of 20-60 nucleotides in length. However the RhPV infectious clone has no such sequence, bar a very short internal poly A stretch. This may be one of the reasons why the RhPV infectious clone is relatively weak, and possibly efforts to make a DCV infectious clone so far may have failed due to missing 3’ poly A tails.

The prototype DCV strain is isolate EB, but sequences of other isolates are available.

We propose to:
- Propagate the cloned DCV sequence. The DCV genome will be cloned into a plasmid backbone such as pUC-type or other vector. Transcription of the viral cDNA into RNA will be under control of a bacteriophage RNA polymerase promoter (T7, SP6 or similar) or eukaryotic promoter, and RNA introduced into insect cells or infectious clone cDNA transfected into insect cells for virus rescue. Where required, ribozyme-encoding sequences (hammerhead ribozyme, hepatitis delta ribozyme or similar) will be added to the genome ends (5’ and/or 3’ ends) to generate correct termini in the transcribed RNA as has been described previously (3).

- Manipulate the cloned DCV genome by molecular biological methods. This will be achieved by insertion of sequences (reporter genes such as luciferase or fluorescent proteins, drug resistance genes, other eukaryotic genes, non-coding sequences), deletion of sequences (point deletions, deletion of larger sequences) or point mutations within the DCV sequence. No changes will be made to sequences encoding the structural proteins, to avoid changes in viral tropism. Alterations to viral sequences such as those described above usually result in a fitness decrease. Modifications of the viral genome sequence will also include adding of poly A tails either by in vitro poly-adenylation or adding a cloned poly A sequence to the viral cDNA. Chimeras between strains of DCV (exchange of protein-coding sequences or non-coding sequences) will be created to study the role of strain-specific differences on replication, immunity and pathogenesis.

- If infectious DCV can be successfully rescued, we will delete the structural open reading frame 2 (or parts of it) to create non-propagating replicons and a packaging system (co-expression of DCV structural proteins in replicon-transfected cells) to obtain virus replicon particles.

- Individual DCV sequences (coding or non-coding) will be cloned into eukaryotic or prokaryotic vectors (plasmid or Semliki Forest virus or derived replicon) for molecular biological manipulation and/or expression purposes. Manipulated sequences may be re-introduced into the DCV infectious clone.

Studies to be undertaken with a DCV infectious clone and/or derived replicons:
- Immune responses of insect cells against DCV infection. We will study RNA interference and other mechanisms (immune signalling) that control DCV replication and viral interference therewith.
- Replication and polyprotein processing in insect cells. We will analyse sequences and mechanisms involved in these processes, as well as cellular factors involved in promoting or inhibiting DCV replication and spread.
- Virus entry, replication compartment formation and exit from insect cells. The tools for DCV manipulation (in particular viruses encoding reporter genes and replicons/virus replicon particles) developed in this project will allow to track these processes more efficiently (timing of events, determination of virus production etc.).
- Above studies will also be carried out in Wolbachia-infected insect cells to further study the mechanisms by which this micro-organism inhibits RNA virus replication.
- No experiments in vertebrate cells are planned.

Recipient or parental organism

Drosophila C virus. The infectious clone will be based on the sequence of strain EB; other strains or sequences from other strains may also be cloned.

Host/vector system

All organisms will be used at containment level 2, which is routine practice throughout the Church Street CVR site.

Plasmid vectors:

Viral sequences (including full length clones or partial sequences of DCV) and other genes (cellular, viral or reporter) are available in plasmid-encoded cDNA form. RNAs can be transcribed through bacterial promoters (ie. T7 or SP6) or eukaryotic promoters. Plasmids contain an origin of replication followed by a prokaryotic selectable marker (usually antibiotic resistance against ampicillin or kanamycin) and sometimes a selectable eukaryotic drug resistance marker such as neomycin or puromycin resistance. The bacterial systems are non-mobilisable vectors in a disabled prokaryotic host.

Hosts:

Prokaryotic hosts:

Disabled, commercially available E. coli strains such as Sure, JM109, XL-strains, DH-strains, Rosetta etc. These strains can only survive in a controlled laboratory environment and will be used for propagation of plasmids. Good microbiological practice and sterilisation of all contaminated waste should prevent release of viable organisms. The risk to the environment is therefore effectively zero.
Eukaryotic hosts: Invertebrate cell lines of various origins (drosophila, mosquito, tick etc.). These will be used to grow virus or express/silence individual proteins or sequences. Cells grown in standard media such as L-15 or Schneiders and are maintained in cooled cell culture incubators.

Origin & function

In prokaryotic cells, only selectable (eg antibiotic resistance) genes will be translated.

Virus sequences will be under the control of a promoter that will only generate transcripts in eukaryotic cells or in vitro transcription reactions.

In eukaryotic cells, RNA will be translated into the following gene products:

- Viral proteins and RNAs: Proteins involved in replication and transcription of viral genetic material and virus structural proteins. Some of these virus proteins will interact with host-cell components and may affect host cell responses to infection (for example 1A RNAi suppressor). If all virus sequences are translated new virions may be generated; replicons are non-propagative viral RNAs (capable of replication). Partial RNAs do not give rise to propagating infectious material but can display biological activities (ie. RNAi inhibitory, expression of some viral proteins for example for packaging of replicons).

- Non-viral genes: Genes of prokaryotic (eg CAT) or eukaryotic (eg. reporter genes such as luciferases or fluorescent proteins such as GFP; inhibitors of insect immunity ie. RNAi inhibitors, signalling inhibitors, melanization inhibitors etc.) origin. The recombinant foreign proteins to be expressed provide no significant increase in the hazard to human health; none are toxic or likely to produce disease in the quantities that could be produced by accidental exposure to these systems. Non-translated RNA sequences have no known toxic effects and pose no risk to human health.

Techniques used to introduce insert or vectors into cells:

Prokaryotic cells: Introduction of DNA into E. coli will be by heat shock/chemical transformation. These techniques have been extensively described and are widely used; they rely on getting DNA very close to the bacterial membrane and introducing the genetic material through pores or membrane fusion.

Eukaryotic cells: Cells will be transfected using reagents such a lipofectamine or by electroporation. Virus genomes will be introduced into cultured cells by infection with virus or virus replicon particles (VRP), using transfection reagents or by electroporation.

Evaluation of foreseeable effects

Foreseeable effects/risk assessment for human health and safety (also see Risk Assessments):

Plasmid vectors:
Viral sequences (including full length clones or partial sequences of DCV) and other genes (cellular, viral or reporter) are available in plasmid-encoded cDNA form. Plasmid vectors are based on bacterial plasmids and contain an origin of replication for prokaryotic cells and selectable antibiotic/drug resistance (pro- or eukaryotic) markers. By themselves these vectors present no risk to human health. Vectors have no selective advantage and would soon be lost from the bacterial population. The bacterial systems are non-mobilisable vectors in a disabled prokaryotic host. Transcription of even complete viral cDNA will result in no infectious RNA since viral elements are not active in prokaryotic hosts. Systems for prokaryotic gene expression are under control of an inducible prokaryotic promoter. Systems for eukaryotic RNA or protein expression are under the control of promoters of viral (such as CMV, baculovirus-derived IE promoter), eukaryotic (eg actin promoter, pathway inducible promoter such as STAT) or prokaryotic (such as T7 or SP6 promoter for in vitro transcription) origin. Plasmids with eukaryotic promoters such as the CMV promoter can be transcribed in human cells. None of the genes used in these studies are oncogenes. The hazard of expressing ‘foreign’ genes from these eukaryotic promoter plasmids would depend on the expected physiological effects of the foreign gene product and is discussed in more detail below.

DCV:
This virus is not known to infect or replicate in human cells or other cells of vertebrate origin. It is not a ACDP pathogen. Work with this virus or recombinant DCV does not pose a risk to human health. Replicons are non-propagating even within virus-replicon particles and pose no risk.
The host/recipient organism:
Prokaryotic organisms: All strains will be disabled, commercially available E. coli derivatives classified as 'especially disabled hosts' by ACDP. These strains cannot colonise humans and are known not to cause harm to humans.

Eukaryotic cells:
Insect cell lines to be used would not survive inside the human body (immune rejection) and are not known to carry harmful pathogens. Addition of DNA or RNA will confer no growth or survival advantage in or outside the laboratory to these cell lines.

The inserted/donated genetic material:
Viral RNA and proteins, cellular proteins: Most individually expressed viral or cellular proteins (for example arthropod immune response inhibitors) are unlikely to have harmful effects in eukaryotic cells, however some could perturb normal arthropod cellular metabolism, predispose or protect against cell death or render cells more or less susceptible to other infections. It is very unlikely that DCV RNA or proteins would have any harmful toxin-like effect outside cells. RNA containing the complete DCV sequence can give rise to infectious virus in insect cells; replicon RNAs are non-propagating and pose no risk. Viral non-coding RNA sequences are likely to have minimal effects outside arthropod cell systems, and do not encode biologically active molecules that are likely to induce physiological effects in humans.

Reporter genes: Reporter genes of prokaryotic or eukaryotic origin (eg luciferase, fluorescent proteins etc.). No harmful properties have been attributed to these proteins. There would be no altered physiology expected if any of these genes were expressed; eGFP for example is a spontaneously fluorescent protein isolated from Aequorea victoria a coelenterate and has no known detrimental effects. Luciferase is another commonly used reporter gene and is derived from the firefly Photinus pyralis or the jellyfish Renilla reniformis. It is an enzyme which catalyses production of light from luciferin and ATP; the light produced is used as a measure of gene activity. The enzyme has no other biological function.

Other non-coding RNA sequences: Any effects these elements have on gene expression are likely to be minimal. They may affect gene function or virus replication in individual cells but are unlikely to lead to whole body physiological effects as they do not code for the production of secreted bioactive molecules, and are unlikely to have any biological effects outside arthropod cell systems.

Sequence changes in viral sequences:
Mutation or deletion will target disruption of non-structural protein functions or non-coding viral sequences and are likely to have no or deleterious effects on viral replication, thus not increasing risk or hazards to human health associated by viruses genetically modified in such a way. Deletions in the structural genes to produce replicons will result in non-propagating virus-derived RNAs that pose no risk, even if packaged into virus replicon particles. Expression of sequences by Semliki Forest virus and derived replicons is covered under GM26/CVR_AK_1.

Control measures – assign provisional containment level:
GM bacteria transfected with plasmids containing viral or other eukaryotic sequences - Containment Level 1.
Eukaryotic cells containing DCV sequences unable to form complete infectious virus – Containment Level 1.
Eukaryotic cells containing full length DCV sequences (capable of forming infectious virus, or capable of undergoing recombination or minor mutations to form infectious virus) – Containment Level 2.

All with Good Microbiological Practice and Good Occupational Safety and Hygiene. Wear laboratory coat and gloves. A microbiological safety cabinet will be used where appropriate.

Foreseeable effect/risk assessment for the environment:
DCV: This virus is not on the SAPO/ACDP lists. It can infect drosophila by ingestion; recombinant virus is likely to be less fit than wild type but may be able to infect
drosophilid species and other insects. Virus is kept within containment and no accidental infections of arthropods can take place. Replicons are non-propagating even within
virus replicon particles and pose no risk. Arthropods and food are kept away from the laboratories and waste sterilized before disposal (see below) and it is therefore
unlikely that any lab-acquired infection and/or escape can take place.

Hosts:

Prokaryotic organisms: Disabled, commercially available E. coli strains. These strains can only survive in a controlled laboratory environment and will be used for
propagation of plasmids. Good microbiological practice and sterilisation of all contaminated waste will prevent release of viable organisms. Acquiring antibiotic resistance
(from the plasmid vector) or additional sequences (virus or marker gene sequences) will not give these strains any survival advantage in the environment. The risk to the
environment is therefore effectively zero.

Eukaryotic cells: Cell lines to be used are not viable outside the laboratory and thus pose no threat to the environment. Addition of plasmid vectors or virus will confer no
growth or survival advantage in the environment.

In summary

i) consequence/severity of effects: Low

ii) likelihood of effects being realised: Low

iii) overall risk: Low

Final classification: GM bacteria transfected with plasmids containing viral or other eukaryotic sequences (unable to cause disease, minimal hazard to health and
environment) - Containment Level 1.
Eukaryotic cells containing DCV sequences unable to form complete infectious virus – Containment Level 1.
Eukaryotic cells containing DCV sequences (capable of forming infectious virus, or capable undergoing recombination or mutation to form infectious virus) – Containment
Level 2.

All with Good Microbiological Practice and Good Occupational Safety and Hygiene. Wear laboratory coat and gloves. As a routine measure all work will be carried out
Containment level 2. A microbiological safety cabinet will be used where appropriate.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids from cell culture (eg plasticware such as flasks, tubes, pipettes tips etc.) - soak in 1% Virkon (w/v) for a minimum of 12 hours. Dispose of as normal solid waste
Other solids (agar plates, gloves etc.) placed in a metal disposal box (lined with clear bag) and disposed of by autoclaving using a make safe cycle of 121°C for 30 minutes.

Liquids (eg samples, culture supernatants, tissue culture media) – add Virkon to final concentration of 1% (w/v) for a minimum of 12 hours, then discharge to drains.

Liquids (E. coli culture medium)- add Virkon to final concentration of 1% (w/v) for a minimum of 12 h, then discharge to drains.

Sharps (in sharps bin, eg needles, syringes, scalpels) - autoclave by using a make safe cycle of 121°C for minutes.

Degree of kill:
Chemical Sterilization by Virkon- effectively 100% kill.
Autoclaving - effectively 100% kill (annual validation).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
1. GM 26 committee comments (approval date 22/02/12; see below):

The CVR Church Street GM subcommittee met on 31/01/12 to consider the proposal:
"Establishment of a reverse genetics system for drosophila C virus"

Subcommittee members:
R E
J M
J M
AP
F R (convener)

As Drosophila C virus only infects arthropods, it is not considered hazardous. Therefore, no objections were raised against the proposed work. However, clarification was requested for the following points:

How will the virus be propagated? The culture conditions should be described.

The Risk Assessment contains the statement “DCV: This virus is not a ACDP pathogen. It is not known to infect or replicate in human cells, and there is no risk associated with using this virus.” (page 7, Vectors and GMOs). In the GM application the same section (page 5, point 7) states “DCV: This virus is not able to infect or replicate in human cells or other cells of vertebrate origin.” These statements should be made to be consistent and accurate.

More clarity is required over the potential for infection of, and expression in, mammalian cells. This is particularly relevant in light of the subsequent discussion over the need for Notification (see below), which would only be required if there is a threat to human health or the environment. For example, it is proposed to clone genes under the CMV (and possibly other mammalian) promoter. Is this promoter active in insect cells and if not, why is it being used?

Also, SFV can infect mammalian cells so its use as a vector is potentially harmful. In the Notification (page 3) it is stated that “-Individual DCV sequences (coding or non-coding) will be cloned into eukaryotic or prokaryotic vectors (plasmid or Semliki Forest virus or derived replicon) for molecular biological manipulation and/or expression purposes.” In the Risk Assessment the sentence reads: (plasmid or Semliki Forest virus replicon or derived replicon). These statements should be made to be consistent and accurate.

Although only experiments in insect cells are listed under “Detailed descriptions and description/use of genetic modification:” (page 2-4 of Notification) a positive statement that no experiments in mammalian cells are planned should be inserted.

On page 2 of the Notification it is proposed to clone the DCV genome into a plasmid backbone. However, the section on Host/vector system (page 4) contains the statement that “Viral sequences (including full length clones or partial sequences of DCV) and other genes (cellular, viral or reporter) are available in plasmid-encoded..."
The discussion on this proposal raised the question of whether a Notification is required in this case. DCV is an insect pathogen that appears to pose no risk to human health and would have low or negligible environmental consequences if it escaped from the laboratory. It therefore resembles baculovirus, which is classified at containment level 1 except when specifically intended as a vector for gene expression in mammalian cells or when encoding viral functions that could themselves transmit to mammalian cells. Page 9-10 of the Risk Assessment Form includes the statement: “If the answer to questions 11 and 12 is negligible, you may believe that you have sufficient information at this stage to classify the project to class 1, as defined in the Contained Use Regulations 2000. In order to do this you should be confident that in the event of a total breach of containment the GMO would be of no or negligible risk to human health or the environment.” The committee therefore requested that the reason for suggesting that work involving DCV is classified as containment level 2 should be further evaluated and the results of such an evaluation be conveyed back to the subcommittee. If a Notification is deemed unnecessary a Risk Assessment would still be required for GM work.

As part of the same discussion it was suggested that to save effort and expense, planned future work on Arboviruses should be assessed in terms of the likely need for further applications for Notification. If more potential applications are identified consideration should be given to the possibility of combining the proposals into a single Notification covering as many viruses as possible.

Response from A K to GM Committee comments (06.02.2012):

I would like to thank the committee members for their helpful suggestions. My response to several comments is outlined below:

- Culture conditions for DCV have now been indicated under “Eukaryotic hosts”, GM notification page 4 and RA page 2.
- It is now stated that “... is not known to infect or replicate in human cells”, to be consistent. Infection of vertebrate cells has to my knowledge never been tried. Although highly unlikely, I do not believe this is a risk as no true insect virus has ever been described as an emerging pathogen, or is known to move between insects and vertebrates for example. However even baculoviruses are known to enter vertebrate cells and initiate transcription. Therefore some precaution is advisable. The CMV promoter is active in some insect cell lines and we use pRL-CMV for example to express luciferase, as well as other eukaryotic reporter plasmids.
- Comment on SFV now reads “plasmid or Semliki Forest virus or derived replicon”.
- Statement “-No experiments in vertebrate cells are planned” has been added (RA page 3, GM form page 3).
- The DCV genome of strain EB is currently being synthesized; we do not have the plasmid in the lab yet but it should be delivered over the coming weeks. I inserted this comment as by the time HSE receive the form, we should be about to receive the plasmid.

I suggest to class this virus as class 2 activity. This is mainly based on the observation that DCV can in fact infect far more species of drosophila than previously thought, and although it is rapidly cleared from mosquitoes it can potentially infect these insects too. There is therefore a theoretical possibility of infecting other species beyond the
drosophilids. With current debates around pollinators such as bees, which are highly susceptible at least to viruses closely related to DCV, it may be advisable to take into account the risk of introducing GM forms of DCV into the environment. In the risk assessment parts of the two forms I have now made it clear that we are aware of the fact that recombinant DCV could potentially infect drosophila “and other insects”. I do not foresee any risk to human health.

The revised documents and explanations were circulated to and approved by the subcommittee members

F. R(convener) 24/02/12.

1. GM 26 committee comments (approval date 22/02/12; see below):

The CVR Church Street GM subcommittee met on 31/01/12 to consider the proposal:
"Establishment of a reverse genetics system for drosophila C virus"

Subcommittee members:
Roger Everett
John McLauchlan
Joyce Mitchell
Arvind Patel
Frazer Rixon (convener)

As Drosophila C virus only infects arthropods, it is not considered hazardous. Therefore, no objections were raised against the proposed work. However, clarification was requested for the following points:

How will the virus be propagated? The culture conditions should be described.

The Risk Assessment contains the statement “DCV: This virus is not a ACDP pathogen. It is not known to infect or replicate in human cells, and there is no risk associated with using this virus.” (page 7, Vectors and GMOs). In the GM application the same section (page 5, point 7) states “DCV: This virus is not able to infect or replicate in human cells or other cells of vertebrate origin.” These statements should be made to be consistent and accurate.
More clarity is required over the potential for infection of, and expression in, mammalian cells. This is particularly relevant in light of the subsequent discussion over the need for Notification (see below), which would only be required if there is a threat to human health or the environment. For example, it is proposed to clone genes under the CMV (and possibly other mammalian) promoter. Is this promoter active in insect cells and if not, why is it being used?

Also, SFV can infect mammalian cells so its use as a vector is potentially harmful. In the Notification (page 3) it is stated that “Individual DCV sequences (coding or non-coding) will be cloned into eukaryotic or prokaryotic vectors (plasmid or Semliki Forest virus or derived replicon) for molecular biological manipulation and/or expression purposes.” In the Risk Assessment the sentence reads: (plasmid or Semliki Forest virus replicon or derived replicon). These statements should be made to be consistent and accurate.

Although only experiments in insect cells are listed under “Detailed descriptions and description/use of genetic modification:” (page 2-4 of Notification) a positive statement that no experiments in mammalian cells are planned should be inserted.

On page 2 of the Notification it is proposed to clone the DCV genome into a plasmid backbone. However, the section on Host/vector system (page 4) contains the statement that “Viral sequences (including full length clones or partial sequences of DCV) and other genes (cellular, viral or reporter) are available in plasmid-encoded cDNA form.” The source and nature of the already available DCV clones should be described.

The discussion on this proposal raised the question of whether a Notification is required in this case. DCV is an insect pathogen that appears to pose no risk to human health and would have low or negligible environmental consequences if it escaped from the laboratory. It therefore resembles baculovirus, which is classified at containment level 1 except when specifically intended as a vector for gene expression in mammalian cells or when encoding viral functions that could themselves transmit to mammalian cells. Page 9-10 of the Risk Assessment Form includes the statement: “If the answer to questions 11 and 12 is negligible, you may believe that you have sufficient information at this stage to classify the project to class 1, as defined in the Contained Use Regulations 2000. In order to do this you should be confident that in the event of a total breach of containment the GMO would be of no or negligible risk to human health or the environment.” The committee therefore requested that the reason for suggesting that work involving DCV is classified as containment level 2 should be further evaluated and the results of such an evaluation be conveyed back to the subcommittee. If a Notification is deemed unnecessary a Risk Assessment would still be required for GM work.

As part of the same discussion it was suggested that to save effort and expense, planned future work on Arboviruses should be assessed in terms of the likely need for further applications for Notification. If more potential applications are identified consideration should be given to the possibility of combining the proposals into a single Notification covering as many viruses as possible.

Response from Alain Kohl to GM Committee comments (06.02.2012):

I would like to thank the committee members for their helpful suggestions. My response to several comments is outlined below:
Culture conditions for DCV have now been indicated under “Eukaryotic hosts”, GM notification page 4 and RA page 2.

It is now stated that “... is not known to infect or replicate in human cells”, to be consistent. Infection of vertebrate cells has to my knowledge never been tried. Although highly unlikely, I do not believe this is a risk as no true insect virus has ever been described as an emerging pathogen, or is known to move between insects and vertebrates for example. However even baculoviruses are known to enter vertebrate cells and initiate transcription. Therefore some precaution is advisable. The CMV promoter is active in some insect cell lines and we use pRL-CMV for example to express luciferase, as well as other eukaryotic reporter plasmids.

Comment on SFV now reads “plasmid or Semliki Forest virus or derived replicon”.

- No experiments in vertebrate cells are planned (RA page 3, GM form page 3).

The DCV genome of strain EB is currently being synthesized; we do not have the plasmid in the lab yet but it should be delivered over the coming weeks. I inserted this comment as by the time HSE receive the form, we should be about to receive the plasmid.

I suggest to class this virus as class 2 activity. This is mainly based on the observation that DCV can in fact infect far more species of drosophila than previously thought, and although it is rapidly cleared from mosquitoes it can potentially infect these insects too. There is therefore a theoretical possibility of infecting other species beyond the drosophilids. 02/03/2022
The Orthomyxoviridae is defined by viruses that have a negative-sense, single stranded and segmented RNA genome. Viruses within the Orthomyxoviridae are classified into five genera: Influenza viruses A, B, C, Thogotovirus and Isavirus. Within a genus, viruses show similar patterns in the sizes of their genome segments as well as structural and non-structural proteins. Influenza A viruses are typical examples of emerging viruses, including pathogens of humans and/or animals (5). Influenza B virus appears predominantly restricted to humans but it has also been isolated from seals; and influenza C virus infects humans and pigs. Types A and B are the cause of seasonal annual epidemics of acute respiratory disease among humans, and type A viruses have caused occasional pandemics – worldwide epidemics caused by a virus having new antigenic surface proteins among an antigenically naive population. Influenza A virus infections can cause a severe and debilitating febrile illness that can lead to fatal pneumonia and increase the risks associated with secondary bacterial chest infections, particularly in the very young, chronically ill, immunocompromised or elderly.

The influenza A virus genome is composed of eight segments of single-stranded RNA of negative polarity that encodes for up to 14 proteins. The genome segments are called PB2 (polymerase basic), PB1, PA (polymerase acidic), HA (haemagglutinin), NP (nucleoprotein), NA (neuraminidase), M (matrix) and NS (non-structural). Influenza A viruses are sub-classified according to the antigenic characteristics of the surface glycoproteins, the haemagglutinin (H) and neuraminidase (N). There are 17 H and 10 N subtypes known to date. The four major pandemics of the last hundred years were caused by H1N1 (1918 [Spanish flu], and 2009 [swine flu]), H2N2 (1957, Asian flu) and H3N2 (1968, Hong Kong flu) viruses. Currently, influenza A virus subtypes H1N1 and H3N2, and influenza B virus, are co-circulating in the human population. Avian viruses (such as H5N1, H7N7, and H7N9 viruses) have also caused human infections, and epizootics of highly pathogenic H5N1 and H7N9 avian viruses in several Asian countries since 1997 have raised the spectre of a new pandemic.

During replication, a positive-stranded antigenome is produced which serves as the template for de novo production of negative-stranded genomes. The influenza A virus terminal 3’ and 5’ sequences are highly conserved and largely complementary, and interact to give the genome a characteristic pan-handle structure. The RNPs are contained within a lipid envelope into which the viral glycoproteins (HA, NA and M2) are inserted. Replication occurs in the nucleus of infected cells.

Most influenza viruses are transmitted by direct and indirect contact. Some influenza viruses are transmitted through aerosol droplets. Cytopathic effect (CPE) depends on both viruses and host cells. For example, pandemic H1N1 virus causes CPE in Madin-Darby canine cells whereas most equine influenza viruses do not. At the same time, some equine influenza viruses cause CPE in dog tracheal explants whereas others do not. Understanding the molecular basis for the different outcomes of infection in these cells and tissues of different origin is of fundamental importance, and may help in the development of new control measures for influenza emergence. This is likely to imply immune responses (which differ in both hosts) and virus-host interactions.

Although much is known about the function(s) of individual influenza virus proteins, much more remains to be learned about the factors involved in host–pathogen
interactions that affect host range and disease outcome. The overall aim of our research is to elucidate the molecular and evolutionary determinants of host range, replication and pathogenicity of influenza viruses.

The work to be undertaken forms part of a comprehensive programme of viral emergence and molecular pathogenesis, involving researchers from different groups within the Centre for Virus Research (CVR). It involves work on several areas including, epidemiology, mathematical modelling of virus evolution, structural biology, and studies on virus-host interactions and molecular pathogenesis. It is the last aspect i.e. virus-host interactions and molecular pathogenesis with which this GM risk assessment is concerned. Within the CVR, the groups of Pablo Murcia and Benjamin Hale will generate the tools to produce recombinant influenza viruses and these viruses will form the basis of the work covered in this risk assessment. The work proposed will involve both in vitro, ex vivo, and in vivo infections. Embryonated chicken eggs will also be used as a system for growing some virus stocks.

Many Hazard Group 2 (HG2) influenza viruses will be at the centre of this project: equine influenza virus (EIV), canine influenza virus (CIV), low pathogenic avian influenza viruses (AIV), and human influenza viruses (H1N1, H3N2). Other viruses which will be used will include laboratory-adapted and mouse-adapted strains, as well as currently circulating influenza viruses and influenza viruses that infect other animal species (e.g. swine). We will also generate viruses that contain segments from highly-pathogenic avian influenza A viruses in the background of an attenuated laboratory strain. These viruses will lack a major virulence determinant from highly-pathogenic viruses and will also be engineered such that they do not possess the antigenic novelty associated with pandemic-potential of these strains. Non-hazardous minigenome systems (see below) of influenza viruses will also be studied.

Reverse genetics systems that allow manipulation of the influenza virus genome are readily available (2). Cultured cells are transfected with a mixture of 8 to 12 plasmids, each containing a full-length cDNA copy of one of the influenza virus genome segments under control of a Pol I promoter and terminator sequences, and a hepatitis delta ribozyme sequence. Intracellular transcription produces exact copy RNA transcripts that act as viral mRNAs and templates for viral RNA synthesis that result in production of infectious virus. Similarly, minigenome systems can be constructed in which only the coding sequences between the terminal influenza A virus sequences (either genomic or antigenomic) are replaced with a reporter gene such as Renilla luciferase (RLuc) or eGFP. A minigenome will be transcribed if the polymerase and nucleoprotein genes are co-expressed from expression plasmids, which is useful to study the role of sequences and proteins in replication and also in packaging as minigenome. Minigenomes are on their own non-propagating and are used to mimic virus replication.

1- In vitro and ex vivo infections to study influenza virus replication, host range and pathogenesis.
We will establish and characterise influenza virus infection in cell lines of various origins (human, canine, equine, etc), primary cultures derived mainly from humans, horses and dogs, as well as canine and equine tracheal explants. Primary cell cultures and explants from other animal species might also be employed.

For the canine/equine project, we will mainly be using H3N8 viruses derived from canine and equine strains (for example A/canine/New York/2008 and A/equine/Ohio/2003). Other equine and canine viruses of the same lineage will also be cloned and rescued by reverse genetics. All equine and canine influenza viruses belong to the ACDP hazard group 2. It should be noted that no equine or canine influenza virus has been associated with human disease.

We will also generate by reverse genetics the following human influenza viruses: mouse-adapted A/WSN/33 (H1N1), A/PR/8/34 (H1N1) and the non-mouse adapted 2009 H1N1 pandemic strains (e.g. A/England/195/2009, or A/California/04/2009) as well as other human seasonal strains (e.g. A/New York/312/2001 (H1N1) and A/Victoria/3/75 (H3N2)) as appropriate. All human influenza viruses used will belong to ACDP hazard group 2 and will be predicted to be antigenically similar to components of the seasonal trivalent or quadrivalent vaccine. The viruses will therefore be used at CL2.

Reverse genetics will also be used to construct recombinant viruses with mixed gene segments enabling identification of virulence determinants or identification of host factors that impact specific strains. The ability to perform site directed mutagenesis to produce viruses containing targeted mutations in specific genes will allow further characterisation of the role of specific proteins. Readouts will include the capacity for virus replication in tissue culture cells, or explants, as well as ability of the viruses to induce histological changes and the susceptibility of infected cells to apoptosis. In addition, we will examine a number of changes in functional attributes following virus infection, such as ciliary beating if appropriate.
2- Viral genetics of host restriction, adaptation, and interactions with host-cell functions. The contribution that individual virus genes (focusing on the 'internal' or non-glycoprotein genes) make to defining host range and pathogenicity will be probed by creating reassortants between the strains of influenza described above in section (1). For the highly-pathogenic avian influenza A viruses, we will not generate nor seek to possess complete sets of reverse genetics clones, and will only use a selection of individual internal segments to generate viruses in the background of attenuated laboratory-adapted influenza viruses (such as WSN or PR8 strains). In this regard, it is important to note that we do not possess reverse genetics clones for the haemagglutinin (HA) or neuraminidase (NA) genes of highly pathogenic avian influenza viruses, and will not attempt to generate viruses expressing such antigens to which the human population does not have herd immunity. We will only generate recombinant reassortment viruses that contain the internal segments of these avian viruses.

We will ensure that reassortants between CIV strains, EIV strains, and between CIV and EIV viruses will not affect any immunological protection as they are all phylogenetically very similar (CIV is a direct descendant of EIV). Reassortants between the H3N8 avian-like strains and PR8 is unlikely to result in any increased risk as use of PR8 internal genes together with novel surface glycoproteins is standardised in traditional influenza virus vaccine production worldwide (even with highly virulent influenza viruses such as H5N1), and has been approved by the World Health Organization (6).

Virus reassortments will be generated by reverse genetics that contain select internal segments from highly pathogenic viruses with the surface glycoproteins (HA and NA) from lab-adapted strains (e.g. PR8 or WSN). This will ensure that the viruses are likely to be antigenically similar to the currently used human vaccine, and sensitive to clinically approved NA inhibitors such as oseltamivir. Reassortants will be limited to the 'internal' genes of the highly pathogenic virus and are therefore expected to retain the basic tropism of the parental strain, as well as any immunological protection. In the case of using the PR8 and WSN backgrounds, this also means that attenuated characteristics are likely to be maintained. The HA gene of H5N1 viruses is a primary pathogenicity determinant and deletion of its polybasic cleavage site severely attenuates the virus in mammalian and avian models of infection. In addition, the classification of HPAI influenza involves the nature of the haemagglutinin – H5 or H7 subtypes with a polybasic cleavage site expected to produce systemic spread in infected poultry. Current ACDP guidelines state that H5 or H7 viruses modified such that they do not possess a polybasic cleavage site in HA can be handled under CL2 conditions. By only working with the 'internal' genes of these reassortants, we will further reduce any risk as not only will the polybasic cleavage site be removed, but there will be no novel HA (such as H5 or H7) to which humans have never been exposed to previously. The reassortants are unlikely to fall under SAPO regulations as no H5 or H7 HA with a polybasic cleavage site will be used. This will be clarified, and appropriate SAPO licences sought, prior to any work commencing. Use of lab-adapted HA and NA genes (from WSN and PR8) will accentuate any attenuation in humans (e.g. Clements et al., J Clin Micro, 1992, 30 655-62, and Clements et al., J Clin Micro, 1989, 27, 219-22) and is likely to provide cross-protection from H1N1-containing vaccines such as the current seasonal vaccine (the 2009 H1N1 pandemic vaccine (still used in current trivalent vaccines) provides protection against "old" H1N1 viruses between the years 1918 and 1947 (Medina et al., Nature Communications, 2010, Manicassamy et al., PLoSPathogens 2010). PR8 was isolated in 1934, whilst WSN was isolated in 1933.

