### Project Additional Information

**Purposes of the contained use**

The pathology of malaria is caused by the adhesion of parasitized erythrocytes to human host cells (endothelial cells in the microvasculature, uninfected erythrocytes and platelets in the blood stream and syncytiotrophoblast cells in the placenta), which leads to obstruction to blood flow and impaired oxygenation of tissues. Parasitized erythrocytes also bind to immunoglobulin (Ig) M natural antibodies present in normal human plasma, which may play a role in allowing the parasite to avoid clearance by the...
host’s immune system. Previous work has identified a family of genes that play a crucial role in the adhesion of infected erythrocytes to host cells. The main purpose of this project is to understand the mechanisms of adhesion of infected erythrocytes infected with the malaria parasite Plasmodium falciparum to human cells in the clinical symptoms of malaria. We aim to investigate the role of putative parasite adhesion proteins in determining the binding of infected erythrocytes to human cells such as uninfected erythrocytes and platelets. We plan to modify or disrupt the parasite adhesion genes in order to analyse their precise role in the parasite’s adhesion capacity.

Recipient or parental organism

Plasmodium falciparum, the causative organism of the commonest form of human malaria.

Host/vector system

A variety of plasmid vectors that have been designed for Plasmodium falciparum transfection and genetic modification will be used.

Origin & function

We are studying P. falciparum genes that play a role in the adhesion of infected erythrocytes to human host cells. The work will focus on the var multi-gene family that encodes the infected erythrocyte variant surface proteins PFEMP1. Domains of PFEMP1 mediate adhesion to human cells such as erythrocytes, platelets and endothelial cells. The plasmid vectors include drug resistance genes that allow selection of transfected parasite under drug pressure. The drugs used for selection are WR99210, ganciclovir, cytosine deaminase and blasticidin. In addition, well characterised non-harmful tags or markers (such as a myc-tag or green fluorescent protein) will be incorporated into the above vectors to enable us to localise expressed/modified protein.

Evaluation of foreseeable effects

The experiments that we aim to perform are not expected to increase the virulence of the genetically modified P. falciparum parasites above the range found in unmodified P. falciparum because all P. falciparum strains have the capacity to display the adhesion phenotypes eg binding to erythrocytes and platelets. Experiments in which putative adhesion-mediating genes are disrupted or mutated are predicted to reduce the virulence of the genetically modified parasite strain. The genetic modifications we plan to carry out will not affect any genes controlling the invasion, host range or transmission potential of the parasite. The transfection process requires the use of vectors containing selectable markers such as WR99210 (an antifolate drug), ganciclovir (an antiviral), 5-fluorocytosine (an antifungal agent) and blasticidin (an antibiotic). As antifolates are frequently used antimalarials, the genetic modification decreases the susceptibility of the parasites to these chemotherapeutic agents. However, parasites resistant to antifolates are very common in nature and the single drug treatment with antifolates is never used chemotherapeutically. Blasticidin, ganciclovir and 5-fluorocytosine are not antimalarials and therefore their use poses no additional risks to induce resistance against currently used antimalarials.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

In accordance with ACDP guidance, various control measures specified at Containment level 3 are not considered necessary for this work with Plasmodium falciparum and are proposed to be omitted. Consent is also sought for derogation of some additional measures, notably the laboratory to contain all its own equipment. Justification for not applying full containment level 3 measures is as follows:- Plasmodium spp. including P. falciparum are unable to form cryptic forms and are very sensitive to dehydration. In addition they depend on nucleic acid precursors for growth that are added to the rich media in which they are grown or provided to these intracellular parasites by host cells. As a consequence they cannot survive in normal media. They are also sensitive to hypoosmolality and for example easily lyse in water. - Plasmodium spp. are not per se invasive and require their bloodsucking mosquito vector for transmission and percutaneous penetration as a condition for successful infection. - The parasites do not represent any hazard of infection through aerosol transfer. Aerosols are tiny droplets of liquid. These dry out within minutes, under the laboratory conditions of constant air flow and room temperature. Once dehydrated, parasites or parasite-infected host cells would not be viable. In relation to the individual control measures to be omitted from laboratory facilities: 1. Laboratory sealable for fumigation: There is no foreseeable need to fumigate the laboratory. In the event of a major spillage, the bulk of material would be soaked up on absorbent paper towels then autoclaved, killing any parasites. The affected area would be treated with appropriate concentrations of a suitable disinfectant. Any aerosols created that were not cleaned in this initial effort would dry out, killing both host cell and parasite. The area of the laboratory would be left isolated for a period to ensure effective drying. Effective parasite transmission is only possible via direct inoculation of
viable parasites. 2. Negative pressure, HEPA filtered extract, microbiological safety cabinet or specified measures to control aerosol dissemination: The organism presents no hazard of infection by the airborne route. Class II microbiological safety cabinets are in use in the dedicated laboratory, they are necessary for sterile culture of the organism; they are not required for operator safety. Activities involve small scale, standard laboratory techniques with no aerosol generating procedures. 3. Some other equipment not within the laboratory: Although the laboratory contains most of the necessary equipment for the work, some activities use specialist equipment that cannot reasonably be accommodated within the dedicated facility. In all cases a safe system of transport involving secondary containment will be used, any equipment used cleaned and disinfected immediately on completion of the work and any contaminated items either returned to the dedicated laboratory or removed for disposal as waste. The following activities will be undertaken outside the dedicated laboratory:i) Fluorescence microscopy: a fluorescent microscope is located within the same building.ii) Fluorescence activated cell sorting and analyses (FACS): a laboratory holding all FACS equipment is located within the same building and operated according to a documented code of practice to accommodate this work. Whilst this work is in progress access to the FACS facility is restricted to authorised workers trained to CL3 standards and all infectious materials are removed on completion and the area cleaned and disinfected prior to return to normal use. iii) Storage: transfected parasite stocks are frozen and stored at –80οC or in liquid nitrogen within the same building. The freezers are locked and accessed only by authorised personnel.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Most of the material that has come into contact with parasites will be soaked for 24 hours in 2% Virkon. Thereafter, or for any items not disinfected first, the following waste disposal procedures will be used:Solids (eg plastic ware such as pipettes, flasks, tubes etc and agar plates) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125οC for at least 15 minutes or 126-130οC for at least 10 minutes or 134-138οC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or heat treatment or via the industrial (black bag) waste stream for landfill. Liquids (eg samples, culture supernatants, tissue culture media) – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125οC for at least 15 minutes or 126-130οC for at least 10 minutes or 134-138οC for at least 3 minutes), discharge to drains. Sharps (in sharps bin, eg needles, syringes, scalpels) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125οC for at least 15 minutes or 126-130οC for at least 10 minutes or 134-138οC for at least 3 minutes), dispose via clinical waste stream for heat treatment. Spills are treated with powdered Virkon (for larger volumes) or 2% Virkon (smaller volumes) and aerosols contained with paper towels. Degree of kill: Autoclaving - effectively 100% kill (annual validation) Disinfection – not applicable, all waste is subsequently autoclaved prior to disposal Heat treatment or Incineration – not applicable, all waste is autoclaved prior to disposal by heat treatment or incineration

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

**Project Additional Information**

**Purposes of the contained use**

Bacterial infection is commonly associated with tissue injury. The injury may be produced by bacterial virulence factors, by inflammatory mediators generated in an-exuberant host response, or by both. Dissection of the relative contributuion to tissue injury of bacterial and host factors is hampered by the inability to study bacterial pathogens in "real time" during the course of an infection.

This unsatisfactory position has been superseded by advances in bioluminescence imaging combined with the use of genetically modified micro-organisms expressing luminescent/flourescent marker genes. These tools provide unique opportunities to study the dynamics of infection and will be used here to study the temporal and spatial dynamics of bacterial infection.

**Recipient or parental organism**

Pseudomonas aeruginosa, Staphylococcus aureus, Streptococcus pneumoniae

**Host/vector system**

Bacterial hosts with standard transforming plasmid vectors

**Origin & function**

---

02/03/2022

Page 4846 of 15326
Well characterised bioluminescent or fluorescent reporter genes such as luciferase (lux) from the bacterium Photorhabdus luminescens and green fluorescent protein (GFP) from the jellyfish Aequoria victoria.

**Evaluation of foreseeable effects**

The incorporation of well characterised, non-harmful reporter genes is not expected to affect virulence, tissue tropism, host range, susceptibility to host defence mechanisms, or susceptibility to available antibiotics. The modified organisms may be expected to have slightly reduced fitness. No antibiotic resistance markers will be introduced.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solids (eg plasticware such as pipettes, flasks, tubes etc and agar plates) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 C for at least 15 minutes or 126-130 C for at least 10 minutes or 134-138C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or heat treatment or via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 C for at least 15 minutes or 126-130 C for at least 10 minutes or 134-138C for at least 3 minutes), discharge to drains.

Sharps (in sharps bin, eg needles, syringes, scalpels ) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 C for at least 15 minutes or 126-130 C for at least 10 minutes or 134-138C for at least 3 minutes), dispose via clinical waste stream for heat treatment.

Animal bedding and carcasses - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 C for at least 15 minutes or 126-130 C for at least 10 minutes or 134-138C for at least 3 minutes), dispose of carcasses via clinical waste stream for incineration and bedding via clinical waste stream for heat treatment or via industrial (black bag) waste stream for landfill.

Degree of Kill: Autoclaving - effectively 100% kill (annual validation using 12 point thermocouple of worst case loads). Heat treatment or Incineration - not applicable, all waste is autoclaved prior to disposal by heat treatment or incineration.

Date of Significant Change

Project Additional Information

Purposes of the contained use

Investigation of bacterial pathogens responsible for opportunistic infection of the cystic fibrosis lung. In particular:
1) Investigate the phenotype associated with putative virulence factors and antimicrobial resistance determinants through gene knockout and complementation studies
2) Assess the importance of individual virulence factors in the ability to establish infection of the mouse lung and/or persistence within human/murine cell lines.

Recipient or parental organism

Burkholderia cepacia complex, Pseudomonas aeruginosa, Ralstonia species

Host/vector system

Standard transforming plasmids / cloning vectors

Origin & function
The genetic material involved will fall into one of two categories:

1) Natural bacterial gene sequences
Putative virulence factors and antibiotic resistance determinants from bacterial species ubiquitous in the environment.

2) Bioluminescent / fluorescent markers
Photorhabdus luminescens luciferase (lux) operon, which has bioluminescent functions allowing gene expression to be monitored by detection of photonic energy (using a charge coupled device); green fluorescent protein (GFP) gene derived from the jellyfish Aequoria victoria, allowing gene expression to be monitored by detection of fluorescence.

Evaluation of foreseeable effects
The GMMOs are likely to display either (a) comparable properties to the wildtype recipient organism, or (b) an attenuated phenotype due to diminished virulence and/or reduced levels of antibiotic resistance. Consequently, harmful properties associated with the GMMOs are comparable to those of the wildtype organism.

**Project Additional Information**
### Purposes of the contained use

Multi-drug resistance develops due to the exposure of bacteria to either low or high levels of antibiotics. High-level multi-drug resistance generally arises through the selection of mutations in specific regulators that control antibiotic resistance mechanisms such as efflux pumps. While the physical mechanisms of multi-drug resistance in clinical isolates of K. pneumoniae, Salmonella spp. and Enterobacter spp. have been studied extensively, the role of transcriptional regulators in the control of these mechanisms and other functions has not.

The primary aim of this project is to understand the regulation of ramA, a key regulator in Klebsiella spp, and related regulators so that mutations leading to multi-drug resistance can be identified. Moreover the work will aim to determine what other factors, other than antibiotic resistance mechanisms, are controlled by this family of regulators.

### Recipient or parental organism

| Klebsiella spp., Salmonella spp. and Enterobacter spp. |
| Disabled strains of Escherichia coli |

### Host/vector system

Bacterial hosts with variety of plasmid vectors that will include pUC vector series, pET expression vector series, pGEM, pBAD, pACYC series, pBR322 and its derivatives.

### Origin & function

Deletion and complementation of regulatory genes, their regulators and associated genes, for example TetR family, ramA and regulators of ramA, and homologues from Klebsiella spp., Salmonella spp. and Enterobacter spp.

Heterologous gene expression of Salmonella spp. or Klebsiella pneumoniae gene(s) above into Klebsiella spp, Salmonella spp and/or Enterobacter.

Genomic libraries.

Well characterised reporter genes such as β-galactosidase, luxAB genes (luciferase) or fluorescent protein reporter genes.

Antibiotic resistance and selection markers

### Evaluation of foreseeable effects

The insertion of antibiotic resistance cassettes to disrupt specific genes would confer resistance to that antibiotic, however none will be inserted that are used therapeutically for the bacteria involved. Random transposon mutagenesis would have a similar effect. Introduction of reporter genes will confer the phenotype of a single reporter such as β-lactamase activity to the host strain. Disruption of specific genes in Klebsiella, Salmonella and Enterobacter spp. will prevent expression of those genes. Depending on the function of the gene this will most likely result (a) reduction in virulence or (b) disabled strain. If a regulatory gene is disrupted it could lead to the up and down regulation of an array of genes under its control. Any effects that might increase pathogenicity are expected to remain within the normal range of wild type populations. Complementation of the mutant gene with the wild type gene should result in the restoration of the parental phenotype. Heterologous gene expression is also expected to result in strains with variations comparable to those seen in wild type populations. No effects on host range or tissue tropism are expected.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Project Ref 207/07.4

Date Ackn'd 06/09/2007  
CU2 Project Title Investigations into the pathogenesis of poxviruses.

Class 2  
CultureVolClass2 1-50 Litres  
CultureVolumeClass3-4
**Project Additional Information**

**Purposes of the contained use**

To investigate how Vaccinia virus (VACV) and Cowpox virus (CPXV) replicate and interact with the host’s immune system, leading to a better understanding of VACV genes that affect virulence. This work requires genetic manipulation of VACV and CPXV including the deletion and modification of genes to investigate their role in viral virulence.

**Recipient or parental organism**

- Vaccinia virus
- Cowpox virus

**Host/vector system**

Viral host with plasmid vector

**Origin & function**

Genes likely to affect the host’s response to viral infection will be deleted or mutated. In particular, genes that may be involved in cytoskeletal rearrangement or the modulation of the ubiquitin / proteasome system. Mutations involve minor alterations to amino acid sequence to identify functional domains. Standard non-harmful marker genes (such as E. coli gpt, β-gal, luc or enhanced fluorescent proteins) and epitope tags (such as Flag, c-myc, His or HA) will also be inserted.

**Evaluation of foreseeable effects**

The genetically modified viruses produced in this work are not expected to have increased virulence, pathogenicity, extended tissue tropism or host range or altered susceptibility to host defence mechanisms when compared to wild type strains and in many cases viruses will be attenuated.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

### Project Additional Information

**Purposes of the contained use**

Following primary infection, human herpesviruses (HV) establish a life-long latent infection in their hosts. Infection is controlled by the host immune system, mainly by cellular immunity. Loss of immune control of human HV infection, as may occur during inherited, acquired or iatrogenic immunosuppression, results in clinical disease. Some of the ensuing disorders may prove fatal as is the case with Epstein-Barr virus (EBV)-associated post-transplant lymphoproliferative disease (PTLD) in immunosuppressed organ transplant recipients. Research in our laboratory aims to explore the tumorigenic potential of EBV proteins, and to use the knowledge gained to devise novel (antibody- and/or T cell-based) immunotherapeutic strategies to target such EBV proteins expressed by EBV-associated cancers.

Analysis of viral gene function is the key to understanding the transforming, growth and transcriptional regimens undertaken by viruses. However, only so much can be achieved by analysis of these genes in isolation from their parent virus. The generation of bacterial artificial chromosomes (BAC5) containing entire HV genomes allows the use of powerful bacterial cloning strategies to introduce precise modifications into the virus. These modified HV BACs can then be introduced into eukaryotic cells, where the full impact of the modification can be assessed at all stages of the virus lifecycle. Using such techniques, the objective of the current project is to investigate the tumorigenic potential of EBV-derived proteins.

**Recipient or parental organism**

Epstein Barr virus

Bacterial artificial chromosomes containing modified EBV genomes

**Origin & function**

Bacterial artificial chromosomes containing modified EBV genomes
The nature of modifications to be introduced to the EBV genome using BACs involve i) deletion (or loss of function by site-directed mutagenesis) of the latent gene products; ii) reinsertion of deleted genes; iii) inclusion of biomarkers or tags (for example, GFP, luciferase, FLAG, nyc, 6xHis) to enable tracking or visualisation of constructs and antibody detection of viral proteins, well-characterized promoters CMV IEp or SV4Op will be employed to drive expression of such genes; iv) inclusion of the oestrogen receptor gene (or its derivatives) to permit conditional (oestrogen-driven) expression of an EBV gene under study.

**Evaluation of foreseeable effects**

The proposed modifications are not expected to improve recombinant virus viability, or to increase its pathogenicity, compared to wild-type virus. These modifications will involve deleting all (or part) of the latent virus gene(s), or mutating specific motifs within those gene(s) in a manner that incurs loss of protein function. Therefore, we expect the planned modifications not to offer any survival advantage to the engineered virus, and, thus, they are defined as deleterious or neutral in terms of recombinant virus fitness/virulence. None of the proposed work will alter virus tissue tropism or host range because none of the work entails changing the virus receptor binding protein. We do not expect any of the proposed modifications to alter virus susceptibility to normal humoral (antibody) defence mechanisms. However, since latent virus antigens will be knocked out in some constructs the CTL immune response to any infection may be affected. However, those same proteins are crucial for B cell transformation in vitro and, thus, the mutant virus is expected to be much less able to drive B cell proliferation than its wild type counterpart. Taken together, therefore, it seems very unlikely that the mutants present a heightened risk to human health.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

| Solids (eg, plasticware such as pipettes, flasks, tubes etc) | autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or heat treatment or via the industrial (black bag) waste stream for landfill. |
| Liquid (eg, samples, culture supernatants, tissue culture media) | autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge to drains. |
| Sharps (in sharps bin - eg, needles, syringes, scalpels) | autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), dispose via clinical waste stream for incineration or heat treatment. |
| Animal bedding and carcasses | autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), dispose via clinical waste stream for incineration or heat treatment. |
| Degree of kill: | **Autoclaving - effectively 100% kill (annual validation)** |

**Project Ref 207/08.2**

**Date Ackn'd:** 14/10/2008

**CU2 Project Title:** INVESTIGATING FACTORS INVOLVED IN VIRULENCE AND ANTIBIOTIC RESISTANCE IN ACINETOBACTER SPECIES

**Class CultureVolClass2 CultureVolumeClass3-4**

Class 2 1-50 Litres

**Non-GMM Consent Granted**

Not Applicable

**Project notified under transitional arrangements**

N

**Project Additional Information**

**Purposes of the contained use**

Acinetobacter species are important hospital-acquired pathogens that colonise and infect immunocompromised hosts such as patients within intensive care units.
Infections can be difficult to treat due to many strains of Acinetobacter being resistant to commonly used antibiotics. This ability to acquire resistance in a hospital environment such as intensive care units containing immuno-compromised patients has led to the emergence of Acinetobacter species as an increasingly important global health problem. However, relatively little is known about the mechanisms relating to virulence, pathogenicity and antibiotic resistance in these species that have allowed them to become established opportunistic hospital pathogens. This study aims to investigate the features of Acinetobacter species that have led to their success as opportunistic hospital-acquired pathogens. A variety of factors may be studied, but the study will initially focus on antibiotic resistance, particularly on carbapenem resistance in Acinetobacter baumannii.

Recipient or parental organism

Acinetobacter species

Host/vector system

Bacterial host/plasmid vector

Origin & function

Natural bacterial genetic sequences that encode antibiotic resistance determinants and putative virulence factors originating from members of the Acinetobacter genus. Also inducible promoter sequences able to express genes under specific defined laboratory conditions. Suicide vectors will contain a fragment of a target gene or genetic element to enable homologous recombination, resulting in insertional inactivation of that gene or disruption of the element. Complementation vectors will encode a full coding sequence of a target gene, or an entire genetic element, in order to re-introduce a functional copy of the gene or complete copy of the element that was previously inactivated or disrupted with a suicide vector. Complementation vectors will only be used to restore expression of the target gene, returning the isolate back to its original wildtype phenotype. Site-directed mutagenesis of a target gene or genetic element may be performed and the resulting mutated sequence cloned into a complementation vector for expression within a recipient isolate.

Evaluation of foreseeable effects

The GMMOs resulting from this study are likely to have either comparable properties to the wildtype recipient isolates, or to have an attenuated phenotype due to reduced virulence and/or reduced antibiotic resistance. As such, the risk associated with the OMMOs is considered to be the same as those posed by the wildtype recipient organisms. Host range, tissue tropism and susceptibility to host defence mechanisms are not expected to be changed. No modifications will involve antibiotics used therapeutically for treatment of Acinetobacter infections.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids (e.g. plasticware such as pipettes, flash, tubes etc and agar plates) — autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or heat treatment or via the industrial (black bag) waste stream for landfill. Liquids (e.g. samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge to drains. Sharps (in sharps bins e.g. needles, syringes, scalpels) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), dispose via clinical waste stream for heat treatment.

Degree of kill:
Autoclaving — effectively 100% kill (annual validation using 12 point thermocouple of worst case loads). Heat treatment or incineration — not applicable, all waste is autoclaved prior to disposal by heat treatment or incineration.

### Project Additional Information

#### Purposes of the contained use

We wish to investigate several key questions about the evolution of social behaviour using the opportunistic pathogen *Pseudomonas aeruginosa* and go on to use our understanding of social evolution theory to understand observations of behaviour in bacterial infections. Specifically, we will investigate the extent to which social behaviour of bacteria effects their ability to infect hosts and cause disease. The social traits we focus on are the production of the iron-scavenging molecule pyoverdine and cell-to-cell communication systems. We will measure the extent to which clinical strains isolated from the sputa of cystic fibrosis patients exhibit these and other social behaviours.

#### Recipient or parental organism

- **Pseudomonas aeruginosa**

#### Host/vector system

- **Bacterial host/plasmid vector**

#### Origin & function

**Inserted genetic material:**
- standard non-harmful reporter genes such as green fluorescent protein (GFP) gene derived from the jellyfish *Aequorea Victoria* and luciferase a gene derived from the firefly *Photinus pyralis*.
- Muc A gene which suppresses the production of alginate in wild type *P. aeruginosa* strains; insertion of this gene restores phenotype of mutant clinical strains to wild type phenotype.
- antibiotic resistance genes for selection purposes.

**Gene deletions:**
- Siderophore (pyoverdine and pyochelin) knockouts are no longer able to chelate bound iron. The ability to chelate iron is crucial to bacterial metabolism and the ability to colonise host tissue where iron is withheld by powerful chelators such as haemoglobin or transferring. The fitness and virulence of these strains is therefore, significantly reduced relative to the wild type in monoculture.
- Quorum sensing knockouts no longer have functioning QS systems. Bacteria with knockouts of these regulatory genes are less able to sense their bacterial neighbours and are disabled with respect to biofilm production, swarming motility and production of secreted virulence factors. As a result, strains that have QS systems disrupted have significantly reduced virulence relative to wild type in monoculture.

**Evaluation of foreseeable effects**

The OMMOs with lux or gfp reporter genes inserted are likely to display comparable properties to wild type organisms.

The GMMOs with social functions disabled by gene deletions or disruptions are either likely to have or have been demonstrated to have reduced fitness and virulence relative to wild type strains. Tissue tropism and host range are not likely to be affected.

Consequently, harmful properties associated with the GMMOs are at the most comparable to those of the wild type organism.

Antibiotic resistance genes will not be ones that are used therapeutically for *P. aeruginosa*.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids (eg plasticware such as pipettes, flasks, tubes etc and agar plates and including lettuce leaves, warm oth pupae and C. elegans) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or heat treatment or via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) — autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge to drains.

Sharps (in sharps bin, eg needles, syringes, scalpels) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), dispose via clinical waste stream for heat treatment.