We will use viruses generated by ourselves and also plan to use recombinant viruses based on A/equine/Ohio/2003, A/canine/New York/2008 (both H3N8), A/WSN/33 or A/PR/8/34 (both H1N1) and A/California/04/2009. In some cases we will add fluorescent tags for labelling and live tracking of viral particles. One possible approach will be to use a FIAshH currently being developed at Institut Pasteur. The FIAshH tag (Invitrogen) is a short (6 residues) peptide tag that has been fused to influenza gene NP and used in a reverse genetics plasmid-based system to produce infectious viral particles carrying the tagged NP protein. Cell-permeable FIAshH reagent, binding with high affinity to the FIAshH tag, is used to stain the cells, and can be excited at 508 nm wavelength. Emission at 528 nm can be detected using standard fluorescence microscopy settings, allowing identification of infected cells. Alternatively, we will use the similar technology SNAP tag, or the autofluorescent GFP/RFP protein domains. Luciferase genes may also be incorporated into recombinant viruses.

In order to compare host range determinants of equine and canine viruses, we will use reverse genetics to construct mutant versions of A/canine/New York/2008 and A/equine/Ohio/2003. The dose of the inoculum will vary, although for most of our experiments we infect explants with a very small dose (200 pfu).

As a reverse genetics system is not currently available for some canine and equine viruses, such a system will be constructed. We will clone various CIV and EIV sequences into an 8-plasmid system widely used for influenza reverse genetics. Genomic segments corresponding to genes coding for proteins HA, NA, M, NS, PB1, PB2, PA and NP including the 3’ and 5’ non-coding regions will be PCR-amplified and cloned into pHW2000 vector in which the cloning site is flanked by the Poll promoter and
hepatitis delta ribozyme sequences. If necessary, sequences corresponding to PB1, PB2, PA and NP genomic segments will be cloned into pHMG, where protein expression will be under the control of a mouse hydroxymethylglutaryl-coenzyme A reductase (HMG) promoter.

The method to be used for the production of recombinant EIV and CIV by reverse genetics is adapted from previously described procedures (3). The 8-12 plasmids will be co-transfected into a sub-confluent monolayer of co-cultivated HEK293T and MDCK (Madin-Darby canine kidney) cells. Subsequent amplifications of the virus will be performed on MDCK cells or embryonated chicken eggs.

Reassortant and wild type influenza viruses will be used to:
- Study viral growth, gene expression, replication and pathogenesis in host cells and tissues.
- Study interactions with the host cell (replication, interaction with host cell factors, immunity).

3- Viral genetics using influenza virus minigenome systems
- Minigenome systems for a broad range of influenza A viruses are already in use (1, 4). We will use minigenome systems that have been generated by others. If required, we will derive existing minigenome systems by cloning the segments of interest of the viruses under study (e.g. EIV, CIV, etc). Minigenome systems will be used (as read-outs) in studies on protein functions (cellular, viral), sequence function, segment packaging (packaging by glycoproteins co-expression, or following co-infection) and complementation studies (ie. CIV PB2 in EIV viral polymerase complex).

4- Functional studies and expression of influenza virus proteins.
- Manipulation of protein sequences by introduction of point mutations, deletions, insertions, fusion to others sequences such as reporter genes, tags etc.
- Expression of influenza virus proteins to study interactions with host cell components and cellular localisation.
- Expression of influenza virus proteins by prokaryotic expression systems, for example for protein purification.
- Expression of influenza virus proteins by eukaryotic expression systems (plasmid, retroviral expression), for example to produce packaging cell lines, cell lines expressing virus-like particles, or cell lines to study protein function.
- Expression of influenza virus proteins by eukaryotic expression systems (plasmid, retroviral expression), to produce packaging cell lines for influenza virus sequences (segments or minigenomes; production of single round infectious particles) and cell lines expressing virus-like particles.

5- Studies on host immunity.
- Interactions of influenza viruses (wild type, reassortants, minigenome) with host responses, and counteraction of host responses will be investigated. Immune signalling/antiviral responses (including activation mechanisms), and viral interference therewith, will be analysed. This will involve transcriptomic studies as well as studies of extra- and intra-cellular host molecules (e.g. proteins). Role of immunity in host cell tropism (infections of cells from different species) will also be investigated. These studies will also use reporter genes inducible upon activation of a given pathway. Cell culture models are available.

Note: that all of the above viruses are HG2, and will therefore be handled under CL2 conditions.

A/Vietnam/1203/2004 (HPAI H5N1), or related [only the internal segments of this virus will be used]
A/Shanghai/1/2013 (H7N9), or related [only the internal segments of this virus will be used]

The above 2 virus types are HG3, but we will only use genetically modified versions (as detailed below in section 11) which are modified to remove major pathogenicity determinants and the antigenic novelty associated with strains of pandemic-potential. The justifications are reasoned in section 11, and such modified viruses have been assessed locally to be HG2 pathogens, which will be handled under CL2 conditions.

### Recipient organisms:

- Equine influenza virus H3N8 (genus Influenzavirus A), and derived recombinant viruses.
- Canine influenza virus H3N8 (genus Influenzavirus A), and derived recombinant viruses.
- Human influenza virus H3N2 and H1N1 (genus Influenzavirus A), and derived recombinant viruses (e.g. see above).
- Other containment level 2 influenza viruses (e.g. avian viruses previously characterised as exhibiting low pathogenicity, or swine viruses, etc.) may be considered as long...
as they are unrelated to those capable of causing infection of humans.

At no point will viruses be produced that have surface antigens with a multibasic cleavage site in H5 or other livestock influenza virus HA proteins. It should also be noted that the equine/canine project and the human/avian projects will be performed by different investigators at different sites. We will therefore physically separate work to minimise the likelihood of reassortment between different viruses. We do not exclude possible future work on viruses expressing H5N1 antigens at CL2 as per current ACDP guidelines (e.g. low-pathogenic H5N1 viruses engineered to lack the polybasic cleavage site: “HALo”). However, such work will only be done after a separate notification to the local safety committee and relevant addendum to our local Risk Assessment.

Human influenza B virus (e.g. B/Yamagata/16/88), and derived recombinant viruses.

Reporter systems mimicking Influenza virus replication:
Minigenomes of CIV, EIV, and other influenza A and B viruses (for example swine influenza virus).

**Host/vector system**

**Plasmid vectors:**
Viral sequences (full length clones of Influenza viruses; partial sequences of these and other influenza viruses) and other genes (cellular, viral, reporter) are available in plasmid-encoded cDNA form. RNAs can be transcribed from bacterial promoters (i.e. T7 or SP6 by in vitro transcription or plasmid-expressed RNA polymerase in cells) or eukaryotic promoters (CMV, SV40, cellular promoters, baculovirus promoters etc.). Plasmids for expression of influenza virus sequences (virus rescue or minigenome) typically contain an RNA polymerase I promoter and a hepatitis delta virus ribozyme or a mouse RNA polymerase I terminator. Plasmids contain an origin of replication followed by a prokaryotic selectable marker (usually antibiotic resistance against ampicillin or kanamycin) and sometimes a selectable eukaryotic drug resistance marker such as neomycin or puromycin resistance. The bacterial systems are non-mobilisable vectors in a disabled prokaryotic host.

**Hosts:**

**Prokaryotic hosts:**
Disabled, commercially available E. coli strains such as Sure, JM109, XL-strains, DH-strains, Rosetta etc. These strains can only survive in a controlled laboratory environment and will be used for propagation of plasmids. Good microbiological practice and sterilisation of all contaminated waste should prevent release of viable organisms. The risk to the environment is therefore effectively zero.

**Eukaryotic hosts:**
Vertebrate cell lines of various origins (typically human, mouse, avian, hamster, bovine, canine, equine, etc.), primary cells and explants of various origins (typically human, swine, equine and canine).

In prokaryotic cells, only selectable (e.g. antibiotic resistance) genes will be translated; prokaryotic cells may also be used for protein expression and subsequent purification. Virus sequences will be under the control of a promoter that will only generate transcripts in eukaryotic cells or in vitro transcription reactions.

In eukaryotic cells, the following RNAs will be produced which may be translated into the following gene products:

1-**Influenza viruses and RNAs (or minigenomes):** Proteins involved in replication and transcription of viral genetic material and virus structural proteins. Some of these virus proteins will interact with host-cell components and may affect host cell responses to infection; few of these interactions are currently known. If all virus sequences are translated new virions may be generated; minigenomes are non-propagative viral RNAs (capable of replication). Partial RNAs do not give rise to propagating infectious material.

2-**Non-influenza virus genes or sequences:** Genes of prokaryotic (bacteriophage polymerases) or eukaryotic (e.g. reporter genes such as luciferases or fluorescent proteins such as GFP; plant or arthropod immunity modulators) origin. Reporter gene sequences will also be present in influenza minigenome RNA. The recombinant foreign
proteins to be expressed provide no significant increase in the hazard to human health; none are toxic or likely to produce disease in the quantities that could be produced by accidental exposure to these systems. Non translated RNA sequences (including T7 terminator and hepatitis delta ribozyme in plasmids used for virus rescue or minigenomes) have no known toxic effects and pose no risk to human health.

Techniques used to introduce insert or vectors into cells:

1-Prokaryotic cells: Introduction of DNA into E. coli will be by heat shock/chemical transformation/electroporation. These techniques have been extensively described and are widely used; they rely on getting DNA very close to the bacterial wall and introducing the genetic material through pores or membrane fusion.

2-Eukaryotic cells: Cells will be transfected using transfection reagents such a lipofectamine or by electroporation. Virus genomes or sequences will be introduced into cultured cells by infection with virus or virus replicon particles (VRP).

**Origin & function**

The genetic material will originate from the parental organisms:

A/California/04/09 (pdmH1N1)
A/Netherlands/602/09 (pdmH1N1)
A/Mexico/4108/09 (pdmH1N1)
A/Brisbane/59/07 (H1N1)
A/Brisbane/10/07 (H3N2)
A/Wyoming/3/03 (H3N2)
A/Moscow/10/99 (H3N2)
A/Panama/2007/99 (H3N2)
A/Texas/36/91 (H1N1)
A/Puerto Rico/8/34 (H1N1) [PR8]
A/WSN/33 (H1N1) [WSN]
A/equine/Miami/1963 (H3N8)
A/equine/Fontainebleau/1979 (H3N8)
A/equine/Argentina/1995 (H3N8)
A/equine/Newmarket/1993 (H3N8)
A/equine/South Africa/2003 (H3N8)
A/equine/Ohio/2003 (H3N8)
A/canine/New York/2008 (H3N8)
A/equine/Mongolia/2009 (H3N8)
A/wild bird/Mongolia/2009 (H3N8)
A/wild bird/Mongolia/2010 (H3N8)
A/wild bird/Mongolia/2011 (H3N8)
A/swine/England/495/2006 (H1N1)
B/Yamagata/88
A/Vietnam/1203/2004 (HPAI H5N1), or related [we will only use the internal segments from these viruses]
A/Shanghai/1/2013 (H7N9), or related [we will only use the internal segments from these viruses]

Alternatively, viral sequences of these and related viruses (similar strains and same ADCP classification) can be synthesised. We do not exclude possible future work on viruses expressing H5N1 surface antigens at CL2 as per current ACDP guidelines (e.g. low-pathogenic H5N1 viruses engineered to lack the polybasic cleavage site:...
The intended functions of the genetic material involved is the production, purification and characterisation of influenza viruses, as well as the production and use of minigenomes. In turn, the viruses produced will be used to infect human or animal cell tissues and cells to determine the cellular processes involved in pathogenesis and replication through virological and molecular biological methods.

**Evaluation of foreseeable effects**

**Plasmid vectors:** Viral sequences (including full length clones or partial sequences of influenza A virus or other influenza viruses) and other genes (cellular, viral or reporter) are available in plasmid-encoded cDNA form. Plasmid vectors are based on bacterial plasmids and contain an origin of replication for prokaryotic cells and selectable antibiotic/drug resistance (pro- or eukaryotic) markers. By themselves these vectors present no risk to human health. Vectors have no selective advantage and would soon be lost from the bacterial population. The bacterial systems are non-mobilisable vectors in a disabled prokaryotic host. Systems for prokaryotic gene expression are under control of an inducible prokaryotic promoter. Systems for eukaryotic RNA or protein expression are under the control of promoters of viral (such as CMV or SV40), eukaryotic (eg actin promoter, pathway inducible promoter such as STAT, interferon etc.) or prokaryotic (such as T7 or SP6 promoter for in vitro transcription) origin. Plasmids with eukaryotic promoters such as the CMV promoter can be transcribed in human cells. None of the genes used in these studies are oncogenes. The hazard of expressing 'foreign' genes from these eukaryotic promoter plasmids would depend on the expected physiological effects of the foreign gene product and is discussed in more detail below.

**Viruses:** Influenza is typically a mild and self-limiting infection, acquired generally by the respiratory route. Severity depends on the strain of virus and host but in general tends to fall in a spectrum between asymptomatic to ~ 1 week of fever and malaise in otherwise healthy people. Severe illness can occur but is rare, occurring in less than 1% of cases (see below). This level of risk applies to most wild type human H1N1 and H3N2 viruses and the porcine viruses. Equine H7N7, H3N8 and canine H3N8 viruses have not been associated with significant illness in humans. In addition, the laboratory adapted PR8 and WSN strains of H1N1 human influenza are known to be avirulent in man from many volunteer challenge studies as well as a long (> 70 years) history of safe use in the lab. The GM viruses containing internal segments from H5N1 or H7N9, but with the surface glycoproteins from WSN or PR8 would retain antigenic properties of the lab-adapted PR8/WSN viruses, which are likely covered by the current human influenza vaccine, and which have not been associated with disease despite their wide use worldwide for decades.

Even seasonal influenza can have potentially serious consequences for anyone who is pregnant, immunosuppressed, asthmatic, or has other respiratory/underlying chronic diseases. Vaccines are available for the circulating human H1N1 and H3N2 strains and the majority of the population has at least some prior immunity to these viruses. All laboratory workers and staff within the department are recommended to receive the annual human influenza vaccine, and all workers using shared resources (even if not directly involved in the work) are made aware of the risk assessment for influenza virus work. Those at risk of severe consequences of influenza (e.g. pregnant women) will be separately notified of the risks of these pathogens immediately after they identify themselves to their PI and occupational health. Individual risk assessments will be carried out governing these specific cases.

The antivirals oseltamivir, zanamivir and amantidine are also available for treatment or prophylaxis if needed. We have procedures for staff to seek medical advice and prophylactic treatment following any possible significant accidental exposure events. Note, we will not handle any known antiviral-resistant strains of influenza virus in the same location as other viruses with different antigenic profiles in order to limit the possibility of accidental reassortment generating an anti-viral resistant virus with new antigenic properties.

Vaccines are also available for horses/dogs against EIV and CIV. Workers with these viruses will be advised to not have contact with either horses or dogs for 48h after last handling the viruses.

Personnel working with these viruses are expected to inform occupational health should they become pregnant or immunosuppressed, and inform the PI so that precautionary measures can be introduced following advice from occupational health. We also have a policy whereby those with flu-like symptoms do not come to work, do not handle influenza viruses experimentally, and inform their PI immediately. This policy will further limit any possible accidental reassortment between laboratory viruses and circulating human viruses, should a worker accidentally expose themselves to a laboratory virus whilst simultaneously infected with a circulating virus. The local PI (Pablo Murcia or Benjamin Hale) will take responsibility for enforcing this, and will similarly assume responsibility for the safety and compliance of any visiting workers.
Influenza A virus minigenomes: Minigenomes pose no risk to human health, including those derived from pathogenic influenza A viruses. They cannot propagate on their own. Even if packaged by co-expression of glycoproteins and thus used to infect cells, their own transcriptional activity would be minimal. If packaged into virions, the associated risk is that of the virus itself as reporter genes in minigenomes are not reported to be toxic.

Note: No reassortment experiments involving the glycoproteins of human and animal influenza A viruses (for example an influenza A virus carrying a human H1 and an equine N8) will be performed, to eliminate the possibility of creating viruses for which humans or animals have no prior immunity. Furthermore, we aim to physically separate work on different influenza viruses such that accidental reassortment to generate a more pathogenic strain, or an antigenically novel strain with new properties, cannot occur from our work (see details in Risk Assessment).

Hosts

The host/recipient organism: Prokaryotic organisms: All strains will be disabled, commercially available E. coli derivatives classified as ‘especially disabled hosts’ by ACDP. These strains cannot colonise humans and are known not to cause harm to humans.

Eukaryotic cells: Cell lines and tissues to be used would not survive inside the human body (immune rejection) and are not known to carry harmful pathogens. Addition of DNA or RNA or infection will confer no growth or survival advantage in or outside the laboratory to cell lines and tissues.

What hazards do the inserted genetic material or other genetic modification pose?

The inserted/donated genetic material:

Viral RNA and proteins, cellular proteins: Most individually expressed viral or cellular proteins are unlikely to have harmful effects in eukaryotic cells, however some could perturb normal cellular metabolism, predispose or protect against cell death or render cells more or less susceptible to other infections if overexpressed or silenced. It is very unlikely that Influenza A virus RNA or proteins would have any harmful toxin-like effect outside cells. Only antigenomic RNA containing an influenza A virus sequence can be translated or give rise to infectious virus (if all necessary genomic information is provided) in eukaryotic cells; minigenome RNAs are non-propagative and pose no harm (individual cells replicating minigenome are likely to die or be eliminated by the immune system). Viral non-coding RNA sequences are important in influenza virus replication but do not encode biologically active molecules that are likely to induce physiological effects in humans on their own. None of the influenza virus gene products are known to be secreted cytotoxins.

Reporter genes: Reporter genes of prokaryotic or eukaryotic origin (eg luciferase, fluorescent proteins etc.). No harmful properties have been attributed to these proteins. There would be no altered physiology expected if any of these genes were expressed; eGFP for example is a spontaneously fluorescent protein isolated from Aequorea victoria a coelenterate and has no known detrimental effects. Luciferase is another commonly used reporter gene and is derived from the firefly Photinus pyralis or the jellyfish Renilla reniformis. It is an enzyme which catalyses production of light from luciferin and ATP; the light produced is used as a measure of gene activity. The enzyme has no other biological function.

Sequence changes in viral sequences:

Mutation or deletion will target disruption of structural and non-structural protein functions or non-coding viral sequences and are likely to have no or deleterious effects on viral replication, thus not increasing risk or hazards to human health associated by viruses genetically modified in such a way.

Foreseeable effects to the environment:

Canine influenza virus: This virus is not thought to be endemic in the UK, and it is not on the SAPO list. In fact, it is not highly transmissible in the only country in which is endemic (USA). Transmission is common only in highly dense dog populations such as those found in animal shelters. CIV was first isolated from greyhounds in USA.
Experimental infection results in mild respiratory disease. Serological evidence of infection in foxhounds in the UK has been shown, although no outbreaks have been associated with it. Given the low transmissibility and low pathogenicity of CIV, the chance of accidentally infecting dogs initiating a transmission cycle sustained by local dogs is negligible. Reassortants carrying gene segments from EIV will likely display lower fitness and will pose minimal risks to dogs, if any. The modified viruses will not have any inserted foreign genes other than non-harmful genes or sequences, or (usually disruptive) changes in viral genes or non-coding sequences; changes in virus pathogenesis are therefore unlikely other than as described above under the human health and safety section. In the absence of a suitable host these viruses would not survive in the environment and the risk is effectively zero. Dogs are kept out of labs and the risk of accidental infection of dogs by contact of contaminated material is minimal for CIV. However, as some members of staff bring their dogs to work there is a potential risk of infection of those animals if they access the laboratories.

Equine influenza virus: This virus has been endemic in the UK for over 40 years and infections are most likely the result of horse movement and inadequate vaccination schedules. EIV is not on SAPO or ACDP lists. There is a vaccine available for EIV, although most horses have natural immunity due to vaccination or natural infections. The modified viruses do not contain anything other than non-harmful genes or sequences, or disruptive changes in viral genes or non-coding sequences; changes in virus pathogenesis are therefore unlikely other than as described above under the human health and safety section. If EIV was to escape the lab and infect local horses, there is minimal risk it could initiate a transmission cycle. Horses are kept out of labs and the risk of accidental infection of horses by contact of contaminated material is minimal. The closest horses to the lab are kept at the Weipers Centre and up to date vaccination against EIV is a requirement for admission.

Avian-like equine influenza virus (H3N8): This virus is highly pathogenic in horses (20% mortality) and there is no cross reactivity between classical EIV and avian-like EIV. Reassortants of this virus will be done using PR8 as a backbone (HA and NA of avian like EIV + the six internal genes of PR8), so the resultant viruses will be highly attenuated. No other reassortant viruses including the surface glycoproteins (HA and NA) of avian like EIV will be generated. Reassortants carrying the internal genes of avian-like EIV and the external genes of classical EIV will have a minimum risk to initiate a transmission cycle as most horses in the UK have immunity against the surface glycoproteins of classical EIV. It is important to note that PR8 has been used as a backbone to generate vaccines against highly pathogenic H5N1 viruses and thus is very safe to use. If these reassortants were to escape they would have very low fitness due to the attenuation conferred by the PR8 genetic background.

Human influenza viruses: Currently circulating human influenza A viruses (pdm H1N1, seasonal H1N1, and H3N2) are globally distributed, there are available vaccines, and the majority of the population has at least some prior immunity to these viruses. The antivirals oseltamivir and zanamivir are also available for treatment or prophylaxis if needed.

Viruses constructed will be based on the widely used laboratory strains A/WSN/33 (H1N1), A/PR/8/34 (H1N1) (all mouse adapted and known [WSN, PR8] to be attenuated in man) or more recent low pathogenicity human strains to which most people will have substantial amounts of pre-existing immunological protection: A/Udorn/72 or A/Victoria/3/75 (H3N2) viruses, the current human influenza strains A/England/195/2009, A/California/04/2009 (both 2009 H1N1 pandemic viruses) and the A/New York/312/2001 strain (‘seasonal’ H1N1). Such antigenic and attenuated properties will be maintained in viruses bearing the surface glycoproteins of WSN/PR8 and the internal segments of H5N1 or H7N9 viruses.

The experiments proposed involve gene deletion, mutation or replacement of specific genes with the corresponding gene from one of the other strains listed. For reassortants between the human-derived or laboratory adapted viruses, this is not predicted to create viruses with novel tropism or pathogenicity as they either already share similar characteristics (the recent human isolates) or are highly attenuated in humans (PR8, WSN). In the case of reassortants incorporating genes from animal strains of influenza, we also do not expect any change in tropism because the human or laboratory adapted HA and NA genes will be retained. In the case of reassortants incorporating genes of the avian-like equine influenza virus, the six internal genes will be derived from PR8, thus attenuating the virus significantly.

We propose to use containment level 2 for all other HG2 influenza A viruses (as specified on page 2) similar to CIV and EIV unless other regulations are in place for a particular pathogen.

Minigenomes: These systems derived from other influenza A viruses are non-propagative and even if packaged, pose no or no additional hazard.
Hosts:
Prokaryotic organisms: Disabled, commercially available E. coli strains. These strains can only survive in a controlled laboratory environment and will be used for propagation of plasmids. Good microbiological practice and sterilisation of all contaminated waste will prevent release of viable organisms. Acquiring antibiotic resistance (from the plasmid vector) or additional sequences (virus or marker gene sequences) will not give these strains any survival advantage in the environment. The risk to the environment is therefore effectively zero.

Eukaryotic cells: Cell lines to be used are not viable outside the laboratory and thus pose no threat to the environment. Addition of plasmid vectors or virus or minigenomes will confer no growth or survival advantage in the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We propose to generate influenza viruses bearing the 6 internal gene segments from H5N1 or H7N9, with the 2 surface glycoproteins of laboratory-adapted H1N1 viruses WSN or PR8. Currently, both H5N1 and H7N9 viruses should be handled at CL3 according to ACDP guidelines.

ACDP guidelines stipulate mitigating circumstances whereby some CL3 viruses can be used at CL2. This includes genetically modifying the HA molecule of HPAI viruses to remove the polybasic cleavage site (a major pathogenicity determinant). This renders the virus apathogenic in chickens, and highly reduces the pathogenicity in mammalian models. We propose to go further, by replacing the entire HA and NA segments of H5N1 virus with the HA and NA segments of the laboratory-adapted strains PR8 or WSN. This will not only remove the pathogenicity-associated polybasic cleavage site, but will also render the virus antigenically similar to existing human vaccines, and susceptible to prophylactic antivirals. The virus will also be expected to be antigenically similar to viruses currently circulating in humans meaning there will be a degree of herd immunity in the general population. Furthermore, such a virus is likely to retain attenuated characteristics of WSN/PR8 in humans due to their extensive laboratory passage over 70 years. WSN/PR8 have not caused any known serious laboratory infections despite their use world-wide in decades.

We will apply the same strategy to generate viruses bearing the internal segments of human H7N9 viruses and the surface glycoproteins of the laboratory-adapted WSN/PR8 strains. Such viruses will thereby lose any possible antigenic novelty, minimising any risk to either worker or the broader human population.

WE DO NOT POSESS THE HA OR NA GENE SEGMENTS OF EITHER H5N1 or H7N9. We do not exclude possible future work on viruses expressing H5N1 antigens at CL2 as per current ACDP guidelines (e.g. low-pathogenic H5N1 viruses engineered to lack the polybasic cleavage site: “HALo”). However, such work will only be done after a separate notification to the local safety committee and relevant addendum to this Risk Assessment.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disinfect influenza virus-contaminated material immediately.

GM26 (CVR Church Street)

Solids from cell culture (eg plasticware such as flasks, tubes, pipettes tips etc.) - submerged soak in a minimum of 1% Virkon (w/v) for at least 12 hours. Rinsed solids then go to landfill. Virkon is added to the plasticware prior to removal from the MSCII.

Other solids (agar plates, gloves etc. ) placed in a sealed container (lined with clear bag) and disposed of by autoclaving using a make safe cycle of 121oC for 30 minutes. Gloves used for influenza virus work should be disinfected with alcohol before putting in containers prior to autoclaving.

Liquids (eg. samples, culture supernatants, tissue culture media) – add Virkon to final minimum concentration of 1% (w/v) for at least 12 hours, then discharge to drains.
Virkon is added to the liquid waste prior to removal from the MSCII.

Liquids (E. coli culture medium)- add Virkon to final minimum concentration of 1% (w/v) for at least 12 hours, then discharge to drains.

Sharps (e.g. needles/syringes, scalpels) - decontaminate in 1% Virkon overnight, then place in sharps bin for incineration.

Spills of infectious liquid - immediately inactivated with powdered Virkon (rather than liquid spray, to minimise aerosol generation - large spill), or absorbed into paper towels soaked in Virkon (minimum 1% - small spill). Soaked paper towels then autoclaved. Surface wiped down with Virkon soaked paper towels and then disinfected with alcohol prior to drying.

Degree of kill:
Chemical Sterilization by Virkon- effectively 100% kill.
Autoclaving - effectively 100% kill (annual validation).

GM223 (CVR Garscube Estate):

Disposable solids (eg plasticware such as flasks, tubes, pipette tips etc.)- soak in 1% Virkon (w/v) for a minimum of 12 hours. Transfer solid contents to clear autoclave bags and autoclave at 121oC for a minimum of 20 minutes prior to final disposal by district council to land fill, remaining liquid to be discharged to drain.

Other solids (agar plates, gloves etc.)- placed in a marked box lined with a clear autoclave bag, and disposed of by autoclaving using a make safe cycle of 121°C for at least 20 minutes. Seal contaminated plates (with for example bacterial GMOs) before placing in bag, to avoid lid falling off. Gloves used for influenza virus work should be disinfected with alcohol before putting in containers.

Liquids (eg. samples, E. coli culture media, tissue culture media)- add Virkon to final concentration of 1% (w/v) for a minimum of 12 hours, then discharge to drains.

Sharps (eg needles, syringes, scalpels) - decontaminate in 1% Virkon overnight then place in sharps bin for incineration.

Degree of kill:
Chemical Sterilization by Virkon- effectively 100% kill.
Autoclaving - effectively 100% kill (annual validation).

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]
1. GM 26 committee comments:

The CVR Church Street GM subcommittee met on 29/04/2013 to consider the proposal:
"Influenza virus pathogenesis, host range and virus/host interactions"

Present:
Roger Everett
John McLauchlan
Joyce Mitchell
Arvind Patel
Emma Thomsen
Frazer Rixon (convener)

The subcommittee agreed the following recommendations.

Vaccination
The existing recommendation is that anyone working with influenza in Church Street should be vaccinated. This requirement for vaccination is not clearly stated in the RA. For example, on pages 16, 20 and 22 of the RA it is stated that vaccines are available against the human influenza but there is no mention that vaccination is advised. In addition, the potential seriousness of infection is downplayed. Thus, on pages 11, 13, 17 and 22 infection is described as mild, or typically mild and self-limiting. This takes no account of the potentially serious consequences for anyone who is pregnant, immunosuppressed, asthmatic, or has other respiratory diseases. We suggest that text is inserted into the forms at appropriate places stating that people working with influenza should be vaccinated and that anyone with a flu-like illness should not report to work or go to A&E, but should inform Occupational Health. In addition, vulnerable groups should be identified in the documents and warned of the potential risk.

Risk
The subcommittee considered that the greatest risk of generating unforeseen viruses through reassortment was posed by workers who were already infected with a circulating strain. Therefore, it is particularly important that the guidelines should make it clear that people suspected to be infected should not work on this project and these guidelines must be enforced. As the proposed work covers two separate sites (Church Street and Garscube), a local PI must assume responsibility for the safety and compliance of any visiting workers at Church Street and this must be clearly stated.

Scope
Although the proposal states (p11 of RA) that “equine, canine, and low pathogenicity avian viruses are unlikely to be used at this (Church Street) site”, the subcommittee did not wish to rule out such use in future. Therefore, the above statement should be removed and the text modified so as not to preclude use of these viruses at Church Street.

Disinfection
Under Waste Disposal (RA page 20) it should be made clear that Virkon is added to infectious liquid waste before it is removed from the safety cabinet.

Text
A number of matters were identified relating to the layout and wording of the RA:

The Church Street site (GM26) is designated as both a primary location (RA page 9) and a secondary location (page 11) for proposed laboratory work. This is ambiguous
and needs to be clarified.
Change BSL 2 laboratory to containment level 2 laboratory (RA page 9).
Church Street policy at present is that oseltamivir-resistant flu can only be handled in room 310. This should be specified.
References to Virkon treatment should make it clear that the final concentration must be ≥1%.
Spills of infectious or contaminated liquids should be inactivated with Virkon before being cleaned up (RA page 15).
Remove the reference to visual inspection of the safety cabinet by the PI (RA page 17).
List COSHH 237 under point 15 (RA page 19).

Following discussion between the co-applicant Ben Hale and Frazer Rixon, a second meeting of the CVR Church Street GM subcommittee was called for 27/05/2013, to
discuss further the handling of reassortants containing genome segments from high pathogenicity avian influenza strains.
Present:
John McLauchlan
Joyce Mitchell
Arvind Patel
Emma Thomsen
Frazer Rixon convener.

Invited: Ben Hale

Apologies: Roger Everet

The subcommittee agreed the following additional recommendations:

Background information on the polybasic site and its importance for pathogenicity should be included in the proposal and it should contain a clear statement that viruses containing a polybasic site would not be generated or used.

The proposal could include mention of low-pathogenic H5N1 viruses engineered to lack the polybasic cleavage site: "HALo" but should contain a clear statement that work with such viruses would require prior consideration and approval by the local safety committee.

Methods to prevent accidental reassortment of genome segments resulting in viruses with potentially novel antigenic properties should be specified.
The requested changes were made and on 23/06/13 the revised documents were circulated to and approved by the subcommittee members on 25/06/13.

2. GM223 committee comments 13/05/13

The comments of GM 223 were that this was a detailed risk assessment with a lot of evidence, justification of arguments and references. The recommendations were primarily in agreement with those of GM 26 as detailed above and the PIs were notified accordingly. Clarification on any SAPO licence requirements was requested. Careful consideration should be given to the potential for reassortment of genome segments and this should be reflected in the laboratory practices. All workers using the designated facilities should be made aware of all pathogens and GMOs being handled in the areas. All solid waste generated from this project will be autoclaved and it is recommended that Virkon treated liquid waste also be autoclaved. Where this is not possible then references/documentation should be provided to support Virkon disinfection as a validated means alone for inactivation of the liquid waste generated.

GM 223 approved the revised documents on 24/06/13

Historical Significant Changes

Project transferred to GM223

02/03/2022
The objective of this project is to investigate the interaction of hepatitis B virus (HBV) and hepatitis D virus (HDV) with host cells with a view to understanding the roles of viral and host factors in virus infection and replication, and their contribution to virus-associated pathogenesis. We will first establish in vitro cell culture systems to generate infectious virus using well-characterized prototype and patient-derived replication-competent viral genomic DNA. Viruses generated thus will be then used to infect different target cell lines to study, at the mechanistic level, the functions of the relevant viral and host components (e.g., proteins and/or nucleic acids) and the impact of their interactions on virus pathogenesis. It is hoped that the results obtained will inform development of novel anti-viral therapeutic avenues and may lead to bats as a new animal model for HDV.

Description of activities:

HBV is the prototypic member of the family Hepadnaviridae, which includes avian, primate and rodent hepatitis viruses. All hepadnaviruses share the property of restricted host range, a strong, but not exclusive, tropism for hepatocytes, and the ability to cause liver damage. HBV is a major human pathogen causing a chronic inflammatory liver disease often leading to the development of hepatocellular carcinoma (HCC). The clinical significance of HBV is easily demonstrated by the fact that more than 250 million people worldwide are chronically infected. HBV has a relaxed circular partially double stranded DNA genome of approximately 3.2 kb. Following infection, the HBV genome is transported to the nucleus and converted to covalently closed circular (ccc) DNA which serves as a template for transcription of viral RNAs. Following transport of the pre-genomic RNA and translation in the cytoplasm, selective encapsidation of the RNA into the nucleocapsid ensues, along with encapsidation of RNA polymerase. In the immature capsid, the 3.5 kb mRNA is reverse-transcribed, to yield minus strand DNA. The RNA is degraded and the DNA strand is replicated, producing the second, shorter DNA strand. Nucleocapsids containing DNA genomes then acquire their outer envelope, probably by budding into the endoplasmic reticulum (ER) in areas where viral surface antigens (HBsAg) are transported. The resulting particles are then transported from the cell by normal pathways of vesicular transport. There are 3 forms of HBsAg (called large, medium and small or L-HBsAg, M-HBsAg and S-HBsAg, respectively) which all share the same C-terminus (i.e. S-HBsAg), with the M-HBsAg being extended at its N-terminus by 55 amino acid (aa) preS2 segment and L-HBsAg additionally containing an N-terminal 108 to 119 aa preS1 domain. HDV belonging to the genus Deltavirus causes chronic hepatitis D. The virion carries a circular single-stranded negative-sense RNA genome of ~1.7 kb in length. The viral replicative intermediate of positive-sense polarity encodes the delta antigen (HDAg) that is not packaged into the virion. HDV requires HBV as a helper virus in the form of its envelope proteins (i.e. HBsAg) to form infectious virus particles. Co-infection with HDV is associated with more severe pathological complications (e.g. increased risk of liver failure in acute infections and development of liver cancer in chronic infections) compared to HBV alone. HDV RNA replication occurs in the nucleus and the viral ribonucleoprotein is transported to the Golgi where it is enveloped by HBsAg. The secretion of the assembled virion is thought to occur via Golgi. Co-expression of HDV genome with HBsAg results in secretion of HDV particles into cell medium. This medium can be used as a source of HDV to infect susceptible naïve cells in which the virus initiates a single-cycle infection; i.e. the virus delivers its replication-competent genome, but is unable to produce progeny virions as the cells lack HBsAg. While HDV has historically been considered a virus of humans, recent metagenomic sequence data obtained here at the MRC – University of Glasgow Centre for Virus Research (CVR) has discovered RNA which appears to represent an analogous virus (HDVb) circulating among wild bats (Desmodus rotundus) in South America (Bergner et al., unpublished data). Little is known of HDVb, but genomic similarities to HDV suggest it is likely to have a similar biology (i.e., narrow host range and requirement for a helper virus such as bat hepadnavirus). Ongoing sequencing studies here at the CVR aim to identify the analogous bat-associated HBV using metagenomic sequencing and PCR. On account of the presence of HBsAg on HBV and HDV virions, both viruses share the same cell entry pathway although their genomes replicate differently. Cell entry is mediated by initial attachment of the virus to the cell surface heparin sulfate proteoglycans (HSPGs) followed by a specific interaction with the hepatocyte-specific sodium taurocholate co-transporting polypeptide (NTCP) (Yan et al., 2012 eLife1,e00049). The virus interaction with HSPG is mediated by the N-terminal preS1 domain of L-HBsAg and the antigenic loop of the S-HBsAg, while the interaction with NTCP is solely mediated by preS1. It is likely that additional as yet unidentified host factors are also required for virus entry into target cells.

The proposed project consists of 6 major components:

1. Generation of infectious viruses: We will use the well-characterized tetracycline-inducible HBV expressing cell line, Hep38.7-Tet (Ogura et al., Biochemical and Biophysical Research Communications 452 (2014), 315–321), to generate HBV for use in work described here. Additionally, we will also transfet mammalian cells (including hepatocytes) with replication-competent HBV DNA derived from well-characterised isolates or patients infected with different viral genotypes and isolates. This is expected to initiate a fully productive virus life cycle in transfected cells. Evidence of virus infection and replication will be monitored by the detection of viral RNA (by
3. Molecular epidemiology of HBV infection: We are interested in studying the molecular epidemiology of HBV infection in different population groups and identifying mutations that confer resistance to current antiviral treatments and vaccines in circulating strains. We are using next-generation sequencing technologies to sequence full-length viral genomes from patient samples. We will use the previously described (Pollicino et al., 2006, Gastroenterology 130, 823-37) HBV cccDNA-dependent transfection system to investigate antiviral resistant variant fitness and assess the evolution of HBV antiviral resistant strains. Briefly, single genome-length linear monomeric HBV DNA will be produced from a subset of the patient sequencing data and introduced into the human hepatocytes cells. The introduced monomers are expected to circularise into cccDNA and act as templates for transcription of HBV genomes, thus initiating and then recapitulating the entire viral replication cycle. We will perform these experiments in the presence or absence of clinically approved antivirals and experimental drugs, and measure the levels of cccDNA, the associated transcripts (e.g. the pre-genomic RNA), the intracellular encapsidated DNA, and the virion-associated extracellular DNA using established methods. We will assess the ability of the extracellular virions produced in this system to infect the human hepatocyte cell lines that stably express the virus entry receptor NTCP. The specificity and the mechanisms of viral entry will be explored further using a panel of in-house generated antibodies to preS1, the N-terminal domain of the L-HBsAg that plays a role in viral entry via its interaction with NTCP. Together, these experiments will allow us to measure and study the mechanics of virus entry and resistance to drugs, and to evaluate vaccine escape.

4. Infection of cells with clinical HBV isolates: Sera collected from HBV-infected individuals will be used as an inoculum for infection of appropriate cell lines. Initially all patients will be recruited in UK and only samples tested negative for cytomegalovirus and HIV will be used. Samples from overseas and/or from patients screened positive for HIV might be used at a later stage of the project. In this case, samples will be screened for the infectious agents most likely to be present in the sera (depending on their origin). Samples containing adventitious agents will be excluded and any import into the CVR will be subjected to the local Safety group approval. Evidence of infection will be monitored as described in step 1 above.

5. Investigating the effects of interferon-stimulated genes (ISGs) in HBV and HDV infection: Type I interferons (IFNs) suppress the replication of HBV in vitro and in vivo. However, the success of IFN therapy is variable and influenced by the HBV genotype. Despite this, relatively little is known about which host ISGs inhibit HBV and why some genotypes respond better to IFN therapy. We have developed libraries of ISGs from humans, rhesus macaques and cows as well as diverse ISGs from diverse vertebrate species (Schoggins et al., 2011, Nature 472(7344):481-485; Kane et al., 2016 Cell Host Microbe 20(3):392-405). These libraries are arrayed so that in a single screen the ability of hundreds of individual ISGs to inhibit viral replication can be considered. Briefly, hepatocytes, including Hep38,7-Tet (or other permissive target cells) will be transduced with lentiviral vectors encoding each ISG prior to infection with HBV representing different genotypes and isolates. Alternatively, ISG-encoding vectors will be co-transfected together with replication-competent HBV DNA and the yield of HBV will be quantified. In all instances, the methods described in step 1 above will be used to quantify the level of virus infection/gene expression and/or replication in order to identify inhibitory ISGs. Similarly, we are interested in which ISGs inhibit the replication of HDV and whether such inhibition is direct or a consequence of HBV inhibition (indirect). Thus, we will examine the ability of different ISGs to inhibit HDV replication in cultured hepatocytes or other permissive target cells (vertebrate origin).

6. In vitro evolution of HBV and HDV: To reveal viral determinants of sensitivity/resistance to antiviral factors and reveal potential resistance pathways to antiviral molecules or antiviral candidates we will propagate HBV (and HBV and HDV) in the presence of antiviral factors (genes from various species), candidate antiviral molecules, approved antivirals, antiviral cytokines or experimental drugs. The methods described in step 1 and sequencing approaches will be used to monitor changes in the viral genome(s) selected during the passage experiments.
We will use a genetically engineered stable cell line, Hep38.7-Tet, conditionally replicating and secreting HBV particles as source of virus in our studies. Additionally, we will generate HBV and HDV by reverse genetics following transfection with patient-derived infectious genomic DNA into hepatocyte cell lines. Where necessary, appropriate genetic modifications will be introduced into the relevant part of the viral genomic cDNA to generate genetically modified (GM) viruses of interest. These modifications may include specific mutation of amino acids that are functionally and structurally important in virus infection/replication, for reactivity to antibodies of interest, and for conferring antiviral resistance (the latter will be based on those observed in circulating strains, or those identified in our studies on ‘In vitro evolution of HBV and HDV’ as described in point 6, of Section 6). Additionally, we will also attempt to generate viruses expressing reporter genes or epitope tags (including but not limited to GFP, RFP and Luciferase). The modifications are not expected to alter host tropism.

**Host/vector system**

**Viruses:** Different WT and GM derivatives of HBV and HDV, including a bat-associated subtype of HDV (HDVb).

**Bacterial:** Disabled E. coli K12-derived strains such as DH5α. These strains can only survive in a controlled laboratory environment and will be used for propagation of plasmids.

**Mammalian:** Various vertebrate hepatocyte and non-hepatocyte stable cell lines.

**Vector systems:** Non-mobilisable pUC-derived plasmids, pBlueScript, pCDNA and lentiviral vectors

**Origin & function**

Virus will mainly be obtained from a HBV producer cell line, Hep38.7-Tet, which will be obtained from collaborators in Japan. This cell line is well-characterised by them (Ogura et al., Biochemical and Biophysical Research Communications 452 (2014), 315-321) and is widely used by different groups. It will be imported from Japan as ‘UN2814 Category A infectious Substance affecting humans’ and will be handled in our Containment Level 3 (CL3) facilities. Additionally, we will produce both HBV and HDV by reverse genetics using patient-derived viral genomic nucleic acids for HBV and HDV and bat-derived viral genomic nucleic acids for HDVb. We also plan to attempt to directly propagate viruses derived from clinical samples (serum/plasma) following inoculation into cultured cells.

GM cell lines that ectopically express host proteins of interest (e.g. the virus receptor NTCP, viral dependency or restriction factors) will be generated. In some cases cell lines lacking host factor(s) identified as of interest in the study will be generated either through transient knock-down or permanent gene knock-out technologies. These GM cell lines will allow assessment of the functions of the relevant viral and/or host factors on virus infection, replication and pathogenesis.

**Evaluation of foreseeable effects**

**Risk associated with HBV and HDV generated in this project:** Viruses will be rescued by reverse genetics. There are no plans to carry out extensive mutational analyses of the viral genomes - mutations introduced will be mainly based on sequences circulating in patients including those conferring resistance to drugs. Additionally, in order to understand and delineate at molecular level aspects of viral life cycle (e.g. entry, replication, assembly) we may create specific amino acid changes in viral or host proteins of interest, or insert reporter genes or epitope tags (including but not limited to GFP, RFP and Luciferase). However, we expect these modifications to not adversely alter the replication, transmission or tropism of the viruses. If anything, the modifications would result in attenuated viruses.

**Risks associated with GM cell lines:** As mentioned above, the HBV producer cell line, Hep38.7-Tet, will be used as one source of virus. This cell line will always be handled under our CL3 facilities: the Richard M. Elliott Biosafety Laboratories (REBL) and/or MacRobert Blood-Borne Virus (BBV) laboratory (see section 11 below). All work will be strictly performed as per the criteria laid out in the REBL and BBV CL3 laboratories Codes of Practice and Risk Assessment associated with this Notification (see disinfection and waste disposal procedures). Risk of accidental infection to personnel working in the CL3 laboratory is very low, and the likelihood of virus being released from the laboratory is effectively nil. GM cell lines modified to express or not host genes of interest are not expected pose any risk to laboratory personnel or the environment. These cell lines would not survive inside the immunocompetent human body (immune rejection) and are not known to carry harmful pathogens. Addition of DNA or RNA or infection will confer no growth or survival advantage in or outside the laboratory to these cell lines.

**Risks to the environment:** Both HBV and HDV are Hazard Group 3 pathogens. In accordance with this classification all work involving the generation and handling of these viruses proposed will be performed in our REBL or MacRobert BBV CL3 facilities as described above (see section 11 below). HDVb is currently unclassified with respect to ADCP Hazard Group, and has never been found or suspected to infect humans or species other than bats. Nevertheless, as a precaution, potentially infectious HDVb will be handled only in our CL3 facilities. All work is strictly performed as per the criteria laid out in the REBL and BBV CL3 laboratories Codes of Practice and Risk Assessment associated with this Notification (see disinfection and waste disposal procedures). Risk of accidental infection to personnel working in the CL3 laboratory is very low, and the likelihood of virus being released from the laboratory is effectively nil. Therefore, the risk to the environment is effectively zero.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We have recently been granted derogation under Regulation 19 of the Genetically Modified (Contained Use) Regulations 2014 to dispense with sealability for the MacRobert BBV CL3 laboratory in relation to work with wild-type and genetically modified Hepatitis C virus (HCV) and Human Immunodeficiency virus (HIV) - notified activities GM26/99.3a and GM223/13.1b, respectively.

Similarly to HCV and HIV, HBV and HDV are blood-borne viruses, they are not infectious through the aerosolised/airborne route. Although aerosolised infection by highly concentrated HBV or HDV stocks remains a theoretical transmissible route, no case has been documented. Moreover, both viruses are sensitive to common chemical disinfectants such as 70% Industrial Methylated Spirit (IMS), Virkon and Distel. Little is known of HDVb, but genomic similarities to HDV suggest it is likely to have a similar biology (i.e., narrow host range and a requirement for a helper virus such as bat hepadnavirus). Considering the transmission routes of HBV and HDV and the scope of work we intend to do (as detailed in this form and the attached risk assessment), we consider that the risk of using highly toxic fumigants (such as formaldehyde or hydrogen peroxide) surpasses the risk of contamination by or release of the viruses and we propose to dispense with fumigation for room disinfection. Instead, we propose to use chemical surface disinfectants for regular and emergency disinfection procedures, as detailed in the attached risk assessment.

Hence, we are seeking derogation from full containment level 3 measures and propose to handle HBV and HDV/HDVb in the MacRobert BBV derogated CL3 laboratory in the same way as already consented by HSE for HCV and HIV: uncontained infectious material will only be handled in microbiological safety cabinets (MSC); no concentration of virus by ultracentrifugation will be permitted and propagation of virus will be limited to no more than 10 to the 6 genome copies/ml. No laboratory-acquired infection of HBV or HDV via aerosols have ever been reported in this concentration range. Any work requiring higher titres of HBV or HDV will necessitate concentration of the virus by ultracentrifugation or other means and will be carried out in the REBL CL3 Suite, which operates under more stringent safety procedures and is suitable for room fumigation for regular and emergency disinfection. See associated risk assessment for fully detailed containment measures, inactivation and waste disposal procedures.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment Level 2 areas:
Liquid waste: add Virkon to final concentration of 1% (w/v) overnight, then discharge to drains.
Disposable solids (eg plasticware such as flasks, tubes, pipette tips etc.): soak in 1% Virkon (w/v) overnight. Transfer solid contents to autoclave bags and autoclave at 121°C for a minimum of 15 minutes prior to final disposal by district council to landfill, remaining liquid to be discharged to drain.
Other solids (agar plates, gloves etc.): place in a marked box lined with a clear autoclave bag, and autoclave at 121°C for at least 15 minutes. Seal contaminated plates before placing in bag, to avoid lid falling off. Gloves should be disinfected with alcohol before putting in containers.
Degree of kill:
Chemical sterilisation by Virkon - effectively 100% kill
Autoclaving - effectively 100% kill (annual validation)

MacRobert BBV derogated CL3 laboratory:
Liquid waste: decontaminate in Virkon 1% w/v (final concentration) overnight. When handling protein rich liquid, Virkon powder should be added to give a final concentration of no less than 1% w/v. After inactivation, discharge liquids to drain.
Solid waste from within the MSC: discard paper waste within the MSC into a metal bin lined with autoclave bag for autoclaving. Cell culture plastics which can be submerged must be soaked overnight in 1% w/v Virkon prior to autoclaving. Flasks, once liquid has been removed, can be rinsed with 1% w/v Virkon, capped, surface-decontaminated with 70% IMS and disposed of into the metal bin outside the MSC for autoclaving. Disposable plastic pipettes must be submerged overnight in 1% w/v Virkon prior to autoclaving. Gloves must be sprayed with 70% IMS prior to being discarded into an autoclave bin.
Sharps which arise inadvertently or glass slides/cover slips must be placed into clearly labelled sharps bins containing enough 1% w/v Virkon solution to cover all material and autoclaved.
Solid waste from outside the MSC: other waste generated within the laboratory, including soiled lab coats/gowns must be placed directly into disposable bags for autoclaving.
All solid waste is to be autoclaved at 121°C for 15 minutes prior to being sent for incineration.
**Degree of kill:**
Chemical sterilisation by Virkon - effectively 100% kill
Chemical sterilisation by 70% IMS - effectively 100% kill
Autoclaving - effectively 100% kill (annual validation)

**The Richard M. Elliott Biosafety Laboratories (REBL) CL3 Suite:**
Liquid waste: decontaminate in Virkon 1% w/v (final concentration) overnight. When handling protein rich liquid, Virkon powder should be added to give a final concentration of no less than 1% w/v. After chemical inactivation, liquid waste must be either autoclaved at 121°C for 15 min or disposed through ACTINI effluent treatment plant (135°C for 2 minutes).

Solid waste from within the MSC: spray paper waste with 1% w/v Virkon within the MSC, then with 70% IMS outside the MSC prior to autoclaving. Solid which can be submerged must be soaked overnight in 1% Virkon w/v (final concentration) prior to autoclaving. Solids which cannot be submerged must be filled with or soaked in Virkon 1% w/v (final concentration) for 10 minutes, wiped down with 1% w/v Virkon within the MSC then with 70% IMS outside the MSC prior to autoclaving. Sharps which arise inadvertently or glass slides/cover slips must be placed into clearly labelled sharps bins containing enough Virkon solution to cover all material and autoclaved.

Solid waste from outside the MSC: other waste generated within the laboratory, including soiled protective clothing, must be sterilised by autoclaving. Solid waste is to be autoclaved at 134°C for 5 minutes, fabrics are to be autoclaved at 134°C for 3.5 minutes.

Following ACTINI treatment or autoclaving, liquid waste is disposed to drain. After autoclaving solid waste is sent for incineration.

**Degree of kill:**
Chemical sterilisation by Virkon - effectively 100% kill
Autoclaving - effectively 100% (annual validation)

1. GM 26 committee comments (approval date 25/08/11; see below):

The CVR Church Street GM subcommittee met on 22/08/11 to consider the proposal:
“Arthropod host cell/arbovirus interactions and immune responses induced by virus replication.”

Subcommittee members:
R E
J M
A P
F R (convener)

The subcommittee members agreed recommendations for modifications to the following topics:

In Section 12 (Describe the waste management measures etc) of the HSE Notification and Section 16 (Proposed experiments etc, sub-heading Waste Disposal) of the Risk Assessment:

Some of the autoclaving cycles specified were not available on the autoclave at the CVR Church Street site.
Procedures appropriate for clinical waste, incineration and microwaving were either not in use at the CVR Church Street site or would be expensive to implement. They were considered to be unnecessary for this proposal.

The procedure specified placing arthropod derived material into a sealed container for autoclaving. However, autoclaving requires containers be open to allow entry of steam.

No procedures for disinfection of contaminated material were described. All material is to be rendered safe by autoclaving, which would entail contaminated material being stored and transported to the autoclaves. This was considered an unacceptable risk, especially for liquid waste, and requires an effective disinfection procedure to be put in place.

The subcommittee decided that the relevant entries under section 12 in the HSE Notification and section 16 of the Risk Assessment should be replaced with the existing waste disposal and disinfection policies employed at the CVR Church Street site. These are available on the local intranet. Before this can be approved, validation must be obtained regarding the effectiveness of Virkon for inactivating LGTV and SFV.

In Section 6 (Purpose of the contained use), reference is made to subgenomic replicons of other arboviruses (eg chikungunya and dengue) that are not otherwise included in this proposal. A full description of the work to be carried out with these agents, the nature of the hazards and the precautions required should be included in both the HSE Notification and Risk Assessment.

Clarification is required for section 8 (Containment and control measures for GMOs that are not micro-organisms; page 11) of the HSE Notification and for section 11, sub-heading Hosts (page 8) of the Risk Assessment concerning the transport of arthropods. The latter states that; “Samples (dead or non-mobile arthropods (our italics) or material from these) will be transported to our CL2 laboratory according to standard regulations.” The subcommittee agreed that no living infected arthropods would be
allowed in the CVR Church Street site and that they should only be handled in an insectary.

The reference to; “the city centre location of our laboratories” on page 10 of the Risk Assessment is not appropriate for the CVR Garscube site and should be removed.

Under section 7, sub-heading Control measures (page 8) of the HSE Notification, the use of appropriate PPE (not just gloves) should be specified.

An estimate of virus quantities (eg pfu/ml) should be provided in addition to the culture volumes in the HSE Notification, section 9 (Maximum culture volumes per experiment; page 11) and the RA section 16 (Culture volumes; page 14).

The requested changes were made and on 25/08/11 the revised documents were circulated to and approved by the subcommittee members.

2. GM223 committee comments (approval date 20.10.2011, see below):

“The risk assessment was clear but clarification on local mosquito activity was required; more detail on any full length viruses being held, and careful consideration of any possible recombination events was deemed essential. Risks to immune-suppressed personnel needed to be mentioned.

These points have been addressed in form CU2 and Risk Assessment, and on the 20.10.2011 the revised documents were approved.

Dr. A G on behalf of the committee.”

Purposes of the contained use

Studies in cancer genetics and developmental genetics, that are an integral component of the concerted research programme on cancer and development genetics that is underway here at the Medical Research Council Human Genetics Unit.

Recipient or parental organism

These lentivirus vectors are infective to non-dividing human cells and are integrative to the genome therein, but are non-replicative, ie, self-inactivating, and so infected cells would not produce viral particles and hence pose no risk.

There is a risk of oncogene activation in infected cells due to the insertion, but the risk is low, and the risk of consequent tumourigenesis very low, as changes to several genes are required for these events to occur.

Host/vector system

A third generation packaging system after Dull et al (1998) J. Virol 72 8463-8471 will be used, which requires genes from three different vectors for packaging into infectious particles. These vectors designed so as not to be packaged into viral particles and not recombine with each other or with the lentivirus.

These vectors transiently provide at high titre the viral functions required for packaging of the lentiviral construct.

The lentivirus vector to be used initially is LentiLox 3.7. This infects non-dividing human cells under the above circumstances, is stably integrative, but is non-replicative, ie, is self-inactivating. Vector expresses no viral functions once transduced. Thus, target cells can be infected with viral particles made in the packaging line but to infectious particles can then be made by the infected target cells. Wildtype virus does not infect mice and is rare in humans, so recombination with wildtype virus very unlikely. Airborne particles, if produced, would be at very low concentration and unstable.

We wish to include other similar lentivirus vectors to be developed in the future which have the same properties as outlined above (or properties giving lower risk) within the scope of this application.

Origin & function

We intend to use the lentiviral system to express the following classes of gene. Construct-specific risks will be covered in (future) GM Risk Assessments, and experiments only permitted if the GM Safety Committee here categorises the proposed work as Hazard Group 2 (or 1).

i) Expression of siRNAs against genes involved in development and tumorigenesis. siRNAs (short inhibitory RNAs) are short dsRNA molecules which can give sequence-specific knockdown of the expression of endogenous target genes, a process also referred to as RNAi (RNA interference). siRNAs will be expressed, if possible, as short hairpin RNA molecules, or otherwise as pDECAp constructs which express long dsRNA hairpins which are endogenously converted to functional siRNAs. Target genes will mainly be murine, so whenever possible the target sequences will be murine-specific. If this is not possible, such as when the target is human cells in culture, if practicable then the expression of the siRNA will be regulated by an inducible system (ie tetracyclin inducible) to further limit the potential risk of siRNA expression in humans. Examples of genes we intend to study are genes involved in testis and kidney development and tumorigenesis, such as WT1 and its downstream target genes. Lentiviral siRNA vectors will be used to infect cell culture (murine or human), organ culture (murine) and in the generation of transgenic mice.

ii) Reporter genes, like lacZ, GFP, or its derivates. Promoters responding to endogenous cellular signals involved in tumorigenesis or development, or tissue-specific promoters, will be cloned in front of these reporter genes and used to monitor the signalling pathways involved. These inserts pose no risk to human health. Reporter constructs will be used in cell culture (murine or human), organ culture (murine) or transgenesis (murine).

After surveying the promoter activity with reporter genes we will use these promoters to drive expression of developmental genes. These genes are predicted to affect early developmental stages and we propose to drive both the active genes and siRNAs. Genes that will be studied for example are Gli3, dHAND, Shh, and members of the Tbx, Nkx, Bmp and Fgf families.
iii) Expression of Cre or FLP recombinases. Cre and FLP are used in combination with conditional mouse models in which part of a gene is placed between loxP or FRT sites. Expression of Cre/FLP will result in deletion of the sequence between the loxP/FRT site and inactivation of the gene. By expressing the recombinases in an inducible or tissue-specific manner full control of inactivation of the target gene is possible. Expression of Cre or FOP poses no risk for human health. Lentiviral expression systems will be used in cell culture, organ culture and transgenesis, all murine.

iv) Expression of accessory genes involved in different tetracyclin responsive expression systems, like rtTA, tTA and Tet-R. These genes regulate the expression of genes the promoters of which have been extended with tet-binding elements, and the expression of the genes will be activated by the presence or the absence (depending on the system) of tetracyclin or its analogue doxycyclin. Expression of rtTA, tTA or Tet-R poses no risk to human health. Lentiviral expression of these genes will be used in cell culture, organ culture and transgenesis.

Evaluation of foreseeable effects

RISK TO HUMAN HEALTH ARISES DUE TO:
Lentivirus vector infective to non-dividing human cells
Lentivirus vector integrative
Lentivirus vector at high titre
thence potential for insertional mutagenesis of body surface cells by the lentiviral vector and thence potential for oncogene activation in infected cells.

RISK TO HUMAN HEALTH AMELIORATED AS:
Third generation packaging system to be used - requires three different vectors which cannot recombine with each other or the lentivirus.
Integration is stable.
Lentivirus vector is non-replicative, ie, self-inactivating - no viral function expressed once transduced
Tumourigenesis very unlikely
Wildtype virus does not infect mice and is rare in humans - recombination thus very unlikely
Airborne particles, if produced, would be at very low concentration and unstable
siRNA whenever possible will be highly specific to murine genes
Knockdown of the siRNA targeted genes in an adult human would not cause transformation
Targeted murine genes under developmental-specific and tissue-specific enhancer and although it is a very unlikely possibility, tests will nonetheless be done to ensure that the lentivirus does not become replicative by recombination

APPROXIMATE EVALUATION OF ABOVE RISK (APPLYING BS8800:1996) TO HUMAN HEALTH:
Estimated likelihood = highly unlikely
Potential severity of harm = extremely harmful
Risk = moderate and thus control = Containment level 2 or rationalising.

According to the ACGM Compendium of Guidance (Part 2B, Annex III, paragraph 26) HIV-derived lentivirus (such as this) should be Hazard Group 3, unless there is justification for a lower classification. The vector here requires three different vectors for packaging (ie a 'third generation system') and is self-inactivating/non-replicative. Further, the probability for oncogene activation in infected cells is anyway low, and for consequent tumourigenesis is very low. We thus consider there to be sufficient justification for classification of this proposed work as Hazard Group 2, rather than 3.

AND RISK TO THE ENVIRONMENT:
Negligible - transduced cells/animals not infective (see above), all changes somatic (see Section 8), and all virus, cells and tissues/animals destroyed (see Section 12).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Any live-birth transduced mice will be entirely reared, housed and killed within our Transgenic Mouse Facility.
This is a secure 'barrier' unit, and as such escape of mice or entry of exogenous rodents is almost impossible. Such animals anyway pose negligible risk to human health or to the environment, as they could not be infective with the lentivirus vector (is self-inactivating/non-replicative).

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Complete immersion in 1% Virkon for at least two hours will be used to destroy all cultures and sterilise all items. Virkon is a potent peroxygen disinfectant that will give 100% kill of all agents used, the lentivirus in particular. Virkon is known to give 100% kill of the closely related HIV (US Environmental Protection Agency). Liquid waste will then be disposed to drains. Solid waste is then routinely autoclaved and then sent for commercial incineration. Larger tissue samples/whole animals (ie mice) are routinely disposed by commercial incineration (there is no viral risk from such items anyway).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Four GM Risk Assessments attached. Relevant comments include the following.

Committee noted this proposed use at high titre of an integrative retrovirus that could infect non-dividing human cells. According to the ACGM Compendium of Guidance (Part 2N, Annex III, paragraph 26) this should be HG3, unless there is justification for a lower classification. It was further noted that the virus requires three different vectors for packaging (ie a 'third generation system') and is self-inactivating/non-replicative. However, the former must be considered in the context of its infectivity once packaged. Committee were mindful of the potential, albeit very low probability, for oncogene activation consequent upon infection of and integration into the genome of a worker's cells. Nonetheless, the non-replicative nature of the construct was agreed as sufficient justification for classification of this proposed work as HG2 rather than HG3. The proposed (section 15) HG1 is not sufficient.

Committee requires, as a condition of this approval, that packaging lines are assayed by plaque formation colony assay or equivalent to ensure that the viral vector has not become replicative by recombination (although it is accepted that this is unlikely, it was considered that the high titres used might possibly increase the overall likelihood). This assay must be performed initially, and then repeated after three months of actual project work, and then after every six months of actual project work thereafter. And the acceptable result is to be zero replicative viral particles.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All contaminated waste, including microbiological cultures, culture medium and plastic ware is collected into 20 litre biohazard bags which are sealed and autoclaved within the building prior to being collected on a weekly basis by a commercial firm for incineration. The autoclave provides a printout of the temperature and pressure throughout the cycle and additional monitoring is provided by autoclave tape attached to the bags. No more than about 10 bags of waste (200 litres) are produced from the site per week.

**Purposes of the contained use**

The aim of this project is to amplify wild-type and deletion mutant oncolytic adenovirus vectors already produced in the applicant's previous lab; to evaluate their anti-tumour efficacy in in vitro and in vivo models of human malignancy, particularly ovarian cancer. Adenovirus serotypes Ad5, Ad11 and Ad35 will be used as reference standards for work performed with Ad5 (mainly E1A) deletion mutants. Replication competent and replication defective mutants will be constructed using the 'Ad-Easy' system to infect permissive human cell lines. These new mutants may encode transgenics that could induce tumour cell killing alone or enhance the anti-tumour properties of replication-competent deletion mutants. Evaluation of viral efficacy of mutants will be performed on Human and Murine cell lines by a variety of methods. Viral manufacture of replication defective vectors will be performed in HEK293 cell line to provide the E1 'in-trans'. Concentration of adenoviral constructs from 750ml final cultures will be via Caesium Chloride centrifugation.
### Recipient or parental organism

The recipient cell lines HEK293 or A549 will be used. Both are commercially available cell lines which require specific laboratory culture and as such pose negligible risk to humans. 

HEK 293 is rated Biosafety level 2 because of an E1 fragment of adenovirus embedded in it. It is this fragment that is essential to this series of experiments with E1 deletion adenoviral mutants. 

Cell line A549 is rated Biosafety level 1.

### Host/vector system

One vector system will be oncolytic deletion mutants of Adenovirus. Replication of oncolytic deletion mutants of Adenovirus is attenuated in normal cells/tissue. Multiple mechanisms for this attenuation exist, depending upon the nature of the deletion. Publications attest to the selectivity of replication – between normal human cells compared to a panel of human malignant cells – see Heise et al Nature Med (2000) 6:1134. In addition, multiple phase I and II trials of oncolytic adenovirus have shown no replication in normal tissues.

Wild-type adenoviral vectors, used as reference standards, are replication competent and could infect humans. However, wild-type adenovirus infection in humans with an intact immune system leads to a mild and self-limiting 'flu-like illness.

### Origin & function

Mammalian genes are to be inserted into the adenovirus genome and have been chosen to perform their intended function; either to increase tumour-specific killing by the virus (e.g. tumour suppressor or apoptosis-inducing genes), to inhibit the activity of oncogenic pathways or to increase the immunogenicity of infected tumour cells. Documentation exists to indicate that this can be achieved safely. No wild-type oncogenes or direct toxins will be inserted.

The virus will be applied to various established human and murine ovarian carcinoma cell lines; obtained from ATCC and other reputable sources and have consequently been screened for bloodborne viruses. In addition, the human cell lines have also all been previously STR verified and are known to be mycoplasma-free.

### Evaluation of foreseeable effects

The deletions induced in adenovirus vectors are designed to narrow the host range, so that there is reduced replication and killing within normal cells, thus increasing the therapeutic index in ovarian cancer cells. Mechanisms to achieve this will include introduction of specific deletions to restrict replication and the use of tumour and tissue-specific promoters.

During process development for clinical grade manufacture of one of the mutants being used, no recombination between vector and HEK293 sequences was detected (limit of detection 1 in 109 genomes) – thus it is believed that the risk of reversion to wild-type virus following amplification in HEK293 cells is extremely low.

Replication-deficient viruses are incapable of replication in cells lacking adenovirus E1 function. Infection of normal human cells as well as malignant cells results in no infectious virion production.

The replication competent adenoviruses used will contain mutations within the viral genome that attenuates replication in normal cells and tissues. The deletions occur in regions of the viral genome that are necessary for replication in normal cells but are complemented by the altered gene expression in cancer cells. Mutants used can only replicate efficiently in cells with deregulated p53 and pRB pathways respectively.

The tumour selective mutants can infect normal cells but the ability to replicate is highly attenuated.

Wild-type adenoviral vectors are replication competent and could infect humans. Wild-type virus infection in humans with an intact immune system leads to a mild and self-limiting 'flu-like illness.

The normal route of adenovirus infection is via aerosol. The use of correctly trained and supervised staff, Class II biological safety cabinets, lab coats and gloves.
disinfection and autoclaving of waste will reduce the likelihood of exposure to an extremely low level.

The virus will be applied to various established human and murine ovarian carcinoma cell lines. Because ovarian cancer cells do not contain any adenovirus genomic DNA, there is no risk of recombination of deletion mutants to generate wild-type revertant virus. Thus, generation of adenoviruses and infection of ovarian cancer cells is not considered to pose any inherent hazard to human health. The GM viruses do not have the capacity for survival outside of the laboratory. The recipient cells will therefore not have any foreseeable effect on human health.