Degree of kill:
Autoclaving - effectively 100% kill (annual validation using 12 point thennocouple of worst case loads)
Heat treatment or Incineration — not applicable, all waste is autoclaved prior to disposal by heat treatment or incineration.

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The generation, refinement and characterisation of induced pluripotent stem cells from mammalian cell lines.

Purposes of the contained use

Revolutionary new opportunities for research into and treatment of diseases will be provided by emerging methods for isolation of pluripotent cells from patients. In groundbreaking recent research by Shinya Yamanaka and colleagues it was shown that the introduction of just four specific transcription factors into clut cells induced a small proportion of those cells to acquire many of the characteristics of embryonic stem cells (Takahashi and Yamanaka, 2006), so called ‘nuclear reprogramming’. These cells were named induced pluripotent or “iPS” cells.

To date, reprogramming of human fibroblasts to an iPS status has been achieved by use of retro/lentiviruses, with subsequent multiple random integration events, while introducing the genes of interest. Although viral gene delivery is efficient, there are associated risks with these systems which include ncogenesis and mutagenesis. Therefore, for the future use of iPS cells in clinical and research situations, more refined methodologies of reprogramming are required. This will necessitate a basic understanding of the mechanisms involved in reprogramming including monitoring changes in gene expression which occur during reprogramming and the identification of other potential factors (genes) that can promote cellular programming to an IPS state.

The aim of this project is to establish the IPS technology within the University of Edinburgh. On establishment of this technology within Edinburgh University a number of reprogramming schemes will be engaged including the generation of specific human disease models. Understanding the mechanism of nuclear programming using the above system, we will use this technology to identify other factors that can affect the ability to reprogram to an iPS state.

Recipient or parental organism

Mammalian cells.

Host/vector system

Mammalian cells/retroviral, lentiviral and Herpes virus based vectors.
Origin & function

Origin of material is mammalian and the intended use is to generate induced pluripotent stem cells (iPS). Gene inserts include Sox2, Klf4, Oct4 and c-Myc, these are all involved in regulation of pluripotency and self renewal.

Evaluation of foreseeable effects

Mammalian cells made immortal or reprogrammed to a "pluripotent state" pose minimal risk of harm since any oncogenes present are integrated. The DNA sequences contained in viral vectors are both oncogenic and non-oncogenic and have the potential to cause significant harm because they are in an efficient gene delivery system. The viral vectors to be used are replication defective and therefore in the event of accidental exposure there would be no potential for onward transmission to other persons. However, if a laboratory worker was exposed whilst the vector would not replicate there is the potential for gene inserts to cause harm to the individual, possibly including tumour formation. However this is extremely unlikely as oncogenes such as c-Myc are not individually oncogenic and indeed will drive normal cells to apoptosis as secondary mutatons are required to form tumours. Additional controls will be used to minimise any such risks.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids (eg plasticware such as pipettes, flasks, tubes etc and agar plates) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 dgr C for at least 15 minutes or 126-130 dgr C for at least 10 minutes or 134-138 dgr C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or heat treatment or via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - either autoclave using a make-safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 dgr C for at least 15 minutes or 126-130 dgr C for at least 10 minutes or 134-138 dgr C for at least 3 minutes), discharge to drains or disinfect within 1% Virkon solution for at least 1 hour then discharge to drains.

Sharps (in sharps bin, eg needles, syringes, scalpels) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 dgr C for at least 15 minutes or 126-130 dgr C for at least 10 minutes or 134-138 dgr C for at least 3 minutes), dispose via clinical waste system for heat treatment.

Degree of kill:

-----------------

Autoclaving - effectively 100% kill (annual validation using 12 point thermocouple of worst case loads). Disinfection - a 1% solution of Virkon disinfectant with a contact time of at least 10 minutes gives a >4.25 log reduction of HIV-1 (data supplied by manufacturer). Heat treatment or Incineration - not applicable, all waste is autoclaved prior to disposal by heat treatment or incineration.

**Purposes of the contained use**

Tissue injury results in a process of healing which constitutes the laying down of scar and tissue regeneration in varying degrees. Many human organ diseases result in the generation of excess scar formation (fibrosis) and inadequate organ regeneration. We therefore aim to investigate these two linked processes in a variety of models and human diseases. To do this we propose to investigate the role of key cell populations and signalling molecules in controlling stem cell behaviour in the context of directed...
models of tissue inflammation and injury.

In order to address the role of Wnt proteins in controlling regeneration in the liver we propose to manipulate the Wnt pathway by delivering inhibitors of the Wnt signalling pathway. Proteins will be delivered via adenoviral vectors due to the efficacy of adenoviral delivery to the liver and inability of adenovirus to integrate genetic material into the host.

We propose to perform a series of experiments to define the role of alveolar and bone marrow derived macrophages in lung fibrosis. Lung fibrosis will be induced by the administration of adenoviruses expressing recombinant molecules that stimulate the production of collagen by myofibroblasts.

### Recipient or parental organism

N/A. Class 2 GMO is replication defective adenovirus as detailed below under vector.

### Host/vector system

Adeonviral vectors are generated in the well-characterised human embryonal kidney cell line 293. The vectors are based on the Adeno5 genome and are deleted in E1 and E3 regions.

### Origin & function

Inhibitors of the Wnt signalling pathway such as Dickkpok (Dkk), Wnt inhibitory factor (WIF) and soluble Frizzled protein (sFz).

Profibrotic molecules such as transforming growth factor beta (AdTGFbeta), connective tissue growth factor (AdCTGF), and members of the interleukin family.

Control genes encoding non-harmful proteins such as murine IgG2Fc.

Reporter genes encoding non-harmful proteins that allow detection of transfected cells.

### Evaluation of foreseeable effects

Recombinant adenoviruses are replication defective and unable to produce infectious viral particles in mammalian cells that do not express E1 genes. In the event of exposure to the recombinant adenoviral, vectors there would be transient expression of the inserted gene. Control and marker genes are not expected to have any harmful effects. The effect of the other active transgenes will be variable and depend on the route of exposure.

Accidental local injection of vectors containing Wnt inhibitors would be expected to be transient and result in a down regulation of cell proliferation locally. Effects of iv administration of Wnt inhibitors would be most marked in the liver but these are expected to be dose related and measures have been taken to not produce quantities of virus likely to cause problems. Exposure to aerosols would be expected to be transient and non-significant.

Accidental exposure to aerosolised fibrosis inducing transgenes may result in delivery of their products to the respiratory tract where transient expression of the transgene could cause fibrosis. However, effects are dose related and the risk of exposure has been minimised and the viral particle number carefully controlled to prevent significant side effects if accidental aerosol inoculation to humans were to occur. Accidental exposure via injection of fibrosis inducing transgenes is unlikely as sharps are not required for the instillation of the vector. As for liver above the predominant site of delivery following accidental injection would be either local, or hepatic if accidentally injected intravascularly. Once again, the expected effects would be transient and non-significant.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

### Project Additional Information

**Purposes of the contained use**

This research project will make a major contribution to the understanding of the fundamental mechanisms of both the human and animal TSEs. It is also the aim to study basic mechanisms of neuronal development, homeostasis and neurodegeneration. Our models are used to understand TSE disease mechanisms from the molecular level through to the whole animal and thus develop novel approaches for eradicating disease. The project spans veterinary and medical aspects of TSE disease and addresses problems relating to both animal and human health. This research will allow us to develop a systems biology approach to the study of TSEs and our expectation is that this will allow us to develop a more predictive approach to TSE infection. Our TSE models are unique when compared with other neurodegenerative disease models in that the precise timing of events is known. This provides an important opportunity to examine the very early events of neurodegeneration and it will be through studying such events that the most effective diagnostics and therapeutics will emerge for these diseases.

There are several basic questions that will be addressed through this project, which cover three areas of research. First is the question of the nature of the agent. What is the molecular connection between PrPSc protein, PrP amyloid and TSE infectivity? Second is the question of the role of protein modifications of PrP in TSEs. How does post-translational modification affect the biochemistry of PrP and change TSE susceptibility or pathology? The third area is the genetics of the prion gene family and their association with the onset and phenotypes of TSE disease. How are changes in prion gene sequences influencing TSE susceptibility?

The scientific goal is to understand the underlying molecular mechanisms that link PrP and other prion-family genes to infectivity and to TSE susceptibility.

**Recipient or parental organism**

- Disabled Escherichia coli

**Non-GMM Consent Granted**

Not Applicable
Bacterial and cell line hosts with plasmid vectors
Animals will be modified by homologous gene replacement or by multicopy random gene integration.
No viral vectors will be used with PrP gene inserts.

Origin & function
Gene inserts are human and animal PrP proteins.
For expression in E. coli the proteins will mainly correspond to wild type or normal polymorphism-carrying mature length proteins. However, truncated proteins and proteins expressed as fusions to other ORFs will be made, thus allowing periplasmic expression, epitope tagging and to provide purification/solubilisation handles.
A wide range of normal, mutant and variant forms of PrPs will be expressed in cell lines and animals. The latter two include PrP proteins with altered posttranslational modifications, those with amino acid changes homologous to human disease-linked mutation and those with amino acid changes associated with human prion diseases.
Other prion-family genes such as shadoo will also be used.

Evaluation of foreseeable effects
There is no evidence for any risk to human health and safety or to the environment from normal PrP proteins and most studies suggest these have a neuroprotective role. Humans and animals with transmissible spongiform encephalopathies (TSEs) which are fatal, degenerative disorders of the central nervous system show deposition of mutated forms of the PrP (prion) protein in their brains. These mutated forms of the PrP protein are pathogenic and have been shown to be transmissible. Several variations (polymorphisms and mutations) in PrP proteins have been linked to these infectious proteins which are called prions. Based on previous findings there is no reason to suggest that any of the recombinant proteins used in this work will be any more harmful than naturally occurring variants and risk assessments have been made on the predictive properties of the PrP proteins by comparisons to naturally occurring disease forms. Further it has already been shown that many PrP proteins expressed in recombinant systems are non-functional and non-infectious. Whilst considerable knowledge has been gained in recent years about prion infectivity and host susceptibility, many questions remain unanswered. Since this work is aimed at better understanding these factors a precautionary approach has been taken in assigning rigorous containment and control measures to these activities.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Animals will be held at animal containment level 2 in a facility with enhanced security and control measures for work with TSEs. These measures will also minimise potential for escape to the environment.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
none

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All bacterial cultures are treated with 20,000 ppm chloros for at least an hour prior to disposal or autoclaved at 134C for 1 hour (Guidance from the ACDP' TSE Working Group) These methods kill E coli bacteria. These treatments are also reliable methods of inactivating TSE agents to undetectable levels. All nucleic acid preparations would be considered to be non-infectious in terms of TSE infectivity due to the use of phenol or guanidinium in the preparative procedures which inactivate protein (Rowher RG (1991) Curr Topics Microbiol Immunol 172: 195-232). Any protein preparations would not leave the building unless treated as above. Bacterial culture plates, ES cell plates, mammalian cell culture plates and flasks and mouse carcasses are autoclaved at 134C for 1 hour prior to disposal. Our standard inactivation procedures reduce TSE infectivity to undetectable levels and containment and decontamination procedures are monitored for compliance. A QA system to cover all activities from experiments to waste disposal is in operation. Waste leaves the building as clinical waste for incineration.

### Project Additional Information
**Purposes of the contained use**

The research undertaken at the Edinburgh Cancer Research Centre aims to understand how chromatin-associated cellular processes and genes that are deregulated in cancer contribute to tumorigenesis and how this can be exploited to design more effective therapeutics. The ability to both down regulate or over express key proteins involved in tumorigenesis forms an integral part of our research and the aim of this project is to develop replication-defective lentiviral vectors for the transfer of siRNA sequences and cDNAs to proteins of interest into mammalian cells.

We plan to use lentiviral-based vectors to introduce short hairpin RNAs into cells to ablate the function of key cellular components of cell-cell, cell-matrix adhesions and other proteins involved in regulation of these adhesions. We will also target proteins which have been shown to enable cells to metastasise to specific target organs and chromatin-associated proteins involved in epigenetic regulation or structural chromatin proteins. Conversely we will introduce cDNAs to these components (either wild type proteins or mutant proteins in which key regulatory elements have been altered).

Together these approaches will allow us to determine the contribution of individual proteins to the target cell behaviour such as growth, motility and ability to metastasise both in vitro and in vivo and to investigate the function of epigenetic pathways to regulate gene transcription and factors responsible for modulating chromatin structure. In some cases we will use RNAi libraries to identify novel proteins involved in regulation of cellular processes.

**Recipient or parental organism**

Well characterised mammalian cell lines.

**Host/vector system**

Cell lines /commercially available third and fourth generation lentiviral systems

**Origin & function**

i) standard reporter genes such as green fluorescent protein
ii) drug selection markers eg puromycin, neomycin, blasticidin resistance genes and
iii) the cDNA or shRNA insert of interest.

The inserts of interest target a number of different classes of human genes. Firstly, those that alter the adhesive properties of cells. Secondly, those that target proteins which have been shown to enable cells to metastasise to specific target organs. The third class of genes are those that encode chromatin-associated proteins.

**Evaluation of foreseeable effects**

Many of the genes that we are targeting for knock-down or over-expression will alter the behaviour of the host cells and allow us to determine the contribution of individual proteins to the target cell behaviour such as growth, motility and ability to metastasise. In the majority of cases these will not be harmful to human health. However, we will over-express oncogenes and knock-down tumour suppressor genes which have potential to cause harm to human health by altering the tumorigenic potential of infected cells. Therefore with these inserts in these efficient lentiviral vectors which can infect humans, specific control measures are needed. To minimise the potential for tumorigenesis insertion of multiple oncogenes or knock-down of multiple tumour suppressors into the same virus will not be carried out. It is now widely accepted that 4 to 5 genetic changes are required for the transformation of normal cells (Hanahan & Weinberg, Cell:100, 57-70, 2000) so it is unlikely that when introduced alone these will induce a malignant phenotype. Secondly, use of appropriate physical containment and inactivation processes including use of microbiological safety cabinet and gloves will be used to prevent human exposure to the viruses. The viral vectors to be used are replication defective and therefore in the event of accidental exposure there would be no potential for onward transmission to other persons. However for the individual who was exposed, whilst the vector would not replicate there is potential for some of the gene inserts to cause significant harm possibly including tumour formation. Assignment to containment level 3 is not considered necessary but additional controls to minimise the risk are warranted. Access to the tissue culture facility will be restricted to trained personnel and only be undertaken at a time when others not associated with the work are not present thus limiting the numbers of people to potential exposure.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
For only GMMs - application for any derogation from full containment for the Class of activity.  (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids (eg plasticware such as pipettes, flasks, tubes etc) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or heat treatment or via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) – either autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge to drains or disinfect with 1% Virkon for at least 2 hours and discharge to drains.

Sharps (in sharps bin, eg needles, syringes, scalpels) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), dispose via clinical waste stream for heat treatment.

Degree of kill:
Autoclaving - effectively 100% kill (annual validation using 12 point thermocouple of worst case loads).
Disinfection - A 1% solution of Virkon disinfectant with a contact time of at least 20 mins gives a >99.999% kill of all viruses (data supplied by manufacturer).
Heat treatment or Incineration – not applicable, all waste is autoclaved prior to disposal by heat treatment or incineration.

02/03/2022
Investigation of changes in gene expression and Chromatin structure in artificially generated cancer cell lines

In the human body a small number of cells usually undergo changes that give rise to cancer. Some of the initial events take months and even years and by the time tumours become detectable the cells have undergone a number of changes. Isolation and studies of very early human cancer lesions is technically challenging. Inactivation of genes that are crucial for the control of cell proliferation and survival is widely accepted as one of the major hallmarks of cancer. Gene silencing often occurs by a mechanism which involves chemical modification (methylation) of DNA at gene promoter regions. In order to study the very early events of gene silencing at the onset of tumorigenic transformation we would like to establish human cell lines that express a defined set of factors: human telomerase enzyme to maintain the ends of the chromosomes intact and two cooperating oncogenes – SV40 large T antigen and constitutively active forms of Ras. Artificially generated cancer cell lines will be used for in vitro analyses of DNA, RNA and protein as well as for studies in vivo that monitor the capacity of the transformed cells to form tumours in immunosuppressed mice. We expect that these studies will produce valuable information on the early events in the formation of human cancers which cannot be easily addressed in any other way for ethical and practical considerations.

Disabled Escherichia coli and mammalian cells – no potential harmful effects identified.

Host/vector system

Cell lines/Retroviral vectors. Latter are self inactivating and replication-deficient.
The genetic material originated from viral oncogenes and mutant human oncoproteins which transform human cells and cause formation of tumours.

Evaluation of foreseeable effects

Retroviral particles are capable of infecting humans and animals but only a combination of several of the retroviruses carrying human oncogenes and telomerase enzyme is capable of producing oncogenic transformation. It is considered unlikely that tumorigenesis would result following exposure to a retroviral vector containing just one of the gene inserts, however since these are known oncogenes and the amphotropic vectors are pseudotyped, it is considered appropriate to apply certain control measures on a precautionary basis and assign the work to containment level 2.

# Project Additional Information

**Purposes of the contained use**

The work to be undertaken forms part of an integrated programme of research on human and avian influenza involving researchers from the Interdisciplinary Centre for Human and Avian Influenza virus Research (ICHAIR) and colleagues from the Roslin Institute. ICHAIR (funded by the Scottish Funding Council and the participating University partners) is a collaboration between researchers in The University of Edinburgh, The University of St Andrews and The University of Glasgow.

Recombinant influenza viruses will be used in order to determine the role of specific virus genes in pathogenesis. The viruses constructed will be based on the widely used laboratory strains A/WSN/33 (H1N1), A/Scotland/20/74 (H3N2) (both mouse adapted); A/PR/8/34 (H1N1) and A/Udorn/72 (H3N2) viruses.

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Recipient or parental organism

02/03/2022
Low pathogenic influenza virus strains

Host/vector system
Mammalian established cell lines and primary cell cultures. Recombinant influenza virus strains.

Origin & function
Influenza virus genes involved in virus replication and virus: host interactions.

Evaluation of foreseeable effects
The experiments proposed involve gene deletion, mutation or replacement of specific genes with the corresponding gene from one of the other strains listed all of which are either of low pathogenicity. The influenza virus strains used in this part of the project are classified by ACDP as Hazard Group 2. Since none of the proposed modifications is expected to make the virus more hazardous than the wild-type parent, the work will be assigned to Containment Level 2.

A/WSN/33 (h1N1) and A/Scotland/20/74 are mouse adapted (the other strains do not infect rodents) and have the potential to infect and cause disease in wild rodents. No natural infection of rodents with influenza virus has been documented so no gene transfer to/recombination with wild type murine influenza is possible. Mouse to mouse transmission of murine adapted influenza virus is inefficient and requires close contact between animals. The mouse work will be carried out in the Category 2 containment facilities that include rodent traps on doors and drains to prevent accidental release and there is minimal likelihood of release of virus from these studies.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

### Purposes of the contained use

The pathology of malaria is caused by the invasion of parasites into human red blood cells and subsequent rupture of these infected cells, releasing new parasites and parasite debris which leads to fever and immune pathology in the human host. Parasites bind to the surface of red blood cells and invade by mechanisms which are not clearly understood. Previous work has identified a number of genes that play a crucial role in the invasion of erythrocytes by the malaria parasite Plasmodium falciparum. We aim to investigate the role of putative parasite invasion proteins in determining the binding to human erythrocytes. We plan to modify or disrupt the parasite invasion genes in order to analyse their precise role in the parasite's invasion capacity.

### Recipient or parental organism

Plasmodium falciparum, the pathogen responsible for the most common and most virulent form of malaria.

### Host/vector system

A variety of plasmid vectors that have been designed for Plasmodium falciparum transfection and genetic modification will be used.

### Origin & function

We are studying P. falciparum genes that play a role in the invasion of erythrocytes. The work will focus on the msp and msp related genes that encode parasite merozite surface proteins. Domains of these MSPs mediate invasion of human erythrocytes. The plasmid vectors include drug resistance genes that allow selection of transfected parasite under drug pressure. The drugs used for selection are WR99210, ganciclovir, cytosine deaminase and blasticidin. In addition, well characterised non-harmful tags or markers (such as a myc-tag or green fluorescent protein) will be incorporated into the above vectors to enable us to localise the expressed/modified protein.

### Evaluation of foreseeable effects

The experiments that we aim to perform are not expected to increase the virulence of the genetically modified P. falciparum parasites above the range found in unmodified p. falciparum because all P. falciparum strains have the capacity to invade erythrocytes. Experiments in which putative invasion-mediating genes are disrupted or mutated are predicted to reduce the virulence of the genetically modified parasite strain. The genetic modifications we plan to carry out will not affect any genes controlling the host range or transmission potential of the parasite.

The transfection process requires the use of vectors containing selectable markers such as WR99210 (an antifolate drug), ganciclovir (an antiviral), 5-fluorocytosine (an antifungal agent) and blasticidin (an antibiotic). As antifolates are frequently used antimalarials, the genetic modification decreases the susceptibility of the parasites to these chemotherapeutic agents. However, parasites resistant to antifolates are very common in nature and the single drug treatment with antifolates is never used chemotherapeutically. Blasticidin, ganciclovir and 5-fluorocytosine are not antimalarials and therefore their use poses no additional risks to induce resistance against currently used antimalarials.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Containment level 3 with derogations (as described and justified below) will be applied with Good Microbiological Practice and Good Occupational Health and Safety.

ACDP guidance on work with P. falciparum:

The Schedule to the certificate of exemption accompanying the Approved List specifies a number of parasites, including P. falciparum, for which full Containment level 3 need not be used. ACDP guidance states that work with such parasites does not generally require an inward flow of air to the laboratory or the use of a microbiological safety cabinet as none of these agents is normally infectious by the airborne route. ACDP recommends that for working with these agents, in research, a separate room...
should be used or a designated area in a larger laboratory. ACDP’s guidance also notes that the laboratory need not be sealable for fumigation.

In accordance with the ACDP guidance detailed above, various control measures specified at Containment level 3 are not considered necessary for this work and are proposed to be omitted. Consent is also sought for derogation of some additional measures, notably the laboratory to contain all its own equipment.

Justification for not applying full containment level 3 measures is as follows:

- Plasmodium spp. including P. falciparum are unable to form cryptic forms and are very sensitive to dehydration. In addition they depend on nucleic acid precursors for growth that are added to the rich media in which they are grown or provided to these intracellular parasites by host cells. As a consequence they cannot survive in normal media. They are also sensitive to hypoosmolarity and for example easily lyse in water.

- Plasmodium spp. are not per se invasive and require their bloodsucking mosquito vector for transmission and percutaneous penetration as a condition for successful infection.

- The parasites do not represent any hazard of infection through aerosol transfer. Aerosols are tiny droplets of liquid. These dry out within minutes, under the laboratory conditions of constant air flow and room temperature. Once dehydrated, parasites or parasite-infected host cells would not be viable.

In relation to the individual control measures to be omitted from laboratory facilities:

1. Laboratory sealable for fumigation:
   There is no foreseeable need to fumigate the laboratory. In the event of a major spillage, the bulk of material would be soaked up on absorbent paper towels then autoclaved, killing any parasites. The affected area would be treated with appropriate concentrations of a suitable disinfectant. Any aerosols created that were not cleaned in this initial effort would dry out, killing both host cell and parasite. The area of the laboratory would be left isolated for a period to ensure effective drying. Effective parasite transmission is only possible via direct inoculation of viable parasites.

2. Negative pressure, HEPA filtered extract, microbiological safety cabinet or specified measures to control aerosol dissemination:
   The organism presents no hazard of infection by the airborne route. Class II microbiological safety cabinets are in use in the dedicated laboratory, they are necessary for sterile culture of the organism; they are not required for operator safety. Activities involve small scale, standard laboratory techniques with no aerosol generating procedures.