E.coli strains are highly attenuated laboratory strains and do not present any hazards to humans.

Human adenoviruses do not replicate in murine tissue - this is true of wild-type, replication-restricted oncolytic viruses and replication-defective E1-deleted vectors.

The only replication following injection into in vivo tissue will be in malignant tumour tissue.

All injections of virus into vivo tissue will be undertaken in class II hoods within the specialist unit, thus minimising the risk of an aerosol-mediated infection during the injection process.

Multiple human studies demonstrate that virus shedding after intraperitoneal, intravenous or intratumoural injection is undetectable. Thus, the risk to humans from murine cell line tissue is negligible as the viruses are replication-deficient or tumour specific and the gene products are not considered harmful to health.

Full containment level 2 will be used, as set out in the Regulations, including appropriate treatments for bulk, contaminated solid waste.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All viral supernatants and spent medium will be inactivated using 10,000 ppm free chlorine before removal from the Containment Level II laboratories for final disposal. This process will result in 100% inactivation of infectious virus.

Solid waste will be bagged in biohazard bags prior to removal from the Containment level II lab and then placed in boxes which are sealed prior to removal from the CL2 suites. Boxes remain sealed and are autoclaved before the contents is removed for collection by accredited waste contractors. Autoclaves produce a digital record of load temperature achieved and are validated by annual thermocouple mapping. This process will result in 100% inactivation of infectious virus.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment
The purpose of the project is to evaluate the anti-tumour efficacy of oncolytic adenovirus and oncolytic Herpes Simplex Virus, in in-vivo models of human malignancy, particularly ovarian cancer. This will be achieved using Wild-type Ad5, Ad11, Ad35 adenoviral vectors as well as a number of Ad5 deletion mutants. Herpes Simplex Virus vectors are based upon HSV-1 single gene "vector 1716" mutants (neuro-virulence gene ICP34.5) as well as derivatives of this single mutant encoding fluorescent markers. Double deletion mutants (e.g. ICP34.5 and ICP47), with increased selectivity for malignant cells may also be evaluated.

Novel derivatives of the adenovirus and HSV vectors (encoding transgenes that could induce tumour cell mortality alone or enhance the anti-tumour properties of...
replication-competent deletion mutants) will be evaluated. In some viral treatments, tumour and tissue specific promoters (e.g. CEA, PSA) may be used to drive virus replication (via transcriptional control of E1A transcription) or to drive transgene expression.

Recipient or parental organism

Viruses are to be evaluated in various human and murine established carcinoma cell lines growing within subjects (either immunodeficient for human cell lines, or immunocompetent for murine cell lines). These cell lines have been obtained from reputable sources and have consequently been screened for HIV, HepB, HepC and EBV. Because these tumour cells do not contain any adenovirus or HSV genomic DNA, there is no risk of recombination of deletion mutants to generate wild-type revertant virus. ICP34.5-deleted HSV vectors have been injected into over 200 human patients with advanced malignancy - there are no records of any wild-type reversion in any patient. The recipient cells are not therefore, considered to pose any inherent hazard or foreseeable effect to human health.

Host/vector system

Replication of oncolytic deletion mutants is attenuated in normal cells/tissue, depending upon the nature of the deletion and the nature of the vector. Multiple publications from the proposer’s lab and others attest to the selectivity of replication – see Heise et al Nature Med (2000) 6:1134. In addition, multiple phase I and II trials of oncolytic adenovirus as well as E1-deleted non-replicating vectors have shown no replication in normal tissues. Wild-type adenoviral vectors are replication competent and could infect humans. However, wild-type adenovirus infection in humans with an intact immune system leads to a mild and self-limiting 'flu-like' illness. ICP34.5-deleted HSV is dramatically attenuated in normal non-malignant tissue including neuronal cells, both murine and human. Direct intra-cranial inoculation of 1716 has been demonstrated to be safe in subjects. No wild-type HSV-1 will be used in any experiment.

Origin & function

Genes that will be inserted into the adenovirus or HSV genome are designed either to increase tumour-specific mortality by the virus (e.g. tumour suppressor or apoptosis-inducing genes), to inhibit the activity of oncogenic pathways or to increase the immunogenicity of infected tumour cells. There are multiple examples in the literature where this can be achieved safely. No wild-type oncogenes or direct toxins will be included.

The deletions induced in adenovirus and HSV vectors are designed to narrow the host range, so that there is reduced replication and mortality within normal cells, thus increasing the therapeutic index in ovarian cancer cells. Mechanisms to achieve this will include introduction of specific deletions to restrict replication and the use of tumour and tissue-specific promoters.

During process development for clinical grade manufacture of one of the mutants, no recombination between vector and HEK293 sequences was detected (limit of detection 1 in 109 genomes) – thus it is believed that the risk of reversion to wild-type virus following amplification in HEK293 cells is extremely low. For HSV, there is no evidence from any previous pre-clinical or clinical study that HSV vector 1716 can transfer genetic material to other organisms.

Evaluation of foreseeable effects

Replication competent adenoviruses contain mutations within the viral genome that attenuates replication in normal cells and tissues. The deletions occur in regions of the viral genome that are necessary for replication in normal cells but are complemented by the altered gene expression in cancer cells. These mutants can only replicate efficiently in cells with deregulated p53 and pRB pathways. Tumour selective mutants can infect normal cells but the ability to replicate is highly attenuated. Human adenoviruses do not replicate in murine tissue - this is true of wild-type, replication-restricted oncolytic viruses as well as replication-defective E1-deleted vectors.

The only replication following injection into tumour-bearing subjects will be in malignant tissue. The normal route of adenovirus infection is via aerosol. 1716 and other ICP34.5-deleted HSV vectors have been administered to over 200 patients with cancer with no significant toxicity. All vectors proposed contain an intact thymidine kinase gene, and thus HSV-infected cells are sensitive to treatment with the anti-viral drugs aciclovir and ganciclovir.

All injections of virus will be undertaken in class II hoods within the unit, thus minimising the risk of aerosol-mediated infection during the injection process. Multiple human studies demonstrate that virus shedding after intraperitoneal, intravenous or intratumoural injection is undetectable. Thus, the risk to humans from subjects is negligible as the viruses are replication-deficient or tumour specific and the gene products are not considered harmful to health.
In addition, laboratory standard operating procedure in relation to biological agent handling and waste management are such that the likelihood of exposure to a biological agent is reduced to an extremely low level. The risk to human health is low.

CU2 Project Title CLONING AND EXPRESSION OF BACTERIAL ENTEROTOXINS

Class 2

Culture Vol Class 2 < 1 litre

Culture Vol Class 3-4
### Project Additional Information

**Purposes of the contained use**

The aim of the project is to clone, express and purify bacterial enterotoxins from Staphylococcus aureus, specifically the SEG and SEI enterotoxins. The genes for these proteins will be obtained by PCR amplification from DNA isolated from a particular isolate of S. aureus obtained from a patient at St Mary's Hospital. The PCR products will be cloned into E. coli expression vectors capable of expressing the clones genes from the bacteriophage T7 promotor in case the gene products are toxic to E. coli.

**Recipient or parental organism**

The genes of SEG and SEI will be obtained by PCR amplification from DNA isolated from a patient at St Mary’s Hospital. The DNA will be cloned into plasmid vectors for propagation in lab adapted disabled strains of E. coli.

**Host/vector system**

Bacterial Host cell lines: E. coli DH5a, E. coli BLR (DE) pLysS, E. coli HMS174 (DE) pLysS, E. coli HMS174(DE) pLysE
Cloning Vector: pCRT7/NT-TOPO

**Origin & function**

Staphylococcus aureus is the origin of the DNA. The genes encode enterotoxins, and the genes will be expressed with the aim of producing recombinant protein.

**Evaluation of foreseeable effects**

The E. coli strains are disabled and there is very little likelihood of the establishment of an infection in humans and/or animals. The encoded gene product may cause symptoms of food poisoning. There is very little possibility of the GMO surviving in the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste is chemically treated with freshly made 2% hycolin for a minimum of 15 minutes, in practice overnight treatment is usual. This effectively yields a 100% kill.

Solid waste is autoclaved at 134 degrees C for 30 minutes, and effectively yields a 100% kill.

Periodic testing of a test culture to determine survival after the above treatments is used for monitoring the effectiveness of the procedures.

Solid waste is subsequently transported in sealed bins for incinerating at an off site facility.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The project concerns the cloning of enterotoxin genes from S. aureus. Due to the nature of the encoded gene products, it was considered that the proposal is assessed as a Class 2 project, even though the project is for the production of the proteins in E. coli cells only.

IC Occupational Health did not consider it necessary for Health Surveillance.

The aim of this project is to transform bacteria used in in-vivo models of infection, with a plasmid vector carrying the gene for green fluorescent protein, in order to develop
Recipient or parental organism

E. coli 0111:B4, E. coli J5 and S. typhimurium LT2 are routinely used in mouse models of E. coli and Salmonella infections. The vector pFPV25.1 is mob+, colE1+ and contains an ampicillin resistance gene (bla). Constitutive GFP expression is under the control of the promoter for the S. typhimurium rpsM gene, which encodes for the S13 ribosomal protein. It has been previously used to transform E. coli and S. typhimurium for similar applications.

Host/vector system

Bacterial Host cell lines: E. coli 0111:B4, E. coli J5 and S. typhimurium LT2. Cloning Vector: pFPV25.1 (mob+, colE1+)

Origin & function

Aequoria victoria is the origin of the DNA encoding the GFP gene. The plasmid construct will express GFP enabling bacterial cells to be visualised fluorescence microscopy and flow cytometry.

Evaluation of foreseeable effects

The E. coli and S. typhimurium strains have been used for studies of salmonella infections. Thus, there is a possibility of the strains causing symptoms of food poisoning. There is very little possibility of the GMO surviving in the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The project concerns the use of a plasmid vector expressing GFP in E. coli and S. typhimurium to enable visualisation of bacterial cells when used to infect mammalian cells. It was considered that the proposal be assessed as a Class 2 project, due to the strains of bacteria that were been used to harbour the plasmid vector. IC Occupational Health did not consider it necessary for Health Surveillance.

Project Additional Information

Purposes of the contained use

The purpose of this work is to exploit the ability of salmonella typhimurium to accumulate and preferentially replicate within solid tumours. A variety of bacterial genes associated with virulence will be knocked out by homologous recombination and their effects on bacterial virulence and anti-tumour ability will be assessed. In addition, vectors carrying the reporter genes GFP and luciferase will be used to follow the location of the bacteria within host cells.

Recipient or parental organism

- S.typhimurium 12023
- S.typhimurium LT2
S. typhimurium SL1344
All three strains are commercially available and have been widely used in several laboratories for many years. They are classified as containment level 2 by the ACDP.

<td></td>
</tr>
</tbody>
</table>

The E. coli strain is a widely used, high attenuated commercial strain.

Origin & function

The vector pGP704 is a simple suicide vector, carrying an oriR for E. coli only. DNA from the parental organism will be amplified by PCR and inserted into the plasmid, using E. coli as a host organism. This will then be transformed into the parental organism and successful recombination events selected for (by antibiotic resistance marker). Genes to be targeted will be involved with LPS biosynthesis, auxotrophy or the type III secretion system. Inserted DNA will be heavily disrupted and so unlikely to be active. The disruption of the targeted genes is likely to reduce the pathogenicity of the parent organism. It will also make the host strain resistant to ampicillin, but suitable alternative therapies are available if necessary.

The vectors pFPV25.1 and pSP-luc+ are expression vectors for the genes encoding GFP and luciferase respectively. All vectors are defective for mobilisation so genetic transfer is unlikely.

Evaluation of foreseeable effects

The results of genetic modification will reduce the pathogenicity of the parental organism. No adverse effects are anticipated.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not Applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste is deactivated using 'Virkon' according to the manufacturer's instructions, it has been validated as being effective at this concentration within 5 minutes, see www.antech.com/virindex.html. All solid waste is first autoclaved at 134 degrees for 30 minutes in an autoclave on the 6th floor, MRC Cyclotron building before being removed for incineration. The autoclave is under a service contract and is serviced quarterly by arrangement with ICSM estates. Thermalogue strips will be included with every run. Steris verify kits used every 6 months. Records to be kept.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The committee recommended that this project be classified as class 2 due to the ACDP classification of the wild type S.typhimurium strains as containment level 2, despite the fact that created GMMs will be attenuated for virulence.

INVESTIGATION OF PROTEIN EXPRESSION OF SALMONELLA PATHOGENICITY ISLAND 2 IN SALMONELLA TYPHIMURIUM, USING A COMMERCIAL EXPRESSION SYSTEM (PET) AND GENE FUSIONS TO A PLASMID ENCODING GFP

- **Class:** Class 2
- **Culture Volume Class 2:** < 1 litre

- **Non-GMM Consent Granted:** not applicable
- **Project notified under transitional arrangements:** N

#### Purposes of the contained use

The aims of this project are twofold. Firstly, to exploit a commercially available E.coli based protein expression system to produce proteins, or parts of proteins, of Salmonella typhimurium. The resultant products will then be used as antigens to stimulate antibody production in rabbits.
Secondly, we wish to employ a strategy of engineering fusion genes to elucidate in which cell lines or stage of infection certain Salmonella typhimurium genes are expressed.

**Recipient or parental organism**

Salmonella typhimurium is ACDP Hazard Group 2, as it is a human and animal pathogen. Escherichia coli BL21 is also ACDP Hazard Group 2, as it may be pathogenic and is able to colonise humans.

**Host/vector system**

Salmonella typhimurium is ACDP Hazard Group 2, as it is a human and animal pathogen. Escherichia coli BL21 is also ACDP Hazard Group 2, as it may be pathogenic and is able to colonise humans.

**Origin & function**

Source of Host cells: E.coli BL21 commercially available (Stratagene UK), Salmonella typhimurium laboratory maintained strains.

Source of Genetic material (inserts): PCR from S.typhimurium genomic DNA template.

Source of Genetic material (vectors): pET 15b from Stratagene. pFPV25 is a gift from collaborator.

**Evaluation of foreseeable effects**

Both the GMMs are ACDP Hazard Group 2. In the case of GM S.typhimurium; the modification takes the form of the addition of an autonomously replicating plasmid which merely serves as a marker for gene expression. The plasmid encodes the green fluorescent protein marker and also confers resistance to ampicillin. As there are a variety of alternative chemotherapeutic agents available for use; this modification is thought to pose no increase risk to human health. The environmental survivability of the GM S.typhimurium is envisaged to be similar to the parental wild type strain. Likewise in the case of E.coli BL21, the modification takes the form of the addition of a self-replicating plasmid, upon which resides the cloned S.typhimurium gene. Expression is controlled and regulated by the addition of IPTG to growing cultures. In the absence of IPTG expression is minimal. The plasmid also confers resistance to ampicillin. As there are a wide variety of alternative therapies available, this modification is thought to pose no increased risk to human health. The environmental survivability of the GM E.coli BL21 is thought to be the same as the wild type.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Chemical Disinfection of liquid GM waste: 2% hycolin solution, as per manufacturer's recommendations, overnight exposure. 100% kill validated by periodic plating out of cultures after exposure to hycolin disinfectant.

Autoclaving of solid GM waste: Large autoclave; solid discard cycle 134 celsius for 30 minutes. 100% kill. Machine and cycle validated by thermograph and testing by manufacturer's engineer.
Autoclaving of liquid GM waste: Large autoclave; liquid discard cycle 134 celsius for 30 minutes. 100% kill. Machine and cycle validated by thermograph and testing by manufacturer's engineer.

The second paper entitled "Investigation of protein expression of Salmonella pathogenicity Island 2 in Salmonella typhimurium using a commercially available expression system (pET) and gene fusions to a plasmid encoded green fluorescent protein" from Professor Holden, this project was approved by the committee, with the following classifications: the Salmonella typhimurium work was classified as Class 2 Containment level 2, work involving E.Coli K12 strains were classified as Class 1, but will be carried out as Containment level 2 due to the level of facilities available, work involving B121 was classified as Class 2 Containment level 2. Again the Class 2 projects must be notified to HSE prior to any work commencing and a new GM Form A completed.

Project reference no. 01/264.

IC reference no. 00083.

# Project Additional Information

## Purposes of the contained use

The aim of this project is to engineer mutants of Salmonella typhimurium by insertional mutagenesis. The genes to be mutated encode proteins involved in different aspects of Salmonella virulence. The strains will then be tested for phenotypic defects in mammalian cell lines.

## Recipient or parental organism

The recipient microorganism is Salmonella typhimurium, which is a human and animal pathogen. It is placed by the ACDP in Hazard Group 2.

## Host/vector system

**Salmonella typhimurium (Host):** pGP704; pFPV25.1; pACYC184 (Vectors).

## Origin & function

- **Source of Host Cells:** Laboratory maintained strain. Originally obtained from the PHLS, UK.
- **Source of Genetic material:** inserts PCR from S.typhimurium genomic template.
- **Source of the material:** vectors pACYC184 and pCR2.1 are commercially available; pGP704 and pFP25.1 are gifts from colleagues.

## Evaluation of foreseeable effects

The GMM is likely to pose no increased risk to human health in comparison with the wild type parental strain. On the contrary, the GMM is likely to be attenuated in its ability to cause disease, since a putative virulence gene will have been mutated; and so in a functional sense, be disabled.

However, the insertional mutagensis protocol utilised in this project renders the GMM resistant to ampicillin. But there are a wide variety of alternative chemotherapeutic agents available should infection by the GMM occur.

Similarly, there is no increased risk to the environment posed by the GMM in comparison to the wild type. The latter is widespread in the environment. The environment survivability of the GMM is envisaged to be the same as the wild type, with the caviat that without appropriate selection pressure reversion to the wild type is likely. All work carried out under this project will take place in appropriate Containment level 2 premises, together with appropriate waste control and management systems.

Project Ref 31/01.7
**Project Additional Information**

**Purposes of the contained use**

The aim of this project is to identify, and characterise the function of Streptococcus pneumoniae genes required for virulence. This necessitates the construction of plasmid vectors containing segments of S. pneumoniae DNA, which are used to transform wild type S. pneumoniae to make GMM strains with specific gene disruptions. The phenotype(s) of these strains will then be assessed using animal and cell culture models of disease.

**Recipient or parental organism**

The recipient microorganism in Streptococcus pneumoniae, which is a human pathogen. It is placed by the ACDP in Hazard Group 2.

**Host/vector system**

**Host.** Streptococcus pneumoniae.

**Vectors:** pJPC9111, pJPC9112, pLS1GFP, pLS70GFPcat, pucMUT, pDE1, pEVP3, pACH74, p10701

**Origin & function**

**Source of Host Cells** - Smithkline Beecham; Prof. James Paton, University of Adelaide

**Source of Genetic material:** inserts - PCR of Streptococcus pneumoniae DNA

**Source of the material:** vectors - Prof. James Paton, University of Adelaide; commercial sources.

**Evaluation of foreseeable effects**

The GMM is likely to pose no increased risk to human health in comparison with the wild type parental strain. On the contrary, since a putative virulence gene will have been mutated the GMM is likely to be attenuated in its ability to cause disease; and therefore be functionally disabled. The insertional mutagenesis protocol utilised in this project renders the GMM resistant to chloramphenicol, spectinomycin, erythromycin or kanamycin. However, there are a wide variety of alternative antimicrobial agents available which are effective against S. pneumoniae infections should infection by the GMM occur. S. pneumoniae is essentially restricted to the human nasopharynx and there is no recognised environmental source. The environmental survivability of the GMM is envisaged to be the same as the wild type, with the caviat that without...
appropriate selection pressure reversion to the wild type is likely, and there is no increased risk to the environment posed by the GMM compared to the wild type.

All work carried out under this project will take place in appropriate Containment level 2 premises, together with appropriate waste control and management systems.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

02/03/2022
The purpose of this work is to exploit the ability of Vaccinia Virus (VV) to accumulate and preferentially replicate within solid tumours. A variety of viral genes associated with virulence or evasion of the host immune system will be knocked out and their effects on viral tissue specificity and anti-tumour ability will be assessed. In addition, vectors carrying the reporter genes GRP and luciferase will be used to follow the location of the virus within host systems.

Vaccinia virus strains Western Reserve, Lister and Wyeth
All three strains are commercially available and have been widely used in several laboratories for many years. In addition, strains Lister and Wyeth have been used as Smallpox vaccines in millions of people worldwide. They are classified as containment level 2 by the ACDP.

Host/vector system
Host cells - E.coli DH5a, K12
Vectors - pUC18, pUC4K, pSJH7
The E.coli strains are widely used, highly attenuated commercial strains.

Origin & function
DNA from wild type VV strains will be amplified by PCR and cloned first into standard, commercially available plasmids (pUC18, pUC4K) where deletion mutants will be constructed. The modified DNA will then be cloned into the specialist plasmids (pSJH7) for transient dominant selection. These DNA manipulations will take place in commercially available E.coli strains, acting as a cloning vector. The plasmids will then be co-transfected into the cell lines TK143 or D98 along with a second vector containing an attenuated version of the wild type VV genome, such that viral replication can only occur following recombination of the two plasmids. Virus can then be
picked from plaques and successful recombination checked by PCR and Southern blotting. Genes to be targeted will be involved with the evasion of the host immune system (IFN binding proteins, anti-apoptotic proteins). Inserted DNA will be heavily disrupted and so unlikely to be active and the disruption of these genes is likely to reduce the pathogenicity of the host organism.

In addition, this same technique will be used to insert the reporter genes GFP and luciferase into the viral genome.

Evaluation of foreseeable effects
The results of genetic modification will reduce the pathogenicity of the parental organism. No adverse effects are anticipated.

Animal Units

Large Scale Activities

Human Clinical Applications

02/03/2022
The study has been set up to assess the biological activity of different strains of attenuated HSV in different types of human tumours in the ex-vivo setting. The study involves injecting vectors directly into either discarded tumour blocks or purified tumour cells extracted from discarded tumour specimens. The purpose of the contained use is to prevent the vectors which are Class 2 GMOs being a hazard to workers.

HSV1 vectors deleted for the neurovirulence factor ICP34.5 and ICP47 with insertion of a human granulocyte macrophage colony stimulating factory (hGM-CSF) or green fluorescent protein (GFP) will be used. These vectors will be produced offsite. ICP34.5 deletion vectors are designed to replicate in tumours but not surrounding tissue (considerable literature demonstrates such a phenotype for HSV1 and 2 ICP34.5 deleted viruses). As ICP47 is an HSV gene that minimise immune responses to HSV infection, it's deletion results in enhanced immune response. ICP34.5 and ICP47 deleted vectors have been shown individually to generate a non-pathogenic, though still replication competent virus. The insertion of the hGM-CSF gene is intended to further stimulate the immune system in the clinical setting. The insertion of the GFP gene is for assessment of the biological activity.

There are two copies of ICP34.5 which are in identical portions of the genome, therefore the virus cannot exist in a stable form with 1 copy different to the other (ie only one copy disabled). This is because recombination with the region around the other copy would occur rapidly, this would either delete the inserted gene to give two copies of ICP34.5 or result in a virus with two insert genes in ICP34.5 ie a disabled virus. Therefore it is not possible for a virus not disabled but with a single copy of the transgene to have a stable existence in the environment.
Herpes Simplex Virus 1.

Origin & function

hCM-CSF gene was cloned from an IMAGE clone 2340997/5808-K14 (UK HGMP Resource Centre). GM-CSF is a potent cytokine responsible for the differentiation and proliferation of dendritic cell precursors and therefore is a potent immune stimulator. Thus if it were to enter a human it would be anticipated to give an improved immune response against HSV.

GFP was purchased from Contech which is not biological active but is used as an aid to assess the activity of the vector in the ex-vivo setting.

Evaluation of foreseeable effects

The gene to be inserted is not anticipated to result in harmful effects.

The aim of this experiment is to evaluate the biological activity of herpes simplex vectors in different types of tumours and will provide invaluable information towards the setting up of clinical trials in the future.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste generated during the activity that has been in contact with the GMM will be treated with 2% freshly prepared bleach for a minimum of 2 hours. This broad-spectrum disinfectant is effective against herpes simplex virus at a 0.5% (w/v) concentration giving terminal disinfection after 10 minutes of contact. The waste is then double bagged, autoclaved and put in incineration bins which will be taken by contractors for incineration or microwaved.

All liquid waste will be treated with 2% freshly prepared bleach for a minimum of 2 hours and then discarded.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

Teh GMSC opinion is that the viruses to be used are probably low risk Class 2.

02/03/2022
The aim of the project is to define the role of a number of exotoxins of the pathogen Pseudomonas aeruginosa in invasion and penetration of the respiratory epithelium. We will construct mutants of this organism lacking specific toxins and investigate the effects of these mutations on invasion of the pulmonary epithelium. To confirm that the effects of a mutation are specific, we will also complement mutated strains with the wild type toxin gene.

Different strains of Pseudomonas aeruginosa will be modified to delete one or more of the genes encoding toxins secreted by the type 1 secretion system of this organism. Some of these strains will then be complemented with the wild type gene for one or more of these toxins. The changes to these microorganisms will be used to define the role of these exotoxins in causing human disease. No material will be introduced into the microbe that does not already exist in wild type strains of this microorganism. Selectable markers to be used will confer antibiotic resistance to the microorganism but this resistance already exists in the wild type organism and other antibiotics are available to treat these infections. The organism can survive in the environment but no enhanced danger is produced by the modification to be carried out in the project.
Host/vector system

Bacterial strains
E.coli K12 derivatives
E.coli SM10
Pseudomonas aeruginosa PAO1 and clinical strains

Vectors:
TOPO series vectors (Invitrogen)
pUCPneo pKS Km
pEX100T pJQ200SK
pUCP18
pSMC2

Origin & function

Genes to be deleted will be replaced by kanamycin resistance cassette from a Gram negative transposon (mTn5). Complementation of deleted genes will be with wild type toxin amplified from clinical strains of Pseudomonas aeruginosa. The genes to be deleted will be for exoenzymes S, T, U and Y. The toxins encoded by these genes are introduced into mammalian cells by the specialised type 111 secretion system. The toxins can only exert their effect when introduced into cells by this means; they are not toxic outside the cell.

Evaluation of foreseeable effects

The deletion of the exotoxin genes will remove known virulence factors of Pseudomonas aeruginosa, reducing its ability to cause disease. Restoration of these genes will increase the virulence of a particular strain that does not express these toxins, but only to the level of naturally occurring Pseudomonal strains. P. aeruginosa does not cause disease in healthy humans. It can cause pneumonia in patients with cystic fibrosis, those who are ventilated and in those with extensive burns. The modifications will introduce resistance to the antibiotic kanamycin into these organisms. Such resistance already exists in naturally occurring strains and other antibiotics can be used to treat infection. Although modified organisms could potentially survive in the environment, they would present no greater risk than naturally occurring P aeruginosa, which is widely spread in the environment eg freely growing in soil and water.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid GM waste will be treated with Hycolin 3% for 15 minutes which produces effectively 100% kill. This is monitored by quantitative plating of treated bacteria. In addition, both solid and liquid GM waste will be inactivated by autoclaving at 121 degrees C for 15 minutes. This provides 100% kill as evidenced by quantitative plating of treated bacteria.

Following autoclave treatment waste is then removed from the site by a contracted service, to be disposed of as clinical waste.

Recombinant vaccinia virus will be grown and used in containment level 2 facilities with class II cabinets.
Recipient or parental organism

GMO: Recombinant vaccinia virus WR strain with disrupted TK gene and insertion of either influenza nucleoprotein or a peptide (366-374) from the influenza nucleoprotein.

TK disruption will attenuate pathogenicity of the virus

Insertion of influenza nucleoprotein or peptide will not have any foreseeable effect.

Host/vector system

Recombinant vaccinia will be cultured in vitro in TK143 cells.

Origin & function

Influenza nucleoprotein is an RNA binding protein that encapsidates the viral genome. It comes from influenza virus.

The influenza nucleoprotein peptide comprises amino acids 366-374 of the nucleoprotein and has no intended function. It serves as a peptide epitope presented by the MHC class 1 molecule Db. It comes from influenza virus nucleoprotein.

The F5 T cell receptor is a T cell receptor that recognises the influenza nucleoprotein 366-374 peptide presented by the MHC class 1 molecule Db.

Evaluation of foreseeable effects

Disruption of the vaccinia virus TK gene will be attenuate pathogenicity.

Insertion of the coding sequence for influenza nucleoprotein or the nucleoprotein peptide 366-374 into the vaccinia virus will allow for expression of the protein/peptide within cells of infected mice. This will stimulate a T cell response to the nucleoprotein.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Laboratory.

Solid waste: Treatment with 1% Virkon for minimum of 10 minutes. 100% kill. This has been validated on the Antec (Virkon) website. The product has been tested to be effective at 1% solution and 10 minutes contact time. The web site will be monitored for any changes in specification.

Solid waste will be placed in sterilin bags and put in specially designated grey boxes within the laboratory or cold room. When these are full they will be tied using a specially designated yellow tag and sent for autoclaving.

Solid waste will be autoclaved at 134 degrees centigrade for a minimum of 30 minutes. A 12 point thermocouple test is conducted every 6 months on a simulated worst case worst load to establish that an effective and validated sterilisation temperature and time is achieved in all areas of the load. An internal thermocouple monitors the chamber temperature on every run. The current autoclave program sets temperature of 134 degrees C for 30 minutes and this ensures that all parts of a worst case load will always achieve a validated lethal temperature for the microorganisms mentioned in this assessment.

Liquid waste: Treatment with 1% Virkon for minimum of 1 hour. 100% kill. This has been validated on the Antec (Virkon) website. The product has been tested to be effective at 1% solution and 10 minutes contact time. The web site will be monitored for any changes in specification.
Mouse bedding and cages: These will be removed for cleaning and decontamination by CBS staff. Bedding will be autoclaved at 134 degrees C for 30 minutes and disposed of via the clinical waste route. Cages will be autoclaved at 121 degrees for 15 minutes and then wasted for re-use.

### Project Additional Information

**Purposes of the contained use**

Induce downregulation of selected genes in various Mammalian cells/Cell lines. Approach could potentially be applied to any gene of interest. In the first instance targets will be hypoxia regulated genes/Genes regulated by HIF (hypoxia inducible factor).

**Recipient or parental organism**

Various Mammalian cells and/or cell lines, primarily of human or mouse origin.

**Host/vector system**

Modified Lentivirus, produced with PLL3.7 vector containing ShRNA inserts. 
Inserts will be various small RNA stretches tailored to the gene to be downregulated. Lentivirus is a 3rd generation multiple vector system with multiple modifications to increase safety and ease of handling, ie

1. Packaging vector lacks both LTRs and has no viral packaging signal ( )
2. The following viral genes have been deleted from the packaging vector: env, tat, rev, vpr, vpu, vif and ref.
3. Rev is supplied in trans on a different vector (RSV-Rev).
4. The vector expressing the packaged viral genome has a self-inactivating LTR (TATA box deletion) and expresses no viral gene products.
5. Envelope, in this case VSVG, is expressed on a separate vector.

**Origin & function**

Intention is to use Modified lentivirus to introduce interfering RNA into cells, leading to downregulation of Targeted Genes. No new genetic material will be introduced.

**Evaluation of foreseeable effects**

Up to 95% downregulation of targeted genes expressed by Mammalian Cells. Gene downregulation is specific dependant on the original ShRNA sequence inserted into the modified Lentivirus. No other effect are anticipated. Modified Mammalian cells are Non micro-organism GMOs. Cells are cultured only in a Class 2 suitable lab, with all relevant control procedures. No viable cells will enter the environment as all cells and Tissue culture waste will be decontaminated by an approved method. Decontamination of liquid and solid (ie flasks, pipettes etc) will be with a 1% virkon solution approved for chemical inactivation.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Chemical inactivation of all liquid and solid (flasks, pipettes etc) waste associated with culture of modified mammalian cells. Agent of choice is Virkon in a 1% solution overnight, giving an effective kill of 100% (independent tests by manufacturer). Monitored with continued reference to manufacturer guidelines and test against culture every six months.

Solid waste is disposed of after chemical treatment in yellow clinical waste bags, tied, labelled and disposed of by the clinical waste route.

Liquid waste is disposed of via the drains after chemical inactivation.

Autoclaving may also be used for solid waste. Autoclaving gives a temperature of at least 120 degrees for 30 minutes monitored by an internal thermocouple, giving an effective kill of 100%. Autoclave function is validated with a 12 point thermocouple every six months.

Is an emergency plan required according to regulation 20? N

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The classification of this GM project was queried by the GMSC and a virologist independent of the GMSC was consulted for further advice. An extract of the advice received is provided here: "the inhibition of gene expression using these vectors is very broad. This is usually not a problem but if inhibition is for say tumour suppressor genes then these vectors, which can infect human cells when Pseudotyped with a VSV0G envelope, could potentially be hazardous and be at a level higher than 1."

Project Additional Information

Purposes of the contained use
The aim of the project is to induce and study inflammation in the heart using models of CVB3 infection. Live CVB3 will be generated from cDNA clones which contain the entire viral genome of the wild-type or mutated forms.

Recipient or parental organism
CVB3 is an ubiquitous picornavirus, a small single positive strand RNA virus. Infection is usually asymptomatic, transmission is mainly faecal-oral.
E coli is a gram negative bacillus that forms part of the normal gut flora.
Vero cell is derived from African Green Monkey kidney.
HeLa cell is derived from human cervix epitheloid carcinoma.

Host/vector system
Hosts:
E coli TG1
XL1
JM109

Eukaryotic cell line
HeLa cells
Vero cells

Vectors:
Bluescript
pGEM
pUC
m13
Lorist6
pSVN (previously generated from pSVA13 by insertion of a Not I linker in the blunter EcoRI site)
p2732B (a derivative of pBR322 containing the ampicillin-resistance gene, the plasmid origin of replication, and a cloning site array between two EcoRI site)

Origin & function

Origins:
Plasmids vectors are obtained commercially and from Enterovirus Research Laboratory, Department of Pathology and Microbiology, University of Nebraska Medical Centre, 986495 Nebraska Medical Centre, Omaha NE68 198-6495, USA and Imperial College London.