3. Some other equipment not within the laboratory:
   Although the laboratory contains most of the necessary equipment for the work, some activities use specialist equipment that cannot reasonably be accommodated within the dedicated facility. In all cases a safe system of transport involving secondary containment will be used, any equipment used cleaned and disinfected immediately on completion of the work and any contaminated items either returned to the dedicated laboratory or removed for disposal as waste. The following activities will be undertaken outside the dedicated laboratory:

   i) Confocal fluorescence microscopy: a fluorescent microscope is located within the same building.
   ii) Fluorescence activated cell sorting and analyses (FACS): a laboratory holding all FACS equipment is located within the same building and operated according to a documented code of practice to accommodate this work. Whilst this work is in progress, access to the FACS facility is restricted to authorised workers trained to CL3 standards and all infectious materials are removed on completion and the area cleaned and disinfected prior to return to normal use.
   iii) Storage: transfected parasite stocks are frozen and stored at −80°C or in liquid nitrogen within the same building. The freezers are locked and accessed only by authorised personnel.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Most of the material that has come into contact with parasites will be soaked for 24 hours in 2% Virkon. Thereafter, or for any items not disinfected first, the following waste
disposal procedures will be used.

Solids (e.g. plastic ware such as pipettes, flasks, tubes etc and agar plates) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or heat treatment or via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS2646, Part 3 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge to drains.

Sharps (in sharps bin, eg needles, syringes, scalpels) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), dispose via clinical waste stream for heat treatment.

Spills are treated with powdered Virkon (for larger volumes) or 2% Virkon (smaller volumes) and aerosols contained with paper towels.

Degree of kill:
Autoclaving - effectively 100% kill (annual validation)
Disinfection - not applicable, all waste is subsequently autoclaved prior to disposal
Heat treatment or Incineration - not applicable, all waste is autoclaved prior to disposal by heat treatment or incineration

The pathogen used in these experiments is the porcine reproductive and respiratory syndrome virus (PRRSV). The overall aim of this project is to define the viral and host molecular determinants responsible for the growth and pathogenesis outcome in infected cells.

PRRSV has a 15kb-compact genome where only minimal alterations are possible without affecting virus viability. To overcome these issues the GFP gene in pSD01-08-GFP will be replaced with a short 6-aa Flash tag (Invitrogen). The Flash epitope will also be tested by tagging structural and nonstructural proteins in the PRRSV genome using pSD01-08-GFP and/or the pFL12 backbone. The growth of the newly formed recombinant cloned will be monitored in vitro. Recombinant viral clones that show stability and growth in vitro will be used to investigate the genetics of host innate immune response to PRRSV.

Established host cell lines:
- PK-15: porcine kidney
- 3D4/31: Porcine moncytic cell
- MARC-145: monkey kidney cell*
- Primary Porcine Monocyte/Macrophage cells.

*Marc-145 cell line is derived from the green monkey kidney cells (Kim et al, Arch Virol, 133 p477). This line is commonly used to amplify PRRSV and generate attenuated live vaccines.

Current vector systems:
Vectors:
Genotype 1: The pSD01-08-GFP vector is based on pACYC177 plasmid, containing a hybrid promoter composed of the cytomegalovirus (CMV) or a T7 promoter.
Genotype 2: The pFL12 vector is based on pBR322 backbone containing a T7 promoter.
Classical attenuated live vaccine: Most of these vaccine originate from genotype2 strains
-Prime-Pac (PP) (accession number DQ779791), Kwon et al, vaccine, 24, p7071
-INGELVAC ATP (EF532801)
-RespPRRS (AF159149, allende et al, Arch Virol. 145, p1149Allende)

Origin & function

pFL12 and pSD01-08-GFP infectious clones encode viable PRRSV particles that infect susceptible clones cells without changing cell tropism when compared with natural PRRSV strains. While FL12 virus can only be detected by conventional immuno-detection methods, SD01-08-GFP virus is readily detected by flow cytometry and confocal microscopy (Fanf et al, Journal of virology, 80, p11447). For some of the recombinant strains that will be generated during this project we will replace the GFP with a FlAsH tag useful for labelling and live tracking of viral particles. The FlAsH tag is a short (6 residues) peptide tag commercially available (Invitrogen). Flash will be fused to nsp2 and then to other structural and non structural proteins and used in reverse genetics plasmid-based system to produce new infectious viral particles carrying the Flash tagged viral particles. Cell-permeable FlAsH reagent binds with high affinity to the FlAsH tag and stains the cells when excited at 508 nm wavelength. Emission at 528 nm can be detected using standard fluorescence microscopy settings, allowing identification of infected cells.

Evaluation of foreseeable effects

There is no evidence that PRRSV infects human cells. PRRS is endemic to many countries including UK/Scotland and is not a notifiable disease. The recombinants are based on a vaccine strain which is non-pathogenic. The experiments proposed involve gene deletion, mutation or replacement of specific genes with the corresponding gene from attenuated live vaccine strains listed above. As a first instance we intend to use the PP vaccine. None of the currently proposed modifications is expected to make the virus more hazardous to the environment i.e. animal health than the wild-type parent strains. If genes from other (non-listed) strains are introduced, the potential for hazards to environment of these recombinants will be considered by the local GM safety committee, with reference to the HSE if thought appropriate.

Recombinant PRRS viruses have the potential to infect pigs only as they retain all properties of the wild type parental vaccine strain. Recombination between different strains of PRRSV has been documented in vitro and in vivo (Murtaugh et al. Journal of Swine Health and Production, 2002, 10:15) and if it were to occur the acquisition by a pathogenic strain of the tagged PRRSV genes is exceedingly unlikely to increase the virulence of such a strain. Therefore the consequence of spread to a pig population is negligible.

The likelihood of infection of pigs is extremely low/effectively zero as no pigs exist within the close vicinity, less than 300m, of the research facility at The Roslin Institute. Tissue culture work will produce small amounts of liquid and no procedures which produce aerosols are to be used. Microscopy will be carried out only on fixed tissue. All waste will be autoclaved or burned in accordance with The Roslin Institute regulations (see appendix). Cat2 researchers involved with PRRSV in-vitro experiments will be quarantined for up to 48 hours before being allowed to visit any pig farms. The risk of spread of the recombinant viruses to the wild population is minimal/effectively zero.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

WASTE DISPOSAL PROCEDURES

Solids (eg, plasticware such as pipettes, flasks, tubes etc) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or heat treatment or via the industrial (black bag) waste stream for landfill.
Liquids (e.g., samples, cultures, supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes, discharge to drains.

Sharps (in sharps bin - e.g., needles, syringes, scalpels) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), dispose via clinical waste stream for incineration or heat treatment.

Degree of kill:
Autoclaving - effectively 100% kill (annual validation)
Incineration and heat treatment - not applicable, all waste is autoclaved prior to disposal by incineration or microwaving.

**Project Additional Information**

**Purposes of the contained use**

RSV expressing red and green fluorescent protein will be used to visualise RSV replication in vitro (Recipient cells will include both human and mouse cell lines and primary cultures. The principal cell type infected will be epithelium, but will also include cells of the immune system such as macrophage and dendritic cells.) and in vivo (both Wild Type (WT) and genetically modified strains of mouse will be infected).

**Recipient or parental organism**

Wild type RSV cDNA (ACDP CLASSIFICATION 2)

**Host/vector system**

We propose to use RSV virus that has been modified to express either a red fluorescence protein (rrRSV) or a green fluorescent protein (rgRSV). Both vectors were generated in the laboratory of Dr M P. Reference the method of their construction can be found at Hallak et al, J. Virolgy p10508-10513 2000 & Guerrero-Plata et al, Am J Respir Cell Mol Biol, p320-329 2006) and references therin. It is also described briefly in a section below.

The fluorescent protein gene was inserted via a series of minigenome steps into a position before the first gene in a full-length cDNA copy of the RSV genome along with the proper gene start and gene end signals. In this construct, the fluorescent protein gene flanked by RSV gene-start and gene-stop signals was inserted at the boundary between the leader region and the NS1 gene. The recombinant RSV virus thus expressed one additional mRNA, namely either green or red fluorescent protein, compared with wild-type RSV. This plasmid was transfected into Hep-2 cells along with four other plasmids encoding the N, P, L, and M2-1 proteins to support RSV transcription and replication. The cells were also infected with vaccinia virus, MVA-T7, to provide T7 RNA polymerase to drive transcription from each of the plasmids. The resulting virus was then amplified via passage in Hep2 cells then stored as frozen aliquots from which we will be supplied.

**Origin & function**

The vector modification of the WT RSV cDNA was performed at another institution by Dr M P (Hallak et al, J. Virolgy p10508-10513 2000).

The inserted gene products encode fluorescent proteins and do not confer any selective, infectious or propagating advantage on the virus.

**Evaluation of foreseeable effects**

Given that RSV is a commonly acquired respiratory virus and that the modified virus has no selective advantage over WT. There are no foreseeable effects on human health.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Project Ref 207/10.4

Date Ackn'd 02/03/2022

CU2 Project Title Class CultureVolClass2 CultureVolumeClass3-4
Ticks carry a number of infections of importance in medicine and veterinary medicine. Little is known about how tick cells and ticks respond to microbial infections, how microbes persist in ticks for long periods of time and whether responses to one microbe affect responses or the outcome of infection to another microbe. This project will use a genetically modified tick-borne virus, Langat virus (LGTV) and a genetically modified tick-borne bacterium, Borrelia burgdorferi to investigate the responses of tick cells and ticks to infection, how one infection affects another and how and where these infections persist within ticks.

For LGTV: Disabled, commercially available E. coli strains and eukaryotic cell lines.

Recipient or parental organism
For LGTV: Disabled, commercially available E. coli strains and eukaryotic cell lines.

Host/vector system
LGTV sequence with changes in the replicase genes or insertion of reporter gene sequences in standard bacterial plasmids containing antibiotic resistance genes.

Non-human eukaryotic cells infected with LGTV, LGTV mutants or LGTV containing inserted reporter genes.

Plasmid JAH2 derived from the pBLS590 B. burgdorferi - E. coli shuttle vector. pJAH2 contains the gene for kanamycin resistance and a reporter gene driven by a bacterial 'erp' promoter.

Origin & function
LGTV containing a reporter gene and B. burgdorferi containing a reporter gene will be used to monitor infection or co-infection of eukaryotic cells, arthropods and rodents

Evaluation of foreseeable effects
The LGTV structural proteins will not be changed; there should thus be no change to the tropism or host range of this virus. LGTV is not associated with human disease and has been used as a vaccine for other tick-borne encephalitis viruses. LGTV is not known to be present in the UK environment. It is not known whether it could be naturally sustained here if released, however release from our laboratories would be very unlikely to result in infection of ticks (naturally infected by blood meal) or vertebrates (naturally infected by bite). LGTV is not on the SAPO list. Borrelia causes borreliosis (Lyme disease) in humans. Laboratory acquired human infections have not
been reported. Infection can be treated with antibiotics. This bacterium is present in the UK environment. The GM bacterium would have no selective advantage for survival and establishment in the environment and if released from our laboratories would be very unlikely to infect ticks or vertebrates (natural route of infection is by bite). No harmful properties have been attributed to the inserted reporter genes.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Waste disposal procedures and protocols for biological material are in place in the Virology Towerblock, Summerhall Square. All biological material is inactivated by autoclaving or incubation with chlorine (as appropriate) before being disposed of through established waste disposal channels.

Solids (e.g. plasticware such as pipettes, flasks, tubes etc and agar plates) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), or disinfect for >16 hrs, discharge any excess liquids to drains, dispose of solids via clinical waste stream for microwave treatment or via the industrial (black bag) waste stream for landfill.

Arthropod-derived material such as the remains of dissected ticks will be placed in a container with a strong solution of disinfectant. This container will be periodically sieved out and the solid wastes disposed of by autoclaving.

Liquids (e.g. samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), or disinfect for >16 hrs, discharge to drains. Sharps (in sharp bin, e.g. needles, syringes, scalpels) - dispose via clinical waste stream for microwave treatment.

**Project Additional Information**

**Purposes of the contained use**

To understand the mechanisms of chromatin regulation in *C. albicans*.

The specific goals are to characterise:

1. The pathways responsible for centromere establishments and maintenance. Genes important for centromere integrity will be mutated and the null mutants analyzed for their ability to maintain centromere function.

2. Regulation of gene expression by the RNAi machinery. Sequence of Small Non-coding RNAs in cells carrying mutations in the RNAi component Ago.

Recipient or parental organism

Project notified under transitional arrangements
C. albicans is a human pathogen in ACDP Hazard Group 2. C. albicans causes superficial infections of mucosal epithelia (thrush) (Odds [1988] Candida and Candidosis, Balliere Tindall). C. albicans can also cause systemic infections which can be fatal, but these only occur in severely immunocompromised patients. To keep things in perspective, it is important to realise that C. albicans is widely distributed. C. albicans is carried commensally at least 60% of the healthy population and most Candida infections arise as an overgrowth of the strains resident in the normal microflora. It is a micro-organism of low pathogenic potential that rarely affects healthy individuals. It only becomes a potential medical problem when an individual's immune responses are significantly impaired. Furthermore, as with most pathogenic micro-organisms, the virulence of C. albicans strains is likely to become attenuated rather than enhanced after prolonged laboratory culture.

The C. albicans strains CA14 (uta13), CAI8 (ura3, ade2), RM1000 (his1, ura3) and BWP17 (arg4, his1, ura3) are the standard hosts for DNA transformation world-wide. These auxotrophies make C. albicans avirulent (Leberer et al. [1996] PNAS, 93, 13217). Transformation with URA3 plasmids partially restores the virulence of CAI4, but this restoration is not complete because the genes neighbouring RA3 remain inactivated. This is enough to attenuate virulence partially (but not completely).

Furthermore, C. albicans strains that have been cultured in the laboratory tend to display reduced pathogenicity compared to strains carried commensally by most individuals.

**Host/vector system**

We will always use non-mobilisable E. coli and C. albicans vectors, in detail:

- Non-mobilizable E. coli vectors (including pUC18/19, pBluescript, pGEM-T; lac-based expression plasmids such as pET vectors).

Specific non-mobilizable C. albicans vectors (low copy replicating and integrating vectors [YPB1, Clp10, Clp20, Clp30]; low copy replicating and integrating vectors for ectopic expression [YPB-ADHpt, pACT1]; integrating expression vectors regulated by methionine [MET3 promoter], maltose [MAL2 promoter], glucose [PCK1 promoter], or doxycycline [tet ON promoter and tet OFF promoter].

**Origin & function**

Pathogenicity in C. albicans is a polygenic trait involving numerous physiological characteristics (e.g. rapid growth cell wall, morphogenesis, secreted hydrolases, phenotypic switching). Therefore, (i) no single C. albicans gene (or combination of genes) will turn E. coli into a pathogen, (ii) a reduction in any one of these parameters can attenuate C. albicans virulence, and (iii) an increase in any one of these parameters is highly unlikely to increase C. albicans virulence.

In addition, the C. albicans transformations will perform inactivate a specific target gene to create a null mutant. These transformations will be performed in multiple disabled C. albicans strains (ura3, ade2, arg4, or his1) to ensure that all transformants will always carry a disabling mutation, thereby rendering them completely avirulent. No null mutations have been described that increase the virulence of C. albicans.

In some experiments, we will express specific genes in C. albicans ectopically using a MET3, MAL or text promoter. In these experiments, the expression level is not maximised. Their ectopic expression levels will be <1% of total cell protein. The ectopic expression of most specific genes is unlikely to affect virulence at all, and in some cases it will be expected to reduce C. albicans virulence by adversely affecting growth. The key point is that the probability of increasing virulence by ectopic expression of a single gene is very low, because pathogenicity is complex and polygenic trait requiring a high level of fitness of the C. albicans cell (Odds [1994] ASM News, 60, 313). Indeed, there is evidence that ectopic expression of factors involved in virulence traits does not increase virulence (Bailey [1997] PhD thesis, University of Aberdeen; Leng [1998] PhD thesis, University of Aberdeen; Rodaki et al. [2006]).

We are planning to generate ectopically express genes involved in:
1. Centromere assembly and propagation
2. RNAI
3. Histone modifications

In all cases, we will express tagged versions (EGFP, FLAG or HA) of genes to be able to examine to localization of specific proteins. The addition of the tag will not effect the function of the gene.
Evaluation of foreseeable effects

Our experiments will be performed on disabled or partially disabled C. albicans strains and the mutations that we will generate will most likely render them completely avirulent. Likewise, the ectopic expression of most specific genes is unlikely to affect virulence at all, and in some cases it will be expected to reduce C. albicans virulence by adversely affecting growth.

Candida species have no effective mechanism for horizontal gene transfer that might allow dissemination of resistance traits.

The likelihood of natural gene transfer to other species is essentially zero. Furthermore, despite the recent discovery of sex in C. albicans, the risk of transfer between C. albicans strains is very low. This is because C. albicans strains mate very inefficiently in vivo [Hull et al., (2000) Science 289, 307-310], probably because the specific growth forms that mate most efficiently aren’t maintained at 37°C [Miller & Johnson (2002) Cell 110, 293-302]. In addition, C albicans must be homozygous at the mating type locus for them to be competent for mating, and the vast majority of clinical isolates are heterozygous at the mating type locus.

The "Likelihood of Hazard" is medium, since we are handling a fungal pathogen and it is not possible to exclude accidents entirely, even though the laboratory of our collaborator has not reported a single accident with a Candida species in over 15years. However, the Candida species of interest are widely distributed, with most individuals already harbouring wild type C. albicans strains. No mobilisable plasmids will be used, and in most experiments, disabled hosts will be used.

The "Consequence of Hazard" is low, since serious infections only occur in individuals with severely compromised immune systems.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

WASTE DISPOSAL PROCEDURES

Solids (e.g. plastic-ware such as pipettes, flasks, tubes etc and agar plates) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or heat treatment or via the industrial (black bag) waste stream for landfill.

Liquids (e.g. samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge to drains.

Sharps (in sharps bin, e.g. needles, syringes, scalpels) - dispose via clinical waste stream for heat treatment.

Waste residues that cannot be autoclaved, or cell culture waste will be inactivated by treatment with disinfectant: 1% Virkon solution for plastic-ware (soak for 2 hours), for treatment of minor contamination (10 min contact time) and surface disinfection (benches and floors), 2% for disinfection of liquid cultures and supernatants that cannot be autoclaved. Equipment that cannot be autoclaved will be disinfected as above; physically clean surfaces may be disinfected with 70% ethanol. Presept may be used as an alternative to Virkon; 1,000 ppm for general wiping of equipment and benches, 2,500 ppm free chlorine for discard containers/liquid cultures.

SPILLAGES

Particular care should be taken to ensure that others in the laboratory do not help with the clear up of accidental spillage (especially where there has been an accident that
involves broken glass) unless they are aware of the potential risks and trained in safe working practices.

If spillage occurs, allow aerosols to settle and then working from the outside of the spill, apply powdered Virkon disinfectant to absorb liquids before mopping up with paper towels and disposing of all waste via autoclave waste.

### Project Additional Information

**Purposes of the contained use**

To immortalize stromal cell lines from human hematopoietic embryonic tissues

**Recipient or parental organism**

293T cells, human primary cells from the AGM region, yolk sac, foetal liver, umbilical vessels, placenta.

**Host/vector system**

Lenti-hTert-GFP ready to use particles will be used. hTert is driven by CMV promoter. GFP promoter is driven by a separate EF1a promoter. No antibiotic resistance gene is included in this vector. Viral particles that are replication incompetent and only carry the gene of interest are produced; therefore, no other viral species are produced.

**Origin & function**

Tert (telomerase reverse transcriptase) is an enzyme that adds DNA sequence repeats (TTAGGG) to the ends of DNA strands in the telomere region. Without this, primary cells normally senesce and die.

Fluorescent reporter genes will be used in some instances to mark infected cells.

**Evaluation of foreseeable effects**

Solids (eg plasticware such as pipettes, flasks, tubes etc and agar plates) - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or microwave treatment or via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatant, tissue culture media - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge to drains.

Waste residues that cannot be autoclaved, or cell culture waste will be inactivated by treatment with disinfectant: 1% Virkon solution for plasticware (soak for 2 hours), for treatment of minor contamination (10 min contact time) and surface disinfection (benches and floors); 2% for disinfection of liquid cultures and supernatants that cannot be
autoclaved. Equipment that cannot be autoclaved will be disinfected as above; physically clean surfaces may be disinfected with 70% ethanol. Presept may be used as an alternative to Virkon; 1,000ppm for general wiping of equipment and benches, 2,500 ppm free chlorine for discard containers/liquid cultures.

Spillages

Particular care should be taken to ensure that others in the laboratory do not help with the clear up of accidental spillage (especially where there has been an accident that involves broken glass) unless they are aware of the potential risks and trained in safe working practices. If spillage occurs, allow aerosols to settle and then working from the outside of the spill, apply powdered Virkon disinfectant to absorb liquids before mopping up with paper towels and disposing of all waste via autoclave waste stream.

Emergency procedures

In case of emergency the research worker will be seen by trained First Aider. In the event of any accident where exposure to potentially infectious material may have occurred, The Occupational Health Unit (508192) should be informed immediately or if not available alternatively contact the nearest NHS Accident and Emergency Department/Minor Injuries Unit. As with any accident the incident must be reported to the Institute Safety Officer, and a report entered into the Accident Book.
Torque teno virus (TTV, previously also known as transfusion transmitted virus) was first isolated from a patient with cryptogenic hepatitis (Nishizawa et al, 1997 Biochem, Biophys, Res, Commun, ) and is implicated in other forms of hepatitis. However, TTV and the related anelloviruses, Torque teno mini virus (TMLV or TTMV) and Torque teno midi virus (TTMDV), are widespread in the human population and despite over a decade of investigation, their role in pulmonary fibrosis, systemic lupus erythematosus and even cancer although whether the increased detection rates of viral loads of TTV in these studies were causative or an effect of immunosuppression and/ or co-infection is still unknown.

Using degenerate TTV primers, TTV-like viruses have been identified in tissue from wild wood mice (Apodemis sylvaticus) collected in the UK. Subsequent work has shown that related viruses are also present in other wild rodent populations in the UK including bank voles (Myodes glareolus) and field voles (Microtus agrestis) but there has not as yet been any related species identified in house mice (Mus musculus), the species commonly used in the laboratory. The aim of this work is to establish a rodent model for pathogenesis of TTV using clonal and recombinant (traceable marker containing) rodent viruses in order to provide an understanding of its role in disease.

Recipient or parental organism

Rodent TTV strains generated from wild rodents caught in the UK.

Host/vector system

The plasmid vectors to be used for cloning rodent TTV genetic material contain an ampicillin resistance gene but are non-mobilisable or mobilisation deficient and are unlikely to be transmitted to wild-type bacterial strains.

Origin & function

Full-length DNA from will rodent TTV will be used which will only produce infectious virus under laboratory conditions. The other genetic material involved for producing tagged virus has all been used in numerous previous studies with no adverse effects observed.

Evaluation of foreseeable effects

Wild-type rodent TTV strains are not only normally present but highly abundant in wild rodent populations with the exception of Mus musculus. Despite this high prevalence, no evidence has been found of any adverse effect of their presence. Any clonal viruses would be produced from rodents caught in the UK and would therefore
be identical to the currently circulating viruses. The insertion of DNA encoding traceable protein tags into the coding sequences should not significantly alter the function of the TTV proteins. If any effect is seen, it is likely to have adverse effects only to the fitness of the virus itself and is highly unlikely to enhance the pathogenicity or host range of the resulting recombinant virus.

In the unlikely event of human infection from recombinant rodent TTV, the pathogenic consequences in healthy individuals would be expected to be negligible at most as no clear reproducible pathology has been demonstrated in studied cases (including humans, pigs, and rodents) which are viraemic for their host-appropriate viruses or in the cases of deliberate cross-species laboratory infections.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids (eg plasticware such as pipettes, flasks, tubes etc and agar plates) - autoclave using a make safe cycle as specified in BS 2646, part 3, 1993 (either 121-125oc for at least 15 mins or 134-138oc for at least 10 mins), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or microwave treatment.

Liquids (eg smaples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, part 3, 1993 (either 121-125oc for at least 15 mins or 134-138oc for at least 10 mins), discharge to drains.

Sharps (in sharps bin, eg needles, syringes, scalperls) - autoclave using a make safe cycle as specified in BS 2646, part 3, 1993 (either 121-125oc for at least 15 mins or 134oc-138oc for at least 10 mins), dispose via clinical waste stream for microwave treatment.

Animal bedding and carcasses- autoclave using a make safe cycle as specified in BS 2646, part 3, 1993 (either 121-125oc for at least 15 mins or 134oc-138oc for at least 10 mins), dispose of carcasses and bedding via clinical waste stream for incineration. If larger animals are used autoclaving may not be feasible and an alternative validated method would be used to inactivate the genetically modified micro-organisms. The detail of any such alternative requirement would be notified to HSE as and when necessary.

Degree of kill

Autoclaving. Effectively 100% kill, the efficiency of all autoclaves and sterilising regimes will be monitored using the Porspore2 validation system.

134-138oc for at least 10 mins is the normal cycle for autoclaves within the CSU

Project Containment
There are two aspects to this project. The first aspect regards the investigation of the functional role of herpesvirus miRNAs. The second aspect involves using endogenous cellular miRNAs to investigate the tissue tropism and pathogenesis of herpsviruses.

The viral vectors in this case are the CMV and disabled lentiviral vectors. The potential risks have been detailed above. The herpesBAC DNA is predicted to be infectious and therefore could theoretically be taken up by and infect a host cell if released from a killed bacterium in the gut. The efficiency by which virus DNA produces an infection following electroporation into permissive cells is low, the likelihood of BAC DNA being released intact and then being taken up by a cell to produce virus is therefore low/effectively zero. The BAC is not mobilized in bacteria.
Human cytomegalovirus is a human infectious pathogen. It is in endemic in all populations reaching levels of infection of between 40-100% depending on geographical and socio-economic group. Infection occurs primarily via close contact spread from bodily secretions such as: oropharyngeal, sperm, milk, tears, faeces and blood. It is though that the majority of infection occurs in children and young adults via oral or respiratory routes. During this phase the parotoid gland, lungs and liver are primary sites of infection. Primary infection in the normal host frequently results in a mononucleosis and lymphocytosis. A transient suppression of cellular immunity may be evident following infection. In the normal host, CMV induced symptoms are generally self-resolving. HCMV is classified as a hazard group 2 agent on the Approved List of biological agents.

It is unclear if CCMV or RhCMV infects humans. CMV viruses normally display strict species specificity, however CCMV in particular, is closely related to HCNV and can replicate efficiently in human fibroblast cell lines. As such both viruses will be treated as hazard group 2 agents with the same considerations as HCMV.

MCMV does not infect humans and therefore presents few risks to humans. Lentiviral vectors are disabled and are only able to replicate in helper cell lines. They are well established reagent and not considered to pose any health risk.

**Origin & function**

Components of the RNAi machinery are constitutively expressed in all cells therefore expression of tagged versions of these components are unlikely to increase pathogenesis of the virus. Reporter constructs such as GFP have been extensively used and deemed as safe. Cellular cDNAs identified as miRNA targets will be tagged and cloned into disabled lentiviral vectors. Because these vectors cannot replicate outside of helper cells the risk of any cDNA inserted is minimal.

**Evaluation of foreseeable effects**

Insertion of tagged components of the RNAi machinery or reporter constructs are unlikely to increase the pathogenicity or associated risk with any of the microorganisms. Because Lentiviral vectors cannot replicate outside of helper cells the associated risk is minimal. However work with these vectors will be carried out in category 2 conditions. The bacteria are laboratory adapted multiple autotrophic strains and therefore pose little to no health or environmental risks.

Non-GMM Consent Granted

Project notified under transitional arrangements N
**Project Additional Information**

### Purposes of the contained use

The aims of this project are to develop and test novel theory regarding the evolution of virulence in opportunistic pathogens. Much of the experimental work will focus on the opportunistic pathogen *Pseudomonas aeruginosa* (hazard group 2 in the Approved List of Biological Agents).

### Recipient or parental organism

The recipient organism is the opportunistic pathogen *Pseudomonas aeruginosa* which is able to colonise and pathogenise humans that are compromised such as sufferers of Cystic Fibrosis and Chronic Obstructive Pulmonary Disease, however it is abundant in the environment, in the soil and waterways and does not cause disease in healthy individuals.

### Host/vector system

Vectors will be standard cloning vectors such as pBluescript II and standard suicide vectors such as pRIC380. These will sometimes be carried by non-pathogenic strains of *E. coli* as the donor strain in conjugation.

### Origin & function

To study gene expression, we will utilise reporter systems based on the luxCDABE operon which is synthetic but was discovered in *Photorhabdus luminescens*. We will also utilise gene interruption and gene deletion protocols where standard antibacterial resistance markers such as GmR and CbR conferring resistance to Gentamycin and Carbenicillin respectively. We will only use resistance markers to 'old' antibiotics outside of clinical use.

### Evaluation of foreseeable effects

In every case our genetic modifications are predicted to reduce the fitness of the parental organism in the environment or reduce virulence in a clinical setting. Though the resulting organisms will pose no extra threat to researchers or the environment, the impact will be reduced to zero via standard class II containment procedures and adhesion to standard laboratory health and safety practices.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Project Additional Information**

### Purposes of the contained use
To image analyse and manipulate fungi expressing recombinant fluorescent and luminescent proteins in vitro

### Recipient or parental organism
A range of containment level I and II fungi and disabled E. coli K12. Some of the fungi are pathogens of plants and humans.

### Host/vector system
Standard host/vector systems used for yeast and filamentous fungi

### Origin & function
Green fluorescent protein, other fluorescent proteins and the luminescent protein aequorin derived from Aequoria victoria and other marine organisms. These proteins will be used to label fungal proteins and organelles, and measure intracellular calcium, in fungal cells.

### Evaluation of foreseeable effects
There is no possibility for increasing the pathogenicity of the pathogenic organisms with the experiments performed on them in the proposed work. The other non-pathogenic fungi to be used are model organisms that are considered generally safe to work with. The genetic material to be inserted into the recipient fungi and E. coli are not involved in pathogenesis and are not expected to have harmful physiological or pharmacological properties or to affect pathogenicity of the cloning host or normal human defence mechanisms. Gene transfer is possible but unlikely to be hazardous

Animal Units Large Scale Activities Human Clinical Applications

02/03/2022 Page 4901 of 15326
Establishing in vitro model of Rett syndrome using human LUHMES cells

Rett Syndrome is a neurological disorder caused by mutation in the MeCP2 gene encoding protein, which is a competent chromatin. The neurological spectrum of Rett Syndrome suggests that this protein plays an important role in the nervous system. Despite many years of research on Rett Syndrome and MeCP2, our knowledge about the molecular and cellular basis of this disorder is still incomplete.

Limitations of in vivo studies such as the accumulation of indirect effects have impeded understanding of direct consequences of the loss of MeCP2. Thus, it is important to develop simplified models of Rett Syndrome to create the "disease in a dish". This can be achieved for instance by differentiating human neuronal progenitors, which carry various MeCP2 mutations, into a homogenous neuronal population.

We will establish neuronal cultures derived from immortalized human mesencephalic cell line (LUHMES cells). We would like to introduce a plant-based protein degradation system into the genome of LUHMES cells using adeno-associated viruses. Also stably silence the expression of endogenous MeCP2 using shRNA and at the same time introduce modified exogenous MeCP2 using lentiviruses.

In order to fulfill objectives mentioned above we have chosen to use adeno-associated viral vectors and lentiviral vectors because they have negligible probability of inducing insertional mutagenesis and immunogenicity problem. They are also very well suited for transduction of post-mitotic neurons.
In order to fulfil objectives mentioned above we have chosen to use adeno-associated viral vectors and lentiviral vectors because they have negligible probability of inducing insertional mutagenesis and immunogenicity problem. They are also very well suited for transduction of post-mitotic neurons.

**Origin & function**

MeCP2 gene encodes a protein which is a component of chromatin.

**Evaluation of foreseeable effects**

To understand the direct consequences of the loss of MeCP2 encoded protein and how it relates to Rett Syndrome.

**Project Additional Information**

**Purposes of the contained use**

To study the pathogenesis of Semliki Forest virus (SFV) in vitro and in vivo. To define determinants of virus phenotypic properties including, ability to stimulate interferon and to activate cellular genes, ability to trigger apoptosis, ability to cross the blood-brain barrier and ability to produce neurological disease.

**Recipient or parental organism**
Semliki Forest VirusS (sfv). Strains to be used include SFV4, A7(74) and L10.

**Host/vector system**

Well-characterised and established or primary (eg haematopoietic lineage, fibroblast) vertebrate and invertebrate cell lines. Laboratory mice.

**Origin & function**

The marker/receptor genes and the inserted sequences that will be used include:

(i) standard fluorescent markers, for example green fluorescent protein (from the jellyfish Aequorea victoria);

(ii) biochemical markers including enzymes such as renilla (Rennila reniformis) or firefly (Phontinus pyralis) luciferase;

(iii) regulatory (miRNA piwiRNA) RNA recognition elements;

(iv) inhibitors/regulators of insect or plant innate immune responses or cellular pathways. Proteins which interfere with immune responses in vertebrates will not be used in studies generating infectious virus.

(v) Sequences encoding for SFV proteins will be swapped between virus strains.

**Evaluation of foreseeable effects**

Transfer of virus genetic material will only be between strains of SFV with the exception of plant or invertebrate virus sequences known to encode regulators of plant or invertebrate cell functions (eg p19,B2) which have no known function or deleterious effect in vertebrates. The only other foreign genes that will be inserted are known non-harmful marker or reporter genes or RNA recognition elements.

None of these changes would be predicted to increase pathogenicity. Natural viruses have been selected to be best fit and these changes, which generally increase the size of the genome and most likely to attenuate fitness and pathogenicity.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solids (eg plasticware such as pipettes, flasks tubes etc) - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or microwave treatment or via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge to drains.

Sharps (in bin, eg needles, syringes, scalpels) - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), dispose via clinical waste stream for incineration or microwave treatment.
Animal bedding and carcasses - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), dispose via clinical waste stream for incineration or animal bedding may after autoclaving also be disposed of via the clinical waste stream for microwaving or via the industrial (black bag) waste stream for landfill.

Degree of kill:
Autoclaving - effectively 100% kill
Incineration and microwaving - not applicable, all waste is autoclaved prior to disposal by incineration or microwaving

Project Ref 207/13.1

CU2 Project Title

Role of telomerase and telomeres in cell transdifferentiation processes

Class

Class 2

Culture Volume

< 1 Litre

Non-GMM

Consent Granted

Project notified under transitional arrangements
The aim of the project is to evaluate the role of telomerase and telomere length in cell transdifferentiation processes (the biological event where a differentiated cell differentiates into another cell type without passing through a staminal state).

In particular, we want to transfect both wild type and telomerase negative mouse embryonic fibroblasts (MEFs) possessing different telomere length with lentiviral vectors coding for genes inducing transdifferentiation from fibroblasts to other cell kinds (neurons and muscular cells at the beginning). We aim to determine if different telomere lengths (or telomerase status) affects the ability to undergo transdifferentiation.

Viral vectors we would like to use are the following:
A) Standard commercially available vectors like Clontech Plvx-Tet-On Advanced. Catalog # 632162
E) Addgene plasmid 8455: pCMV-dR8.2 dvpr (packaging plasmid for Lentiviral constructs).

Insert code for normal mammalian genes and standard marker genes.
MyoD (MGI:97275)
Ascl1 (MGI:96919)
Brn2 (MGI:101895)
Myt1l (MGI:1100511)
These genes are involved in mammalian neural differentiation processes (Ascl1, Brn2, and Myt1) and myoblast differentiation (MyoD). Therefore, the expectation is that they will induce the recipient cells to adopt a phenotype more similar to neurons.

**Evaluation of foreseeable effects**

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solids (e.g. plastic-ware such as pipettes, flasks, tubes etc and agar plates) - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121 - 125°C for at least 15 minutes or 126 - 130°C for at least 10 minutes or 134 - 138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or heat treatment or via the industrial (black bag) waste stream for landfill.

Liquids (e.g. samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121 - 125°C for at least 15 minutes or 126 - 130°C for at least 10 minutes or 134 - 138°C for at least 3 minutes), discharge to drains.

Sharps (in sharps bin, e.g. needles, syringes, scalpels) - dispose via clinical waste stream for heat treatment.

Waste residues that cannot be autoclaved, or cell culture waste will be inactivated by treatment with disinfectant: 1% Virkon solution for plastic-ware (soak for 2 hours), for treatment of minor contamination (10 min contact time) and surface disinfection (benches and floors); 2% for disinfection of liquid cultures and supernatants that cannot be autoclaved. Equipment that cannot be autoclaved will be disinfected as above; physically clean surfaces may be disinfected with 70% ethanol. Presept may be used as an alternative to Virkon; 1,000 ppm for general wiping of equipment and benches, 2,500 ppm free chlorine for discard containers/liquid cultures

**SPILLAGES**

Particular care should be taken to ensure that others in the laboratory do not help with the clear up of accidental spillage (especially where there has been an accident that involves broken glass) unless they are aware of the potential risks and trained in safe working practices.

If spillage occurs, allow aerosols to settle and then working from the outside of the spill, apply powdered Virkon disinfectant to absorb liquids before mopping up with paper towels and disposing of all waste via autoclave waste.

**Is an emergency plan required according to regulation 20?**

The genetic modification safety committee agreed that the appropriate containment and control measures have been assigned.
Project Additional Information

Purposes of the contained use

A combination of microarray and CAGE data has been analysed and used to define a list of cell cycle genes expressed in neonatal human dermal fibroblasts (NHDFs). The analysis also resulted in the identification of c100 putative novel cell cycle genes. In order to study the cellular localization of the products of these genes and to provide evidence of involvement in the cell cycle, proteins will be fused to eGFP at either the N- or C- terminal and expressed in B+NHDF, HEK-293 ad HEK293T cells.

Recipient or parental organism

NHDF, HEK-293 and HEKs93T cells (Human origin)
### Host/vector system

| E.coli (K12 derived non-colonizing strain)/pDONR223, pcDNA DEST47, pcDNA DEST54 (Invitrogen) |

### Origin & function

| cDNA derived from Human mRNA |

### Evaluation of foreseeable effects

| No sequences known to be oncogenic or tumorigenic will be cloned or expressed in NHDF cells or HEK293 cells. However as c100 unknown genes are being studied, there is a very small risk of cloning and expressing an oncogenic or tumorigenic sequence. The risk of naked DNA entering cells of laboratory workers by electroporation-based methodology or lipid based transfection is negligible. Taking into account the characteristics of the manipulated genes, the vectors employed and the recipient cells as described above, none of the genetically modified micro-organisms or cultured cells used in this work present a risk to human health. |

**Please enter comments on the GM safety committee on the risk assessment**

The genetic modification safety committee agreed that the appropriate containment and control measures have been assigned.
Cells cultured in vitro can be used for many studies of basic molecular and cell biology as well as for diagnostic purposes. When considering cultured cells as replacements for animals in research it should be remembered that the use of primary cells does not reduce the use of animals; animals are either killed to gain access to the cells of interest or the cells are harvested from accessible sites, some of which cause limited distress (e.g. blood sampling), but others which are more traumatic (e.g. broncho-alveolar lavage on a living animal). Primary cell lines have significant limitations, including heterogeneity, limited capacity to divide in culture and the early onset of senescence. Immortalised cell lines have a number of advantages: unlimited supplies of characterised cells with the same genotype can be used by multiple researchers over prolonged periods of time. The purpose of the contained use for this project is to generate immortalized pig macrophage cell lines and demonstrate their potential for the study of host-pathogen interactions. The generation and evaluation of the cell lines will be addressed through four specific interdependent objectives:
1. To generate a replication defective MMLV-based recombinant vector which encodes the human telomerase reverse transcriptase (Htert).
2. To generate immortalised macrophage cells lines from a range of pig genotypes
3. To determine whether immortalised macrophage cells respond similarly to resident lung macrophages upon challenge with viral pathogens with a macrophage tropism

Recipient or parental organism

Recipient organisms are E. coli, HEK293T cells and primary macrophages

Host/vector system

Host and vector system combination will be as follows: i, E.coli and cloned Htert into the pFBNeo vector to generate the pFB-Htert-Neo recombinant vector, pVPack-VSV-G and the gag-pol vector pVpack-GP; ii, HEK293T cells for the packaging of MMLV and iii) Primary macrophages transduced the replication-defective MML-Htert

Origin & function

The telomerase reverse transcriptase (tert) has a human origin (Htert). The biological function of Htert is to cause immortalization of the transduced macrophages.

Evaluation of foreseeable effects

The biological function of inserted genetic material, the telomerase gene (Htert), will cause the immortalization of the transduced macrophages. Copy number and level of expression are unpredictable. It is possible that depending on the region of insertion into the pig DNA and the conversion to immortalized cells, recombinant cells will potentially harbour new functional characteristic including production of cytokines, allergens or other molecules. As part of the normal procedure set for this experiment we intend to assess the emergence of any new properties of the recombinant immortalized cells. We will screen for cytokines using available ELISA test and RT-PCR assays and compare the results to normal non-immortalised primary macrophages. New recombinant immortalized macrophages that will harbour excessive alteration in its biological response, such as to enhance cytokine production, will be discarded as described in sections below on additional control measures.

Considering the potential remodelling genetic activity of Htert, the likelihood of reactivating/complementing PERVs is not negligible and need to be considered in this work to reduce risk of transmission to human or other cells. Finally it is possible that the inserted genetic material may be oncogenic. Indeed remodelling genetic activity of the Htert inserted genetic material may be oncogenic. Telomerase activity has been found in almost all human tumours but not in adjacent normal cells (Kim, N.Wet al (1994) Science, 266, 2011-2015). The most prominent hypothesis is that maintenance of telomere stability is required for the long-term proliferation of tumours. Thus, escape from cellular senescence and becoming immortal by activating telomerase, or an alternative mechanism to maintain telomeres (Bryan, T.M.(1995) EMBO J., 14, 4240-4248). Constitutes an additional step in oncogenesis that most tumours require for their ongoing proliferation. To reduce the risk associated with the use of oncogenic recombinant cells, work will be carried out in Class II Microbiological Safety Cabinet (MBSC) in line with CL2 facility controls.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste must be inactivated by validated means before pouring fown the drains or leaving the site for incineration. Inactivation may be achieved by autoclaving or disinfection.

1- Autoclaving

This is the preferred means of inactivation and is mandatory for all waste generated in CL2 facilities. In other areas it must be used for waste that cannot be effectively inactivated by disinfection.

Such items may include: Agar plates, cell/bacterial pellets, small tubes, plastic loops, tips and gloves.

Autoclaving procedure: Where autoclaving is used, a cycle of 121°C for 45 minutes, with full steam penetration to the centre of the load, has been shown to be sufficient to
render most materials sterile. Validation in this case will rely on the annual testing of the autoclave to demonstrate, using independent thermocouples placed at the centre of the load, that the correct time and pressure have been reached for the required time. On subsequent runs verification that the correct conditions were reached can be obtained through the use of, for example, chart recorders or appropriate indicators autoclaved with the load.

Bags and Containers: Proprietary autoclave bags should be used. These should not be filled more than 3/4 full in order to allow the necks to be closed with coded ties/tags. Some means of identifying the source of the waste must be shown [lab number/operator]. Bags should be transported to the autoclave in robust leak-proof containers.

2-Disinfection

This generally refers to the use of chemical agents to destroy the potential infectivity of a material. Effective disinfection is dependent upon: i) activity; ii) concentration and iii) length of contact.

Disinfection is not as effective as steam sterilisation in destroying viable organisms, nor is it easily monitored.

Disinfection is a suitable means of inactivation for:

- Reusable items that are heat sensitive
- Liquid cultures of, and equipment used in association with Group 1 organisms
- At the end of the work for decontamination of surfaces and equipment that cannot be autoclaved.

The choice of disinfectant:

Before choosing a disinfectant it is important to refer to the manufacturers data to ensure that the disinfectant will be effective against the organism(s) in question and to determine the recommended concentrations and contact times. The aim of the disinfectant is to reduce the titre by at least 5 logs and that large amounts of protein can interfere with chemical inactivation.

Disinfectants currently in use in the lab 2.073: Haz-tab, Ethanol and Distel (www.tristel.com) however (this current work on immortalized macrophage will exclusively use Virkon (www.antechh.co)m see document 5a, b and c in appendix section) to increase the effectiveness of the disinfection of retroviruses and bacteria and potential PERVs.

The overall aim of this project is to identify molecular and cellular factors that govern the development and function of the immune system in the mouse. To this end, we will be following the immune response and the development of immunological memory in vivo following infection of mice with Listeria monocytogenes (PMID 21349093).

Listeria monocytogenes is an opportunistic pathogen that gives rise to extremely rare cases of food poisoning. However, in the elderly, in neonates and among immunocompromised individuals it can cause severe disease, e.g. meningoencephalitis or septicemia. Listeria monocytogenes also poses an additional risk to pregnant women and their unborn child as it actively travels through cells and, therefore, can be transmitted from a mother to the fetus transplacentally and may result in abortion or still birth. Mainly we will use L. monocytogenes that carries a deletion of the gene ActA, aimed to make the bacteria less harmful (attenuated) and specifically to reduce its ability to spread intracellularly, which decreased its ability to transmit to the fetus 1000-fold (PMID 1286064, PMID 17118980). The greatest risk when working with L. monocytogenes is infection via pricking of the skin by contaminated sharp objects. Therefore, it is advisable to use cut-resistant gloves during injection of the bacterial suspension into mice. L. monocytogenes will be handled at containment Level 2. Pregnant women to be advised not to carry out this work due to the possible risks. A separate risk assessment to be completed if they still wish to participate in this research.

The chicken ovalbumin (OVA-albumin) expression cassette carries resistance to the antibiotic erythromycin to allow selection of L. monocytogenes containing the expression cassette. However, the standard treatment of listeriosis includes ampicillin and an aminoglycoside drug and the Listeria monocytogenes we would use is sensitive to the standard treatment antibiotics (PMID 10471548). There are naturally occurring erythromycin-resistant Listeria strains in the UK, but these strains are sensitive to other relevant antibiotics (PMID 10471548). Containment Level 2 precautions will be used when handling bacteria and all potentially infectious waste will be decontaminated before disposal.
The chicken ovalbumin gene is non-pathogenic and it has been introduced into L. monocytogenes and the ActA disabled variants of the bacteria to facilitate monitoring of immune responses to the bacteria. The OVA-albumin expression cassette also carries resistance to the antibiotic erythromycin to allow selection of L. monocytogenes containing the expression cassette. However the standard treatment of listeriosis includes ampicillin and an aminoglycoside drug and the Listeria monocytogenes we would use is sensitive to the standard treatment antibiotics (PMI 10471548).

**Origin & function**

L. monocytogenes are widely distributed in the environment, are not exotic to the UK, are not pathogenic to plants, and none cause notifiable diseases under specific surveillance by DEFRA. The ActA deleted attenuated L. monocytogenes strain is less harmful than naturally occurring Listeria strains, since its dissemination in an infected person is impaired. As there is the possibility for natural spread of L. monocytogenes to other animals within the animal unit, appropriate containment measures will be used to prevent unplanned infection. This normally involves filtered cage tops and use of a quarantine room or use of an isolator in a shared room, to minimise the risk of dust-mediated transmission. In practice, this particular risk is extremely low, as a high infectious dose is required for this organism. Listeria is an intracellular pathogen that is destroyed by innate immune cells that rapidly clear primary and secondary infection. There is a very low likelihood of shedding and cross-infection between mice. Listeria interacts with the adherens junction protein E-cadherin to transverse the intestinal epithelium, but the efficiency of invasion is greatly reduced in mice compared to humans due to a single amino acid substitution in E-cadherin (PMID 21349093). Gloves will be worn where appropriate with particular attention to procedures to minimise any risk of sharps injury. Within the animal units, mice are held in cages inside individually ventilated cages and generally within a quarantined room. Catch trays are used for any injection or manipulation procedures and before starting this work we will clean surfaces with 70% ethanol and after finishing the surfaces are to be decontaminated with Virkon. No special immunisation is required for work with these organisms and good microbiological practice/good hygiene is normally adequate forms of protection. The likelihood of accidental environmental release of the GMMs is very low or negligible, given the measures that will be applied to control any risk to human health and safety (level 2 containment). If release was to occur, the consequences can also be graded as very low or negligible. Therefore, the environmental risk can be judged as effectively zero.