CVB3 genome cDNA derived originally from CVB3 isolated from infected human tissues eg Nancy strain are obtained Enterovirus Research Laboratory, Department of Pathology and Microbiology, University of Nebraska Medical Centre, 986495 Nebraska Medical Centre, Omaha NE68 198-6495, USA and Imperial College London.

Intended functions:
These genetic materials are used to generate live infectious CVB3 with genomic sequences identical to that of the original wild-type isolate or modified in a controlled manner. Briefly entire RNA genomes of CVB3 are cloned as infectious cDNA copies in plasmids. Disabled E. coli host is used for cloning and amplification of the recombinant plasmids. Transfection of eukaryotic cell lines are used to generate live infectious CVB3 with genomic sequences dictated by the cDNA insert in the recombinant parental plasmids. CVB3 recovered from the supernatant medium and cell lysates can be further propagated by CVB3 infection of eukaryotic cells, purified and kept as stocks. Wild-type and genetically modified CVB3 thus generated will be tested in established models of enteroviral myocarditis to assess phenotype, including changes due to particular sequence modification of the viral genome. Strategies for genetic modification will include site-directed mutagenesis and substitution of homologous regions of the genome (resultant cDNA genomic constructs verified by restriction endonuclease mapping and sequence analysis).

Evaluation of foreseeable effects

General human health and environmental hazards of CVB3
CVB3 is an ubiquitous picornavirus (commonly present in the environment), of which man is the natural host. It has been estimated that at least 70% of the human population has come into contact with the endemic CVB3. Infection is usually asymptomatic. Uncommonly, CVB3 infection may manifest clinically as aseptic meningitis, meningocerebralitis, paralysis (infrequent), pleurodynia, myo- or peri-carditis, upper respiratory illness and pneumonia, rash, hepatitis, conjunctivitis, undifferentiated febrile illness, severe systemic infection in infants and fatal neonatal disease. The disease is likely influenced by host and viral genetic/non-genetic determinants. Currently there is no specific therapy for CVB3 infection. There is no vaccine.

In addition to viral and host determinants (eg virulence of the strain, host immune status), animal data suggests that the higher the infecting dose the greater the risk of infection/severity of the disease. In man, CVB3 infects via the mouth or oropharynx. Incubation period is 7-14 days (range 2-35 days). The virus infects the mucosal tissues of the pharynx. Gut or both, finally entering the blood stream and gaining access to cells of the reticuloendothelial system and specific target organs such as the meninges, myocardium and skin. The virus can generally be recovered from the pharynx during the first week of illness and from the faeces for 1-4 weeks after onset of illness; they have been isolated from CSF, spinal cord, brain, heart, conjunctivae and skin lesions.

To date, laboratory acquired CVB3 infection in man has not been reported in the literature. Although the risk of transmission to the laboratory worker varies throughout the natural history of CVB3 infection in mice, at all times the risk of transmission to the laboratory worker is small, and reduced to negligible levels with routine laboratory practice eg. wearing personal protective equipments such as laboratory gown/coat, mask, gloves in the containment areas. Changing animal cages at least 3 days post inoculation to remove bedding contaminated with infectious animal excrements (+/- blood from fights) may further reduce the risk of transmission to the laboratory worker. Possible routes of transmission of CVB3 infection to the laboratory worker are: (i) needle-stick injury or splashes/aerosol of CVB3 inoculum; (ii) faecal-oral or accidental ingestion of infectious matter; and possibly (iii) bites from infected animals.

Mice are rarely susceptible to natural CVB3 infection (ie through the faecal-oral route). Thus CVB3 infection in mice in the laboratory is achieved by direct inoculation of the virus ip. Housing of CVB3 infected adult mice in the same case as non-infected adult mice showed no evidence of cross-infection by virus isolation, serology or tissue histology.

CVB3 is a small single positive strand RNA virus. It does not have a lipid envelope and is therefore resistant to ether and other water-immiscible solvents. CVB3 may
CVB3 is a small single positive strand RNA virus. It does not have a lipid envelope and is therefore resistant to ether and other water-immiscible solvents. CVB3 may survive at room temperature for days, this is prolonged to weeks when in faeces. However, it is rapidly inactivated by ultraviolet light, drying temperature (esp > 50C), Virkon, Cidex OPA High Level Disinfectant Solution and formalin. All infectious animal tissues retained will be rendered non-infectious with formalin before transported out of Hammersmith BSU. Movement of wastes containing viable CVB3 will be as per existing local protocol and outlined below:

Non-radioactive wastes containing viable CVB3/plasmids/E. coli
Sharps waste will be place in sharps bin. At the end of the experiment, the lid will be closed, the outside of the bin sprayed with 1% Virkon* and the bin disposed of via the local autoclave route at routine times. Tissues, paper towels, gloves and other non-sharps will be placed in autoclavable waste bags, sealed, the outside sprayed with 1% Virkon* and the bag disposed of via the local autoclave route at routine times and incinerated by waste contractor. Formalin fixed tissues are non-infectious and can be disposed as non-infectious biological wastes. Liquid wastes will be rendered non-infectious by mixing with Virkon, aiming for a final concentration of 2% Virkon in the mixture, allowed to stand for at least 10 min, and disposed down the laboratory sink with copious amounts of water.

Radioactive wastes containing viable CVB3/plasmids/E. coli
CVB3 biologically contaminated radioactive material should not be autoclaved as this will create radioactive aerosols. Soak CVB3 biologically contaminated radioactive waste in 1-2% Virkon for at least 10 min then dispose the liquid down the designated radiation sink, recording an estimate of the level of radioactivity disposed. Then double bag the well drained waste in Radiation disposal bags. Spray the outside of the bag with 1% Virkon,* and remove immediately to an appropriate radiation bin for solid waste disposal. Record the radioactivity levels of waste disposed and monitor all areas that have been in contact with the waste for radiation contamination. Clean as appropriate. Existing college safety rules will be observed.

Likely effects due to genetic modification of CVB3
The virulence of genetically modified CVB3 will be attenuated or no more severe than wild-type/parental strain because candidate sequences (eg determined previously by comparative nucleotide sequencing of wild-type, attenuated and revertant viruses) will be introduced into the wild-type sequence. Wild-type CVB3 (eg Nancy strain - originally isolated from a patient with febrile illness in Connecticut USA) is both pancreovirulent and cardiovirulent in mice. Genetically modified CVB3 can be non-cardiovirulent +/- non-pancreovirulent in mice. This is similar to known CVB3 strain isolates from human tissues. Virulence is assessed by dose-effect comparisons between wild-type/parental and modified strains, as well as changes in phenotype ie revertant or disappearance of cardiovirulence or pancreovirulence. Currently the virulence determinant region(s) of the viral genome is not well understood. The human health and environmental hazards of genetically modified CVB3 are not expected to differ significantly from natural CVB3.

E. coli obtained commercially are disabled strains. Plasmids do not naturally infect humans or bacteria.
The degree of kill which should be achieved by Virkon, Cidex OPA High Level Disinfectant Solution, formalin, or autoclaving is 100%. Process testing and monitoring measures will include regular renewal and dating of disinfectants, monitoring of autoclave print outs as well as maintenance and testing of safety cabinets and autoclaves. Routine decontamination of other laboratory equipment will be undertaken. Regular inspections and internal reviews will take place. Workers will be under appropriate health surveillance. Information, instruction and training will be in the form of attendance at College Safety courses, local induction and procedures training, and the use of Good Microbiological Practice. Procedures for containment work on ACDP Group 2 pathogens will be followed. This work will only be undertaken by trained workers or whilst supervised by competent persons.

*The outside of the waste bag/sharps bin is sprayed with 1% Virkon to remove any glove contamination during the process.

### Project Additional Information

#### Purposes of the contained use

To study cellular immune responses. In their recombinant form vaccinia virus and adenovirus can be used in vitro as a vector for protein preparations in mammalian cells, studying protein functions or assessing protein cytotoxic T cell antigenicities. This will form the basis for the development of control strategies such as vaccines. The recombinant viruses are also useful vectors for delivery of genes in vivo for animal model studies.

#### Recipient or parental organism

K12 and B derivatives of Escherichia coli will be used as bacterial cloning hosts. These are disabled strains that cannot colonise the human gut and have a history of safe use. These hosts may be considered equivalent to ACDP hazard group 1.

293T, TK143. The mammalian cell lines used all can be regarded as low hazard for GM activities and, as hosts, are suitable for containment level 1 precautions. However for the purpose of COSHH risk assessment, any human or primate cells or lines that are not well characterised and authenticated (eg unscreened or primary material or from sources that cannot verify status) will be handled at Containment Level 2 with a microbiological safety cabinet.

#### Host/vector system

The vaccinia virus vector is based on the Western Reserve (WR) strain. This is a replication competent strain that is able to infect humans and cause disease. Genes are inserted into the thymidine kinase (TK) locus. The TK minus phenotype reduces the virulence of the virus in mice but no comparable data are available for humans.

The adenovirus Ad5 vector has a deletion removing most of the E1 region and as such is unable to replicate except in complementing cell lines such as 293 (a human embryonic kidney cell line that expresses the left 11% of the Ad5 genome). Gene inserts are put into the E1 site. Deletion of the E3 region allows insertion of larger sequences and also makes the virus less fit. E1 deleted hosts are regarded as unlikely to cause disease and assigned to ACDP hazard group 1.

Genes to be inserted into the Vaccinia viral genome will first be cloned into transfer vectors such as pSC11 and their derivatives under a synthetic, vaccinia derived early or early/late promoters. Followed by in vitro homologous recombination between a transfer plasmid and the wild type vaccinia in TK143 cells. Recombinant E1 deleted Ad5 adenoviruses will be produced by cotransfection of plasmids into 293T cells (E1 helper cell lines).

#### Origin & function

**Details of the inserted genes and gene sequences:**

1. From viral sources
   - I) Influenza A virus genes: fragments and full length proteins. They are coding for constitutive viral genes:
     - M1 matrix protein, major structural protein lies under lipid bilayer
     - M2 matrix protein acts as proton channel
NS1  non-structural protein, unknown function
NS2  non-structural protein involved in export of vRNA
NP  nucleoprotein, associates with RNA, aids replication and transcription
PB1  subunit of RNA polymerase which copies viral genome
PB2  subunit of RNA polymerase which copies viral genome
PA  subunit of RNA polymerase which copies viral genome
HA  haemaglutinin, surface glycoprotein
NA  neuraminidase, surface glycoprotein

ii) Dengue virus genes: fragments and full length proteins:

C    nucleocapsid protein

preM/M precursor membrane glycoprotein
E    envelope glycoprotein
NS1 non-structural protein 1, role in early RNA replication
NS2A non-structural protein 2A, binds strongly to the 3' untranslated region, NS3 and NS5
NS2B non-structural protein 2B, cofactor of NS3
NS3 non-structural protein 3, serine protease and NTPase-helicase
NS4A non-structural protein 4A, unknown function but binds strongly to most of the non-structural protein
NS4B non-structural protein 4B, unknown function
NS5 non-structural protein 5, RNA-dependent RNA polymerase

iii) HIV & SIV genes:

a) individual whole HIV or SIV proteins and their truncations:

gag group specific antigens - structural capsid proteins, RNA nuclear transport
pol enzymes - protease, reverse transcriptase
env envelope (gp41+gp120=gp160) - external viral glycoprotein
nef many functions - e.g. downregulation or upregulation of some specific cellular proteins
tat viral transcriptional transactivator
rev RNA transport and stability
vif promotes virion maturation and infectivity
vpr promotes nuclear localisation, inhibits cell division
vpu promotes release of virions, degrades some specific cell proteins
vpx SIV homologue of vpr

2. From various sources

i) CTL epitopes: CTL recognize and kill cells displaying on their surface 8- to 10- amino acid-long peptides derived from microbial proteins. To study T cell responses it is sometimes necessary to express target antigens by transfection into recipient cell lines. Another approach to minimize the amount of protein administered during vaccination is to engineer artificial proteins consisting of CTL epitopes. The sequences coding for short peptide epitope are derived from HIV, SIV, influenza virus or
expression of other proteins in vaccinia virus would also not be expected to affect host range or tissue tropism.  Similarly, the virus envelope during morphogenesis because of the unusual way in which vaccinia virus acquires its outer envelope from the trans-Golgi network.  Recombinant vaccinia virus has been widely used and there is no evidence that its tissue tropism or host range has been altered such that the expressed sequences will not be biologically active because, for example, they are synthesised as modified or disrupted coding sequences or the expression products will be rapidly degrade.

The insertion of gene sequences from mammalian sources and many of the genes from viral sources is not expected to affect the pathogenicity of the viral vectors.  However, some of the viral genes that will be expressed are known to modulate immune responses.  In the majority of cases the effect will be to upregulate the immune response resulting in a less virulent virus.  Some of the inserted sequences may downregulate the immune response.  Particular attention will be paid to ensure no gene sequences are expressed in vaccinia virus whereby it is reasonably foreseeable this would increase the virulence of the virus by downregulating the immune response.  For recombinant adenovirus, since this is a replication defective adenovirus, down regulation of the immune response does not present significant additional risk.  Adenoviruses have no mechanisms for cytolysis so viral particles remain cell associated and any effect would remain localized.

For the mammalian cell line and bacterial hosts no significant hazards have been identified.  Insertion of the foreign sequences into these is not expected to result in harmful physiological or pharmacological properties or to affect the pathogenicity of the cloning host or normal human defence mechanisms.  Gene transfer is possible but unlikely to be hazardous.  The resulting GMOs are not expected to carry any additional risks compared to that of the un-modified recipients.

No hazards to the environment were identified for genetically modified bacteria and cell lines.  The E. coli recipient strains K12 and B derivatives are disabled and neither these nor cell lines can survive in the environment.  Expression of inserted genes does not present a hazard.  Since these genetically modified micro-organisms are non-colonising, and none of the inserted sequences would affect the level of risk, they would not be harmful to animals, plant or humans in the environment.

Adenoviruses are non-enveloped viruses that are relatively resistant to desiccation and can survive in aerosols.  Consequently the adenovirus may survive in the environment in the event of accidental release.  Recombination between modified and wild type adenoviruses could possibly occur, but because the foreign genes are inserted into the E1 deleted site it is highly unlikely that a replication competent virus carrying foreign sequences would result.  Further, there is no evidence that human serotypes can naturally infect animals and the recombinant viruses are not expected to have altered host specificity.  If the recombinant adenoviruses were to survive for a short time in the environment it is unlikely that these would cause harm.  Recombination between modified vaccinia and other poxviruses resulting in the transfer of foreign sequences is extremely low because there is no natural reservoir within the UK.

Vaccinia virus is able to survive in the environment for some time.  The natural host of vaccinia is unknown but it is able to infect a wide range of mammalian species.  Of particular note regards environmental risks is that there was no colonisation of domestic or wild animals in the UK following the widespread administration of vaccinia virus to humans in the smallpox eradication campaign, nor has the recombinant vaccinia virus that has been used to control rabies in parts of Belgium or France led to colonisation of wild species.  There is no reason to believe that the recombinant vaccinia viruses produced in this work are any more likely to survive and become established in the environment than the wild type virus.

There is no intention to modify the tissue tropism or host specificity of the viral vectors and it is thought unlikely that any of the modifications would affect these.  In any case the recombinant adenoviruses are replication defective.  Recombinant vaccinia virus has been widely used and there is no evidence that its tissue tropism or host range has been altered by expression of any membrane protein from any other virus.  This is probably because foreign membrane proteins do not get incorporated into the vaccinia virus envelope during morphogenesis because of the unusual way in which vaccinia virus acquires its outer envelope from the trans-Golgi network.  Similarly, the expression of other proteins in vaccinia virus would also not be expected to affect host range or tissue tropism.
The insertion of gene sequences from mammalian sources and many of the genes from viral sources is not expected to affect the pathogenicity of the viral vectors. However, some of the viral genes that will be expressed are known to modulate immune responses. In the majority of cases, the effect will be to upregulate the immune response resulting in a less virulent virus. Some of the inserted sequences may downregulate the immune response, this is discussed further in the risk assessment. For recombinant adenovirus, since this is a replication defective adenovirus, down regulation of the immune response does not present significant additional risk. Adenoviruses have no mechanisms for cytolysis so viral particles remain cell associated and any effect would remain localised.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste, non-disposable plastics and culture vessels - chemical inactivation in 1% Virkon (final concentration) for a minimum contact time of 30 minutes following manufacturers validation data against the organism in use. After 100% inactivation liquid waste can be disposed of to the drains.

Solid phase GM waste, disposable plastics, pipettes and pipette tips, animal bedding - double bagged in autoclave bags, autoclaved (134 degrees C for 30 minutes). Autoclaving is validated by using indicator strips and chart data from the autoclave. Autoclaves are validated by annual 12 point thermocouple testing. After autoclaving all solid waste is incinerated.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

**Project Ref 31/06.1**

**Use of a lentivirus-based vectors for the transfer of complementary DNA into human and murine cells.**

**Date Ackn'd**: 01/02/2006  
**CU2 Project Title**: Use of a lentivirus-based vectors for the transfer of complementary DNA into human and murine cells.  
**Date Project Ceased**:  
**Class**: Class 2  
**Culture Vol**: < 1 Litre  
**Non-GMM**: Not Applicable  
**Consent Granted**: Not Applicable  
**Project notified under transitional arrangements**: No

### Historical Significant Changes

- **Historical Significant Changes**
- **Historical Date of Additional Info**
- **Significant Change ID**
- **Date of Significant Change**

### Project Additional Information

**Purposes of the contained use**

The proposed lentiviral vector is pHR-SIN-CSGWdlNotl that contains the WPRE sequence which has been implicated in the development of liver tumours in mice in a pre-clinical study using lentiviral vectors (SACGM Information Note, November 2004). Therefore the pHR-SIN-CSGWdlNotl vector will be used under conditions of Class 2 containment, as recommended by the SACGM Secretariat.

**Recipient or parental organism**

pHR-SIN-CSGWdlNotl will be expanded in the bacterial strain E. coli-derived Top 10F: F’(lacI q Tn10 (tetR)) mcrA. (mrr-hsdRMS-mcrBC) O80lacZ.M15.lacX74 deoR recA1 araD139.(ara-leu)7697 galU galK rpsL endA1 nupG. This is a highly disabled laboratory variant of E. coli. The presence of pHR-SIN-CSGWdlNotl is not expected to modify the properties of the host and thus pose increased risk to humans or environment. In addition, bacteria carrying pHR-SIN-CSGWdlNotl cannot survive outside the conditions offered by the optimum culture medium.

**Host/vector system**

The vector system pHR-SIN-CSGWdlNotl is a lentivirus-based plasmid that when co-transfected with gag-pol and pMDG VSC-G expressing plasmids in packaging cell lines such as 293T generates VSV-G pseudotyped virions released in the supernatants that are capable of infecting human as well murine cells. Primary human and murine cells of haemopoietic and epithelial origin as well as a variety of cells lines will be subjected to infection.

**Origin & function**

HR-SIN-CSGWdlNotl, gag-pol and pMDG VSC-G plasmids were from UCL, London. cDNAs amplified from human and murine cells will be inserted into pHR-SIN-CSGWdlNotl and expressed in human and murine cells respectively. The functions of these cDNAs include transcription regulation, promotion of haemopoiesis, presentation of antigens to immune cells.
Evaluation of foreseeable effects

In some cases, lentivirus-infected human or murine cells will be transferred to murine recipients by parenteral route. However, direct injection of the virus or the vector will not be undertaken. Mice treated with lentivirus-infected human or murine cells will be maintained according to the procedures and rules of the local Biosafety Unit.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All the procedures with regards the handling of GMM are Containment level 2.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be treated with Virkon 5% overnight and then discarded in the sink. Solid waste: immersion of all solid materials used (tips, pipettes, glassware) into Virkon 5% overnight before disposal of solid waste into GM designated bins and autoclaved at 134 degrees Celsius for 30 min. Overnight treatment with Virkon 5% is expected to kill 100% of GMM (manufacturer's warranty).

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

The proposal was considered satisfactory with no alterations required.

Project Ref 31/06.2

Date Ackn'd 02/03/2022  CU2 Project Title

Class CultureVolClass2 CultureVolumeClass3-4
**Project Additional Information**

**Purposes of the contained use**

The aim of the project is to prepare recombinant retroviruses and lentiviruses to transduce human or mouse muscle precursor cells with high titre, helper-free recombinant lentivirus or retrovirus coding for nuclear or cytoplasmic GFP, or for nuclear or cytoplasmic B-gal, or proteins such as Pax3, Pax 7, or for therapeutic proteins, such as dystrophin, or for U7 constructs designed to skip specific exons of the dystrophin gene. These transfected cells will either be used for in vitro studies and/or be implanted into mouse muscle. The contribution of marked cells to the host muscle will be analysed on sections of injected muscles, or in cells cultured from injected muscles. The virus may be used to mark and track cell clones using the sequence and/or integration sites of the virus as well as the GFP or B-gal reporter.

Other experiments, with vector/host systems of similar or lesser risk, may also be performed, eg. Retrovirus or lentiviruses coding for a growth factor, or viruses coding for genes such as CD34, c-met, or microRNA's involved in myogenesis, eg. miR181, miR1, miR-133 (and others, as they become available).

**Recipient or parental organism**

1. The lentiviral or retroviral vector plasmids will be grown up in bacteria from glycerol stocks and may be purified by caesium choride/ethidium bromide gradient.
2. The vector plasmid, packaging plasmid, and envelope plasmid will be transfected into a packaging cell line, eg. Human kidney cell line. The cell line that we will most commonly use is 293T, a human renal epithelial cell line which is transformed by adenovirus E1A gene product, which also expresses SV40 large T antigen, allowing episomal replication of plasmids containing the SV40 origin and early promoter region. Such producer cells are capable of producing helper-free ecotropic and amphotrophic non-replicating retroviruses or lentiviruses.
3. Alternatively, retroviral or lentiviral producer cells will be grown up in tissue culture and supernatent medium containing helper-free recombinant virus will be collected.
4. Viruses may be concentrated by centrifugation and may either be used immediately, or frozen in aliquots for later use.
5. Retroviruses or lentiviruses will be used to infect mouse or human cells, stem cells of blood, bone marrow or other origin, in tissue culture.
6. In some experiments, we will obtain lentiviral or retroviral vectors from collaborators, eg. The lentivirus coding for U7 and antisense oligonucleotides designed to keep dystrophin exons. These will be used to infect muscle or stem cells in tissue culture.

**Host/vector system**

Human 293 T cells
Phoenix 293 T cells
Bosc 23 cells
Mouse muscle cells
Human muscle cells
Human or mouse stem cells, e.g. Bone marrow, mesenchymal stem cells, AC 133+ cells

pMSCVpuro (modified to add IRES-eGFP and Pax7)

AmpliGPE LNPOZ
pSUB201 containing IGF1 driven by the MLC1/3 promoter
pMCSext-IRES2-eGFP
pMSCVpuro (modified to add IRES-eGFP and Pax7)
pMDLg/pRRE.REV 3rd generation core packaging
pRR1-SIN-18PPTpgk.GFPW self-inactivating (SIN) transfer
pMD2VSV.G envelope plasmid
pCMVdR8.74
pRSV-Rev
pCCL.hPGK.nlsLacZ
pRRL.CMV.LacZ

Origin & function
Plasmid constructs, and producer cells have been obtained either from collaborators or from commercial suppliers.
The expressed genes include marker genes, proteins such as Pax3, Pax7, therapeutic proteins, such as dystrophin, U7 constructs designed to skip specific exons of the dystrophin gene, growth factors, CD34, c-met, microRNA's involved in myogenesis.

Evaluation of foreseeable effects
Lentiviral or retroviral vectors coding for marker genes (eg. GFP, b-gal), or proteins such as Pax3, Pax7, or for therapeutic proteins such as dystrophin, or for U7 constructs designed to skip specific exons of the dystrophin gene, or coding for a growth factor, or viruses coding for genes such as, CD34, c-met, or microRNA's involved in myogenesis, eg. miR-181, miR-1, miR-133.
These vectors will be used to infect mouse or human cells in tissue culture, so that the gene of interest is expressed in the transduced cells and their progeny.
Retrovirally and lentivirally transduced cells and their progeny, will express the gene of interest. In the case of a marker gene, this may be used to follow the fate of cells following their transplantation in vivo. As these viruses are integrated into the host genome, the insertion site may be used to determine the fate of individual clones of cells.
When a potentially therapeutic gene has been introduced into muscle or other stem cells, these will contribute to regenerated muscle fibres following their transplantation into host mouse muscles. We will then determine whether the therapeutic gene is expressed within muscle fibres and whether it has a beneficial effect.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Culture media - Virkon, presept or Klercide 5 will be applied via spray or direct mixing/aspiration. Contact time is of 5 minutes minimum. Dilutions are made following manufacturer's directions (Virkon 1%, presept 10,000ppm, Kercide neat). 100% kill achieved, no viable cells present when disinfected cultures returned to incubator. Disposal via laboratory sink.

Solid waste - cell pellets, tissue culture plastics, scalpels, syringes - Autoclave 134 C for minimum 30 minutes. Internal temperature continuously monitored and displayed on chart recorder annual 12-point termocouple test. Disposal via clinical waste after autoclaving.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Project Ref 31/06.3

Date Ackn'd 22/12/2006

CU2 Project Title Use of Listeria DPL-1942 (ova) to examine the CD8 T cell response to a bacterial

Class 2

CultureVolClass2 < 1 Litre

CultureVolumeClass3-4

22/12/2006
Listeria monocytogenes DPL-1942 (ova) was constructed and described by Pope, C., et al. in 2001: A rLM (rLM-ova) was constructed that expresses a secreted form of OVA and an erythromycin-resistance marker. An Ag expression cassette was constructed that consists of the entire coding sequence of OVA fused to the signal sequence and promoter of the hly gene and an erythromycin resistance gene for selection. The Ag expression cassette was introduced into the Listeria, and double-crossed into the Listeria chromosome by homologous recombination. Integration of the Ag cassette into the LM genome and secretion of the OVA fusion protein by rLM-ova were confirmed by PCR and Western blot analyses, respectively. "-- Pope, C., et al. 2001. "Organ-specific regulation of the CD8 T cell response to Listeria monocytogenes infection." J. Immunol. 166, 3402-9.

Origin & function

Chicken ovalbumin is a major component of the chicken egg and is widely used in many experimental systems. The antigenic epitopes of ovalbumin have been very well characterized and many experimental reagents are available for its study.

Evaluation of foreseeable effects

This DPL-1942 strain is attenuated (ActA-deficient). The addition of the chicken ovalbumin gene does not increase its virulence or pose any additional risks.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Liquid and solid waste will be disinfected with a minimum of 2% Virkon for at least 30 mins. Pipettes, tissue culture flasks, gloves and paper towels will be autoclaved at 134°C for 20 min. at a full cycle time of 1hr 44 min.

Historical Significant Changes
The aim of the work is to better understand the transmission and colonisation plus pathogenicity of pathogenic Staphylococci using new models of infection (both in vitro and in vivo). This project aims to generate bioluminescent and/or fluorescent derivatives of laboratory and clinical isolates of Staphylococci e.g. S. aureus. The reporter genes (including native and synthetic codon-optimised luciferases derived from bacteria, insects and marine crustaceans and fluorescent proteins) will be carried either on replicative plasmids or integrated into defined regions of the Staphylococcal genome. The purpose of the genetic modification is simply to create strains that can be more easily tracked in these models.

The following are laboratory strains used in the initial genetic manipulations: Escherichia coli (Novoblue, DH5alpha, and similar).
S. aureus RN440 (reference/lab strain)
S. aureus CYL316 (RN440 strain harbouring the pYL112619 vector). CmR
S. aureus CYL557 (RN440 strain harbouring pLL2787 vector). CmR
Clinical isolates of S. aureus are then transduced with the bioluminescence enzymes/fluorescent protein containing plasmids. The majority of these clinical isolates will be methicillin sensitive (MSSA) strains (<1% will be methicillin resistant/MRSA). GMMs derived from the most virulent parental strain will be the most virulent e.g. clinical strains from patients with bacteremia. The inserted reporter genes encode for enzymes that catalyse bioluminescent reactions (such as from the firefly or luminescent bacteria), or for fluorescent proteins (such as from sea pansies and jellyfish). Therefore no GMM is expected to be more virulent than the parent strain. Genetically-modified strains of S. aureus obtained from collaborating laboratories will not be any more virulent than the naturally-occurring parent strains thus there is no extra perceived hazard from use of these GMMs. Furthermore, the antimicrobial resistance patterns of these previously-modified host strains are limited to the same range antimicrobial selection markers as the GMMs described in this current proposal.

S. aureus isolates are as indicated above. The vectors being used (with their resistance markers indicated) are:
pCL55 – AmpR, CmR. S. aureus integrative vector; possesses the Staphylococcus bacteriophage L54a int gene and attP attachment site.
pCL25 – TetR, SpecR. S. aureus integrative vector; possesses the L54a attP site.
pLL29 – TetR, SpecR. S. aureus integrative vector; possesses the L54a and φ11 attP sites.
pMK4 – AmpR, CmR. S. aureus replicative plasmid.
pYL112619 – CmR. Possesses the L54a int (integrase) gene.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All mouse experiments are conducted in the facilities of the central biomedical services (CBS) at the Hammersmith or South Kensington campuses of Imperial college. There is already a separate risk assessment for use of bacterial pathogens in CBS Hammersmith that encompasses work with S. aureus. Transport of GMOs between laboratory and CBS- secondary containment to be conducted. Bacteria transported in sealed tubes, not in syringes.

Theoretical risk of aerosolisation when drawing up or administering bacterial suspension in CBS (though this risk is also encountered in the normal laboratory environment). Needles are not attached until after syringe is filled. The CBS experimental mouse area has been approved for administration of bacterial GMOs im, ip, iv as the risk to other personnel sharing the procedure room is minimal, especially as all personnel are wearing FFP2 or FFP3 masks and PPE. Needles are not attached until after syringe is filled. The CBS experimental mouse area has been approved for administration of bacterial GMOs im, ip, iv as the risk to other personnel sharing the procedure room is minimal, especially as all personnel are wearing FFP2 or FFP3 masks and PPE.

Intranasal infections will not use sharps and will be conducted in the containment area of the CBS to facilitate autoclaving of cages, as there is a theoretical risk that cage bedding is contaminated. Infections will be initiated in a safety cabinet. Mice infected experimentally with S. aureus either clear the bacterium completely or die. One exception is the case of nasal colonisation, where staphylococci may be carried in the nasopharynx for up to 42 days without illness. If such a mouse escaped, there is a theoretical risk that the GMO could spread into the environment. However, this risk is considered to be extremely small, as (i) indefinite carriage does not occur and (ii) the bacterium is a human pathogen and does not spread naturally among other animal species (iii) escape is a remote possibility. Rarely, infections in bacteria may be inoculated into the skin via a bite from a bacteremic animal, potentially causing human skin infection needing antibiotics or via respiratory secretions (in the case of nasal carriage experiments), causing human nasal carriage. The risk of mouse to human respiratory transmission is considered to be significantly less than the usual risk of human to human transmission of wildtype S. aureus. All handlers will be notified of the infected status of the animals. Any bite or scratch will prompt an accident report and must be discussed with occupational health with regard to antibiotic prophylaxis; resistance patterns of strains will be notified to Occupational Health and kept on record. Masks will be worn to protect staff from the theoretical risk of respiratory transmission in the case of pharyngeal carriage experiments, and mice with pharyngeal infection will be housed in filter cages, as advised by Occupational Health/Safety Office.

There are new cage washing facilities in the west wing of the CBS. BD disposes of bedding into orange bags for alternative technology disposal. All incineration is conducted off-site at Hammersmith. Infected cadavers from the CBS are disposed of in labelled orange bags for immediate incineration via the designated fridge in containment.

For nematode (Caenorhabditis elegans) killing assays this work will be carried out in the designated class II laboratories (BS4+5 of the Commonwealth building, Hammersmith campus) in class II safety cabinets. All petri dishes containing GMM infected C. elegans are wrapped in parafilm to prevent accidental opening of dishes outside containment. Infected C. elegans are disposed of by autoclaving as per for solid bacterial waste.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid bacterial waste (e.g. agar plates, pipette tips, falcon tubes) are placed in clear autoclavable bags. These are then loosely folded when 1/2 full and placed in a grey box used for autoclaving. A blue tag is used to temporarily lock the box, which is transported down a corridor to the room housing the primary autoclave. Autoclaving is performed at 134°C, 30 minutes (waste disposal cycle). All runs are recorded and kept in log books. There is an annual validation of the waste cycle by 12 point thermocouple testing as part of the maintenance schedule. Autoclaved waste is disposed via biological waste route on campus.

Liquid bacterial waste (e.g. centrifugation supernatant, culture media) is treated with Virkon or Trigene/Microsol at 1% for 30 minutes. Efficacy data sheets are obtained from suppliers. All inactivated liquid waste is poured down the drain.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y
The GM Safety Committee made the following comments:
- Old version of form has been completed. Please fill in new version of form.
  1.21: Transfer information provided in 2.3.2.1 to fully answer this question.
  1.22: Add ‘with known antibiotics used...’ to the strain Clinical isolates of S. aureus. Also add more information from 2.3.2.1 such as details for pathogenicity of main isolates of interest i.e. in comparison to the wild type and lab strains.
  2.1.1.4: Answer: n/a
  2.1.1.5: Typo in line 5: Italy not Ialy
  2.3.2.1: Remove information about in vitro and in vivo and transfer to Part 1 of the form.
  2.3.2.2b: What other Class 2 organisms are being worked on in the vicinity?
  2.3.3.1a: The centrifuge tubes should really not be opened outside of a MSC.
  2.3.3.3.a: Add in brackets: Total 200mL.
  2.3.3.3b: As this is a class 2 project, the centrifuge should be opened in the MSC if a sealed rotor is not being used.
  2.3.3.6: CBS only use orange bags at present. New cage washing facilities in West Wing, BD disposes of bedding into orange bags for alternative technology disposal. All incineration is conducted off-site at Hammersmith.
  2.3.3.7: State source and type of human cells and purpose of the experiment.
  2.3.3.9.c: Delete answer and replace with: ‘None’
  2.3.4.2: ‘Local CoP is prepared...’
  3.1.1.b: Confirm that all solid waste from CBS (including cadavers and cage bedding) is being transported back to 8N1 for autoclaving as stated on form.
  3.2.b: GMM’s are being transported to CBS as stated in part 2. Please detail containment measures for this. Also cadavers and bedding being transported to 8N1 (see above), please detail containment measures for this. Also transport from TC labs to autoclave.
  3.3: Total is 200 mL
  3.6.1: Add the CID numbers of personnel.
  3.6.2: Cleaners, maintenance staff for labs (EVS etc).
  3.7: PI to check box.

Comments: C. Bateman gave a brief summary of the project. CR emailed his comments to be included. YH confirmed that this proposal will have to be notified to the HSE.

Agreed: Class 2, Containment Level 2. This project is notifiable to the HSE.

All of the comments have been addressed and the required changes incorporated into the risk assessment attached to this form.

**Project Ref**  31/11.1
### Project Additional Information

#### Purposes of the contained use

The research group is interested in studying how the immune system responds to infection with different pathogens. This is of particular importance as many patients with chronic lung damage are susceptible to infection and as such have a worse prognosis. Lung associated pathogens (Streptococcus pneumoniae and pyogenes, Staphylococcus aureus, Pseudomonas aeruginosa and Haemophilus influenzae, Aspergillus fumigatus) will be transformed with a vector containing the operon for a luciferase or fluorescent protein. This will label the pathogen to allow for imaging. Other vectors and/or imaging luciferases / fluorescent proteins may be used.

#### Recipient or parental organism

- **Streptococcus pneumoniae and pyogenes**
- **Staphylococcus aureus**
- **Pseudomonas aeruginosa**
- **Haemophilus influenzae**
- **Aspergillus fumigatus**

#### Host/vector system

- pAUL-A Tn4001 transposon encoding bacterial luxCDABE

Alternative vector systems and/or luciferases and/or fluorescent proteins and/or labelling techniques may be used.

#### Origin & function

Lung associated pathogens (Streptococcus pneumoniae & pyogenes, Staphylococcus aureus, Pseudomonas aeruginosa, Haemophilus influenzae, Aspergillus fumigatus) will be genetically modified to express a single copy of bacterial luciferase (luxCDABE) from Photorhabdus luminescens. This will lead to the pathogens to bioluminescence.
or "glow" to allow for imaging. Alternative vector systems and/or luciferases and/or fluorescent proteins and/or labelling techniques may be used.

### Evaluation of foreseeable effects

The pathogens used in this project can potentially infect people. However, insertion of bacterial lux operon into these pathogens is not linked with increased virulence and should not pose any additional hazard to the user. Precautions must be taken when culturing the microorganisms. These issues have been addressed with risk assessments (GMIC-1375) to minimise potential contamination and/or hazards to the user.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

| None |

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid cultures for GMMs will be decontaminated with virkon or a similar agent overnight before disposal down the drains. Plating out decontaminated liquid will confirm the GMMs have been killed. All solid waste (bacterial plates, tips, stripettes, sharps that have come into contact with GMMs) will be autoclaved within the department before disposal by incineration. Autoclaves are maintained and monitored routinely. All waste management has been covered by risk assessment (GMIC-1375).

N
This project has been reviewed by and approved by the Imperial College genetic modification safety committee. Following the discussion of your proposal entitled "Infection with bioluminescent pathogens", GMIC-1375 at the last GM Safety Committee meeting, the Committee request that the following amendments are made to the proposal prior to approval:

**Part 1: GM Centre Number is GM31**
1.23: Change answer to ‘Yes’ and the reference number to the Form B is GMIC-01266.1
1.4: Containment level 2

**Part 2: GM Reference number required**
2.3.3.1.a: Change answer to ‘Yes’
2.3.3.a: Include all lab location/rooms
2.3.3.3.c: Room number should be 8S5, not 9S5.
2.3.3.3.d: Include final concentration in this paragraph.
2.3.3.5: Please state that the biological hood is a Class 2 Microbiological Safety Cabinet
2.3.3.8.c: Answer question.
2.3.4.2: Local Code of Practice has to be submitted to be sent to the HSE. Answer “Yes”.
2.3.5: To be completed by Occupational Health.
2.3.6: Complete this section.
3.1.1.a: Typo, ‘virkin’. Reduce 24 hours.
3.31.a: Remove hatch in ‘Low risk’ box
3.31.c: Remove ‘yes’ by inhalation
3.32.b: Explain that the 500ml culture volume will be in smaller volumes of .XXml. Please specify volume.
3.42: Typo ‘infec’
3.5.b: Typo ‘wiht’
3.6.1: Include all labs and 4S1
3.7.1: Move the names from 3.7.2 to this section.
3.7.2: Add the names of the CBS Staff from Professor Sriskannd in this section.
3.8: PI to complete this section.

Comments: DC gave a brief description of the project.

MJ queried if they were using normal human pathogens.

AS confirmed they were original wild type pathogens that were already modified and from a company.

AC asked about where the imaging would take place.

DC stated that she would like the IVIS to be located in a specialist lab. A room number will be provided.

MJ requested a flowchart outlining the experimental process from beginning to end. This should make it clear which parts of the work are conducted in different labs. It should show techniques such as imaging, transport between locations and culture work.

The Committee also suggested that they add other strains and organisms that may be used in future such as Aspergillus fumigatus to the risk assessment before it is submitted to the HSE to avoid charges associated with significant changes.

Please provide SOP’s and COP for work in the 8th floor culture labs

Agreed: Class 2, Containment Level 2. This project is notifiable to the HSE

02/03/2022
The aim of the project is to identify DNA damage and resulting genomic lesions that are associated with successful human malignancy.

Recipient or parental organism

a) Non-invasive/non-pathogenic TOP10/DH10B bacteria cells (E.coli, Invitrogen) will be transfected with expression vectors during vector design and cloning (non-hazardous GMMs).

b) Expression vectors will be purified from cells generated in a), and BOSC/293T and GP2-293 cells (human) will be transfected with these expression vectors together with helper plasmids to produce mouse-specific retrovirus. Mouse bone marrow cells and spleenocytes will be then infected with viral supernatant from these cultures to induce expression of selected genes.
Retroviral mammalian expression vectors (MuLV related or MSCV related backbones) deficient for GAG and POL genes (replication-incompetent, infection-incompetent). These vectors will be used together with ecothrophic pECO vectors, which allow infection of mouse cells but NOT human cells. To produce virus, these will be introduced into a packaging cell line (293T cell derivative) expressing GAG and POL. Resulting virus produced by these cells is infectious to mouse cells but NOT to human cells and replication incompetent.

a) pRetroX-TRE3G (Clontech/Takara) system: the pRetroX-TRE3G Tetracycline-inducible expression vector and the pEco helper plasmid for packaging into mouse-specific retroviral particles. These vectors will be used to induce oncogene expression in mouse bone marrow B cells and to further induce mouse leukemia in vitro. These are derived from MuLV.

Please note: Produced mouse leukemia cells are not infectious and do not represent a potential harm for human workers. Furthermore, oncogene expression in this system requires the further addition of the tetracycline derivate TetEXPRESS and is therefore tightly controllable by the investigator.

b) pSingle-tTS-shRNA vector (Clontech/Takara) system: pSingle-tTS-shRNA vector and the pEco helper plasmid as described above. These vectors will be used to induce shRNA expression in bone marrow B cells, which leads to a downregulation of a yet undefined target gene.

Please note: Also here, the artificial expression of the shRNA in target cells is dependent on the presence of the tetracycline derivate Doxycycline and is therefore tightly controllable by the investigator.

c) pMX-IRES-GFP expression vector (DF Robbiani, Nussenzweig Laboratory), including pEco Vector helper plasmid (DFR) for packaging into mouse-specific retroviral particles. These vectors will be used to induce oncogene expression in mouse bone marrow cells, which are already infected with the expression vectors described in (b). Its backbone is derived from murine stem cell virus (MSCV).

d) pRRL.PPT.T6-GFP-PGK-M2-pre, pRRL.PPT.T11-GFP-PGK-M2-pre are inducible expression vectors that might be used for oncogene expression as (a) and that are a kind gift from the laboratory of Dr A. Karadimitris.

e) TRMPV is an inducible shRNA expression vector that is from Addgene and a kind gift from the laboratory of Dr A. Karadimitris. It might be used as in (b). Its backbone is derived from murine stem cell virus (MSCV).

Please note: As the viral particles are mouse specific and replication incompetent, these infections do not bear any harm for human workers. Similarly, the mouse leukemia cells produced in vitro are not infectious and do not represent any harm to human workers.

**Origin & function**

The vectors described will be used to induce the expression of BCR-ABL1, v-Abl, RAS and C-MYC (and potentially E2A-PBX1 and TEL-AML1) in in vitro cultured mouse bone marrow cells.

The Vectors described will also be used to induce expression of shRNAs targeting mouse candidate genes.

**Evaluation of foreseeable effects**

Introduction of oncogene-encoding expression vectors in recipient cells will result in malignant transformation of the recipient cell resulting in tumour clones in cell culture media. If injected into immunocompromised mice these cell will induce development of leukaemia in thses chimeras.

GMM bacteria produced are non-invasive/non-pathogenic. Viral particles are mouse cell specific and NOT infectious to human cells and replication-inactive. Mouse lines used are non-pathogenic. Infected mouse cells are nonpathogenic.

In the unlikely case of a release of the virus to the wild mouse population, this could result in the development of leukemia in the infected mice. As the virus is replication incompetent, these mice would die by leukemia but would not infect any further mice. The release would thereby terminate itself.

Therefore, there are no GMM's produced in this project that are hazardous to human health, but there is a low risk of harm to the environment that requires us to work at containment level 2.
GM animals are not part of this notification.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste containing GMOs or GMMs will be incubated with Virkon (1% final concentration, 10min contact time) to neutralise any potential capacity to affect environment of health, solid waste including sharps will be autoclaved (121C, 20min).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Reviewer 1
The big question with this project relates to the Mouse specific Lenti virus. From the description in 1.2 it appears to me that this is a GMO. If it is a GMO according to the GM contained use regulations this is likely to be a class 2 virus unless evidence can be produced that it is heavily attenuated and unlikely to spread to the environment. Please see below for further comments.

2.9 Section 2.14 describes the mouse specific retro virus as "no GMM" If that is true it should be listed in section 2.9
2.14 In this paragraph it is stated that the mouse retro virus is "no GMM" However section 2.16 describes several vectors for packaging into a mouse specific lenti virus, this seems to indicate that the lentivirus is genetically modified. Please explain the process more fully and clarify whether the mouse specific lenti virus is a GMO. Section 1.2 paragraph a seems to indicate that the lentiviral particles are GMO's

2.18 If the mouse specific lentivirus is a GMO then this may represent a hazard to the environment. Please clarify in the GM section whether the virus is GM or wild type and also whether it is attenuated.
3.1 If the mouse lentivirus is GM then this may be a class 2 project on environmental grounds unless the virus can be demonstrated to be highly attenuated. More explanation is required as requested in the comments above.
4.15 What about the environment? If the GM virus is infectious to mice then this should be mentioned as it is a potential environmental concern as defined by the GM contained use regulations.
4.16 This is subject to clarification on the GM status of the mouse specific lenti virus.
4.17 If the Mouse specific Lenti virus is a GMO then this must be considered in this section.
4.18 If the Mouse specific Lenti virus is a GMO then this must be considered in this section.
4.19 If the Mouse specific Lenti virus is a GMO then this must be considered in this section.
4.20 If the Mouse specific Lenti virus is a GMO then this must be considered in this section.

Section 5. If the mouse retro virus is a class 2 GMO (see comments above) then we will need to see a COP for this work.
5.1 If the Mouse specific lentivirus is a GMO then this must be considered in this section and the MSC may be required to protect the environment from contamination.
5.2 What about the risk to the environment?
5.4 Will this material be shipped to other campuses or outside of the University?
5.6 Section 4.21 states that no GMO will be stored but 5.6 states that the retro virus will be stored if the virus is a GMO please explain this apparent contradiction.
5.7 If the retro virus turns out to be a class 2 GMO then you will need to use sealed rotors to spin these plates.
5.9 What are these processes and is there an SOP?
Section 6. If the mouse retro virus is a class 2 GMO (see comments above) then we will need to see a COP for this work.
Section 7. If the mouse retro virus is a class 2 GMO (see comments above) then we will need to see a COP for this work.
Section 8. 9 10 and 11 will need to be completed if the mouse retrovirus is a class 2 GMO
Section 13. If the mouse retro virus work is class 2 then this section will need to be altered to reflect this
Section 14 If the mouse retro virus work is class 2 then this section will need to be altered to reflect this
Reviewer 2
Section 6.6 Remove reference to restroom handwash facilities as hands must be washed before leaving the lab areas.
A Form B needs to be completed.
Section 2.18: Please consider the environmental impact on virus release to the wild mouse population.
Section 4.15: Please consider the environmental impact on virus release.
Section 4.16: The question is asking about the hazards posed by the vector systems being used. Please modify your response accordingly.
Section 4.20: E. coli can infect humans and therefore the question does require to be answered fully.
Section 4.21: You have stated that no GMM will be stored. However in section 5.6 you have stated storage in -80C freezer. Please correct this discrepancy.
Section 5.13: LN2 is indicated for cell storage but this is not listed in section 5.6. Please amend as appropriate.
Section 7.4: Packing material is highlighted for disposal but section 5.5 states no receipt of material. Please correct discrepancy.
Reviewer 4
Section 2.2(a) – luciferase not luciferase
2.4 NR only needs checking and not the other boxes
2.8 No
Reviewer 5
Section 2.18: need to identify the most hazardous GMM (the answer does not reflect this, plus the environment need to be considered).
Section 4.15: Need to consider not only risk to human health but the environment.
Section 4.16: As above
Section 4.18: Need to consider the consequences (not explained what would happen, only that it is unlikely / prevented from happening)
Section 4.21: States no GMM will be stored. This in not consistent with Section 5.6 and 5.13 (storage in LN2)
Section 5.3: Secondary containment recommended while transporting cells
Section 5.7 & 7.1 : Contact time for virkon only 10 mins.

### Project Additional Information

**Purposes of the contained use**

A number of associated projects are being undertaken to analyze the roles of different host innate immune receptors and adaptor molecules in infection and inflammation. TLRs, NLRs, MyD88, ASC, Casp-1, NLRP3, NLRs, NPC, SLCs are all mammalian proteins that are directly involved in these processes, and are being investigated in the lab. The aims of these projects are to study the individual roles of these proteins in cells and mice lacking these proteins. Additionally, these proteins will be over-expressed in mammalian cells to study their precise functions. From a microbial perspective, we are interested in deciphering the roles of different microbial antigens, including cytolysins, in the modulation of innate immunity. Thus, we will employ microbial strains either wild-type or lacking individual antigens to evaluate their ability to modulate the above-mentioned host signaling molecules/pathways. Cells (or mice) lacking different host innate molecules will be exposed to microbial antigens or microbes. In addition, they will be exposed to pathogens lacking distinct antigens or cytolysins to decipher their roles in innate immunity. Different plasmids expressing wild-type or mutant forms of the above genes will also be employed to over-express the DNA/proteins in E. coli and mammalian cells.

**Recipient or parental organism**

Listeria monocytogenes (GFP/RFP-labelled, or lacking hly, LLO, ActA, ActB) - HG2
Salmonella typhimurium (GFP/RFP labelled, or lacking SPI1, SPI2, flagellin, SipB - HG2
Citrobacter rodentium, (GFP/RFP labelled) - HG1 (Class 2 GMO)
Hazard group 1 recipients (leading to Class 1 GMOs) Included for information as they are relevant to the project as a whole.
(E. coli K12-derived lab strain (GFP/RFP-labelled) - HG1
Francisella novicida (GFP labelled, or lacking mglA, iglA, iglC) - HG1
M. smegmatis (lacking ESX-1) - HG1
Cell lines - J774, U937, Hep2, HEK293, RAW, mouse primary macrophages or derived cell lines, THP1, 16HBEs

Origin & function
NLRs 1-22, involved in host defense
NPC 1-2, involved in cholesterol trafficking
ASC, adaptor molecular in the inflammasome complex
Casp-1, a protease
TLRs 1-11, involved in host-defense
RLRs, involved in viral sensing
ALRs, involved in DNA sensing
GFP, Green fluorescent protein
RFP, Red fluorescent protein
LLO - codes for Listeriolysin O
ActA,B - genes involved in actin-dependent movement
Flagellin - flagellum,
SPI - Salmonella pathogenicity island
ESX-1 - codes for bacterial secretion system

Evaluation of foreseeable effects

The GMO's listed above are no more hazardous than the non GM recipient organism. Additionally, since the GMMs will lack important factors required for their virulence, both mice and likely humans are expected to be more resistant and in the event of infection the symptoms are likely to be mild until the infection is cleared by the immune system.

Listeria monocytogenes: potential, but low, infection risk from accidental inoculation or ingestion, ranging from subclinical to severe systemic illness. Specific risk of harm to fetus through transplacental infection in 3rd trimester.

Higher risk if significantly immunocompromised.

Salmonella typhimurium: Infection risk [gastro-enteritis] from accidental inoculation or ingestion of culture. Likelihood low.

E. Coli: K12 derived non pathogenic strains

Citrobacter rodentium: not pathogenic in humans, may cause mild infection in rodents depending upon the dose and route of infection.

Franciscella novicida: rare opportunistic human pathogen. Risk of infection even if exposed will be low. Main symptoms include muscle pain, pneumonia, and fever.

Mycobacterium smegmatis: Considered non-pathogenic in humans and rodents.

The listed vector system hazards are the same or less. These are common, non infectious systems and with appropriate handling and containment processes (mainly Hazard Group I), they do not constitute a hazard. The transfer plasmids are all replication incompetent and thus there is no risk of transfer to other organisms.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid Waste - Microbial cultures- Inactivated by adding Distel (a commercially available chemical disinfectant classified as a biocide under the EU Biocides Regulation) used at a final concentration of no less than 1:100 for a contact time of at least 30 minutes. At least a log5 reduction in viable organisms.

Solid Waste - Laboratory plastic disposables and glass - Sterilized by validated autoclave (compliant to British and European Standards). Minimum 121 degrees for a holding time of 15 minutes. At least a Log 5 reduction in viable organisms.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
Following the discussion of your proposal entitled "Innate immune receptors in infection and inflammation" (GMIC-7900), the committee request that the following amendments are made to the proposal prior to approval:

Reviewer 1
2.3 “most of these…” Please be more specific. I agree that Igose obtained commercially are unlikely to be infected with pathogens, but what about the PBMC's from patients mentioned in 2.2? what are these screened for?
2.15 Please indicate the ACDP or the DEFRA classification. FYI Listeria monocytogenes and Salmonella Typhimurium are HG2 hosts. Citrobacter rodentium, is ACDP HG 1 (but will be a class 2 GMO as it causes disease in an environmental organisms i.e. mice) Francisella novicida HG1 M. smegmatis HG1 You also mention E.coli without further description. E.coli is a pathogen and may be HG2 or HG3 unless it can be demonstrated that it is suitably attenuated – Please provide a more detailed description E.g. K12 derived non toxigenic auxotrophic lab strain or something more hazardous such as E. coli O157:H7. 2.15 Regarding this statement “The above listed GM infectious agents have been obtained from collaborating labs. They will not be modified any further and thus there are no further vectors listed for these in section 2.16.” Unfortunately it is still classed as your GM work whether or not they were obtained from colleagues. If you can obtain more information please include the vectors that were used to create the GMO in 2.16.
2.17 Please add the inserts mentioned in the added organisms in 2.15
2.18 Please complete this section. If you are certain then you can state that none of the GMO’s are expected to be any more hazardous to human health or the environment than the non GM host. Please identify the most hazardous GMO’s regarding human health and the environment. 4.16 The recipients are not all HG2 organisms. Please identify the disease and harm that they can cause to human health and the environment. You need to consider each HG2 organism in turn and describe the disease and symptoms
8.1 Centrifuges will need to be inspected and maintained if they are used to handle and contain pathogens. Elements of the inspection e.g. condition of bio seals on rotors or buckets, can be carried out by the users and recorded monthly. Please specify what these arrangements are.
MSC’s will need to be airflow checked monthly by the users and this recorded if used to handle pathogens as stated in 5.1 of this Bio1
Section 15. Not all the work is Class 2. Please separate and identify what is Class 1 and what is class 2.
Reviewer 2
Section 2.18: Please complete
Section 4.5: Centrifugation (see 4.6)
Section 4.17: Please answer the question asked. E.g. can the vector system transfer material to other organisms?
Section 4.18: Please answer the question asked. Some of the GMO hosts are pathogens
Section 4.20: Please answer the question asked. Some of the GMOs are pathogens
Section 5.10: Discrepancy in routes of infection listed in sections 5.10 and 4.21 also M. bovis and M. avium missing from section 4.21. Also discrepancy between organisms listed in section 5.10 and 2.15.
Reviewer 3
The comments concerning about Q 2.3, 2.4, 2.5 and 4.8, it was mentioned 4.2 that PBMC from patient and health individuals will be used therefore ethic approval has to be provided. It was not clear from where PBMC from healthy individuals will be obtained? And will they be screened for infectious agents? Please make this clear in section 2.2
Need answers for the following questions
Page 2 Q2.4 last question " If yes, and for human material, how will the information be disseminated in the course of the project"
Page 5 Q2.18
Page 6 Q4.14

CU2 Project Title
Generation of a genetic tool in stable and transient passaged primary cells, cell lines and mice to analyse cancer heterogeneity in 3D models
Class 2
Culture Vol Class 2
≤ 1 Litre
Consent Granted

Historical Significant Changes
Historical Date of Additional Info

02/03/2022
The aim of the project is to establish heterogeneity in cell lines, primary cells and in murine mammary glands and monitor tumour development over time. Plasmids under the control of an inducible promoter will either overexpress, downregulate or knock out genes involved in breast cancer evolution, which will be delivered to the targeted cells via viral systems. The multigene construct will be designed in several steps. Where first, genes involved in breast cancer evolution will be tagged with fluorophores in lab-adapted bacterial strains. Secondly, these constructs will be cloned into functional lentiviral vectors to validate the functionality of the tagged genes. Once validated the multigene constructs will be integrated into a baculovirus delivery system to infect host organisms.

For the lentivirus system generation, two or three plasmids will be used for overexpression, knock down and knock out. Both generations of lentiviruses are encoding for a replication-defective system, which will be produced in HEK293 and will enclose a plasmid with multigene constructs.

For the baculovirus-mediated gene delivery, multigene shuttle plasmid will be designed using E.coli Rec-strains. Afterward a recombinant virus DNA is produced by a site-specific integration in to a variation of a DH10Bac E.coli. Isolated viral DNA will be transfected into Sf9 or Sf21 insect cell and will be either purified for murine experiment or used to directly transduce mammalian cells.

Both transduction methods will be used to produce stable expression and promote an integration of the multigene construct into the host genome. The induction of the multigene construct will promote the modification of genes that are involved in breast cancer evolution and will allow spatio-temporal analysis of tumour development in a heterogeneous background.

Recipient or parental organism
- E.coli lab-adapted strains (hazard group1) - NEB stable, STBL3, DH5a, Top10, CCdB
- Panel of breast cancer cell lines including MCF10A, MCF7, MDAMB-231, MDAMB468, BT474, T47D, SKBR3
- murine mammary cells
- passaged primary epithelial/luminal cells
- HEK293
- Insect cells Sf21 or Sf9

Host/vector system
To design the multigene construct the MXS vector system will be used. MXS_MCS1, MXS_MCS2, MXS_MCS3, MXS_MCS4, SMX DEST vector, MXS_TagBFP, MXS_Cerulean, MXS_LSS-mKate2, MXS_mEGFP, MXS_mAzamiGreen, MXS_Citrine, MXS_mKO2, MXS_tdTomato, MXS_mCherry, MXS_mPlum, MXS_E2-Crimson, MXS_IRFP670, MXS_PA-GFP, MXS_Kaede, MXS_PGK, MXS_minPGK, MXS_PGKenhancer, MXS_CMV, MXS_minCMV, MXS_CMVenhancer, MXS_CAG, MXS_EF1a, MXS_Tet, MXS_BiTet, MXS_bGpA, MXS_bGhpA, MXS_SV40pA, MXS_CreERT2, MXS_rTA2, MXS_tTA2, MXS_IoxP, MXS_linker, MXS_H2B, MXS_P2A, MXS_PEST2D, MXS_CMV::HygroR-bGhpA, MXS_PGK::HygroR-bGhpA, MXS_CMV::NeoR-bGhpA, MXS_PGK::NeoR-bGhpA, MXS_CMV::PuroR-bGhpA, MXS_PGK::PuroR-bGhpA, MXS_CMV::ZeoR-bGhpA, MXS_PGK::ZeoR-bGhpA, MXS_CMV::CreERT2-bGhpA, MXS_PGK::CreERT2-bGhpA, MXS_CMV::rTA3-bGhpA.
Additionally, the breast cancer evolution genes of interest will be subcloned into the pDONR223 to perform a Gateway cloning to get an overexpression construct, which will be tested in the pINDUCER21 (Addgene 46948) containing the mutated (non-oncogenic) WPRE. For knock down or knock out gene silencing constructs will be cloned into the 3rd generation plasmid TET-pLKO-puro (mutated WPRE; Addgene 21915) or 3rd generation CROPseq-Guide-puro (Addgene 86708) or similar plasmids respectively. Envelope and packaging plasmids will be pMDLg/pRRE, pRSVRev, pCMV pCMVR and pMD2.G or similar. Other plasmids used for subcloning will be pcDNA3.1, pUC18, pUC19, Pjet, pTOPO, pM5, pBABE-puro, pLenti6/V5-TOPO and similar.

For the baculovirus system a shuttle plasmid based on the pFastBac1 plasmid will be used to introduce a mammalian multigene construct, consisting of an inducible promoter and a SV40 promoter controlling a resistance gene, into the baculovirus genome via a transposition between a mini-att Tn7 target site.

Genes characterised as being involved in breast cancer evolution, like TP53, PTEN, Her2, MP3KCA and similar genes. Those genes will be manipulated via overexpression, shRNA or CRISPR.

To mark the cells for lineage tracing fluorescent proteins line GFP, dsRed, Citrine, Azurite, Plum, mCherry and similar will be introduced.

Chosen virus systems are not able to propagate due to lack of structure proteins and/or not able to replicate in mammalian cells. At the same time the risk posed by the genetic insertions is minimised by using inducible promoters. All vectors will be engineered using only an inducible promoter for expression of the genes potentially involved in cancer evolution.

Low risk nature of most baculoviral systems to both humans and environment indicates that minimal containment measures will be required. Nevertheless, the lentiviral particles will contain a tropism for expended host range, which could lead to insertion of the vector into hosts/human genome, this could in rare cases lead to a risk. The best methods to prevent exposure are proper technique, training, and personal protection equipment. This will include carefully reviewing the use of sharps in laboratory procedures and eliminating them when possible: for example, plastic substitutes for glass Pasteur pipettes are commercially available. Needle/syringes should only be used if no alternative is possible.

Indirect aerosol exposure with droplets containing lentiviral particles may occur in the laboratory. It can be prevented if working in MSC and centrifuge in sealed containers.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Virus injection into mouse mammary tissue will be undertaken to induce heterogeneous tumours in CL2 facilities.

Human lentivirus or insect baculovirus does not replicate in murine tissue. Therefore the risk of shedding is negligible.

Needles will be used to infect mice with baculovirus via intraductal, injection. Staff will be trained in the correct use and disposal of sharps and gloves will be worn at all times.

Sharps may be occasionally used to prepare cell lysates or to dissect tissue samples.

All tissue dissection will take place in a class 2 safety cabinet. Sharps will be disposed in yellow sharps bin after use.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

| Liquid Waste: | 10% final concentration distel solution for a minimum of 1 hour at room temperature for bacterial cell cultures or 10% final concentration distel overnight for tissue culture waste. These can then be dispensed down the laboratory sink. Bacterial cultures <5ml are autoclaved prior to disposal. |
| Solid Waste: | All solid waste including bacterial cultures on agar plates and contaminated tissue culture plates and other disposable plastics, cell pellets and other material in contact with GM material will be collected inside a clear autoclave bag and transferred into another autoclave bag after completion of experiment or at the end of the day. The double-bagged GM waste is then labelled and left in the GM waste bin located in the cold room. The GM autoclave waste run is carried out twice a week where the waste is autoclaved at 121 degrees C for 15 minutes. A chart recorder attached to autoclave and thermolog strips in autoclave bags will be used to validate treatment. Solid waste is autoclaved and then disposed of in orange clinical waste bags into EUROCARTS for Alternative Treatment. Tips and stripettes are collected within a designated clearly labelled sharps box for autoclaving with the other GM waste prior to disposal. |

Please enter comments on the GM safety committee on the risk assessment
Following the discussion of your proposal entitled “Generation of a genetic tool in stable and transient passaged primary cells, cell lines and mice to analyse cancer heterogeneity in 3D models” GMIC-8832 at the last GM Safety Committee meeting, the Committee request that the following amendments are made to the proposal prior to approval:

Please describe in the form or a flowchart what vectors are proposed to be built. The Committee is aware that this is not exactly known yet and likely change during the project, therefore provide a broad description of potential vector/plasmid outcomes and in which organisms these are planned to be used in. Set some boundaries of what will and will not be done for this project. Add vector maps for the backbones.

2.9 and 4.9: Remove the details from the Biological Agents section.

2.14: Make sure the boundaries of the project are described here.

2.15: The appropriate ACDP classification would be ‘hazard group’ and not ‘level’ for bacteria/virus. Remove the level/classifications of the cell lines and hazards in the pink sections. For E.coli; describe these as ‘lab-adapted strains’ with some of the examples, i.e. what is in the green section. Lentivirus and baculovirus are not really hosts, these are vector systems.

2.16: Name the vectors used and describe the WPRE gene in the 2nd generation lenti virus.

2.17: Name the genes being proposed to investigate, make it broader by saying ‘gene x and related genes’. A description is required here to understand the boundaries of the work.

2.18: Replication incompetent lenti-virus, with human tropism are able to infect human cells and integrate their genome into the host cells, whether or not they are induced. This increases the risk of accidental exposure. Think carefully about this section and identify the real risks.

4.3: Typo ‘underwent’

4.4: Increase volumes to either 100ml or 250ml to avoid restriction of 25ml and 4 flasks.

4.16: Remove ‘present no harm’ and ‘impose no risk’ when producing lentiviral particles with the WPRE gene, as this will upregulate potential oncogenes. Re-write this section carefully addressing the potential risk/harm.

4.18: See 2.18

4.20: Typo ‘specific’

4.22: Give a best estimate on how many virus particles might be produced/used.

5.6: Give an estimate what high or low titre might be?

5.7: Clarify that everything will be in the MSC and remove “…leave for 30 minutes to allow aerosol to settle.”

5.9: Change ‘category’ to ‘class’

5.12 and 5.13: Please provide a Standard Operating Procedure for the FACS and Sorting. This is not the same as the FACS facility Code of Practice. In this SOP identify what the operators of the Sorter must use to disinfect the machine after your sort.

10.1: Clarify that everything will be in the MSC and remove “…leave for 30 minutes to allow aerosol to settle.”

10.1: ‘category II waste’ change to either ‘GM waste’ or ‘containment level 2 waste’

11.2 ‘category II’ change to ‘containment level 2’

14 and 15: Change to classification and containment level 2.

Agreed: Class 2, Containment level 2.

IC reference number: GMIC-8832

Project Containment
Patients with cystic fibrosis and bronchiectasis are susceptible to infection by a number of different pathogens. Pathogens that are problematic for this patient group are **Burkholderia cenocepacia**, **Burkholderia multivorans** and **Pseudomonas aeruginosa**. Our research group is interested in understanding the underlying disease pathology in the lung.

**Recipient or parental organism**

**Burkholderia Multivorans**, *Burkholderia cenocepacia* and other similar virulence strains, *Pseudomonas aeruginosa*. All ACDP classification hazard group 2

**Host/vector system**

pAKN69 plasmid carrying YFP gene (or similar fluorescent markers), pBluescript or similar commercially available phagemid cloning plasmids

**Origin & function**
Genetically modified Burkholderia multivorans strains are less hazardous than their wild-type counterparts due to the antibiotic sensitivity conferred by their mutation. Genetically modified Pseudomonas aeruginosa in this work are less hazardous than their wild-type counterparts. Introducing YFP or similar fluorescent markers into a bacterium has no impact on pathogenicity.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

| Not applicable |

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

| Liquid waste: Placed into Distel (2%, final concentration) for a minimum contact time of 30 minutes in line with the manufacturers recommendations. A minimum of a log5 reduction in viable microorganism numbers is anticipated. Solid Waste: Placed into an autoclave waste bag and autoclaved before disposal. The autoclave is validated annually for this waste type by a competent service engineer complying with the relevant BS and using a calibrated 12 pt thermocouple monitoring device. Minimum temperature achieved in the waste load is 121 degrees celcius for at least 15 minutes. Complete sterilisation of the waste load is anticipated. |

| Is an emergency plan required according to regulation 20? | N |

| Tick to confirm that you have attached a risk assessment to this form | Y |
| Tick if you are claiming exemption from disclosure for section of the risk assessment | Y |

Please enter comments on the GM safety committee on the risk assessment
Request for partial non disclosure - see section 17.