WASTE DISPOSAL PROCEDURES

Solids e.g. plastic-ware such as pipettes, flasks, tubes etc., and agar plates) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or heat treatment or via the industrial (black bag) waste stream for landfill.

Liquids (e.g. samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge to drains.

Sharps (in sharps bin, e.g. needles, syringes, scalpels) - dispose via clinical waste stream for heat treatment.

Waste residues that cannot be autoclaved, or cell culture waste will be inactivated by treatment with disinfectant: 1% Virkon solution for plastic-ware (soak for 2 hours), for treatment of minor contamination (10 min contact time) and surface disinfection (benches and floors); 2% for disinfection of liquid cultures and supernatants that cannot be autoclaved. Equipment that cannot be autoclaved will be disinfected as above; physically clean surfaces may be disinfected with 70% ethanol. Presept may be used as an alternative to Virkon; 1.000 ppm for general wiping of equipment and benches, 2,500 ppm free chlorine for discard containers/liquid cultures.

### Project Additional Information

**Purposes of the contained use**

This project will utilise a range of viruses modified to express reporter genes as tools to better understand and define how host cellular pathways and pathogen interactions at the molecular and protein level influence the establishment and pathogenesis of viral infection, and provide insight into potential targets for novel anti-viral therapeutics.

**Recipient or parental organism**

In this connected programme a range of different viruses will be used including Adenovirus, HSV-1 and HSV-2, VZV, CMV, EBV, KSHV, MDV, mHV-68, Influenza A virus, RSV, FMDV, SFV and Buyamwera virus.

**Host/vector system**

Several different vector systems including BACs, MVA, adeno- and lentiviral vectors as well as plasmids will be used. For FMDV, a non-infectious replicon system will be used.

**Origin & function**

Several different standard, well-characterised genetic marker genes, such as the jellyfish green fluorescent protein (GFP) and/or other fluorescent proteins (CFP, YFP, DsRed), and firefly (or Renilla, Gussia) luciferase as well as selection markers such as antibiotic resistance genes with no harmful physiological or pharmacological properties will be used.

**Evaluation of foreseeable effects**

All recombinant infectious pathogens used in this study will not be modified with respect to their determinants of tropism i.e. viral glycoproteins. The GM pathogens used and generated within this study will at most be equal to wild-type with respect to transmissibility, virulence, pathogenicity and tropism, an equal containment level is appropriate. In all cases, taking into account the control measures assigned above, the overall risks to the environment form the genetically modified micro-organisms produced in this work is effectively zero.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable
WASTE DISPOSAL PROCEDURES

All pathogen waste is decontaminated with TriGene (Hayman Medichem). TriGene is a halogenated tertiary amine detergent, a category of detergents proven to be virucidal against enveloped and non-enveloped viruses including HIV, yet with minimum toxicity to man. TriGene is thus a suitable detergent for disinfection of liquid media and plastics used for culture and use of all infectious agents described herein. Furthermore, Virkon powder, a broad spectrum disinfectant active against all known virus families, is used in the event of spillages of infectious material.

Autoclaving is by using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121°-125°C for at least 15 minutes or 126°-130°C for at least 10 minutes or 134°-138°C for at least 3 minutes). This procedure has a degree of kill of 100%. The autoclave undergoes an annual twelve-point validity check to ensure sterilisation effectiveness.

Class II microbiological safety cabinets are tested every 6 months, as recommended by HSE/Scottish Executive guidelines.

Solids (e.g. plasticware such as pipettes, flasks, tubes, etc)
All used tissue culture plastics, pipettes, micro-pipette tips, micro-centrifuge tubes, cryovials, plastic haemocytometers and other plastics are rendered safe by soaking overnight in a solution of 1.25% TriGene (or equivalent). Liquid is drained down the disposal sink within the Containment Level 2 tissue culture laboratory and decontaminated plastics disposed of via the clinical waste stream for incineration or microwave treatment. Both solid and liquid waste will be autoclaved after infected material has been exposed to 1.25% TriGene to ensure 100% kill of all viruses. Non-contaminated, non-laboratory waste, such as empty media bottles, is disposed of via the clinical waste stream for microwave treatment. Non-contaminated, non-laboratory waste (plastic/cardboard wrappings etc) is disposed with general waste for collection by cleaning staff.

Liquids (e.g. samples, culture supernatants, tissue culture media)
All used tissue culture media and other liquids are treated with 1.25% Trigene (or equivalent) for a minimum of 2 hours to inactivate virus prior to discharge to drains.

Sharps (in sharps bin, e.g. needles, syringes, scalpels, glass slides/cover-slips)
All sharps used are disposed directly into a sharps bin, then autoclaved using a make safe cycle as specified above prior to disposal via the clinical waste stream for incineration or microwave treatment.

Spill management
Liquid spills will be bordered and covered with Virkon powder for 30 mins until all liquid is absorbed and liquid is decontaminated before mopping up with plenty of water.

Additional waste disposal procedures for use of FMDV replicon.

All liquid and waste will be discarded directly into 1.25% Trigene (or equivalent) within the Class II cabinet and inactivated by overnight treatment prior to autoclaving.

**Project Additional Information**

**Purposes of the contained use**

*Pseudomonas aeruginosa* is a bacterium that is well known for quorum sensing: individual bacteria produce chemical signals that are detected by other bacteria. The aim of this project is to monitor the growth of colonies of *P. aeruginosa* cells, tracking their individual growth rates (ie fitness) and the spatial structure of the resulting microcolonies, using constitutively fluorescent strains. The induction of various gene expression responses (eg quorum sensing) will be tracked with fluorescent reporters. To achieve this we may need to use mutant strains in which one or more gene is deleted as well as reporter strains in which genes encoding fluorescence, luminescence or...
other standard reporter proteins have been incorporated.

Recipient or parental organism

Pseudomonas aeuginosa: we will use the wild-type laboratory strain PA01 and gene-inactivated derivatives, as well as clinical isolates from the sputum of healthy individuals or cystic fibrosis patients, and natural isolates from soil.

Host/vector system

The vectors will be non-hazardous, widely used and/or commercially available standard plasmid or phage vector systems, some of which confer resistance to standard antibiotics such as kanamycin, ampicillin, chloramphenicol. Where mobilisable (i.e. capable of being mobilised if in the presence of a vector which expresses the components needed for conjugal pilus synthesis and assembly) plasmids are used, they will only be used with a debilitated host or in a host which does not contain the necessary and appropriate set of genes for conjugation of the plasmid.

Origin & function

Inserted DNA will usually encode reporter genes such as green fluorescent protein, luciferase or beta-galactosidase.

We may also make mutants in key quorum sensing genes such as lasl, lasR, rhl, rhlR, pqsA, pqsH, pqsE, pqsR and other genes encoding extracellular products such as EPS and siderophores.

Some of the genetic modifications will result in resistance to antibiotic markers.

Evaluation of foreseeable effects

We do not expect the insertion of reporter genes into the host to alter the disease causing properties of the organism in any way.

Concerning the mutations in key quorum sensing genes, and gene encoding other extracellular products, all of these mutations are expected to reduce the number and amount of exported products such as enzymes, toxins and polymers. Since these products are associated with virulence, our mutations are predicted to decrease virulence. All of the mutants we propose to make have been made previously in other labs and none has been reported to increase virulence.

Although some of our modifications will result in resistance to antibiotic markers, we see no danger in the routine acquisition of resistance to laboratory antibiotics such as Tetracycline, Gentamycin, Chloramphenicol and Ampicillin with no clinical use. Ceftazidime and tobramycin are the mainstay of anti-pseudomonas treatment but ciprofloxacin and meropenem are also occasionally used. There is no expectation that cross resistance between laboratory markers and clinical antibiotics will occur. In addition the carriage of such markers often bears a fitness cost to the organism since its persistence requires the presence of the antibiotic.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

WASTE DISPOSAL PROCEDURES

Solids (e.g. plasticware such as pipettes, flasks, tubes etc and agar plates) - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or microwave treatment or via the industrial (black bag) waste stream for landfill.
Liquids (e.g. samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge to drains.

Sharps (in sharps bin, e.g. needles, syringes, scalpels) - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), dispose via clinical waste stream for microwave treatment.

Degree of kill:
- Autoclaving - effectively 100% kill (annual validation)
- Microwaving or incineration - not applicable, all waste is autoclaved prior to disposal by microwaving or incineration.

Project Ref 207/14.6

Date Ackn'd 25/09/2014
CU2 Project Title Viral transduction of mammalian cells in culture
Class 2
CultureVolClass2 < 1 Litre
Non-GMM Consent Granted

Date Project Ceased 02/03/2022
For many researchers, the method of choice for genetic alteration in mammalian cells is through viral transduction. In this regard, retroviral and lentiviral particles are particularly commonly-used vectors, with adenovirus and adeno-associated virus (AAV) also in use. None of these vectors are wild-type virus, nor are they replication competent. Therefore, in many cases they will be categorised as class 1, but in some cases they are class 2 and hence fall under this risk assessment. Guidance for classification of research at the IGMM has been obtained from the SACGM Compendium of Guidance.

The mammalian cells that we transduce in tissue culture are predominantly of very low risk. The majority are mammalian cell lines (e.g. HeLa, HEK293) that are well established, well characterised and available from commercial sources such as ECACC or ATCC. Primary mammalian cells are also used as recipient cells. Where these are from patients, they may also fall under separate COSHH risk assessments for ACDP Hazard Group 2 organisms.

The four viral vectors covered under this assessment are retroviruses, lentiviruses, adenovirus and AAV. Each vector is dealt with separately. Retroviruses & Lentiviruses insert into the host chromatin and, as such, are effective in promoting long-term expression of transgenes. In addition, a successful infection carries the risk of insertional mutagenesis. For potentially harmful inserts (e.g. oncogenes etc.), long-term expression of transgenes. In addition, a successful infection carries the risk of insertional mutagenesis. For potentially harmful inserts (e.g. oncogenes etc.), long term expression in a human subject could give rise to pathological outcomes and are considered class 2.

Adenovirus: because of the risk of escape of replication-competent virus, all adenoviruses are considered class 2. Recombinant AAV can integrate into the host genome, although the lack of the rep gene in the transfer vector renders this a very low frequency occurrence. Extensive studies (including clinical trials) have failed to observe insertional mutagenesis and so this poses negligible risk in a laboratory setting. However, long term episomal expression of inserts is often observed. Thus where inserts are of a potentially hazardous nature (e.g. oncogenes, cytokines, biologically active molecules etc.) these vectors are considered class 2.

In all cases the inserted genetic material is designed to have biological properties that could pose a risk to human health and safety. Likely factors to be introduced include oncogenes, sequences that lead to inactivation of tumour suppressor genes, gens involved in innate immunity and sequences that modify basic biology in many ways. For all of the viral vectors described below, expression of oncogenes, cytokines or other molecules that could have detrimental effects on cell or organismal function will be considered class 2. Inserts of unknown (and therefore potentially hazardous) function will be considered class 2.

Mammalian cell lines are highly sensitive to their environmental requirements and survive for very short periods outside the well-controlled tissue culture environment. The risks that these cells pose to the environment is negligible. And with the risks to human health, the inserts would have similarly detrimental effects if introduced into other
mammalian hosts. Some of the vectors used can infect multiple species of mammals and so a hypothetical route for environmental harm does exist. However, the control measures in place in the CL2 laboratory (including proper waste disposal) reduce that risk to a negligible level. The vectors in use are capable of infecting other mammalian species. An important safety feature of the viruses is that they are rendered replication-incompetent and this greatly limits their risk of causing environmental harm. In conjunction with the control measures in place in the CL2 laboratory, these vectors pose negligible risk to the environment. The transduced mammalian cells pose no more risk to the environment than their untransduced counterparts. In all cases, these cells present minimal risk to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**Historical Significant Changes**

- **Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

Wild type and recombinant plant RNA viruses will be used to study antiviral defence mechanisms in Arabidopsis thaliana, Nicotiana benthamiana, Solanum tuberosum and Brassica napus. In the process live virus particles of Potato virus X (PVX), Potato virus Y (Pvy), Turnip mosaic virus (TuMV), Tobacco rattle virus (TRY) and Cucumber mosaic virus (CMV) will be re-assembled in planta from cDNA and may be capable of spreading systemically. The viruses are non-pathogenic to humans or animals and do not present a health risk.

**Recipient or parental organism**

Standard marker genes such as GFP will be cloned into viral cDNAs to allow virus movement to be followed. In addition recombinant viruses will be engineered to carry an or part of the 35S promoter in order to investigate sequence requirements of virus-induced transcriptional gene silencing. Neither the expression of wild-type viruses in binary vectors, the insertion of GFP sequences or the use of the 35S promoter have been reported to increase the virulence of plant viruses. As such, these approaches do not pose additional risk compared to the use of viruses as they are found in nature.

**Host/vector system**
The methodology for the expression of the viral vectors will be by agroinoculation into the host plant (in which standard cloning and plasmid construction will be employed using well-characterised methods with a history of safe use) or by direct inoculation of virus particles into the plant.

**Origin & function**

GFP-tagged clones will result in expression of fluorescence of virus particles in vivo, enabling virus movement to be monitored. Replication of recombinant viruses will trigger the antiviral gene-silencing pathway in tobacco, resulting in virus specific sANAs and sequence-specific viral degradation. Virus-specific sRNAs may direct DNA methylation in the nucleus, thus silencing of the constitutive expression of the GFP reporter gene in N. benthamiana 16c will be monitored.

**Evaluation of foreseeable effects**

Neither the expression of wild-type viruses in binary vectors nor the insertion of GFP sequences have been reported to increase virulence. The well described phenomenon of virus induced gene silencing will occur in planta in all cases (Baulcombe 0.1999) and will ameliorate viral load and virulence. Standard marker genes such as GFP tags are not expected to have harmful physiological or pharmacological properties or to affect pathogenicity of cloning host. Resulting GMOs carry no additional hazards compared with the endemic pathogens already present in the environment. Any transfer of genetic material to other organisms would be of minimal hazard. GMOs would not survive outside laboratory conditions. The risk to plants, animals, humans or environment is negligible.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Growth of Agrobacterium constructs containing virus sequences will be in maximum 100 ml volumes and infiltrated into leaves by a 1 ml syringe-no aerosols will be created. An experimental solutions, materials or consumables used to grow or handle viruses will be autoclaved before disposal. Lab coats and disposable gloves will be worn for the handling of infected plants to prevent mechanical transmission. Transport of plants between growth facilities will be inside sealed plastic containers. In addition to the physical barrier that a glasshouse/growth rooms provides between cultured transgenics and the environment, the glasshouse/growth rooms are equipped with a filtered air system, which will prevent any pollen escape from the facility. Those plants that are allowed to flower for seed production will be bagged at the time of flowering. All plants will be grown using the systemic insecticide, Intercept 60WP, as a soil drench. This has been shown to be highly effective at controlling aphids under greenhouse conditions. All compost used within the glasshouse/growth rooms will be autoclaved before disposal, any wash-off from plants will be collected and treated with appropriate chemicals before disposal. All staff must follow the SOPs for the relevant areas, either the Rutherford Controlled Environment Rooms or the Transgenic Glasshouse. Copies of the SOPs are prominently displayed in the areas, and attached to this RA. Good Occupational Safely and Hygiene will be applied.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids (e.g. plasticware such as pipettes, flasks, tubes etc. and agar plates) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-1 300C for at least 10 minutes or
134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or heat treatment or via the industrial (black bag) waste stream for landfill.

Liquids (e.g. samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge to drains.

Sharps (in sharps bin, e.g. needles, syringes, scalpels) - dispose via clinical waste stream for heat treatment.

Waste residues that cannot be autoclaved, or cell culture waste will be inactivated by treatment with disinfectant: 1% Virkon solution for plasticware (soak for 2 hours), for treatment of minor contamination (10 min contact time) and surface disinfection (benches and floors); 2% for disinfection of liquid cultures and supernatants that cannot be autoclaved. Equipment that cannot be autoclaved will be disinfected as above; physically clean surfaces may be disinfected with 70% ethanol. Presept may be used as an alternative to Virkon: 1,000 ppm for general wiping of equipment and benches, 2,500 ppm free chlorine for discard containers/liquid cultures.

**SPILLAGES**

Particular care should be taken to ensure that others in the laboratory do not help with the clear up of accidental spillage (especially where there has been an accident that involves broken glass) unless they are aware of the potential risks and trained in safe working practices.

If spillage occurs, allow aerosols to settle and then working from the outside of the spill, apply powdered Virkon disinfectant to absorb liquids before mopping up with paper towels and disposing of all waste via autoclave waste stream.

02/03/2022
The purpose of our research is to determine the functioning and regulation of immune responses to ensure tissue homeostasis and immunity. So have we for instance shown that the Epidermal Growth Factor (EGF) receptor plays a central role for the functioning of the immune system and for the homeostasis of inflamed tissues. The quality of EGF-R induced signals is dependent on the type of ligand that binds to the receptor. Different EGF-R ligands are expressed under distinct inflammatory conditions and we argue that the state of inflammation is linked via the EGF-R directly to the phenotype of local cell populations. Several pathogens have recognized this specific link and have targeted it as a means of immune escape. To address these different aspects we would like to use in vivo infection models. The chosen pathogens appear particularly suited for such a study, since they have become standard infection models for immunologists, the immune responses upon infection have been studied extensively, and the pathogen-specific immune responses can be quantified in very precise ways. In order to facilitate our research, these pathogens are often gene-deficient for specific genes (attenuated) or express model antigens (such as for instance different forms of ovalbumin) or express fluorescence or enzymatic reporter genes.

The recipient or parental organism

The used pathogen can infect human beings and each of these pathogens could potentially cause severe infections: Listeria monocytogenes is an opportunistic pathogen that gives rise to extremely rare cases of food poisoning. However, in the elderly, in neonates and among immune-compromised individuals it can cause severe disease, e.g., meningoencephalitis or septicemia. Listeria monocytogenes also poses an additional risk to pregnant women and their unborn child as it actively travels through cells and, therefore, can be transmitted from a mother to the foetus.
Transplacentally and may result in abortion or stillbirth. Thus, the spread of L. monocytogenes away from our working places has to be restricted as good as somehow possible and all work with L. monocytogenes will be handled with Good Microbiological Practice and Good Occupational Safety and Hygiene at containment Level 2. Nevertheless, the greatest risk when working with L. monocytogenes is infection via pricking of the skin by contaminated sharp objects. Therefore, it is advisable to use cut-resistant gloves during injection of the bacterial suspension into mice. Upon accidental infection, simple treatment with antibiotics, such as Ampicillin, will rapidly clear the bacterium from the infected person. Pregnant women are advised not to carry out this work due to the possible risks. A separate risk assessment to be completed if they still wish to participate in this research.

Vaccinia virus (VACV) VACV is the live vaccine used to eradicate smallpox and is the prototype orthopoxvirus. During its wide usage as a vaccine, it became apparent that some complications in a small fraction of humans can occur. Possible clinical signs in humans include: Locally: 3-4d post inoculation: papule IS-6d: pustule 18-9d: well-formed pustule / 12d+: scab 117-21 d: scar. Mild systemic illness can accompany the localised reaction, including lever and malaise. Therefore, all work with VACV will be handled with Good Microbiological Practice and Good Occupational Safety and Hygiene at containment Level 2. Vaccination is possible and highly protective. Pregnant women or immune-compromised individuals (e.g. the elderly, those infected with HIV or those taking immune-suppressive drugs such as systemic corticosteroids, alkylating agents or antimetabolites) are advised not to carry out this work due to the possible risks. VACV may also cause complications in people with active skin disorders such as significant eczema or psoriasis. Therefore also individuals with these types of disorders are advised not to carry out this work due to the possible risks. A separate risk assessment to be completed if they still wish to participate in this research.

Influenza virus: Influenza infections can lead to high fever and can be lethal. Nevertheless, the viruses being handled are closely related to currently circulating human viruses and mouse attenuated Influenza strains have lost the capacity of infecting uninjected lillermals and transmission to humans is highly unlikely. Thus, taken together, the used strains have no realistic potential to develop into pandemic strains. Further can be expected that all individuals have naturally been exposed to Influenza viruses that confer protection against the experimentally used strains.

Vaccination with formalin inactivated virus particles is highly effective and transmits full protection. Pregnant women or immune-compromised individuals (e.g. the elderly, those infected with HIV or those taking immune-suppressive drugs such as systemic corticosteroids, alkylating agents or antimetabolites) are advised not to carry out this work due to the possible risks. A separate risk assessment to be completed if they still wish to participate in this research.

The official guidelines for work using Influenza viruses: http://www.hse.gov.uk/biosafety/diseases/acdpflu.pdf has been studied extensively and all our statements are in accordance with these guidelines.

No new recombinant organisms will be created, but existing GM will be imported and used. Typical examples of vector transmissions into the genome of the pathogens are described in the publications stated in the accompanying risk assessment for the individual pathogens.

In brief, for most recombinant Listeria strains (exception for Lm-E1 strains) stable insertion into the bacterial genome was based on transfection with shuttle vectors such as pH5-LV, pAT29, pLSV16 and similar vectors.

Introduction of vectors into viral genomes was normally achieved by co-transfection into virus-infected cells and thus by reverse genetics. Recombinant viruses were then selected by either clonal selection or plaque assays in the presence of selection markers, such as Mycophenolic Acid, xanthine and hypoxanthine.

Vaccinia: pSJH7, that contains the E. coli guanine phosphoribosyl transferase (Ecogp) gene linked to a VACV promoter, flanked by DNA fragments of the viral gene of interest, as well as similar vectors

Influenza: pT3-WSN, pM-PR8-NA-2A- based and similar vectors pH5-LV or pLSV16.
In most cases (please see note 2), the used vectors will have already been deleted in those pathogen strains we receive. Of the remaining parts of the vectors, no harmful properties can be expected.

Of note 1: The different bacterial strains carry antibiotic selection markers such as for Erythromycin (Lm-OVA), Kanamycin (Lm-gp33) or Spectinomycin and Chloramphenicol (Lm-E1). Nevertheless, none of the bacterial strains are resistant for Ampicillin, which is normally used to treat Listeria-infected patients.

Of note 2: The Lm-E1 strains still contain the pAT29 vector that confers Spectinomycin-resistance.

Origin & function
The recombinantly expressed antigens are:
(i) Typical immunological model antigens, which include (but are not restricted to) ovalbumin, hen egg lysozyme or other recombinant forms of model antigens.
(ii) Reporter genes, which include (but are not restricted to) enzymatic reporters, such as ~galactosidase, luciferase, or fluorescent reporter proteins, which include (but are not restricted to) GFP, YFP and derivatives of these.
(iii) Other well-characterised, non-harmful marker genes may also be used.

Evaluation of foreseeable effects
The used pathogens are infectious for humans and can cause disease even in healthy humans. The performed gene manipulations can be expected to induce no greater risk than the wild type strains they were derived from. In most situations, these gene modifications lead to an attenuation of the resulting pathogen. No harmful properties can be expected from the inserted genetic material and its products.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

WASTE DISPOSAL PROCEDURES
Solids (e.g. plastic-ware such as pipettes, flasks, tubes etc. and agar plates) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-1300C for at least 10 minutes or 134-1380C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or heat treatment or via the industrial (black bag) waste stream for landfill.

Liquids (e.g. samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-1300C for at least 10 minutes or 134-1380C for at least 3 minutes), discharge to drains.

Sharps (in sharps bin, e.g. needles, syringes, scalpels) - dispose via clinical waste stream for heat treatment.

Waste residues that cannot be autoclaved, or cell culture waste will be inactivated by treatment with disinfectant 1%

Virkon solution for plastic-ware (soak for 2 hours), for treatment of minor contamination (10 min contact time) and surface disinfection (benches and floors); 2% for disinfection of liquid cultures and supernatants that cannot be autoclaved. Equipment that cannot be autoclaved will be disinfected as above; physically clean surfaces may be disinfected with 70% ethanol. Presepl may be used as an alternative to Virkon; 1,000 ppm for general wiping of equipment and benches, 2,500 ppm free chlorine for discard containers/liquid cultures.

SPILLAGES
Particular care should be taken to ensure that others in the laboratory do not help with the clear up of accidental spillage (especially where there has been an accident that involves broken glass) unless they are aware of the potential risks and trained in safe working practices.

If spillage occurs, allow aerosols to settle and then working from the outside of the spill, apply powdered Virkon disinfectant to absorb liquids before mopping up with paper towels and disposing of all waste via autoclave waste stream.

Project notified under transitional arrangements  
- No
This work aims to understand how the genetic information stored on DNA and packaged into chromosomes is transmitted to the next generation. To understand how the molecular mechanisms segregating chromosomes are conserved in evolution, we need to compare these processes in different species. To complement our current work using Saccharomyces cerevisiae and Schizosaccharomyces pombe, we will characterize chromosome segregation in Candida spp. Candida spp. have a similar genome organisation to Saccharomyces cerevisiae, though some chromosomal features are more similar to those of Schizosaccharomyces pombe. Combining work on Candida spp. will allow us to understand how the chromosome segregation process has diverged in these species.

To do this work, we will tag the endogenous proteins with an epitope tag which will allow us to use antibodies to immuno-precipitate the protein, find its binding sites on chromosomes and determine its subcellular localization. We will delete genes and test their function on chromosome segregation processes.

Recipient or parental organism

(Candida spp. as obtained from the National Yeast Resource Centre (Disabled, partly disabled or wild-type).
C. albicans is a human pathogen in ACDP Hazard Group 2. C. albicans causes superficial infections of mucosal epithelia (thrush) (Odds [1988] Candida and Candidosis, Balliere Tindall). C. albicans can also cause systemic infections which can be fatal, but these only occur in severely immunocompromised patients. C. albicans is carried commensally at least 60% of the healthy population and most Candida infections arise as an overgrowth of the strains resident in the normal microflora. It is a micro-organism of low pathogenic potential that rarely affects healthy individuals. It only becomes a potential medical problem when an individual's immune responses are significantly impaired. Furthermore, as with most pathogenic micro-organisms, the virulence of C. albicans strains is likely to become attenuated rather than enhanced after prolonged laboratory culture.
The C. albicans strains CAI4 (ura3), CAI8 (ura3, ade2), RMT000 (his1, ura3) and BWP17 (arg4, hist, ura3) are the standard hosts for DNA transformation world-wide. These auxotrophies make C. albicans avirulent (Leberer et al. (1996) PNAS, 93, 13217). Transformation with URA3 plasmids partially restores the virulence of CAI4, but this restoration is not complete because the genes neighbouring URA3 remain inactivated. This is enough to attenuate virulence partially (but not completely). Furthermore, C. albicans strains that have been cultured in the laboratory tend to display reduced pathogenicity compared to strains carried commensally by most individuals.
C. glabrata is a haploid yeast which is non-dimorphic (takes only one non-filamenleous form). It is considered part of the normal flora of healthy individuals and has generally been considered non-pathogenic. Recently, however, it has been recognised as a human pathogen in immunocompromised individuals [Bolotin-Fukuhara and Fairhead, 2014].
As for C. albicans, we will use auxotrophic laboratory strains to reduce their pathogenicity [Schwarzmuller et al., 2014].

In most experiments, disabled hosts will be used although a small number of experiments may require the use of nondisabled
hosts.

(ii) Standard disabled E.coli strains

**Host/vector system**

(i) Specific non-mobilisable C. albicans vectors (low copy replicating and integrating vectors (YPB1, Clp1 0, Clp20, Clp30); low copy replicating and integrating vectors for ectopic expression [YPB-ADHpt, pACT1 j; integrating expression vectors regulated by methionine (MET3 promoter), maltose [MAL2 promoter], glucose [PCK1 promoter], or doxycycline [tet ON promoter and tet OFF promoter]
(ii) Non-mobilisable E. coli vectors (including pUC18/19, pBluescripl, pGEM-T; lac-based expression plasmids such as pET vectors).

**Origin & function**

This work will target cell division processes including cell cycle control and chromosome segregation control. Pathogenicity in C. albicans is a polygenic trait involving numerous physiological characteristics (e.g. rapid growth, cell wall, morphogenesis, secreted hydrolases, phenotypic switching). Therefore, (i) no single C. albicans gene (or combination of genes) will turn E. coli into a pathogen, (ii) a reduction in anyone of these parameters can attenuate C. albicans virulence, and (iii) an increase in anyone of these parameters is highly unlikely to increase C. albicans virulence.

The Candida spp. transformations we will perform will inactivate a specific target gene to create a null mutant. These transformations will be performed in multiple disabled Candida spp. strains (e.g. combinations of trpl, ura3, ade2, arg4, or his l ) to ensure that all transformants are avirulent. In none of the cases we will be studying is this likely to increase virulence, instead transformants will always carry a disabling mutation, thereby rendering them completely avirulent. No null mutations have been described that increase the virulence of Candida spp.

In some experiments, we will express specific genes in C. albicans ectopically using a MET3, MAL or tet promoter. In these experiments, the expression level is not maximised. Their ectopic expression levels will be <1 % of total cell protein. The ectopic expression of most specific genes is unlikely to affect virulence at all, and in some cases it will be expected to reduce C. albicans virulence by adversely affecting growth. The key point is that the probability of increasing virulence by ectopic expression of a single gene is very low, because pathogenicity is complex and polygenic trait requiring a high level of fitness of the C. albicans cell (Odds (1994] ASM News, 60, 313). Indeed, there is evidence that ectopic expression of factors involved in virulence traits does not increase virulence (Bailey (1 997) PhD thesis, University of Aberdeen; Leng [1999] PhD thesis, University of Aberdeen; Rodaki et al. [2006]).

**Evaluation of foreseeable effects**

Our experiments will be performed on disabled or partially disabled Candida strains and the mutations that we will generate will most likely render them completely avirulent. Likewise, the ectopic expression of most specific genes is unlikely to affect virulence at all, and in some cases it will be expected to reduce C. albicans virulence by adversely affecting growth.

Candida species have no effective mechanism for horizontal gene transfer that might allow dissemination of resistance traits. The likelihood of natural gene transfer to other species is essentially zero. Furthermore, despite the recent discovery of sex in C. albicans, the risk of transfer between C. albicans strains is very low. This is because C. albicans strains mate very inefficiently in vivo (Hull et al., (2000) Science 289, 307-310), probably because the specific growth forms that mate most efficiently aren't maintained at 37°C (Miller & Johnson (2002) Cell 110, 293-302). In addition, C. albicans must be homozygous at the mating type locus for them to be competent for mating, and the vast majority of clinical isolates are heterozygous at the mating type locus.

The genetic modification safety committee agreed that the appropriate containment and control measures have been assigned.
This work will involve the culturing of trypanosomes (Trypanosoma brucei) in vitro, generation of transfected parasite lines that express fluorescent proteins, and infection of mice with trypanosomes (either derived from culture or in mouse blood) via intraperitoneal, intravenous, subcutaneous or intradermal needle inoculation.

The aims are to:

a) Generate and maintain trypanosome cell lines that stably express fluorescent proteins at a level enabling visualisation in vivo.

b) Amplify trypanosome population in mice from tissue culture or cryostabilated infected mouse blood in order to...
generate a population of viable parasites adapted to in vivo conditions (Le. tissue culture parasites have adapted to in vitro medium, and cryostabilated parasites are variably viable), for the purposes of extracting parasites in order to initiate viable infections in further mice.

c) Analyse the infection dynamics of trypanosome infections, in particular the interaction between parasites and host immune cells at the inoculation site (s kin) and draining lymph nodes.

Recipient or parental organism

T. brucei STI8247

For T. brucei, while some subspecies are human infective, the strain to be used in this laboratory, T. brucei ST18247, has been confirmed by collaborators on multiple occasions to be non-human infective (by assays including incubation with human serum and recombinant serum lytic components, e.g. Capewell et al, 2011, PLoS NTD, 5, e1287). It is extremely unlikely that introduction of transgenes for fluorescent proteins will alter this phenotype.

This strain will, if inoculated into the bloodstream, initiate infections and potentially cause disease in non-primate mammalian species. T. brucei is a SAPO 2 class organism. Trypanosomes will only survive within mammalian (nonhuman or non-primate) hosts or relevant vectors (tsetse flies, which are not endemic to the UK, and some mechanical vectors such as Tabanid flies) - they rapidly die when not in these contexts, and therefore represent minimal environmental risk. If inoculated into susceptible mammalian hosts by mechanical transmission (i.e. insect vector or syringe) the parasites may cause infection and disease, but if these transmission routes are controlled then the risk of this is minimal. T. brucei is an animal pathogen exotic to the UK and is a SAPO-listed organism, and SAPO regulations will therefore pertain to all trypanosome or trypanosome-derived waste.

Host/vector system

The expression construct backbone is T. brucei sequence (comprises PCR products of target genes, plus flanking regulatory sequences, as well as a selectable marker - puromycin resistance gene - these are initially ligated into bacterial plasmids for amplification in bacteria, then the plasmid is extracted, linearised and relevant sequences isolated by restriction enzyme), which enables integration of sequence into the target locus by homologous recombination (trypanosomes will not maintain plasmids or similar extrachromosomal DNA constructs).

Origin & function

The proteins expressed by the transgenic proteins (GFP and mCherry) are fluorescent reporter genes that have been widely used in multiple organisms. In the lines used here, the proteins are expressed in their native forms and are simply used to enable visualisation of the trypanosomes (i.e. are not fused to any other protein whose function or expression level may influence other phenotypes). There is no evidence from other systems that the expression of these proteins in this form alters pathogenicity, and it must be considered extremely improbable that this manipulation will influence the phenotype of human infectivity. Puromycin resistance is equally unlikely to impact on human infectivity.

Evaluation of foreseeable effects

The pathogenicity of the transgenic parasites in the mouse model is unlikely to be affected by the genes inserted, and particularly so with regards to human infectivity. The transgenic parasites will represent minimal potential environmental hazard to human or animal health.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

## Project Additional Information

### Purposes of the contained use

To understand the molecular mechanisms underpinning genome regulation by RNA interference and chromatin modification in Cryptococcus neoformans.

**Objectives:**
1. Identify proteins involved in mediating and regulating RNA interference and chromatin modification
2. Characterise the molecular functions of these proteins
3. Determine the biological functions of these pathways in genome regulation

We will employ a combination of genetic, molecular and biochemical approaches. DNA from C. neoformans will be expressed from episomal plasmid vectors in C. neoformans, S. pombe, S. cerevisiae and E. coli to allow further analysis of expressed proteins. C. neoformans genes of interest will be disrupted by insertion of specific selectable markers such as bacterial drug resistance cassettes (e.g. the nat1 gene from Streptomyces noursei, conferring resistance to nourseothricin, or the Hph gene from Klebsiella pneumonia, conferring resistance to hygromycin B). Some manipulations will involve the introduction of specific DNA elements from other sources e.g. Aequorea victoria green fluorescent protein (GFP), in order to tag proteins of interest to permit either affinity purification or visualisation.

### Recipient or parental organism

Cryptococcus neoformans var neoformans and Cryptococcus neoformans var gattii (wild-type or auxotrophic mutants) have been assigned to ACDP hazard group 2. They are opportunistic pathogens that can infect humans causing...
diseases including meningoencephalitis and pulmonary cryptococcosis, predominantly in immunocompromised individuals. Spores or desiccated yeast cells enter the respiratory tract by inhalation. C. neoformans var neoformans and var gattii are also potential allergens. C. neoformans var neoformans and var gattii are found naturally in the environment, in particular in soil, decaying vegetation and avian guano, and can infect various domestic and wild animals via spore inhalation.

Saccharomyces cerevisiae and Schizosaccharomyces pombe (yeast strains are multiple auxotrophs and are unlikely to survive outside of the culture media) have been assigned to ACDP hazard group 1.

Escherichia coli K12 or 8 derivatives (disabled) which cannot colonise the human gut

E. coli, S. pombe and S. cerevisiae strains to be used have no harmful effects to plants or animals

Host/vector system

Vectors are based on standard plasmids that are well-characterised and non-hazardous. The plasmid vectors that will be used are based on the bacterial pBS, pSr and pUC plasmids and their derivatives, many with the addition of sequences required for replication and selection in the host. These include pET and related vectors for expression in E. coli, pGAD/pGBK yeast-2-hybrid vectors for S. cerevisiae, the pRep series of vectors and derivatives for expression in S. pombe, and pCnTel and derivatives for expression in C. neoformans, as well as other fungal related plasmids known to drive expression in Cryptococci.

Origin & function

Inserts including genes involved in RNAI and chromatin modification and standard selection markers are not expected to have any harmful physiological or pharmacological properties or to affect infectivity or pathogenicity of the recipient host (RNAI and chromatin modification genes are not thought to be involved in pathogenicity, and drug resistance cassettes used do not confer resistance to drugs used in treatment of C. neoformans infection).

Evaluation of foreseeable effects

Resulting GMMOs are not expected to pose any additional risks to human health and safety compared to the unmodified recipients. The resulting GMMOs pose no additional risks compared to those already present in the environment. The risk of transfer of genetic material to other organisms is very low and would be of minimal hazard.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

The genetic modification safety committee agreed that the appropriate containment and control measures have been assigned.
Our aim is to gain a better understanding of molecular mechanisms that allow Listeria monocytogenes (Lm) to invade and to replicate in eukaryotic host cells. Standard cell culture systems are used to analyse how Lm gains entry into different types of eukaryotic cells (e.g. macrophages, epithelial cells), how the bacterium evades the innate immune response and how it replicates in the cytosol and spreads to neighbouring cells. For these analyses we will make use of Lm strains that carry stably integrated fluorescent or bioluminescent marker genes in their chromosome. The project will also make use of mutant Lm strains in which known virulence factors for cellular invasion/replication/cell spreading are inactivated by genetic modification. In vivo infection challenge experiments in mice (wild type and transgenic mouse strains) will analyse the virulence capacity of different Lm strains, mechanisms of host cell tropism and immunological host responses that are involved in pathogen host defence. The objective of this work is to improve our understanding of protective host responses, of pathogenesis mechanisms associated with listeriosis, and to develop vaccines that optimise immunological memory responses in the host. To investigate if identified host defence responses are specific for Lm, infection experiments will be carried out with other bacterial pathogens (e.g. wild type Staphylococci (GM207 05.2, GMt 0/07) and Streptococci (BAI 0414) to compare experimental outcomes. This project will also use eukaryotic expression systems to express reporter tagged (e.g. Flag, GFP) host cDNAs in mammalian cell lines and primary cells. It is not intended to generate new immortalised cell lines in the project. Expression systems will be also used to ablate the function of cellular host genes (e.g. expression of siRNAs or CRISPR/Cas9 constructs). The objective of these experiments is to characterise the function of host genes in innate pathogen defence and/or induction and maintenance of inflammatory responses.

### Project Additional Information

#### Purposes of the contained use

Our aim is to gain a better understanding of molecular mechanisms that allow Listeria monocytogenes (Lm) to invade and to replicate in eukaryotic host cells. Standard cell culture systems are used to analyse how Lm gains entry into different types of eukaryotic cells (e.g. macrophages, epithelial cells), how the bacterium evades the innate immune response and how it replicates in the cytosol and spreads to neighbouring cells. For these analyses we will make use of Lm strains that carry stably integrated fluorescent or bioluminescent marker genes in their chromosome. The project will also make use of mutant Lm strains in which known virulence factors for cellular invasion/replication/cell spreading are inactivated by genetic modification. In vivo infection challenge experiments in mice (wild type and transgenic mouse strains) will analyse the virulence capacity of different Lm strains, mechanisms of host cell tropism and immunological host responses that are involved in pathogen host defence. The objective of this work is to improve our understanding of protective host responses, of pathogenesis mechanisms associated with listeriosis, and to develop vaccines that optimise immunological memory responses in the host. To investigate if identified host defence responses are specific for Lm, infection experiments will be carried out with other bacterial pathogens (e.g. wild type Staphylococci (GM207 05.2, GMt 0/07) and Streptococci (BAI 0414) to compare experimental outcomes. This project will also use eukaryotic expression systems to express reporter tagged (e.g. Flag, GFP) host cDNAs in mammalian cell lines and primary cells. It is not intended to generate new immortalised cell lines in the project. Expression systems will be also used to ablate the function of cellular host genes (e.g. expression of siRNAs or CRISPR/Cas9 constructs). The objective of these experiments is to characterise the function of host genes in innate pathogen defence and/or induction and maintenance of inflammatory responses.

### Recipient or parental organism

(i) Listeria monocytogenes (WT, gene inactivated derivatives, expressing fluorescent or bioluminescent reporter genes). Listeria monocytogenes (Lm) is widely distributed in the environment where it can be isolated from multiple sources such as human and animal faeces, soil, water, plants and food. The vast majority of human Listeria infections are foodborne in which the pathogen is transmitted to humans through consumption of contaminated food. A rare cutaneous form of listeriosis can occur as a result of a zoonotic transmission of Lm from an infected animal into human skin lesions (concerns certain occupational groups such as veterinarians and farm workers). Cutaneous listeriosis presents clinically with development of papular or pustular lesions in infected skin areas that can be easily treated with antibiotics.

Foodborne listeriosis is a rare but life-threatening disease if certain high-risk groups of patients get infected. Such vulnerable individuals have often predisposing conditions which make them immunocompromised and susceptible to invasive listeriosis. Examples of immunocompromised, high-risk patients are individuals infected with HIV, cancer patients on chemotherapy, patients with chronic diseases affecting immune functions (e.g. hepatitis, chronic lymphocytic leukemia), and the elderly. Severe invasive listeriosis is often associated with sepsis (bacteraemia).
meningitis, and meningoencephalitis. Foodborne Lm infections in healthy persons are usually mild and self-limiting and may cause febrile gastroenteritis with no other complications. Symptoms of febrile listerial gastroenteritis may include diarrhoea, fever, headache and myalgia.

Another specific risk group of Lm infections are pregnant women. Due the capability of the bacteria to pass the blood-placenta barrier, listerial infections may cause foetal loss (spontaneous abortion) or neonatal bacteremia and meningitis in new born babies.

Health and Safety

Executive

The approximate infective (oral) dose of L. monocytogenes is estimated to be 10^7 to 10^10 colony forming units (CFU) in healthy persons, and 10^5 to 10^7 CFU in individuals of high-risk groups (PMID: 19812983; PMID: 8988887). Listeria monocytogenes is an ACDP hazard group 2 organism and will be handled under containment level 2 conditions as specified in an associated BA1 risk assessment (Roslin Institute BA1 0215). This project will mostly make use of already established genetically modified Listeria monocytogenes (Lm) strains. The biological characteristics of these Lm GMO are outlined below. These GMO strains have been widely used in the Listeria research field and are all well characterized (see references for the specific Lm strains listed below). In rare cases, we will genetically modify Lm strains to integrate fluorescent protein reporter genes (e.g. derivatives of green or red fluorescent proteins (GFP, RFP)) into the bacterial genome. Reporter genes will be inserted into well-defined loci in the listerial genome. It is not expected that such genetic modification will increase the pathogen virulence in any way. These strains will be used for bioimaging and analysis of infection phenotypes in cell cultures and experimentally infected mouse strains.

Established Lm strains with genetic modifications and biological effects of introduced mutations:

- Listeria monocytogenes Xen32, lux operon tagged derivative of the parental strain Lm 10403s. This strain is bioluminescent and attenuated in mouse infection models (PMID: 23856386). It expresses the harmless bacterial luciferase and biosynthetic enzymes for synthesis of luciferase substrates from Photobacterium luminescens (PMID: 18370150).

- Listeria monocytogenes EGO-lux EGD::pPL2luxP helB, bioluminescent strain, lux operon tagged derivative of the parental strain Lm EGO. Translational fusion of the listeriolysin promoter hylA with the lux operon (luxABCDE) from Photobacterium luminescens. Constitutive expression of high levels of luminescence, no other phenotype (PMID: 17351089).

- Murinised Listeria monocytogenes strains of parental Lm strains EGOe, 10403s, and Xen32 expressing a modified internalin A gene (InIA) with two amino acid substitutions (Ser92Asn and Tyr369Ser) that allow enhanced binding of InIA to the murine E-cadherin protein. These strains show efficient crossing of the murine intestinal barrier after oral inoculation of mice (PMID: 17540170, PMID: 23617550, PMID: 23856386).

- Listeria monocytogenes rLM-Ova expressing the harmless chicken ovalbumin (OVA) under the listeriolysin 0 (LLO) promoter hylA. This strain will be used for characterisation of T cell responses against Lm in mouse infection experiments (PMID: 11207297).

- Listeria monocytogenes .1.actA, this strain carries a deletion in the actA gene, a virulence factor needed for host actin polymerisation and spreading of Listeria to neighbouring cells. The LactA mutant is heavily attenuated in virulence in mouse infection models (PMID: 1739966, PMID: 23382675).

- Listeria monocytogenes .1.hylA, this strain is deficient of listeriolysin 0 (LLO), a pore-forming toxin needed for bacterial escape from the host phagosome. The .1.hylA mutant demonstrates drastically reduced virulence in mouse infection models (PMID: 250936, PMID: 3138189).

- Listeria monocytogenes strain L028 .1.mdrT, the L028 strain is a commonly studied laboratory strain of Lm which...
carries a naturally occurred mutation which leads to overexpression of the cycI-ic-di-adenosine monophosphate (c-diAMP)-secreting efflux pump MdrT (PMID: 22290148). This upregulation of the MdrT efflux pump leads to induction of strong type I interferon responses in murine macrophages. For the project we will use for control experiments a L028 Lm strain with an intragenic deletion within the mdrT gene. This mutant is unable to induce c-di-AMP stimulated type I interferon responses in mice (PMID: 24970844).

Listeria monocytogenes that will be used in this project is widely distributed in the environment, is not exotic to the UK, is not pathogenic to plants, and does not cause notifiable diseases under specific surveillance by DEFRA. Listeria monocytogenes is a zoonotic pathogen and may cause infections in ruminants and companion animals. These bacteria are ubiquitous in the environment and spontaneous infections in animals occur rarely. The pathogenic mechanisms of L. monocytogenes for animals are the same as for humans and therefore all the conclusions reached in the above sections in relation to the possible hazards to human health are also valid for their potential animal hosts.

The loss-of-function mutations described above for GM L. monocytogenes strains are in most cases in-frame deletions, which do not leave any trace of foreign DNA in the listerial genome. Mouse infection challenge experiments have demonstrated that all of the above described GM listerial strains are strongly attenuated in virulence in vivo. They will compete less well within any animal host and will be cleared from the infected tissues sooner than the wild type. The risk of pathogenicity is therefore reduced when compared with the corresponding wild type parental strain. Consequently, in an unlikely scenario that these gene-disabled GMM are accidental released into the environment, they are not expected to displace any indigenous wild type L. monocytogenes due to a reduction in fitness.

(ii) Escherichia coli

Escherichia coli K-12 and B strains are used for regular cloning experiments in the laboratory. They are disabled, unlikely to survive out with laboratory conditions and with no known capacity to cause human disease. These strains will be used for the cloning of eukaryotic host genes as specified above. E. coli K12 or B strains harbouring fragments or full-length eukaryotic genes will not pose any risk on human health as oncogenes or proto-oncogenes will not be propagated. In rare occasions we will use E. coli laboratory strains to clone targeting vectors for the insertion of fluorescent reporters (e.g. GFP, RFP) or antibiotic selection markers into the listerial genome. These selection markers I reporter genes will not affect the virulence of the host bacterium and therefore will not have any harmful effects on human health. E. coli K-12 and B strains are assigned to ACDP hazard group 1.