Following the discussion of your proposal entitled “Infection with Burkholderia cenocepacia and Pseudomonas aeruginosa.” (GMIC-8925) at the last GM Safety Committee meeting, the Committee request that the following amendments are made to the proposal prior to approval:

1.3. Add the location of the FACS and Sorter

5.1 Add that MSC's will be used for all work involving manipulations of the HG 2 and Class 2 micro-organisms and this includes the FACS and Cell sorter

5.7 Amend the lid closed time from 30 mins to 60 mins

8.1 Add that Centrifuge maintenance will be carried out in accordance with the user manual.

10.1 State that you will use at least an “equal” volume of 2% virkon / Distel to treat the spill.

Comments:

gave brief description of the work is aware of the need for occupational health screening in case anyone would be at increased risk due to their health status.

asked are they all class 2?

responds yes

1.3. Where is the FACS machine located?

responds the FACS machine is in a Class 2 cabinet on the 8th floor.

Added that a sorter is also located on the 8th floor and is enclosed in a class 2 MSC

Commented on the phrase “A class 2 Microbiological safety cabinet will be used for all procedures involving this bacterium” asked Which bacterium? Or should this be “These Bacterium”

responded All hazard group and GM class 2 bacteria

commented that it was unlikely that there would be no hazards.

Responded that they meant that the GMO would be easier to treat than the wild type. They would remove the word none and leave the explanation about the GMMs sensitivity to antibiotics.

5.7 I would recommend that the lid of the centrifuge is left closed for 1 hour rather than 30 minutes. This is based on previous correspondence with the HSE. This also matches your ERPs described in 10.1 asked about the answer to 5.9 as it states no sharps but 7.4 states that there is sharps waste

8.1. Centrifuge maintenance should be carried out at the frequency indicated in the user manual. Some will be daily, weekly, monthly and annual, for example visual o ring inspections and visual checks of the rotor integrity should be carried out every time the centrifuge is used, swing out bucket trunnions may only require cleaning and greasing monthly.

recommended stating ‘at the frequency indicated in the user manual’ to answer the question regarding maintenance frequency for centrifuges.

Please specify that you will use at least an “equal” volume of 2% virkon / Distel to treat the spill.

stated that this would be amended

Asked for the SOPs to be uploaded to RADAR

On RADAR you mention use of PA and Burkholderia multivorans as GM hosts, which agrees with the Bio1. and pointed out that work with GMOs included any use and therefore we need to record the GM characteristics of all GMOS in use on the Bio1

There was a discussion about how to broaden the scope of the assessment to include possible further expansions to the work so a re-submission would not be required.

confirmed that he would send and some guidance.

Agreed: Class 2, Containment level 2. This is notifiable to the HSE.

Could you please ensure that the risk assessment is revised and the amendments above addressed. I will then forward the form onto Occupational Health to complete
# Project Additional Information

**Purposes of the contained use**

The enteric nervous system is an important pathway in the regulation of glucose homeostasis and is made up of both neural and endocrine components. The neurotensin receptor 1 (NtsR1) has been identified in the enteric nervous system and is implicated in controlling a profound glucose lowering effect following glucose challenge. This project aims to investigate the expression of the NtsR1 on neural projections extending between the gut and pancreas by injecting an attenuated transsynaptic, retrograde pseudorabies virus (PRV-Bartha) that expresses fluorescent proteins (e.g. PRV152 or PRV614) into the pancreas. This virus will then trace neural projections between the gut and pancreas allowing for specific analysis of NtsR1-expression on distinct enteric neuronal populations.

Mice will be injected with PRV-Bartha into the head, body and tail of the pancreas. This should lead to transsynaptic, retrograde labelling of neurons from the pancreas.
back to the wall of the gut. 3 days following surgery, animals will be culled and tissues collected for immunofluorescent analysis. This will be visualised on a microscope.

Recipient or parental organism

Pseudorabies virus

Host/vector system

No new GMOs will be created as part of this project.

PRV-Bartha is a pseudorabies virus created by the Viral Neuroengineering Laboratory, Princeton Neuroscience Institute, Princeton University. It is an attenuated vaccine strain of the wild-type PRV-Becker that contains the CMV-mFP reporter gene cassette inserted into the gG locus of the viral genome that allows for transsynaptic retrograde tracing of neuronal circuits.

Origin & function

PRV-Bartha infection is initiated by binding to cellular receptors to allow penetration into the cell. After reaching the nucleus, the viral genome directs a regulated gene expression cascade that culminates with viral DNA replication and production of new virion constituents. Progeny virions then self-assemble and exit host cells. This allows for retrograde transsynaptic tracing of enteric neurons that originate in the myenteric plexus of the gut wall and terminate in the pancreas.

Evaluation of foreseeable effects

PRRV-Bartha is a pseudorabies virus created by the Viral Neuroengineering Laboratory, Princeton Neuroscience Institute, Princeton University. It is an attenuated vaccine strain of the wild-type PRV-Becker that contains the CMV-mFP reporter gene cassette inserted into the gG locus of the viral genome that allows for transsynaptic retrograde tracing of neuronal circuits. PRV-Bartha is less virulent than PRV-Becker due to the fact it only travels via efferent routes in the PNS en route to the brain, unlike PRV-Becker that transits via both afferent and efferent routes. Due to the fact that PRV-Bartha is an attenuated virus, its cytotoxicity is reduced meaning that animals live several days longer after infection without significant symptoms. Unlike the virulent PRV strain (PRV Becker) that causes self-mutilation of mouse flank skin in response to virally induced pruitus and death due to infection of the CNS, PRV-Bartha-infected animals have no skin lesions and do not appear pruirtic at any time during infection. Infection of the CNS occurs following infection with PRV-Bartha. However, PRV-Bartha infected animals survive approximately three times longer than PRV-Becker infected animals. For this reason, animals will be culled 3 days after injection.

The virus replicates and is shed via aerosols. However, PRV-Bartha can only be transferred to other animal by injection of the virus, not by aerosol or inadvertent or casual contact. Studies have shown that leaving an uninfected animal in a cage with an infected animal resulted in no cross-infection. PRV-Bartha causes no risk to human health.

The largest risk when using PRV-Bartha is the causation of Aujezky's Disease. This is a viral disease that occurs in swines. No pigs are kept at the Hammersmith Campus at ICL and the risk of this occurring is therefore very low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All labware that comes into contact with the material will be either autoclaved or treated with 10% sodium hypochlorite for 5 minutes to inactivate the material. Waste will be double bagged to minimise risk of spillage if a bag bursts. Liquid waste will be collected and autoclaved to inactivate the material. This can then be safely put down the sink.
Infected animals will be culled 3 days after injection with PRV-Bartha. All animals will be immediately transcardially perfused with phosphate buffered saline (PBS), followed by 4% paraformaldehyde (PFA). Tissues will then be extracted and placed in 4% PFA overnight. Tissues will be further processed by paraffin-embedding or set in 1% agarose. Carcasses will be placed in yellow clinical waste bags to be collected by CBS staff for transfer to CBS yellow Euro Carts and disposal by contracted clinical waste service managed by the Trust.

Infected animals will be kept in individually ventilated cages in Containment, H1. These cages are washed according to specific Cat2 procedures. This includes the spraying, bagging and autoclaving of cage waste and high temperature wash followed by acid-clean of the cages themselves.

Following the discussion of your proposal entitled “Neural Tracing” (GMIC-9493) the committee request that the following amendments are made to the proposal prior to approval:
- Section 4.7: does not need to be completed (as far as I can tell, PRV-Bartha is a GM virus) this will make the form consistent as section 2.11 was not completed.
- Section 5.11: How will post-perfused PBS (potentially containing live virus be disposed of (as no liquid waste treatment in section 7.1)?
- Points 2.27 and 4.17: “Studies have shown that leaving an uninfected animal in a cage with an infected animal resulted in no cross-infection” please provide a reference.
- I am not aware of the cleaning system of mouse cages. If they are washed (with anti-viral agent) and sterilised then it is fine. If not, should it not be done?
- I suggest we add some comments to the Bio1 regarding the survivability and stability of the Pseudorabies in the environment in the event of a breach of containment, as this is a requirement under SACGM (reference https://www.hse.gov.uk/biosafety/gmo/acgm/acgmcomp/)

Class 2 agreed for this project.

Project Ref 31/21.2
Single molecule imaging of herpes simplex virus type 1 DNA replication

Herpes simplex virus type 1 (HSV-1) is a widespread pathogen, which has been studied extensively. Nevertheless, we still lack a complete understanding of the mechanism of genome replication. Although a model for replication exists, this model fails to explain certain observations made. We propose to revisit long-standing questions of HSV-1 replication using cutting-edge single molecule imaging techniques. Single molecule assays enable the detection of transient structures and heterogeneous behaviour, revealing crucial insights into the fundamental process of genome replication. The current model for HSV-1 genome replication comprises an origin-dependent followed by an origin-independent stage. Whereas we have evidence and a good understanding of the origin-independent phase, we completely lack evidence for the proposed structures of the origin-dependent phase. We want to study aspects of the origin-dependent replication phase. Specifically, we want to reveal the role of the HSV-1 origin binding protein UL9 during replication since UL9 was proposed to act as a switch from the first to the second stage. It has been shown that UL9 is an essential protein during the origin-dependent stage but dispensable and even inhibitory during the second, origin-independent stage. We propose to use single-molecule imaging techniques to reveal the inhibitory effect of UL9 on HSV-1 mediated replication, characterise the specific conditions of UL9 origin binding and assess its role during the assembly of the HSV-1 replication machinery.

Recipient or parental organism

Herpes simplex virus type 1 (HSV-1) strains F, 17 and KOS.
Most HSV-1 infections are asymptomatic, the most common symptom are cold sores (blisters on mucosal skin), in rare cases HSV-1 infections lead to keratitis, encephalitis or meningitis. HSV-1 infections can be life-threatening for newborn babies. HSV-1 infections are irreversible, the virus will establish latency in sensory neurons and might lead to recurring cold sores.

Common E.coli strains will be used for cloning.

HSV-1 will be passaged in and harvested from common cell lines (Vero and HEK293 cells)

Host/vector system

HSV-1 (strains F, 17 and KOS)
Origin & function

Wildtype HSV-1 DNA will be used because the aim of the project is to clone individual viral proteins involved in HSV-1 genome replication and will be tagged for example to enable a visual readout at the microscope (e.g. fluorescence) or to purify the specific protein (e.g. with a streptavidin tag).

BAC plasmids containing the entire HSV-1 genome (e.g. YE102)

Established cloning and protein expression vectors such as pCM, pUC18, pGEX, pET30, pRF or similar and derivatives thereof (in which the MCS has been modified in-house or commercially for different fusion proteins, different cleavage sites etc)

Evaluation of foreseeable effects

HSV-1 strains will be modified to include fluorescent or non-fluorescent (e.g. GST-tag) tags

HSV-1 deletion mutants where specific genes are missing will be used

HSV-1 GMMs used have the same biohazard classification as the wild type strain, as the genetic modifications do not enhance any virulence factors. The HSV-1 GMMs used in this project generally show lower infectivity and virulence when compared to the wildtype strain.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

no derogation from full containment

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

HSV-1 containing liquid waste will be treated with disinfectant (e.g. Distel (1%), Microsol (10%) or 2% Virkon, hypochlorite bleach (1% 10,000ppm)) (decontamination for 10 min) before being flushed with running water down the drain. Small volumes of liquid waste (<5ml) in eg. culture tubes may be disposed of with tube as solid autoclave waste

HSV-1 contaminated solid waste will be treated with disinfectant (e.g. Distel (1%), Microsol (10%) or 2% Virkon, hypochloric bleach (1% 10,000ppm) and then autoclaved before disposal as clinical waste.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Reviewer 1: I'm happy that this is GM Class 2.

Reviewer 2: I am happy with the class 2 classification.

Section 5.2: Why so many different decontamination chemicals used – would it not be easier to standardise on 1 protocol?

Section 5.7: Why not using sealed buckets/rotors?

Section 6.1: How does wearing gloves impact laser safety?

Section 7.2: Why use bleach for liquid waste but other chemicals for solid waste? Why use both chemical disinfection and autoclaving (Just autoclaving would reduce handling of contaminated plasticware which would save time and be safer for the staff).

Section 7.6: Storing hazardous waste if fume cupboards is not recommended.

Section 8.3: Please uncheck N/R box

Section 9.5: Please uncheck N/R box

Section 10.1: As centrifuge will only be opened in MSC (Section 5.7), waiting for 1 hour for aerosols to settle is not required.

Reviewer 3: I agree that this project is Class 2.

Reviewer 4: The PI has checked low risk of infection since the virus is most likely rendered inactive by the extraction method (but to be verified) in 2.6 and High risk in 3.1 but HSV1 is not a Schedule 5 pathogen and toxins. I would suggest 3.1 to be changed to low risk. I think it is a CL2 project.

Reviewer 5: I am in agreement with the classification of Class 2, since the wildtype strain is Hazard Group 2.

Reviewer 6: I’m happy with the proposal.

02/03/2022
Fluorescent tagged bacteria (M. bovis BCG, S. pneumoniae and S. pyogenes) will be used for microscopy and/or flow cytometry purposes to identify percentage of infected cells and their cellular location and potential interaction with other molecules. S. pneumoniae and S. pyogenes without bacterial capsule may also be used to study the effect of the bacterial polysaccharide component in modulating the host immunometabolic responses.

Recipient or parental organism

No effect is foreseen as fluorescent tag is not known to be transferable across species or to increase virulence. Bacterial strains without the capsule are known to be more readily killed by the host cells as they cannot easily escape from phagocytosis. The non-capsule strains are highly unlikely to acquire genes for the capsule through the environment as horizontal transfer of such large genetic regions is rare.

Host/vector system

Fluorescent tagged strains are expected to have the same effect as parental strains to the host. For bacterial strains without the capsule, they are expected to have the same or less impact to the host than the parental strains due to loss of major virulence factor.

Origin & function

For the fluorescent tag, green fluorescence protein (GFP) originates from jellyfish, while red fluorescence protein (RFP) originates from Discosoma sea anemones. These proteins emit visible colour when exposed to light and have long been used in microscopy. For the uncapsulated bacteria (Streptococci species), some of the strains are naturally occurring, while others are genetically modified by removing genes that encode for the polysaccharide capsule (conserved genetic regions between dexB and aliA genes). Capsules are major virulence factor of Streptococci species that allow the bacteria to escape host immune response such as phagocytosis. It is important to use the GM strain to allow a direct comparison to the parental strain.

Evaluation of foreseeable effects

The fluorescently tagged strains are expected to have identical properties as to their unmodified parental strains counterparts. Genetic removal of capsule from Streptococci bacteria is anticipated to have either no effect or to weaken the virulence of the bacteria as the capsule is a major virulence factor.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
All GM waste will be disinfected and disposed in accordance to COP. Plastic containers used to culture GM microbes or GM-infected cells will be disinfected for at least 30mins with approved disinfectants (e.g. Virkon, Distel, or Microsol) before being discarded in biohazard bags for sterilisation (autoclaving). Other work surface such as biosafety cabinet will be sprayed with 70% Ethanol for disinfection.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

All members of the committee agreed that the project is GM class 2.

Project notified under transitional arrangements N
**Project Additional Information**

### Purposes of the contained use
To immortalize primary human and mammalian cells to produce cell line models for in vitro investigation.

### Recipient or parental organism
**Human cell line HEK-293T** - for virus particle production.

Primary human and mammalian cells (for example stromal and endothelial cells). Human and mouse embryonic stem cells and adult stem cells either obtained commercially or from collaborators and repositories or from biopsy material (for example; mesenchymal stem cells).

### Host/vector system
**Lentivirus (or retrovirus) cultured in HEK-293T cells for oncogene induction (e.g. hTERT, HPV, BMI-1, SV-40)** in recipient (primary) cells for the purpose of their immortalization.

**Human cell line HEK-293T** - for virus particle production.

### Origin & function
The genes to be expressed for immortalization are potential oncogenes such as:
- **human telomerase reverse transcriptase (hTERT)**. hTERT is a ribonucleoprotein polymerase that maintains the length of telomeres. Telomerase expression plays a role in cellular senescence and is normally suppressed in postnatal somatic cells.

- **human papilloma virus 16 E7 (HPV16-E7)**. HPVs have been found in 90% of cervical cancers as well as other carcinomas. Viral early proteins E6 and E7 induce immortalization and transformation in a variety of rodent and human cell types.

- **SV40 Large T-antigen (from the DNA tumour virus simian virus 40)**. The SV40 large T-antigen is found in early region of the virus together with the small T-antigen which together are sufficient for transformation of cell lines.

- **B lymphoma Mo-MLV insertion region 1 homolog (BMI-1)**. Overexpression of Bmi1 role in several types of cancer, such as bladder, skin, prostate, breast, ovarian, colorectal as well as hematological malignancies. Bmi-1 is required for the maintenance of some adult stem cells partly because it represses genes that induce cellular senescence and cell death.

### Evaluation of foreseeable effects
The use of lentiviral second generation (or later) vector systems, in which all accessory genes have been deleted, and where gag, pol, env and rev genes are provided in...
trans (either on additional accessory plasmids or integrated into the genome of packaging cell lines), means that the risk of production of replication-competent or infectious virus is effectively zero.

Most commonly the crude viral supernatant from a packaging cell line (where the max viral titre is unlikely to be higher than 10E+9 particles per ml), will be used to transduce a primary cell culture. In those circumstances, and in the absence of significant concentration of the viral titre and elimination of sharps, it can be argued that the risk of accidental systemic administration, such that the vector is delivered to the in sufficient quantity to induce a significant health hazard (e.g. hepatocellular carcinoma linked to WPRE protein X), is negligible. Thus the use of lentivirus would be assigned to Class 1 (provided that there is nothing more hazardous in the vector - see below), even in the presence of WPRE expressing protein X.

However, given that inserted immortalization genes can pose a specific oncogenic hazard, and the expression of these known or potential oncogenes could act in concert with the insertional effects (lentiviral vector system) to contribute to oncogenic pathways (but only in the event of self-inoculation), this work could pose an increased risk to workers and thus is required to be assigned as Class 2. This risk will be controlled by eliminating sharps, and by other measures at Containment Level 2.

The following activities will NOT be permitted within programme of work:-
1. Preparation of high-titre retroviral or lentiviral stocks by methods that require the use of needles to harvest the virus
2. The use of sharps, including hypodermic needles and glass pipettes
3. Expression of a major pathogenesis factor or a toxin gene.
4. The use of retroviral or lentiviral vectors for which there is evidence for the presence of replication-competent virus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste:
Tissue culture medium/liquid waste will be treated with Virkon for 24 hours, the final concentration of Virkon must be 2% or higher. Virkon treated liquid waste (minimal contact time of 24 hours) an then be disposed off down drain.

Solid waste (plasticware, tips, cell pellets etc.):
All solid waste (pipettes, tips, plasticware etc.) will be treated by immersion in 2% virkon overnight (24 hours), then autoclaved at 121°C for 30 min in a validated autoclave before being disposed in clinical waste route.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N
In the risk assessment Bio 1 form, immortalisation of primary cells using lentiviral vectors is considered by the Imperial Biosafety team as containment level 2 because of the cumulative risks. Other activities on this Bio 1 form are considered containment level 1.

Following an overview of the project by WS, the committee discussed various aspects of the work with particular reference to what classification the work required. The work involves using replication incompetent 2nd and 3rd generation of adeno, lenti and retro viruses to transfect and immortalise primary adipocytes. It was confirmed that the viruses would be pseudotyped with VSV-g and that some of the work would involve using viral vectors containing transformative hTERT, HPVE6/7 or BMI-1 oncogenes. However, the target cells would initially only be exposed to a single vector (vector constructs would always contain only one of the oncogenes). If necessary, and following a period of 2-3 weeks, selected cells may undergo a second transfection with a vector containing an alternative oncogene. It was confirmed that doing this would not significantly increase any risk to the researchers.

The use of VSV-g pseudotyped viruses was deemed the most appropriate technique to create the desired immortalised cells. Buying in pre-immortalised cells would be prohibitively expensive and use of alternatives such as liposomes is ineffective in these cells.

It was deemed that not all the work described in the bio 1 necessarily falls under a class 2 classification. However, HSE guidance indicates that in a situation as described in this assessment where there is a combination of a pseudotyped virus containing oncogenes then this would require containment level 2 control measures and, as such, this work needs to be classified as class 2. Once cells have been transfected with the lentivirus and after there has been a period of washes and passaging, those cells can be taken out and worked with at containment level 1 as the replication deficient lentivirus will have been cleared from the cultures.

The following information is required prior to approval:

1. Amend the overall project classification to GM class 2
2. Section 4.5: tick box answer should be changed to yes
3. The distinction between the different gene work and their classification needs to be made clear on the bio1 – oncogenes in VSV-g pseudotyped viruses for immortalisation is class 2 but other genes for screening metabolic functions in similar pseudotyped viruses is class 1.

Project Additional Information

Purposes of the contained use

Recipient or parental organism

Host/vector system

Origin & function

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid cultures for GMMs will be decontaminated with virkon or a similar agent overnight before disposal down the drains. Plating out decontaminated liquid will confirm the GMMs have been killed. All solid waste (bacterial plates, tips, stripettes, sharps that have come into contact with GMMs) will be autoclaved within the department before disposal by incineration. Autoclaves are maintained and monitored routinely. All waste management has been covered by risk assessment (GMIC-1375).

Historical Significant Changes This should have been notified originally under GM31 but was put under GM32 - has now transferred back to GM31 as of 22/12/2005

Project notified under transitional arrangements N

Recipient or parental organism

E. coli DH5α cells will be transformed with pONY3.1 pRV67 and pSMART2G (or a genetically modified form of pSMART2G - see below). 293T cells (human embryonic kidney cell line) will then be co-transfected with 3 vector plasmids to generate single cycle infective pseudotyped EIAV viral stocks. D17 cells (canine osteosarcoma cell line) will be transduced for routine titration of lentiviral vector stocks. Dendritic, endothelial and mesenchymal stem cells will be transduced with genetically modified EIAV lentivirus for in vitro and in vivo studies.

02/03/2022 Page 1554 of 1532602/03/2022
Host/vector system

Vectors for third-generation, self-inactivating (SIN) EIAV lentivirus will be used (provided by Oxford Biomedica). Functional, non-replicating/self-inactivating EIAV lentiviruses generated by modifying the transcriptional enhancer and promoter regions in the 3' U3 long terminal repeats (LTR). The following lentiviral plasmids will be used:

- pSMART2G - Oxford Biomedica (GFP expression construct)
- pONY 3.1 - Oxford Biomedica (EIAV gag/pol expression construct - also expressing Tat, REV,S2 and part of ENV)
- pRV 67-Oxford Biomedica (VSV-G expression construct - ENV expression)
- pESynRev - Oxford biomedica
- pONY 8.7 NCG Si - Oxford Biomedica (GFP expression construct)

Origin & function

The immunomodulatory genes used encode intracellular fusion proteins such as CTLA4-KDEL and ICOS-KDEL, and extracellular fusion proteins such as CTLA4-Ig, ICOS-Ig, PDL-1/L-2 Ig, and CD83-Ig. CTLA-4, ICOS and PDL-1/L-2 are molecules involved in T cell costimulation, and KDEL is an endoplasmic reticulum retention sequence. IDO (indoleamine 2,3-dioxygenase) is a tryptophan-degrading enzyme that has been demonstrated to have immunoregulatory properties. The enhanced green fluorescent protein (eGFP) is a protein obtained by adding an enhancer sequence to a naturally fluorescent protein (GFP) found in the jellyfish Aequorea victoria.

The aim of the scientific project is to genetically modify dendritic and endothelial cells to express novel intracellular fusion proteins and an immunomodulatory enzyme such that there is a substantial downregulation in T cell alloreactivity and subsequent induction of transplantation tolerance. This would be achieved by inhibition of dendritic cell/T cell co-stimulation in the former case (due to the retention of key costimulatory ligands within the endoplasmic reticulum of dendritic cells), and T cells tryptophan starvation in the latter case (due to upregulation of IDO activity in dendritic cells). EIAV lentiviruses will be used to genetically modify dendritic and endothelial cells.

Mice will be injected with dendritic cells that have been transduced with EIAV lentiviral vectors to express the intracellular fusion proteins stated above. Corneal and heart transplantation will have to be carried out on mice for the latter/in vivo stages of the project. Histopathological analysis will have to be carried out on mice injected with transduced cells for the in vivo stages of the project.

Mice will be injected with Mesenchymal Stem cells that have been transduced with EIAV lentiviral vectors to express the eGFP reporter protein stated above.

The aim of the scientific project is to genetically modify dendritic and endothelial cells to express novel intracellular fusion proteins and an immunomodulatory enzyme such that there is a substantial downregulation in T cell alloreactivity and subsequent induction of transplantation tolerance. This would be achieved by inhibition of dendritic cell/T cell co-stimulation in the former case (due to the retention of key costimulatory ligands within the endoplasmic reticulum of dendritic cells), and T cells tryptophan starvation in the latter case (due to upregulation of IDO activity in dendritic cells). EIAV lentiviruses will be used to genetically modify dendritic and endothelial cells.

Evaluation of foreseeable effects

There is no human pathogenicity associated with the lentiviral vector to be used in this activity (Equine infectious Anaemia Virus). There is no possibility of in vivo infection and subsequent in vivo propagation. E.Coli DH5a cells (which will be transformed to produce the 3 vectors pSMART2G/pSMART-CTLA-KDEL/pSMART-IDO, pRV67 and pONY 3.1) are non-colonising and disabled, and we are not pathogenic to humans or animals.

Although the gene product expressed will be biologically active, there are no hazards or pathogenicity associated with the proposed intracellular and extracellular fusion proteins. The fusion proteins will only express the extracellular porteins of the T cell co-stimulatory markers. The enhanced green fluorescent protein (EGFP) is a protein obtained adding an enhancer sequence to a naturally fluorescent protein (GFP). No specific hazard can be identified.

The host strains are not human pathogenic and the inserted gene does not subsequently alter/increase the pathogenicity of the host. A3 plasmid technique will be used for transduction of endothelial and dendritic cells - EIAV is not human pathogenic.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Cellular work will be undertaken within a designated containment 2 laboratory which is adequately separated from other areas. This containment 2 laboratory has restricted access only to workers who will be involved in using intracellular and extracellular fusion proteins for the T cell immunomodulatory effects stated in section 7. A microbiological safety cabinet will be required for routine cell culture of 293T cells, D17 cells, and dendritic and endothelial cells that will be transduced with the lentiviral vector stocks. Aerosols or splashes generated during the activity will not pose a risk of infection to the workers. No other form of local exhaust ventilation will be required. There are no particular requirements for room ventilation.

Static shelf incubators will be used for the culture of 293T cells post co-transfection with three vectors to generate single-cycle infective pseudotyped viral stocks. Shelf incubators will also be used to culture dendritic and endothelial cells transduced with EIAV lentiviral vectors.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Lentiviral vector supernatant stocks will be stored in liquid nitrogen within protective cryotubes with screw-top lids. This will prevent any release of material until cryotubes are opened within microbiological safety cabinets for subsequent transduction of cells of interest. Security measures are in place for liquid nitrogen storage—routine catalogues are maintained. Any missing samples from liquid nitrogen compartments would be immediately identified. Ultracentrifugation (~17,000 RPM) will be used to concentrate lentiviral supernatant harvested from transfected 293T cells, and centrifugation will be used to pellet lentivirus-transduced cells. Buckets will be used with screw-top lids for this activity. In the case of a leak or spillage, immediate containment, extensive use of Virkon and spillage granules will be used if necessary.

Protective laboratory coats are always available, laundered weekly, and stored in the department wash room. Powder-free nitrile gloves will be worn during any cell culture activity associated with this project. Face shields will be used for liquid nitrogen usage. All staff to be involved with project have experience with genetic modification and have attended safety courses.

Vaccination is not required as EIAV is not human pathogenic. The GMM does not have the ability to establish in vivo infection in humans and subsequent in vivo propagation. Health Surveillance is not required. Hepatitis B immunisation would be required (related to isolation of peripheral blood mononuclear cells (PBMCs) not related to GMM product).

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For liquid GMO cultures and non-disposable material, 2% Virkon will be used for a maximum of 12 hours. Virkon has been tested by independent laboratories and been proven to be effective against a total of 20 virus families (including HIV/AIDS), 43 bacterial genera and 27 fungal genera Disposables that come into contact with liquid GMO cultures will be autoclaved at a 134°C, a sterilisation time of 20 mins, and full cycle time of 1 hour 44 mins. This treatment will be monitored using test strips and validated using quarterly multi point thermocouple tests of the autoclave.

Risk Assessment Designated Class 2, Containment 2 Activity.

Project Containment
Project Additional Information

Purposes of the contained use

The aim of this project is to evaluate the therapeutic potential of selectively replicating ('oncolytic') Herpes simplex virus 1 vectors in human cancers, especially ovarian cancer. Specifically, we aim to evaluate the pathways of cell death activated by oncolytic HSV in ovarian cancer and the role of innate and adaptive immune responses in modulating therapeutic efficacy of oncolytic HSV1 vectors.

Recipient or parental organism

Human ovarian cancer cells; murine ovarian cancer cells; African green monkey kidney cells

Host/vector system
Origin & function

All vectors will be based upon the vector 1716, which is HSV-1 deleted in the neurovirulence gene ICP34.5. 1716 itself has no inserted viral gene products. There are also derivatives of 1716 encoding GFP, Firefly luciferase and RFP. Further double deletion mutants (eg ICP34.5 and ICP47) with increased selectivity for malignant cells may also be evaluated.

Evaluation of foreseeable effects

Deletion of ICP34.5 dramatically reduces neurovirulence. Although 1716 remains capable of replicating within malignant cells, replication is dramatically attenuated in normal neuronal tissue, as confirmed in clinical trials of 1716 and other ICP34.5-deleted vectors. Risk to human health is therefore effectively zero. Parental Wild-type HSV1 causes fatal encephalitis in mice. However, previous data show that 1716 is avirulent in mice, including by direct intracranial injection. There is no reason to suspect that 1716 has enhanced environmental survival factors or altered host range compared with HSV-1, which is already present in the environment. Overall risk to organisms other than humans and to the environment is therefore effectively zero.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

To minimise the risk to the laboratory staff all work will be undertaken within dedicated MSC class 2 cabinets within class 2 tissue culture facilities. All materials will be decontaminated in 10,000 ppm chlorine (e.g. Virkon, Chlorsept) before removal from MSC class 2 cabinets and autoclave-mediated destruction. Virus is stored at -80°C in cryovials. Following defrosting on ice, cryovials are not opened until placed within MSC class two cabinets, thus minimising the risk of spillage within the lab. In the case of accidental spillage either within or without the MSC class two cabinet, all materials will be decontaminated with 10,000 ppm chlorine.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disinfection
All materials potentially contaminated with 1716 will be decontaminated in 10,000 ppm chlorine (Chlorsept) before removal from MSC class 2 cabinets.

Autoclaving
All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving, using the following regime; gradual pulsing of temperature and pressure to final pressure of 3040mBar and temp of 134°C - 39 mins, sterilisation cycle @ 3040mBar, 134°C - 20min, Pressure venting - 1min drying and pressure vent – 30s, air wash, pressure vent and cooling - 3mins, air Break - 1min, cooling - 11mins (100% kill), prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each...
run will be monitored by continuous chart (or digital) recording of the temperature/time profile. Following disinfection and autoclaving, all waste will be incinerated.

The project was assessed as Class 2 by the GM383 Safety Committee in February 2014.

Please enter comments on the GM safety committee on the risk assessment

### Project Additional Information

#### Purposes of the contained use

The work will use bacterial plasmids and E.coli K12 to generate eDNA which will be put into lentiviral vectors to deliver genes to cells. The use of the lentiviral vector system will enable the efficient infection of cells grown in tissue culture with lentiviruses expressing genes that control cardiac cell growth, differentiation, and survival.

#### Recipient or parental organism

E.coli K12 will be used and plasmids will include pQE3I, pET28b, pGST. K12 is non-colonising and disabled. Lentivirus particles will be produced by transfection of the 293 human embryonic kidney cell line. Human and mouse cells grown in tissue culture including NIH 3T3, C2C12, primary mouse and rat cardiac myocytes and fibroblasts, miRuse, rat and human stem cells and mouse and human ES cells will be the recipients of virus. These cells will express the transgene but not produce or contain transferral virions so are nongenous.

#### Host/vector system

1) pLL3.7 - Lentiviral vector. 2) Packaging vector - psPAX2 - lacks both LTRs and has no viral packaging signal. rev is supplied in trans on a different vector, expresses no viral gene products. Envelope (VSV C) is expressed on 3) pMD2.G 4) pWPl containing the WPRE element. Second generation lentiviral vectors are replication incompetent. No structural genes are present, therefore no replication-competent virions can be produced.

#### Origin & function

E.coli, all strains are K12 derivatives. K-12 derivatives are recognised as non-colonising and disabled. They are not considered pathogenic to humans or animals. They are expected to have limited survivability in the environment and often have auxotrophic requirements, which are unlikely to be satisfied outside of laboratory culture. Second generation lentiviral vectors which are replication incompetent. No structural genes are present, therefore no replication-competent virions can be produced.

For shKnockdowns: pLL3J - A Lentiviral vector that expresses shRNA under the mouse U6 promoter. A CMV-EGFP reporter cassette is included in the vector to monitor expression. Packaging vector - psPAX2 - lacks both LTRs and has no viral packaging signal. The following viral genes have been deleted from the packaging vector: env, tat, rev, vpr, vpu, vif and nef. Rev is supplied in trans on a different vector (RSV-Rev). The vector expressing the packaged viral genome has a self-inactivating LTR (TATA box deletion) and expresses no viral gene products. Envelope (VSV C) is expressed on a separate vector - pMD2.G And pWPl containing the WPRE element.

For conditional shKnockdowns: This bicistronic vector allows for simultaneous expression of a transgene and EGFP marker to facilitate tracking of transduced cells. The EGFP marker cDNA has been inserted downstream of EMCV IRES. Tet-on systems will also be used. Any modifications made to the plasmids under this system are biologically neutral and do not change the biosafety of the original second generation lentiviral vectors.