(iii) Mammalian cell lines:
Human: HeLa, THP1, HEK 293, A549, CaC02, HaCaT, Cos7
Rodent: J774, RAW 264, CT-26

(iv) Primary murine cells from SPF mice:
Mouse embryonic fibroblasts (MEFs) and Bone marrow-derived macrophages (BMDM)

The likelihood that eukaryotic genes with potential immune modulatory functions will be expressed with eukaryotic expression systems is low. Nevertheless, all such experiments will be carried out under CL2 containment conditions which will prevent environmental release. In the extreme unlikely event that environmental release should occur, the risk to human health can be regarded as very low or effectively zero.

The likelihood of accidental environmental release of the GMMs is very low or negligible, given the measures that will be applied to control any risk to human health and safety (Level 2 containment). In the extreme unlikely event that environmental release would occur, the environmental risk can be regarded as very low or effectively zero.

Host/vector system

The cloning vectors will include many different types that have been developed for molecular biological purposes of propagation in E. coli or Listeria including: pAUL-A Tn4001 luxABCDE, pPL2luxPhelp, pUC series-based vectors, pBR322, pTOPO, and pBluescript II and derivatives of all of these.
Typical vectors used for expression or targeting in mammalian cells include pIRES2EGFP, pCDNA3.1, pDONR-207, pENTR-11, pYFP-DEST, pCFP-DEST, pTH2-Halo Tag, pCMV-Tag1, pHA, pEGFP-N1, pSPCas9 or derivatives of these. Additional novel plasmid vectors may be used as they become available.

All these vectors are non-mobilisable or mobilisation-deficient. The resistance genes used in these vectors have been approved for use at containment level 1 and confer resistance to gold ~ antibiotics for which resistance in clinical isolates is already widespread (and therefore are no longer used in clinical practice). The selection markers I reporter genes to be used are unlikely to cause any harm to human health.

Insertion of antibiotic resistance cassettes in order to disrupt specific genes will confer resistance to that antibiotic. The antibiotic profile of the new generated GM L. monocytogenes strain will be known so that in the unlikely eventuality of an accidental listerial infection caused by a particular GM strain appropriate treatment can be advised. Fluorescent reporter genes might be integrated into the listerial genome in order to make the bacteria amenable to bio imaging. The various reporter genes are commonly used (e.g. red or green fluorescent proteins) and are well characterised and non-harmful. Therefore, the virulence of the new GM listerial strain should not be affected.

Therefore such modified organisms are not expected to represent an increased risk to human health when compared to the wild type equivalent.

Eukaryotic host genes that will be cloned in E. coli laboratory strains or targeted or expressed in mammalian cell lines will not cause additional risk to human health. Examples of such eukaryotic host genes are genes encoding pathogen pattern-recognition receptors, signal transduction proteins, or genes induced or suppressed by cytokines (e.g. tumour necrosis factor a, interferon ~)

Typical examples of such genes are:
- Toll-like pattern recognition receptors
- NLR/Nod-like inflammasome components
- AIM2-like inflammasome receptors
- RNA-helicases
- NF-KB and IRF3/7 signalling components
- JmjC domain containing dioxygenases
- STING pathway DNA-sensing molecules
- Interferon stimulated genes (ISGs) or Interferon-induced genes (IFIS))

Sources of these eukaryotic genes may be genomic DNA or cDNA from different mammalian (e.g. human, mouse, swine, cattle) or avian species (e.g. chicken). We do not anticipate that these potentially immune modulatory genes create a risk to health if introduced and expressed in a human host. We also do not anticipate resulting function of such genes to be toxic or allergenic. Nevertheless, any biomaterial generated from such eukaryotic expression experiments will be treated as potentially hazardous. Experiments will be carried out in CL2 containment laboratories and the generated waste will be appropriately inactivated.

The genetic donor material that will be used has no hazardous potential. This project will not clone or propagate vectors with listerial DNA that may encode bacterial virulence factors. All used inserts will be non-pathogenic and will not be able to cause adverse effects in an unlikely scenario of natural transfer to other organisms.

All antibiotic resistance markers introduced are specific for antibiotics which are not in routine use for the treatment of listerial infections. The main antibiotics used for the treatment of listerial infections are ampicillin, amoxicillin and an aminoglycoside drug (usually gentamicin) and combinations of these drugs (PMID: 24822197). So in the unlikely eventuality of escape and infections occurring the normal treatment protocols would be still effective. Erythromycin resistant listerial strains exist in nature. So a very unlikely escape of the L. monocytogenes rLM-Ova strain from containment level 2 conditions would therefore not introduce a novel phenotype into the environment.
The L. monocytogenes gene knockout derivatives, in which one or more genes are inactivated, will normally be attenuated and less fit to spread in vivo in the event of an accidental infection. However, if the targeted genes play none- or only a minor role in virulence, the deletion mutants will retain the virulence of the parental wild-type strain. Therefore, all of these deletion mutants will need to be handled under the same containment level as the parental strain (i.e. containment level 2).

For example, the attenuated L. monocytogenes GMO strains (6.actA, 6. hly) are mutated derivatives which lack critical virulence genes and have lost their host-colon ising properties. They can be considered to be non-pathogenic but will be nevertheless handled under containment level 2 conditions. The introduced mutations are intragenic deletions with no foreign donor DNA left in the listerial genome.

L. monocytogenes rLM-Ova expresses and secretes the non-pathogenic chicken ovalbumin (OVA). The OVA-albumin expression cassette also carries resistance to the antibiotic erythromycin to allow selection of L. monocytogenes harbouring the expression cassette. However, the standard treatment of listeriosis includes ampicillin and an aminoglycoside drug and the listeria monocytogenes we would use is sensitive to the standard treatment antibiotics (PMID 10471548). There are naturally occurring erythromycin-resistant listeria strains in the UK, but these strains are sensitive to other relevant antibiotics (PMID 10471548).

L. monocytogenes harbouring fluorescent or luminescent reporter genes normally carry no other mutation and will likely retain their wild type level of virulence. These strains will therefore also be handled under the same containment level as the parental strain (i.e. containment level 2).

All GMO strains of L. monocytogenes that will be used in the project or will be used for genetic modification are well-characterised strains of known genotype and antibiotic sensitivity profile.

Escherichia coli K-12 and B strains containing prokaryotic or eukaryotic cloning vectors with the above described inserts are classified under ACDP hazard group 1. Nevertheless, these will be used in containment level 2 laboratories (2nd floor, East Wing, Roslin Institute). Very rarely, we might clone listerial virulence factors in E. coli K12 or B strains to repair or trans-complement previously generated listerial mutations. In such cases we will use vectors (e.g. pE194 derivatives) for Listeria which are non-mobilisable in BSL-2 containment.

Mammalian cell lines transfected with the above expression or targeting vectors are classified ACDP hazard group 1. These cell lines may be also infected with other ACDP hazard group 2 pathogens to characterise host defence responses. Therefore, the cell culture work will be carried out under containment level 2 conditions. Cell lines will or are obtained from certified repositories (e.g. ATCC, DSMZ) which have standardized quality assurance schemes for their products in place (e.g. cell lines are mycoplasma free and tested negative for human pathogenic viruses).

We may also transiently transfect primary cells (e.g. mouse embryonic fibroblasts (MEFs), or bone marrow-derived macrophages (BMDM) from mutant or wildtype mice with expression reporter constructs to complement genetic deficiencies in pattern recognition pathways or to ablate the functions of such genes with siRNA constructs or oligonucleotides. These experiments are classified as ACDP hazard group 1. If such cells are subjected subsequently to infection experiments with class 2 pathogens such as Listeria monocytogenes wildtype or mutant strains they are classified as ACDP hazard group 2. Primary cells will obtained from mouse strains maintained in a specific-pathogenfree (SPF) barrier facility (Roslin BRF). These mice undergo regular FELASA health screens and will not process an additional hazard risk on these experiments that will be carried out in class 2 laboratories (2nd floor, East Wing, Roslin Institute).

The GM listerial strains used in this project will most likely not represent an increased risk to animal health compared to wild type strains should they be released into the environment. Taking into account the control measures assigned for this work the overall risks to the environment from the GMMs produced in this work is effectively zero.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Pipette tips, spreaders, loops must be discarded in the "Dispo safe" jars and inactivated by autoclaving.
Liquid cultures and used bottles I flasks I tubes must be inactivated by first using a disinfectant (e.g. Virkon) and then subsequently autoclaved.
Plates must be taped and discarded in an autoclave bag prior to autoclaving. Autoclave bags should have the group name and date before disposal. They should be loosely sealed with cable ties.
Autoclave bags should be taken to the Roslin central service facility when full. Loosely seal the top with tape and stick a label with lab number on the bag.
Carcasses (dead mice) are inactivated by autoclaving on a make safe cycle (120°-125° C, 15 min) and afterwards incinerated.
Specifics for autoclaving contaminated waste:
Solids (e.g. plasticware such a pipettes, flask, tubes, etc. and agar plates) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130 °C for at least 10 minutes or 134-138 °C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration.
Liquids (e.g. samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121·125°C for at least 15 minutes or 126-130 °C for at least 10 minutes or 134-138 °C for at least 3 minutes), discharge to drains.
Sharps (in sharps bin, e.g. needles, syringes, scalpels) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121·125°C for at least 15 minutes or 126-130 °C for at least 10 minutes or 134-138 °C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration.
Animal bedding and carcasses - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126·130 °C for at least 10 minutes or 134·138 °C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration.

**Project Additional Information**

**Purposes of the contained use**
To investigate how Vaccinia virus (VACV) and Cowpox virus (CPXV) replicate and interact with the host's immune system, leading to a better understanding of the genes that affect their virulence. This work requires genetic manipulation of VACV and CPXV including the deletion and modification of genes to investigate their role in viral virulence.

**Recipient or parental organism**
(i) VACV and CPXV are both ACDP HG2 micro-organisms, capable of causing disease in healthy humans. VACV strains differ in virulence. We will be using low virulence strains (Copenhagen, Lister, MVA) when the experimental aims of the study allow, however it will be necessary to use a higher virulence strain Western Reserve (WR) when
characterising the effect of immunomodulatory proteins.

Poxviruses can be transmitted via droplet, aerosols and direct contact. VACV and other poxviruses have the capacity to survive for considerable periods in dried material such as spills of virus solution. Live VACV can be isolated from solid surfaces and fabric for as long as two weeks after contamination. Infection with wildtype VACV or CPXV is usually mild and localised. Treatment for accidental VACV inoculation is anti-Vaccinia virus immunoglobulin. Cidofovir is effective against poxvirus infection but is not currently licenced for this use. Adverse effects following exposure to VACV are estimated to occur in approximately 1 in 1000 people. A laboratory workers who will be handling VACV must register with occupational health and discuss potential health issues.

VACV is known to be capable experimentally of infecting a wide range of species, however no self-perpetuating cycle of infection in any species has been identified in the UK.

Poxviruses are known to survive in the environment for extended periods of time and there is evidence of wildlife reservoirs of CPXV in the UK and VACV in South America. Cowpox virus has been reported in Great Britain and mainland Europe only. The virus reservoirs in Great Britain are believed to be wild rodents such as bank voles (Clethrionomys glareolus), field voles (Microtus agrestis), wood mice (Apodemus sylvaticus) and house mice (Mus musculus). There have been no reports of disease in wild rodent populations due to CPXV infection. Poxviruses are resilient organisms capable of surviving hostile environmental conditions. Release of VACV into the environment would represent a low risk, CPXV a moderate risk.

(ii) Human cell lines and CV-I monkey kidney cell line

Host/vector system

The Transfer plasmids used in virus construction pose no hazard to human health and safety or the environment.

Origin & function

Marker genes which are not harmful will be expressed in Vaccinia virus and Cowpox virus and include E. coli guanine phosphoribosyl transferase, β-galactosidase, luciferase and enhanced fluorescent proteins.

Genes will be deleted from VACV and CPXV that are predicted to encode virulence factors including: Kelch repeat proteins; Ankyrin repeat proteins; VACV A42R (a profilin-like molecule); VACV FSL (a major membrane protein which is truncated in some attenuated strains of the virus and may therefore be a virulence factor); VACV A47L (encodes CD8+ T cell epitopes); CPXV A59R (predicted to encode a protein with a guanylate kinase-like motif, and could be involved in junctional adhesion of cells) and CPXV M5R (may affect the energy metabolism of an infected cell).

VACV or CPXV proteins will be tagged with epitopes including Flag, c-myc, His or HA.

Evaluation of foreseeable effects

The expression of marker genes encoding products such as fluorescent proteins, luciferase proteins, or E. coli guanine phosphoribosyl transferase by VACV or CPXV has never been reported to alter the tissue tropism or host range or the susceptibility of these viruses to the human defence system, and, if anything, decreases the virulence of the organisms. In some instances, the insertion of the marker gene is designed to disrupt a VACV virulence gene, resulting in significantly decreased fitness of the viruses.

Placing epitope tags on the proteins and expressing them in VACV or CPXV is unlikely to increase risk.

The genes that will be deleted or mutated in VACV and CPXV are predicted virulence factors. Deleting them is expected to make the virus more likely to be destroyed by the host, and therefore have lower virulence and cause less severe disease. On the basis of previous work and by studying the predicted role of the genes to be targeted, it is believed to be highly unlikely that the viral gene deletions planned in this project will result in a more virulent virus, and are much more likely to result in attenuation. It is theoretically possible that a particular mutation could enhance the
function of the protein, causing a greater suppression of host immunity and increasing the virulence of the virus. There is no precedent for this in poxvirus research, and we believe it to be very unlikely to occur. We will not mutate proteins to make them similar to proteins found in viruses of higher virulence. If evidence of increased virus virulence is seen in the murine models of disease, further risk assessments will be carried out.

Deleting multiple immunomodulatory genes from VACV or CPXV will make the virus more susceptible to the host killing mechanisms and therefore less virulent. Other combinations such as employing both a tag and mutation to a VACV gene, or tagging one gene and deleting another, will be very unlikely to increase the virulence of the virus. VACV and CPXV both have very wide tissue tropism and are capable of infecting a wide range of cell culture lines and species including humans. Given the known properties of the genes targeted in this project, there is no reason to expect any effects on host range or tissue tropism.

Given the known properties of the genes targeted in this project, there will be no alteration to the virus epitopes or the DNA replication machinery therefore no change in the efficacy of treatment is expected.

The modifications proposed for VACV and CPXV will not result in additional hazards to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids (eg plasticware such as pipettes, flasks, tubes etc and agar plates) - autoclave at 121°C for at least 15 minutes, discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or heat treatment or via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - chemical disinfection then to drain for liquid waste. The disinfectant Virkon™ will be used, as the standard poxvirus disinfectant. Virkon contains 50% w/w potassium peroxomonosulfate, 5% sulfamic acid, 15% sodium alkylbenzene sulfonate. A 10% w/v solution will be made fresh on the day of use and diluted a maximum 1:4 in liquid waste (final concentration 2.5%). Minimum contact time 30 minutes. Alternatively liquids may be autoclaved at 121°C for at least 15 minutes before discharge to drains.

Animal bedding and carcasses - autoclave at 121°C for at least 15 minutes discharge to drains. dispose of carcasses via clinical waste stream for incineration and bedding via clinical waste stream for heat treatment or via the industrial (black bag) waste stream for landfill.

## Project Additional Information

**Purposes of the contained use**

To understand the genetic and molecular network controlling the timing of DNA replication in mammalian cells using genetically modified mouse embryonic stem cells or primary mouse embryonic fibroblasts. The expression of candidate genes will be knocked down using short interfering RNAs, delivered as lentiviral particles. In addition, we are interested in understanding the impact of some of the DNA replication factors or nuclear structural components on the...
replication timing. We will therefore express some of them in tagged form to test interaction with Rif1 or to verify their subcellular localisation in Rif1 deficient cells.

**Recipient or parental organism**

(i) Commercially available E.coli disabled strains such as STBL3 or TOP10 which cannot colonise the human intestine.

(ii) pLKO.1 is a commercially used replication incompetent lentivirus compatible with third generation systems. The probability of generating replication-competent virus through recombination is negligible. The system has also removed virulence genes that are not necessary for shRNA packaging. These features combined have improved biosafety and handling. There are no known incidents of third generation systems producing replication competent virus. The virus can cause harm if gains access to the body as it inserts stably in the genome. However, no secondary effect (e.g., immortalisation or transformation) has ever been detected as a consequence of replication incompetent lentiviral insertion in human cells. pLKO.1 poses no threat to the environment, even in the case of accidental release.

(iii) Transgenic and wild type mouse embryonic stem cells or primary mouse embryonic fibroblasts which pose no threat to human health & safety.

**Host/vector system**

pLKO1 is a commonly used, commercially-available replication incompetent lentivirus compatible with third generation systems. The four plasmid system consists of: the packaging vectors, encoding for Gag/Pol and Rev separately; the vesicular stomatitis virus G-protein envelope vector; and the shANA transfer vector. Resulting particles are replication-incompetent and deletion in the U3 portion of the 3’ LTA eliminates the promoter-enhancer region, further negating the possibility of viral replication. The system has also removed virulence genes which are not necessary for shANA packaging. These features combined have improved biosafety and handling. The probability of generating replication-competent virus through recombination is negligible. There are no known incidents of third generation systems producing replication competent virus. The virus can cause harm if gains access to the body as it inserts stably in the genome. However, no secondary effect (e.g., immortalisation or transformation) has ever been detected as a consequence of replication incompetent lentiviral insertion in human cells. pLKO.1 poses no threat to the environment, even in the case of accidental release.

**Origin & function**

For the lentiviral pLKO.1, the inserts are various shRNA directed against against mouse Rif1 or mouse genes involved in DNA replication or nuclear organisation. The shRNAs would not be able to target the human homologues as even for highly conserved proteins the nucleotide sequence diverges sufficiently to impair recognition by the shANA. In addition, in the majority of the cases, should the shRNA be effective, this would cause severe growth disadvantage to cells.

**Evaluation of foreseeable effects**

(i) Recombinant microorganisms generated from disabled E.coli strains such as STBL3 or TOP10 will pose no threat to human health & safety or the environment.

(ii) The pLKO 1-shRNA lentiviruses are replication incompetent. The probability of generating replication-competent virus through recombination is negligible. The system has also removed virulence genes that are not necessary for shRNA packaging. These features combined have improved biosafety and handling. There are no known incidents of third generation systems producing replication competent virus. The virus can cause harm if gains access to the body as it inserts stably in the genome. However, no secondary effect (e.g., immortalisation or transformation) has ever been detected as a consequence of replication incompetent lentiviral
insertion in human cells, pLKO1 lentiviruses cannot spread in the environment even in the case of accidental release. Even if these viruses did recombine with wild type viruses, the inserted genes are either deleterious for cell growth (shRNAs) or innocuous.

(iii) Mouse cell lines resulting from lentiviral infection pose no threat to human health & safely or the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disinfection is performed as follows: Waste residues that cannot be autoclaved, or cell culture waste will be inactivated by treatment either with 1*10 Virkon solution for plastic-ware (soak for 2 hours), for treatment of minor contamination (10 min contact time) and surface disinfection (benches and floors); 2% for disinfection of liquid cultures and supernatants that cannot be autoclaved. Alternatively 10% Sodium hypochlorite may be used; 1,000 ppm for general wiping of equipment and benches, 2,500 ppm free chlorine for discard containers/liquid cultures.

Physically clean surfaces disinfected with 70% ethanol.

The autoclave settings for both solid and liquid waste are as follows:
1. Plastic discard (e.g. plastic-ware such as pipettes, flasks, tubes etc.) - the standard autoclave setting is 134°C for a holding time of 5 minutes.
2. Liquid discard (e.g. samples, culture supernatants, tissue culture media) - the standard autoclave setting is 121°C for a holding time of 15 minutes.
3. Sharps waste in sharps containers (e.g. needles, syringes, scalpel blades) - disposed via the clinical waste stream for heat treatment via the University approved contractor.

Project Containment
The use of disabled rabies virus expressing Green Fluorescent Protein to label oligodendrocytes in the mouse brain

The disabled rabies virus can infect oligodendrocytes but cannot spread to infect other cells. An oligodendrocyte infected by the virus will be highlighted by the expression of Green Fluorescent Protein, so that the number and position of each cell processes can be traced, and the contacts made with other cells identified.

Recipient or parental organism

The disabled rabies virus, described in the following section, will be injected into mouse brain, or cultured with mouse brain slices or in vitro cultured oligodendrocytes. The virus does not integrate into the host cell genome and so the recipient animals/tissues/cells will not be genetically modified.

Host/vector system

We will be using an attenuated version of the rabies virus produced at the National Institute of Natural Sciences, Okazaki Japan:
HEP-ΔG-GFP
HEP - Strain 01 rabies virus HEP-flury
ΔG - Deletion of the G gene from the rabies genome
GFP - Green fluorescent protein

Origin & function

The HEP-flury strain of rabies virus has been modified by the deletion of the gene encoding the G protein, which is essential for viral packaging. The gene has been replaced with the insertion of the gene for the Green Fluorescent Protein from Aequorea victoria. The insertion of GFP has no effect on the pathogenicity or toxicity of the virus.

Evaluation of foreseeable effects

Due to the deletion of an essential coat protein gene the virus cannot transmit from cell to cell therefore the normal disease progression of the rabies virus cannot occur. Mice subjected to injection of the attenuated virus will have a small localised population of neurons and oligodendrocytes take up the virus. The virus will be unable to spread to other cells. The localised containment has been found to cause no cell death or adverse effects over the time period that the animal will be infected. The mice will therefore suffer no adverse effects due to the virus and will remain completely non-infectious to other organisms including humans.

In the unlikely case of human exposure. If an individual is accidentally exposed, peripheral nerves may take up the virus. This cannot spread following infection of these cells due to the disabled nature of virus yet may cause cell death in the infected population. The ultimate effect of this will depend on the number and nature of the nerves affected. Symptoms could include varying degrees of muscle weakness and loss of sensitivity. Although this is an unlikely event, as a vaccine exists for the rabies virus we will enforce that all individuals involved in viral work are vaccinated against the rabies virus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The virus will be handled all containment level 2. Animals once injected will be housed in isolators until sacrifice.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Rabies virus itself is a Hazard Group 3 pathogen classified under SAPO. The deletion of the G gene in the virus prevents the normal packaging and export of virus particles and renders the virus replication defective and unable to be transmitted further. The deleted virus is thus effectively disabled or attenuated and we would argue should be classified at a lower Hazard Group, capable of adequate containment at level 2.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For disposal, any solutions or materials that contain, or have come into contact with viral particles will be decontaminated by soaking in Virkon (10%) and then subjected 10 autoclaving. Autoclaving (132 degrees celsius, 15 minutes holding time) will give 100% kill at this temperature and time. Surfaces will be sprayed with Virkon 10% solution after use. The carcasses of the animals which will receive injections of deltaG-Rabies Virus will be autoclaved prior to incineration.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N
The genetic modification safety committee agreed that the appropriate containment and control measures have been assigned.

**Project Ref** 207/16.5

**Date Ackn'd** 11/08/2016

**CU2 Project Title** The expression of normal cellular prion protein in prokaryotic and eukaryotic hosts to provide substrates for subsequent cell-free prion protein conversion assays

**Class** Class 2

**Culture** Consent Granted

**Consent Granted** Non-GMM

**Project notified under transitional arrangements** N

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**
We wish to prepare normal cellular prion protein (PrPC) in the form of purified recombinant PrPC expressed in E.coli and in the form of cell extracts containing PrPC from eukaryotic cells genetically engineered to over-express the protein. These will then be used as substrates for seeded prion protein conversion assays.

Recipient or parental organism

The recipient eukaryotic organism is the HEK 293 cell line. It is a commercially available, well-characterised cell line established from primary embryonic human kidney cells transformed with sheared human adenovirus type 5 DNA. The 293-F cell line is a variant of the 293 cell line that has been adapted to grow in suspension culture. The recipient prokaryotic organism used to prepare recombinant PrPC is E.coli BL21 Rosetta strain and the DHS alpha strain.