Clonal cell lines including 293, C2C12, 3T3. Primary cells, rat and mouse cardiac myocytes and fibroblasts, Mouse, rat and human stem cells (bone marrow and cardiac). Mouse and human ES cells.

#### Evaluation of foreseeable effects

K12 is non-colonising and disabled, all plasmids used in K12 will not allow propagation of the strain outside of the laboratory environment. Each lentiviral vector produced will be able to infect cells but will not be able to replicate and spread to new cells. The virions produced are replication-incompetent. The foreign proteins that will be expressed in the transfected cell and ultimately injected into mice will not affect the hazard group of the vector or host and will only be expressed by the infected cell. The WPRE element as present in pWPl has been shown to be potentially oncogenic, but as the virus it will be contained within is replication incompetent, an on-going infection in laboratory personnel is not possible.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

02/03/2022
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Bacterial and lentiviral cultures: Liquid culture, sp11s - For metal surfaces that may corrode - Trigene final concentration of 1 :100. For all other surfaces - Viricon final concentration of 2%. Treatment for 30 minutes at room temperature and then disposed of via the drain and paper towels etc will be placed in GM waste bins. Tissue Culture Plastics, pipettes will also be placed in GM waste bins. These will be autoclaved at 121 degrees for 20 minutes and disposed of by the Imperial College clinical waste route which ends in incineration off site. Autoclaves are monitored by a chart recorder with temperature readout and validated by an annual 12 point thermocouple test.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The Committee agreed with the classification of Containment level 2, Class 2 assigned to the project, as lentiviral vectors containing WPRE are to be used and injected into animals necessitating the use of sharps. The P1 was advised to separate out the Class 1 aspects of the project, involving the use of attenuated adenoviral and retroviral vectors so that this work could start after College approvals are in place.

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

Lentiviral, adeno-associated viral vectors (AAV) and Sendai viral vectors will be used to deliver reporter or therapeutic genes. Wild-type adenoviruses AD5 will be used for AAV titration. The above vectors, except Sendai, be manipulated to receive the genes listed below. Viruses will be produced in cell culture under the appropriate conditions and tested for the absence of replication competence. Each gene will be tested for levels of expression and their effects on the recipient organisms. The vectors below will be used to transfer the gene(s) of interest to recipient hosts. The effects of each vector/gene insert will be screened for therapeutic effects or toxicity on the host.

**Recipient or parental organism**

<td>SODKI and LVG-1 cells</td>
<td>(HIV-1 based producers, 3rd generation) will be used to generate defective 3rd generation lentiviruses. (HIV-1 based producers, 3rd generation) will be used to generate defective 3rd generation Lentivirus (HIV-1 based) will be produced by transient transfection using a 4 plasmid transfection system which ensures minimal recombination likelihood. The viral genes used to produce these vectors are the gag, pol, rev and VSV-G envelope genes each on discrete plasmids. (1). pMDLg/pRRE induces the rev-dependent expression of gag and pol from the CMV promoter. (2)p tet rev expressed rev under tet control. (3)pVSV-G expresses the VSV-G envelope. (4). plasmid CLL.GFP.CLL contains the viral backbone with the gene inserts detailed below. All other wild-type viral genes have been removed. Homology has been reduced to a few tens of nucleotides. 293T cells will be used to produce these vectors.</td>
</tr>
<tr>
<td>Sendai virus</td>
<td>will be used as a wild-type recombinant virus. Only the few genes detailed below will be used. No potentially oncogenic genes will be used. Sendai is a respiratory pathogen of rodents which may cause an inflammatory response. The Sendai to be used is derived from the Z-strain. The use of the recombinant virus has significantly less pathogenicity than the wild-type. Animal studies will be short term to determine pathogenic effects. If low pathogenicity is observed then long term studies will be performed on isolated animals. This virus is to be used as an alternative vector which infects the apical surface of lung epithelia unlike the other vectors detailed above which use the baso-lateral surface for infection.</td>
</tr>
<tr>
<td>Adenoassociated viruses</td>

induction expressing GFP. This cell line has doxycycline repressible and sodium butyrate induction of expression of REV/gag/pol and the VSV-G envelope protein. LVG-1 (HIV-1 based 293 human embryonic kidney producer cells, 3rd generation) will be used to generate defective 3rd generation lentiviruses after tetracycline induction expressing GFP. This cell line has doxycycline repressible expression of REV/gag/pol and the VSV-G envelope protein.

Adenoassociated virus with rep and cap genes removed encoding the gene inserts listed above. AAV will be used to infect Hela (human fibroblasts), HT1080 (human fibroblasts), NIH3T3 (mouse fibroblasts), HEPG2 (human liver hepatocyte cells) HUH 7 (human liver hepatocyte cells), COS 7, CHO (Chinese hamster ovary cells), V79 (Chinese hamster lung cells).

A plasmid pDG will be used encoding the rep, cap and Ad genes E2A, E4 and VA for production of AAV viruses from 293 cells. 3rd generation Lentivirus (HIV 1 based) with doxycycline repressible expression of REV/gag/pol and the VSV-G envelope protein. Sendai virus will be wild type and only contain lac Z, GFP or CFTR genes to recipient organisms.

Evaluation of foreseeable effects

The introduction of the above genes and vectors into recipient organisms will not alter the pathogenicity of the genes used.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All materials used in this work will be disinfected using 1% Virkon and autoclaved as per manufacturer's instructions. Waste will include solid and liquid. Degree of kill be expected to exceed 90%. Sterilised materials will be tested for kill by tissue culture infectivity assays to ensure viruses are inactive. The testing procedures will be carried out for each virus preparation and use.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The Imperial College Safety Committee has accepted the containment levels proposed.

Purposes of the contained use

The lentiviral vectors contain wood chuck hepatitis posttranscriptional regulatory element (WPRE) to enhance transgene expression. This element may be capable of expressing part of the X protein from WHV. A number of publications have suggested that truncated hepadna virus X-proteins may have oncogenic properties and as such WPRE are currently being investigated for oncogenic potential. Appropriate precautions in line with class 2 work therefore need to be used until this has been evaluated.

Recipient or parental organism

Plasmids will be cloned and amplified using competent E. coli cells. Bacteria containing plasmids pose no additional risk to human health.

Lentivirus, AAV and adenovirus will be produced by transient transfection using several plasmids to ensure minimal likelihood of recombination. Vectors will be monitored for replication competence. All viral vectors are designed with low homology to prevent recombination with the host. The multiplasmid transfection system ensures the likelihood/possibility of recombination is effectively zero. Genetic material needed to create a wild-type virus is not carried over with the viral particles and therefore recombination cannot take place.

The GMM cannot survive outside laboratory conditions and so hazard to the environment is minimal. None of the genes to be inserted encode a pathogen or pathogenic determinant or are known to be oncogenic.
The lentiviral vector contains Woodchuck hepatitis post-transcriptional regulatory element (WPRE) to enhance transgene expression. This element however may be capable of expressing part of the X protein from WHV. A number of publications have suggested that truncated hepadna virus X-proteins may have oncogenic properties and as such WPRE are currently being investigated for oncogenic potential. Appropriate precautions in line with class 2 work therefore need to be used until this has been evaluated.

Adenovirus is deleted in E1 rendering it replication defective and therefore unable to cause illness.

AAV production can involve the use of a helper virus, usually wild-type adenovirus or Herpes Simplex Virus. Although both of these can infect humans, the infections are easily treatable.

The GMM cannot survive outside laboratory conditions and so hazard to the environment is minimal. In essence no hazards arise from the alteration of existing traits of the host.

Host/vector system

Replication defective HIV-1 based lentivirus will be produced using a 3/4 plasmid transfection system.

Packaging plasmids:
- pSPAX2 is a second generation packaging plasmid, deleted in viral auxiliary genes vpr, vif, vpu and nef and without env. The HIV-1 viral genes remaining are gag (virion structural proteins), pol (retrovirus specific enzymes), rev (post transcriptional regulator) and tat (regulatory gene) under a CAG promoter (consisting of a CMV enhancer, chicken b-actin promoter and chicken b-actin intron).
- pMDLg/pRRE and pRSV-Rev are third generation packaging plasmids. pMDLg/pRRE contains genes gag and pol under control of CMV promoter and gene Rev is positioned on plasmid pRSV-Rev separately.
- Envelope: pMD2.G

Expressing the VSV-G envelope using a CMV promoter.

Vectors: This is the only genetic material transferred to target cells and contains the viral backbone and transgene cassette.
- pWPXLd-GFP: a standard vector containing an EGFP reporter gene expressed from an EF-1alfa promoter.
- pWPT-GFP: a standard vector containing an EGFP reporter gene expressed from an intron-less version of EF-1alfa, EF-short.
- pWPI: a bicistronic vector allowing simultaneous expression of a transgene and EGFP marker to facilitate tracking of transduced cells using EF-1alfa promoter.
- pHRsinSFFV: Spleen focus forming virus (sFFV) promoter is driving expression of the transgene, which is fused to the EGFP reporter.

Production of replication defective adenovirus is through homologous recombination with pAd.CMV-Link.1 derived plasmids and Ad5 strain d17001. This strain is deleted in E1 and the majority of the E3 region (3.2kb). The resulting adenovirus will contain a therapeutic or reporter gene under the control of CMV promoter.

AAV vectors are based on the non-pathogenic human papovavirus and are deleted for virally alal virally encoded proteins. The vectors consist of an expression cassette and minimal cis elements necessary for replication and packaging of the recombinant genome. AAV replicative and structural (rep and c ap) genes are supplied in trans on a separate plasmid. Production of AAV is possible by transfecting these plasmids into adenovirus or HSV infected cells. It can also be achieved by co-transfecting with a "helper plasmid" containing the minimal Ad components necessary for helper-function thus avoiding use of helper virus. Replication defective adeno-associated virus of various serotypes will be produced using either a helper plasmid or virus and used to investigate and determine the optimal AAV vector/serotype for the transduction of specific cell types of interest. See ref. JP. Louboutin, L. Wang and J M Wilson J Gene Med2005; 7:442-451. Once this is determined AAV containing therapeutic genes will be produced.

Origin & function

Genes to be inserted:
- EGFP (Enhanced Green Fluorescent Protein) is a reporter gene which will aid in determining efficiency of gene transfer.
- REP-2 is a functional isoform of REP-1 and will be used as a control to demonstrate specific requirements for REP1.
GDI extract Rabs from the membranes and can recycle them. Rab 27a, 27b, 38 and others participate in intracellular transport and targeting of proteins. Rab effectors, such as melanophilin and myRIP, determine specificity of Rab function and participate in formation of complexes with other molecules such as motors (myosin V, VII) and cytoskeletal elements (actin).

**Evaluation of foreseeable effects**

No hazards should arise directly from the inserted gene product or by alteration of existing traits.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Due to the presence of the WPRE in the lentiviral vectors all work involving these vectors will be carried out strictly in line with class 2 work.

Adenovirus and AAV are class 1.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid waste such as tissue culture supernatant will be chemically treated with 2% Virkon overnight, validation will be according to manufacturers instructions and disposal will be down the sink.

Solid waste such as pipette tips, culture plates and glass pasteur pipettes will be autoclaved for 20 mins at 120 degrees C 15lb/sw.inch. Validation will be via qualitative monitoring and chart recoder in addition to an annual service maintenance contract. It will then be incinerated and disposed of as clinical waste by an off site contractor.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form Y

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

**Project Containment**

Lentivirus vectors containing WPRE are potentially oncogenic. At the moment this is one of the most efficient to use, although in future a safer alternative may be found. The researches are proposing to use both lentiviral and adenoviral vectors, if can avoid lentiviral then will.

Committee advised the Principal Investigator to incorporate adeno-associated vector (replication deficient Cat 1) to risk assessment.

This project is notifiable to the HSE.

Agreed: Class 2, containment level 2.
**Project Additional Information**

**Purposes of the contained use**

The lentival vectors contain wood chuck hepatitis posttranscriptional regulatory element (WRPE) to enhance transgene expression. This element may be capable of expressing part of the X protein from WHV. A number of publications have suggested that truncated hapapdna virus X-proteins may have oncogenic properties and as such WPRE are currently being investigated for oncogenic potential. Appropriate precautions in line with class 2 work will therefore need to be used until this has been evaluated.

**Recipient or parental organism**

Plasmids will be cloned and amplified using competent E. Coli. Bacteria containing plasmids pose no additional risk to human health.

Lentivirus and adenovirus will be produced by transient transfection using several plasmids to ensure minimal likelihood of recombination. Vectors will be monitored for replication competence. All viral vectors are designed with low homology to prevent recombination with the host. The multiplosasms transfection system ensures the likelihood/possibility of recombination is effectively zero. Genetic material needed to create a wild-type virus is not carried over with the viral particles and therefore recombination cannot take place.
The GMM cannot survive outside laboratory conditions and so hazard to the environment is minimal.

None of the genes to be inserted encode a pathogen or pathogenic determinant.

The lentiviral vector contains Woodchuck hepatitis post-transcriptional regulatory element (WPRE) to enhance transgene expression. This element however may be capable of expressing part of the X protein from WHV. A number of publications have suggested that truncated hepatitis virus X-proteins may have oncogenic properties and as such WPRE are currently being investigated for oncogenic potential. Appropriate precautions in line with class 2 work therefore need to be used until this has been evaluated.

Adenovirus is deleted in E1 rendering it replication defective and therefore unable to cause illness.

The GMM cannot survive outside laboratory conditions and so hazard to the environment is minimal.

In essence no hazards arise from the alteration of existing traits of the host.

Host/vector system

HIV vectors
Replication deficient HIV-1 based lentivirus will be produced using a 4 plasmid transfection system to generate vectors.

Packaging plasmids: pMDLg/pRRE and pRSV-Rev are third generation packaging plasmids. pMDLg/pRRE contains genes gag and pol under control of the CMV promoter and gene Rev is positioned on plasmid pRSV-Rev.
Envelope: pMD2.G expresses the VSV-G envelope from a CMV promoter.
Vector: This is the only genetic material transferred to target cells and contains the viral backbone and transgene cassette.

pWPI is a bicistronic vector allowing simultaneous expression of a transgene and EGFP from the EF-1alpha promoter.
pWPXl-d-GFP: a standard vector containing an EGFP reporter gene expressed from an EF-1alpha promoter.
pWPX-t-GFP: a standard vector containing an EGFP reporter gene expressed from an intron-less version of EF-1alpha, EF-short.

Adenovirus vectors
Production of replication deficient adenovirus is through homologous recombination between pshuttle (an expression cassette containing the gene of interest and promoter) and pAdEasy-1 (plasmid containing the adenoviral backbone deleted in E1 and E3). The resulting adenovirus will contain a gene under the control of CMV promoter.

Origin & function

Genes to be inserted:
TGFbeta (transforming growth factor) superfamily members and downstream effectors (to include TGFbeta, activin and bone morphogenic protein and the receptor serine threonine kinases (ALK1-6) and Smads). We will initially focus on the Smad proteins: The transforming growth factor-beta superfamily members transduce their signal from the membrane to the nucleus through distinct combinations of transmembrane type I and II serine threonine receptors and their downstream effectors, the Smad proteins, which play a central role in transduction of receptor signals to specific target genes in the nucleus (In the first instance Smad2 will be used).

Cyclin dependent kinase inhibitors. Progression through the cell cycle is regulated by cyclins and cyclin dependent kinases (CDK). The kinase activities of the cyclinD/CDK complexes are negatively regulated by several different molecules including the WAK1/CIP.KIP family which exercise broad acting inhibition of the CDKs and includes p21waf, p57kip2 and p27kip1 and the INK4 family, which specifically inhibit CDK4 and CDK6 and include p15, p16, p18 and p19. (In the first instance p21waf will be used).

EGF (epidermal growth factor) receptor family: The EGF family exert their biological effects by binding to and activating the EGF receptor (c-erbB1), a receptor tyrosine kinase.

02/03/2022
kinase, which occupies a prominent role as a primary regulator of epithelial cell function. (In the first instance c-erbB1 will be used).

FGF (fibroblast growth factor) receptor family: The FGF family contains 23 members in mammals and have been implicated in regulation of many key cellular processes including proliferation, differentiation, migration, apoptosis, angiogenesis and wound healing. They bind to five related, specific cell surface receptors.

Evaluation of foreseeable effects

No hazards should arise directly from the inserted gene product or by alteration of existing traits.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Due to the presence of the WPRE in the lentiviral vectors all work involving these vectors will be carried out strictly in line with class 2 work. Adenovirus are class 1.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste such as tissue culture supernatant will be chemically treated with 2% Virkon overnight, validation will be according to manufacturers instructions (see www.antechh.com) and disposal will be down the sink.

Solid waste such as pipette tips, culture plates and glass pasteur pipettes will be autoclaved for 20mins at 120°C 15lb/sq.inch. Validation will be via qualitative monitoring and chart recoder in addition to an annual service maintenance contract. It will then be incinerated and disposed of as clinical waste by an off site contractor.

Please enter comments on the GM safety committee on the risk assessment

Following the discussion of your proposal entitled "Molecular and cellular pathways underlying development and resolution of airway remodelling" (GMIC -01421.2) at the last GM Safety Committee made the following comments.

Comments: The Chair clarified that the genes to be inserted were not oncogenic. Lentiviral vectors containing WPRE are potentially oncogenic. This project is notifiable to the HSE.

Agreed: Class 2, Containment level 2.

Project Containment
Project Additional Information

Purposes of the contained use

The induction of transplantation tolerance by genetically modifying denticritic and endothelial cells to express novel intracellular molecules such that there is substantial downregulation of alloresponses. This will be achieved using genetically modified lentiviral vectors (EIAV). The mechanism of homing and engraftment of mesenchymal stem cells will also be evaluated by genetically modifying these cells with a lentiviral vector to express a long-term fluorescent marker.

Recipient or parental organism

E. coli DH5α cells will be transformed with pONY3.1 pRV67 and pSMART2G (or a genetically modified form of pSMART2G - see below). 293T cells (human embryonic kidney cell line) will then be co-transfected with 3 vector plasmids to generate single cycle infective pseudotyped EIAV viral stocks. D17 cells (canine osteosarcoma cell line) will be transduced for routine titration of lentiviral vector stocks. Dendritic, endothelial and mesenchymal stem cells will be transduced with genetically modified EIAV lentivirus for in vitro and in vivo studies.

Host/vector system

Vectors for third-generation, self-inactivating (SIN) EIAV lentivirus will be used (provided by Oxford Biomedica). Functional, non-replicating/self-inactivating EIAV
lentiviruses generated by modifying the transcriptional enhancer and promoter regions in the 3' U3 long terminal repeats (LTR).

The following lentiviral plasmids will be used:

- pSMART2G - Oxford Biomedica (GFP expression construct)
- pONY 3.1 - Oxford Biomedica (EIAV gag/pol expression construct - also expressing Tat, REV,S2 and part of ENV)
- pRV 67-Oxford Biomedica (VSV-G expression construct - ENV expression)
- pESynRev - Oxford biomedica
- pONY 8.7 NCG Si - Oxford Biomedica (GFP expression construct)

**Origin & function**

The immunomodulatory genes used encode intracellular fusion proteins such as CTLA4-KDEL and ICOS-KDEL, and extracellular fusion proteins such as CTLA4-lg, ICOS-lg, PDL-1/l-2lg, and CD83-lg. CTLA-4, ICOS and PDL-1/L-2 are molecules involved in T cell costimulation, and KDEL is an endoplasmic reticulum retention sequence. IDO (indoleamine 2,3-dioxygenase) is a tryptophan-degrading enzyme that has been demonstrated to have immunoregulatory properties. The enhanced green fluorescent protein (eGFP) is a protein obtained by adding an enhancer sequence to a naturally fluorescent protein (GFP) found in the jellyfish Aequorea victoria.

The aim of the scientific project is to genetically modify dendritic and endothelial cells to express novel intracellular fusion proteins and an immunomodulatory enzyme such that there is a substantial downregulation in T cell alloreactivity and subsequent induction of transplantation tolerance. This would be achieved by inhibition of dentritic cell/T cell co-stimulation in the former case (due to the retention of key costimulatory ligands within the endoplasmic reticulum of dentritic cells), and T cells tryptohan starvation in the latter case (due to upregulation of IDO activity in dentritic cells). EIAV lentiviruses will be used to genetically modify dentritic and endothelial cells.

Mice will be injected with dentritic cells that have been transduced with EIAV lentiviral vectors to express the intracellular fusion proteins stated above. Corneal and heart transplantation will have to be carried out on mice for the latter/in vivo stages of the project. Histopathological analysis will have to be carried out on mice injected with transduced cells for the in vivo stages of the project.

Mice will be injected with Mesenchymal Stem cells that have been transduced with EIAV lentiviral vectors to express the eGFP reporter protein stated above.

**Evaluation of foreseeable effects**

There is no human pathogenicity associated with the lentiviral vector to be used in this activity (Equine infectious Anaemia Virus). There is no possibility of in vivo infection and subsequent in vivo progation. E.Coli DH5a cells (which will be transformed to produce the 3 vectors pSMART2G/pSMART-CTLA-KDEL/pSMART-IDO, pRV67 and pONY 3.1) are non-colonising and disabled, and we are not pathogenic to humans or animals.

Although the gene product expressed will be biologically active, there are no hazards or pathogenicity associated with the proposed intracellular and extracellular fusion proteins. The fusion proteins will only express the extracellular portiane of the T cell co-stimulatory markers. The enhanced green flourescent protein (eGFP) is a protein obtained adding an enhancer sequence to a naturally flourescent protein (GFP). No specific hazard can be identified.

The host strains are not human pathogenic and the inserted gene does not subsequently alter/increase the pathogenicity of the host. A3 plasmid technique will be used for transduction of enothelial and dentritic cells - EIAV is not human pathogenic.

**Cellular work will be undertaken within a designated containment 2 laboratory which is adequately separated from other areas. This containment 2 laboratory has restricted access only to workers who will be involved in using intracellular and extracellular fusion proteins for the T cell immunomodulatory effects stated in section 7.**
A microbiological safety cabinet will be required for routine cell culture of 293T cells, D17 cells, and dendritic and endothelial cells that will be transduced with the lentiviral vector stocks. Aerosols or splashes generated during the activity will not pose a risk of infection to the workers. No other form of local exhaust ventilation will be required. There are no particular requirements for room ventilation.

Static shelf incubators will be used for the culture of 293T cells post co-transfection with three vectors to generate single-cycle infective pseudotyped viral stocks. Shelf incubators will also be used to culture dendritic and endothelial cells transduced with EIAV lentiviral vectors.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Lentiviral vector supernatent stocks will be stored in liquid nitrogen within protective cryotubes with screw-top lids. This will prevent any release of material until cryotubes are opened within microbiological safety cabinets for subsequent transduction of cells of interest. Security measures are in place for liquid nitrogen storage-routine catalogues are maintained. Any missing samples from liquid nitrogen compartments would be immediately identified. Ultracentrifugation (~17,000 RPM) will be used to concentrate lentiviral supernatent harvested from transfected 293T cells, and centrifugation will be used to pellet lentivirus-transduced cells. Buckets will be used with screw-top lids for this activity. In the case of a leak or spillage, immediate containment, extensive use of Virkon and spillage granules will be used if necessary.

Protective laboratory coats are always available, laundered weekly, and stored in the department wash room. Powder-free nitrile gloves will be worn during any cell culture activity associated with this project. Face shields will be used for liquid nitrogen usage. All staff to be involved with project have experience with genetic modification and have attended safety courses.

Vaccination is not required as EIAV is not human pathogenic. The GMM does not have the ability to establish in vivo infection in humans and subsequent in vivo propagation. Health Surveillance is not required. Hepatitis B immunisation would be required (related to isolation of peripheral blood mononuclear cells (PBMCs) not related to GMM product).

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For liquid GMO cultures and non-disposable material, 2% Virkon will be used for a maximum of 12 hours. Virkon has been tested by independent laboratories and been proven to be effective against a total of 20 virus families (including HIV/AIDS), 43 bacterial genera and 27 fungal genera. Disposables that come into contact with liquid GMO cultures will be autoclaved at a 134°C, a sterilisation time of 20 mins, and full cycle time of 1 hour 44 mins. This treatment will be monitored using test strips and validated using quarterly multi point thermocouple tests of the autoclave.

Project Ref 36/01.1

Date Ackn’d 25/01/2001

Date Project Ceased

Withdrawn N

CU2 Project Title THE DEVELOPMENT OF VACCINES AGAINST TB USING THE MOUSE AND GUINEA PIG MODEL

Class 2 CultureVolClass2 < 1 litre

Non-GMM Consent Granted not applicable

Project notified under transitional arrangements N
### Project Additional Information

**Purposes of the contained use**

Recombinant vaccinia virus expressing non-toxic proteins will be used in Mycobacterium tuberculosis (MTB) immunogenicity studies using the mouse and guinea pig models. These recombinant viruses have been constructed elsewhere. No genetic modification will take place at CAMR. The recombinant vaccinia viruses will be propagated in, or used for in vitro assays in, 143B, CV1, EL4 and CEF cells. The viruses will be delivered to animals via several routes for example; intra-nasally or by intra-muscular injection.

**Recipient or parental organism**

Vaccinia virus (VV) or modified vaccinia Ankara (MVA)

**Host/vector system**

Vaccinia virus (VV) or modified vaccinia Ankara (MVA) 143B, CV1, EL4 and CEF cells.

**Origin & function**

The proteins to be expressed individually, are the 38kDa and 19kDa non-toxic proteins of M.tuberculosis. The 38kDa protein is a binding protein in phosphate transport, it is associated with complex-specific antibody response in smear-positive patients and proliferative T-cell responses in infected individuals and after BCG vaccination. The 19kDa protein is a lipoprotein and evokes an antibody response and a proliferative T-cell response in humans. They are intended only to function as antigens after expression in VV or MVA infected cells.

**Evaluation of foreseeable effects**

The functions/properties of the MTB proteins suggest that the tissue tropisms, host range, infectivity and pathogenicity potential of the virus vector will be unaltered by the modification. The efficacy of the vaccinia virus as a protective vaccine will also be unaffected. No disabling feature of the vector will be altered. However, acyclovir and gancyclovir will no longer be effective as thymidine kinase has been disabled. However these are not normally used as therapy against these viruses.

**Effects on Humans:** Vaccinia virus is capable of infecting humans but does not normally cause disease except in immunocompromised individuals. Handling vaccinia virus in Class 2 containment laboratories should prevent release of the virus into the population. When the intra-nasal inoculation of experimental animals is performed this will be performed in a Class 1 safety cabinet, to control increased risk from aerosolisation.

**Effects on Animals:** Vaccinia virus can infect cows, pigs, buffaloes and rabbits. The risk of exposure however is low/negligible when using the appropriate containment levels.

**Effects on the environment:** Vaccinia virus is capable of surviving in the environment for extended periods of time. When the appropriate containment levels are used however the releases of virus into the environment is unlikely.
### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

| n/a |

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

| n/a |

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| Virus suspension: fluid containing live virus will be inactivated autoclaving (121°C for 10 min) to achieve sterilisation (100% kill). |
| Contaminated glassware: will be autoclaved (121°C for 10 min) to achieve sterilisation (100% kill). |
| Contaminated waste: will be incinerated or autoclaved (121°C for 10 min) to achieve destruction (100% kill). |
| Surfaces: will be decontaminated with 10% Chloros (approx 100% kill) |
| Animal wastes: will be autoclaved to destruction or incinerated. (100% kill) |

02/03/2022
Individual domains (the enzymatic domain (DipA) and the cell targeting domain (DipB)) of diphtheria toxin will be cloned and expressed in E. coli. The isolated protein domains will be characterised and used in cell targeting experiments.

Recipient or parental organism

E. coli K12 is a laboratory adapted strain of E. coli unable to colonise or survive outside the laboratory.

Host/vector system

E. coli K12

Plasmid vectors are based on pUC and defective for the functions required for transfer to other hosts. The vectors can be considered to be non-mobilisable.
The diphtheria toxin gene was supplied by Dr Cesare Montecucco, University of Padova as a plasmid clone of the non-toxic variant CRM197. The point mutation in CRM197 will be corrected to allow the expression of an isolated active DipA domain.

The dipA and dipB genes will be expressed and the proteins purified. These proteins will be used to define the regions involved in the interaction between the two domains and in cell targeting studies.

Evaluation of foreseeable effects

Individually DipA and DipB are non-toxic.

The host is unable to persist in the environment. The vector system is non-mobilisable and cannot be transferred to other organisms.

### Project Additional Information

**Purposes of the contained use**

To express and purify inactivated clostridial neurotoxins in E. coli for characterisation.

**Recipient or parental organism**

E. coli K12 is a laboratory adapted strain of E. coli unable to colonise or survive outside the laboratory.

**Host/vector system**

E. coli K12

Plasmid vectors are based on either

(a) pUC based; Defective for the functions required for transfer to other hosts. The vectors can be considered to be non-mobilisable.

(b) pMAL, pET, pGEX based; Defective in mobilisation functions. Considered mobilisation defective.

**Origin & function**
Neurotoxin fragments from native and synthetic genes prepared at CAMR. The toxins have multiple mutations in the active site and are non-toxic. The purified protein will be used for cell binding and delivery studies.

Evaluation of foreseeable effects
The neurotoxin fragments to be expressed are non-toxic. The host is unable to persist in the environment. The vector system is either non-mobilisable or mobilisation defective, minimising the risk of transfer to other organisms.

The Committee was broadly happy with this submission. There was some discussion of the likelihood of the mutant form of the L-chain reverting to wild type, and the advantages of employing a deletion mutant. However, 2 separate independent point mutations would be required to produce a protein with activity. The likelihood was therefore very low. However, the Committee did recommend that details were included in the proposal relating to the absolute activity/toxicity of the mutant L-chain.

Project Ref 36/02.2
**Project Additional Information**

**Purposes of the contained use**
The work aims to produce novel therapeutic agents for the treatment of disease.

**Recipient or parental organism**
E.coli K12 is a laboratory adapted strain of E.coli unable to colonise or survive outside the laboratory.

**Host/vector system**
E.coli K12
Plasmid vectors are based on the vector pUC or equivalent. Defective for the functions required for transfer to other hosts. The vectors can be considered to be non-mobilisable.

**Origin & function**
Gene fragments from native and synthetic genes prepared at CAMR. The proteins to be expressed are prototype therapeutic agents for treatment of human disease.

**Evaluation of foreseeable effects**
The proteins as expressed are inactive.
The host is unable to persist in the environment. The vector system is non-mobilisable minimising the risk of transfer to other organisms.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste will be incinerated. Culture waste will be disposed of in 10% hypochlorite solution and autoclaved.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment

ok

Project Ref 36/03.1

Date Ackn'd 15/05/2003

CU2 Project Title EXPRESSION OF HUMAN, BOVINE AND MOUSE PRION PROTEIN

Class 2

CultureVolClass2 1-50 litres

CultureVolumeClass3-4

Non-GMM Consent Granted not applicable

Project notified under transitional arrangements N

Historical Significant Changes GM36/03.2
**Project Additional Information**

**Purposes of the contained use**
To use the product in analysis of therapeutic agents.

**Recipient or parental organism**
An especially disabled derivative of E. coli K12 - a laboratory adapted strain of E. coli incapable of surviving outside the laboratory.

**Host/vector system**
X1776, MRC1
pGEX-4T-2, pQE, or pMAL. Plasmids considered to be mobilisation defective.

**Origin & function**
Gene fragments from native and synthetic genes prepared at Health Protection Agency, Porton Down. The proteins to be expressed will be used in the design of therapeutic agents.

**Evaluation of foreseeable effects**
The system described is expected to produce the PrP in the cellular non-pathogenic isoform. The host is especially disabled and therefore incapable of existing either within the human gut or in the environment. The vectors selected are mobilisation defective, minimising any possibility of gene transfer.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
Full containment would be level 3, however, as the PrP expressed is not expected to cause the conversion of human PrP to the pathogenic isoform, the HSE guidelines (Part 2A - AnnexIII) indicate a containment level of 2 is sufficient.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
Disposal of liquid waste in sodium hypochlorite solution for 12 hours followed by autoclaving. Solid waste by incineration.

**Project Ref** 36/04.1

- **Date Ackn’d**: 15/07/2004
- **CU2 Project Title**: The Creation of Master and Working Cell Banks for non-replication competent retroviral (Lentiviruses) packaging and producer cell lines
- **Class**: Class 2
- **Culture Volume**: < 1 litre
- **Non-GMM Consent Granted**: Not Applicable
- **Consent Granted**: Not Applicable
- **Project notified under transitional arrangements**: N

**Project Additional Information**

- **Purposes of the contained use**: This notification describes our intent to create Master and Working cell banks for retroviral packaging cell lines and non-replication competent retroviral producer cell lines. The viral potency of infection produced by conditioned - medium from producer lines will be assessed using a standard viral titre assay in recipient cells.
In this particular instance we propose to create cell banks from expanded cultures of lentivirus packaging or producer cell lines to the extent where we will be able to cryopreserve stock ampoules of these cell lines, typically 2 x 10^6 (to the power of 6) cells per ampoule. For each cell line we will establish a Master bank of 10 ampoules and a Working cell bank of 25 ampoules. These ampoules of frozen cells will stored in liquid nitrogen vapour-phase and will be eventually distributed to the research community.

Non-replicative competent retroviruses have the ability to infect cells but do not carry the genetic material necessary to reproduce themselves within a cell. They irreversibly integrate into the host DNA and are not capable of producing complete viruses. The safety aspect is achieved by the viral packaging genes being cloned from the wild type virus into a simple plasmids which are then transfected separately into a candidate cell line to produce a packaging cell line. Packaging cell lines containing these cloned genes express the proteins required for the production and packaging of the non-replicative virus.

The viral vector carrying, the gene to be expressed, as an engineered expression vector carrying the minimum number of viral gene sequences, typically just the viral promoter region, required for the expression of that gene. This vector is transfected into the packing cell line where the transcript of the candidate gene is packaged into a non-replicative virus by the expressed proteins from the genes previously transfected into the cell line.