Host/vector system

For expression in HEK 293-F cells the ptRESne03 vector has been used. piRESne03 is a mammalian expression vector that contains an expression cassette including a multiple cloning site (for the gene of interest) and the gene conferring resistance to neomycin. The cassette is driven by the cytomegalovirus (CMV) major immediate early promoter/enhancer.

For recombinant PrP expression and purification from E.coli, the commonly used pET and pUC vectors are used.

Origin & function

The inserted genetic material is the coding sequence of the prion protein gene (PANP in humans and Prnp in other animals). The gene sequence inserted into the piRESneo3 expression encodes the full length human prion protein amino acid sequence. Thus, transfected 293-F cell lines will over-express (-10 fold) normal cellular prion protein (PrPC). The pET vector is used to express hamster and other mammalian PrPC in E. coli. The pEX vector is a pUC derivative that is used for maintaining the plasmid.

The normal form of human PrPC is expressed in most mammalian cell and tissue types with the highest expression levels found in the brain. The exact role of PrPC is not known, however, it is believed to be involved in signal transduction, cell adhesion and neuronal stress resistance and survival. Prion diseases arise through the conversion of this normal cellular protein to a misfolded and aggregated form. The products of PrPC expression in GM prokaryotes (purified recombinant PrPC) and eukaryotes (cell extracts containing PrPC) will subsequently be used in seeded prion protein conversion assays that mimic this process.

Evaluation of foreseeable effects

293-F is a well characterised, commercially available cell line, which should be 01 no risk to human health and would be incapable of surviving within an accidentally inoculated immunocompetent host. The possibility of contamination with adventitious human viruses or other cell lines is thought to be negligible. Mycoplasma contamination cannot be excluded, but this will be tested for. E.coli BL21 and DH5 alpha are commercial strains that cannot survive in the wild, but carry one antibiotic resistance gene, which could be transferred to other bacteria. Both are disabled and do not colonise the human gut.

It is conceivable that PRNP could mutate or PrPC could spontaneously misfold, leading to the production of pathogenic forms of PrPC associated with prion disease. This potential risk is highlighted because of the severity of the potential consequences even though there is no good evidence to suggest that such spontaneous events occur in cultured cells or E. coli. It is also possible that 293-F cells could be accidentally infected by human or bovine prions in
cultur media but this risk is considered remote. At normal physiological levels human PrPC is not considered a risk to human health. However, Section 34, Page 45 of Part 2 of The SACGM Compendium of Guidance states that GMMs expressing normal prion proteins should be handled at Containment Level 2 as they may be pathogenic at high levels and may also become mutated to forms associated with other human prion diseases in GMM vectors. No constructs will be used in either eukaryotic or prokaryotic cells encoding disease-associated PrP gene (PRNP) mutations.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste generated from the culture of the transfected 293-F cell line and E. coli will be treated as potentially infectious and decontaminated according local SOPs in line with SACGM Compendium of Guidance to consider the prion risk. Specifically, all bacterial and eukaryotic cell culture waste and consumables will be decontaminated using 2N NaOH for a minimum of 1 hr prior to disposal. This is one of the ACOP prescribed methods for decontamination of prion infectivity and is also sufficient for inactivation of host prokaryotic and eukaryotic cells, and for hydrolysis of nucleic acids. Liquids will be absorbed and contained, and along with similarly decontaminated consumables, join the laboratory clinical (yellow bag) waste stream for subsequent incineration.

Large Scale Activities

Human Clinical Applications

02/03/2022
The generation of induced pluripotent stem cells, induced trophoblast stem cells and refinement of the new reprogramming technology using lentivirus delivery of transcription factors

Converting human cells such as skin to other specialised cells such as neurons, blood, heart, liver and pancreas will make it possible to regenerate any damaged or diseased tissue and develop personalised therapies. It is now possible to reprogram biopsied human cells to become stem cells in the laboratory. These stem cells are pluripotent, which means they can potentially give rise to all cell types of the body. However, the current reprogramming technology uses genes called transcription factors (TFs) that are highly inefficient in reprogramming and often linked to oncogenesis, making this technology quite unreliable and risky to use for therapeutic purposes. Thus, we urgently need novel and safe methods to effectively generate cells with the quantity and the quality needed for regenerative therapy.

Strikingly, the TFs; Oct4, Sox2, Klf4 and c-Myc (OSKM) can reprogram fully differentiated cells into a pluripotent state (iPSCs), while Gala3, Eomes, Tafap2c, and c-Myc (GETM) can reprogram differentiated cells to a trophoblast stem cells (iTSCs). We still have extremely poor mechanistic understanding of how TFs operate and impose cell-type specific reprogramming activity. We aim to use this reprogramming technology to address fundamental questions in developmental and stem cells biology. Importantly, we aim to elucidate the molecular features of TFs that impart reprogramming. By defining the minimal domains of TFs that explain reprogramming, we will eliminate the unnecessary risks associated with superfluous domains. This will enable us to engineer new proteins that can deliver efficient, safe and reliable reprogramming.

In our lab we will generate iPSCs and iTSCs with lentiviral delivery of TFs to fibroblasts. Using a Dox-inducible
system, the ectopic expression of TFs will be tightly controlled during the reprogramming process. This will allow us to map the temporal interactions of these reprogramming factors with both the genome and the proteome. Other delivery systems such as plasmid transfection and retrovirus infection are strongly silenced during reprogramming (30 days process) and lack control over a sustained ectopic expression TFs. Therefore, it is essential to use a doxycycline-inducible lentivirus system to deliver and control the expression of TFs during reprogramming.

Chromatin, proteins and RNA will be isolated from infected cells in a time-wise fashion, but not earlier than 5 days post infection, surpassing the 24 hr half-life of lentviruses. All of recipient cells, including the infected fibroblasts are non-pathogenic and cannot survive outside cell culture conditions. There is no risk of virus transmission because the ViraSafe Lentiviral Packaging System (3rd generation) used is replication defective. In our lentivirus delivery system, all the genes are under the control of the Tet-ON regulatory element, requiring the presence of the reverse tetracycline transactivator M2rtTA (a separate gene) and doxycycline (tetracycline antibiotics) for induction. The three separate elements of this system will minimize any inadvertent risk associated with using oncogenic factors. These genes are inserted within two LoxP sites, allowing the complete removal the integrated insert from the genome upon Cre-recombinase treatment.

Recipient or parental organism

E.coli (Stbl3) will be used for cloning and propagation of lentivirus vectors. All packaged genes are under the control of promoters that are not-active in bacteria and the three plasmids needed for viral propagation in mammalian lines will be generated independently in bacterial systems. Thus, there will be no gene expression and no production of virus in E.coli.

293T cells will be used for packaging viral particles. Harvested viruses are highly infectious. Therefore, cultures will be destroyed accordingly after viral harvest using sodium hypochlorite. This cell line is non-viable outside of laboratory conditions.

All recipient cells, including the infected fibroblasts are non-pathogenic and cannot survive outside cell culture conditions. There is no risk of virus transmission because the viral vectors are replication defective.

All recipient cells will not express the inserted lentiviral genes, because they are under the control of the Tet-ON regulatory element requiring the presence of rtM2TA and tetracycline antibiotics. The gene encoding rtM2TA is inserted in a separate vector and will be packaged as a separate lentivirus. Hence, the recipient cells have to be infected with rtM2TA lentivirus plus another lentivirus carrying the gene under the Tet-ON control elements and they have to be treated with more than 1 ug/ml of doxycycline in order to induce the ectopic expression of the lentiviral inserted genes. This will reduce to inadvertently induce the expression of oncogenic factors. The virally integrated genes are bordered by LoxP sites and can be removed by Cre recombinase if required.

Host/vector system

FUW-TetO-LoxP vectors for protein expression: Vectors with cloned coding sequences are on FUW-TetO-LoxP backbone that are replication-incompetent lentiviral vectors. All genes cloned in this vector are expressed under the control of Tet-On promoter, requiring the presence of both rtM2TA (separate gene) and doxycycline (externally supplemented). The vector also contain LoxP sites upstream the LTR integration region, allowing the removal of the inserted gene from the host genome post-infection if required.

The ViraSafe lentivirus packaging system: (pCMV-VSV-G, pRSV-REV, pCgpV) encode for the VSV-g envelope protein and Rev, Gag and Pol packaging proteins. This will convert the Tet-ON vectors to lentiviral particles for subsequent infection with and that gives it broad host range and high transduction efficiency. The viral particles produced contain no HIV coding sequences and are replication incompetent. This system has no inserted sequence under the control of a bacterial promoter. This system improves the packaging plasmid 10 increase performance and reduce the likelihood of recombination between vector components.
All vectors including packaging vectors are separate, allowing flexibility to optimize the vector ratio for maximal lentivirus production and minimize the risk of producing live viral particles from a single plasmid. The lentivirus vectors are replication incompetent, thus reducing the risks of generation of replication competent virus.

Origin & function

mCherry, EGFP are fluorescent proteins used as controls. These proteins are considered harmless and don't pose any risk.

The transcription factors: OCI4, Sox2, Klf4, c-Myc, Gata3, Eames, Tlap2c directly regulate gene expression of target genes. Some of these factors such as c-Myc are known to oncogenic and thus considered as harmful. The reprogramming activity of these transcription factors require the combinatorial ectopic expression of three or more factors together. Each factor will be packaged in a separate virus to reduce the risk of their combinatorial reprogramming activity.

Evaluation of foreseeable effects

293T Lenliviral packaging cells after viral vector transfection are potentially harmful. Produced virus is highly infectious to mammalian cells including human cells. Careful handling of the virus will be carried out in the specified hood and incubator at containment level II. NO sharps or glass will be used during the work phase involving virus. The hood and incubator will be cleaned with 1% Virkon every time after the viral work. Waste management of plastic-ware, culture medium, is described in waste disposal section.

The viral vectors are replication defective and therefore no potential for onward transmission from infected target cells. Inserted genes in the lentivirus will be under the control on a TET-ON system and will not be expressed in the absence of rtM2TA and doxycycline in mammalian systems. The inserted genes are bordered by LTR and Lox? sites, which will integrate into the host genome and can be reversibly removed by Cre-recombinase.

Half-life of the virus particles are about 24 hours in the culture condition. Culture plates which have had contact with active virus particles will not be taken out of the specified tissue culture room before 48 hours and not before being washed more than 3 times with sterile PBS.

The infected cells that had direct contact with live virus particles will be cultured for at least 5 days and passaged at least once, prior to ectopic gene induction with doxycycline. Chromatin, protein and RNA will be purified from cells that have cultured for at least 7 days and washed more than 5 times. No viral particles can be reassembled from the purified chromatin, DNA/RNA or proteins.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All users working with virus must have taken the University GM Safety Course and be working under an approved GM
risk assessment. For each project the TC manager must be informed prior to the start of TC work. Use Disposable lab coat and do not use the same lab coat for other techniques. Disposable lab coats must be worn when working with high titre virus stocks and for the first 7 to 10 days after transduction. They should be autoclaved before disposal via the orange bag route. No glass or sharps should be used when working with virus. All solid and liquid waste should be decontaminated/disposed of by the user at the end of every TC session. For Chemical decontamination of solid waste, a soaking bucket is used which must be labelled with name and the date. Then the waste is disposed 24 hours later. Solid waste disposal:

Stripettes

Soak for 24 hours in 1% Virkon, then red incinerator box.

Plastic ware such as flasks, tubes and agar plates:

Soak in 1% w/v Virkon, or 1,000 ppm Precept (four 0.5g tablets into one litre of water) for 24 hours before discharging any excess liquid via drains. Following chemical decontamination, place all plastic ware and agar plates into the autoclave orange bags within the tin autoclave drums, tie orange bag and place in the white plastic bin - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-1300C for at least 10 minutes or 134-13BoC for at least 3 minutes).

Liquid waste disposal
samples, culture supernatants, tissue culture media

Any liquid potentially containing virus should be collected in an autoclavable screw top plastic bottle (stored under the sink). It should NEVER come into contact with the vacuum system. The liquid waste should be chemically disinfected by soaking in 1 % w/v Virkon, or 1,000ppm Precept (four 0.5g tablets into 1 litre of liquid) for 24 hours before discharging via the drains. The container must be labelled with name, group and date.

1% Virkon solution

Virkon Water

1ag Virkon

Sag Virkon (Sachet)

109 Virkon (2x sachet)

1 litre
5 litre
10 litre

Note: Virkon solutions are stable for 7 days and should be discarded after this time or if colour fades.

1,000 ppm Precept:

Four 0.5g tablets into one litre of water

Animal Units

Large Scale Activities

Human Clinical Applications

02/03/2022
Haematopoietic stem cells (HSCs) have the ability to produce every blood cell type of an individual and are therefore of enormous clinical potential for cell replacement therapies. Despite this long-standing interest in HSCs and the employment of bone marrow transplants in the clinic for decades, robust methods for the expansion of HSCs in culture and their derivation from pluripotent stem cells are still lacking. A lot can be learned about the basic mechanisms of HSC production, expansion and differentiation from the study of how these cells are generated and disseminated during development. Furthermore, knowledge of these early processes can shed light on the mechanism of cancer development, as this often involves the re-activation of developmental pathways. The purpose of our work is therefore to identify the mechanisms that regulate HSC generation, expansion, differentiation and migration during development and how some of these early blood cells can give rise to paediatric leukaemias. The results of our studies will help improve current protocols for HSC expansion and generation from pluripotent stem cells and may highlight novel treatment strategies in paediatric leukaemia.
Host/vector system

293T cells will be transfected with the 3rd generation lentiviral vector (miRZIP, Lenti-miR MicroRNA Precursor Clone, pLL3.7, miR-Selection-Fir-Ctx LentiVector, pWPI and pRRL_AF4-MLL_2AdT-1i) or the 2nd generation retroviral vector (MDH1-PGK-EGFP, pMSCVhygro and pMSCV-IRESCFP).

The cells will also be co-transfected with the standard packaging vectors

Lentiviral Vector
- pMD2.G plasmid (encoding the vesicular stomatitis virus glycoprotein)
- psPAX2 (encoding gag-pol and Rev)
- or
- pMD2.G plasmid (encoding the vesicular stomatitis virus glycoprotein)
- pRSV-REV (encoding Rev)
- pMDLg/pRRE (encoding gag-pol)

Retroviral Vector
- pECo (encoding ecotropic envelope protein)

The lentiviral vector based system (miRZIP, Lenti-miR MicroRNA Precursor Clone, pLL3.7, miR-Selection-Fir-Ctx LentiVector, pWPI and pRRL_2AdT-II) will be used to package vectors that allow the inhibition or overexpression of potential oncogenes and tumour suppressor genes. These viral particles will be used on mouse cell lines, primary mouse cells, human-derived immortalized cell lines and primary human cells.

The retroviral vector based system (MDH1-PGK-EGFP, pMSCVhygro or pMSCV-IRESCFP) will be used to package vectors that allow the overexpression of microRNAs or leukaemia fusion genes that could act as oncogenes or tumour suppressor genes. This system can only infect mouse cells.

Origin & function

The viral vectors may contain cDNAs of candidate haematopoietic regulators that we wish to overexpress in target cells to assess how this affects haematopoiesis. Potential regulators could also include miRNAs we wish to overexpress. The vectors may also include knockdown constructs for potential haematopoietic regulator genes or miRNAs. In addition, we also have reporter vectors containing regulatory DNA elements that will express a resistance gene or a fluorescent marker when bound by a transcription factor or miRNA.

As our lab also works on leukaemia, we may wish to use viral constructs for the overexpression or knockdown of leukaemic oncogenes.

The cDNAs, miRNAs and oncogenes may be of human or mouse origin that were cloned in-house, obtained from a commercial source or from a collaborator.

Evaluation of foreseeable effects

All of the host cell lines are non-pathogenic and cannot survive outside cell culture conditions or without recipient mice. No harmful effects are expected.

None of the inserted genetic material is likely to cause any harm to humans. No adverse effects are likely. They are not toxic or immunogenic. The risks of recombination-related problems are minimal.

Our retroviruses can only infect rodent cells and are replication-incompetent.

Our lentiviruses can infect mammals including humans. However, lentiviral particles generated by this system are replication incompetent and all work will be carried out at containment level 2. The genes subject to this study are known oncogenes (e.g. leukaemia fusion genes) or potential oncogenes (e.g. microRNAs). Some of them are potential tumour suppressor genes (e.g. microRNA). Taken together, like in any other lentiviral work, it is possible that knockdown/overexpression of the genes of interest might be harmful to humans in the event of an accidental
exposure, thus all these procedures will be done in the specified hood under the stringent control.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid and liquid waste is treated with virkon for several waste before disposal in tissue culture waste that is then incinerated. 100% kill is achieved with this method.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

The genetic modification safety committee agreed that the appropriate containment and control measures have been assigned.

Project Ref  207/17.3

Date Ackn'd  CU2 Project Title  Class  CultureVolClass2  CultureVolumeClass3-4

29/03/2017  The impact of co-infection on the evolution of drug resistance in Pseudomonas  Class 2  < 1 litre
Purposes of the contained use

Experiments designed to assess competitive ability and antibiotic resistance. *P. aeruginosa* (Laboratory strain, non GMO) will be cultured in isolation and co-cultured with the other, genetically modified (in terms of motility and social signalling), strains of *P. aeruginosa*, and their resistance to common laboratory antibiotics assessed.

Recipient or parental organism

*Pseudomonas aeruginosa* WT laboratory strains will be the target for genetic modifications. We will use the WT and gene-inactivated derivatives.

Host/vector system

Commercially available mobilisation defective cloning vector pBluescript II for *E. coli* and *P. aeruginosa*. pRIC380 suicide vector and derivatives used to mutate lasI. As this is mobilisation defective there is no risk of spread to other organisms should the vector get into the environment.

Origin & function

Mini-CTX and mini-CTX lux derivatives will be used for the integration of exogenous DNA (*P. aeruginosa* promotors) into the chromosome of *P. aeruginosa* with *E. coli* S17-1 as a donor strain. Lastly the plasmids pSB401, pSB403, pSB404 and pSB1075 comprising reporter systems to detect *P. aeruginosa* signal molecules will be hosted by S17-1. By altering the ability of the *P. aeruginosa* strains to respond to signals, we expect them to differ in the way that they respond to antibiotics. These are stable genetic modifications and as such do not pose a risk of spread to other organisms.

Evaluation of foreseeable effects

As our vectors are mobilisation defective there is no risk of spread to other organisms. In addition to this, we will use mutant strains of *Pseudomonas aeruginosa* in genes such as lasR, rhlI, pqsA, pqsE and pqsR which are stable modifications resulting in the organisms to have reduced or negated ability to respond to signal molecules as well as reducing their mobility. These changes mean that in the environment the genetic changes have a very low risk of spread to other organisms and the modified organisms have reduced fitness and competitive ability with wild strains which will greatly diminish survival in an environment outside of the laboratory.

As regards human health and safety our gene modifications are not expected to alter the disease causing properties of the organism and have been shown not to increase virulence in a laboratory setting. The introduction of the new genetic material to these will not increase the pathogenicity of *P. aeruginosa* and thus does not pose an
increased risk to humans.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

School of Biological Sciences waste inactivation and disposal will be followed.

There will be no use of sharps.

1% final concentration Virkon disinfectant will be used for cleaning. 2% final concentration for spillages with an overnight contact time. Procedures followed will be those identified in the School waste guidance documentation.

Plastic discard (e.g. plasticware such as pipettes, flasks, tubes etc.) - the standard autoclave setting of 134 deg. C for a pulsed holding time of 5 minutes will be used.

Liquid discard (e.g. liquid culture and supernatants) - the standard autoclave setting is 121 deg. C for a pulsed holding time of 15 minutes.

Degree of kill:
Autoclaving - effectively 100% kill (annual validation)
Disinfection — all spillage waste is subsequently autoclaved prior to disposal

Solid waste disposed via University contracted competent waste contractor.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

02/03/2022  Page 4969 of 15326
Genome-wide perturbation using lentiviral delivery of CRISPR/Cas9 systems leading to loss or gain of gene expression in mammalian or avian cells

Recipient or parental organism
Replication defective lentiviruses expressing Cas9; guide RNAs targeting host cell genes and selectable markers. Cell lines and primary cells of human and animal source.

Host/vector system
A lentivirus construct containing gene editing components (CRISPR/Cas9, guide RNA and selection marker) will be packaged in and harvested from HEK cells.

Origin & function
CRISPR is a prokaryotic defence response to foreign DNA. Cas9 is an bacterial endonuclease which is targeted to a specific sequence of DNA by short guide RNAs (sgRNA). The Cas9 complex induces double stranded breaks in targeted DNA providing a defence mechanism against the original pathogen. Host animal cells will be transduced with a lentivirus(es) expressing Cas9 and sgRNA(s) to perform editing/deletion in specific regions of the genome in order to determine the function of particular genes. The lentiviral vector will not be able to replicate within the host.
Evaluation of foreseeable effects

The use of a genome-wide CRISPR/Cas9 knockout library will result in some growth perturbation effects in a proportion of the host cells used in vitro. This presents a potential oncogenic risk to the user. For this reason, and in particular, due to the relative similarity between the porcine, mouse and human genomes, appropriate care at the standard practice of Containment Level (CL) 2 will be adhered to during all handling of this utility to prevent contact between the lentiviral particles with skin of the operator/researcher. Only screw cap eppendorfs will be used. No sharps will be used. Waste media will be removed and any remaining retroviral particles inactivated by treatment with Distel® a broad spectrum virucidal disinfectant, in a biosafety cabinet to avoid aerosol generation, at a 1:10 dilution overnight at a designated place. All waste bottles will be clearly labelled with date and content.

None of the bacterial strains or lentivirus are able to colonise hosts both due to the extremely low probability that they would survive outside of the special culture environments in which they are designed to propagate. 293-T viral packaging cells do not survive out of tissue culture conditions and pose no threat to the environment. Transduced cells will not survive out of tissue culture conditions and pose no threat to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids (e.g. plasticare such as pipettes, flasks, tubes etc) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121 - 125C for at least 15 minutes or 126 - 130C for at least 10 minutes or 134 - 138C for at least 3 minutes), discharge any excess liquids to drains. Autoclaved solids are sent for microwave treatment and subsequent disposal.

Liquids (e.g. samples, culture supernatants, tissue culture media) are treated in a sealed container with 10% Distel overnight and discharged to drains. These procedures will be reviewed when new waste management guidelines are published by the local H&S team.

## Project Additional Information

**Purposes of the contained use**

To produce lentiviral particles containing trypanosome cDNAs that can be used for use in the production of transgenic mice.

**Recipient or parental organism**

Plasmids will be constructed and propagated in XL-10 gold ultracompetent cells [TetrD(mcrA)183D(mcrCB-hsdSMRmrr) 173 endA1 supE44 thi-1 recA1 gyrA96 relA1 lac Hte [F proAB lacQZDM15 Tn10(TetR) Amy Camr] Plasmids will be transfected into Human Embryonic Kidney (HEK)293T cells to produce replication defective lentiviral particles (second generation) pseudotyped with VSV-G. Lentiviral particles will be injected into the perivitelline space of mouse zygotes (single cell embryos) which will then be transferred to pseudopregnant female recipients.

**Host/vector system**

Host cells will be XL-10 gold ultracompetent cells [TetrD(mcrA)183D(mcrCB-hsdSMR-mrr)173 endA1 supE44 thi-1 recA1 gyrA96 relA1 lac Hte [F proAB lacQZDM15 Tn10(TetR) Amy Camr], Human Embryonic Kidney (HEK)293T cells and mouse cells (zygotes). The cargo of the lentiviral vector particles will integrate into the genome of the mouse.
zygotes, and offspring born will be transgenic in all tissues. The replication defective nature of the lentiviral vector system means that the genetic elements integrate stably into the mouse genome and will not be mobilised further.

**Origin & function**

Lentiviral vectors will contain a liver specific promoter driving a reverse tet transactivator and a tet response element driving expression of the trypanosome cDNA. In the absence of tetracycline (or a derivative such as doxycycline) it is anticipated that the transcriptional units will be silent. In most cell types, even in the presence of doxycycline, it is anticipated the transcriptional units will be silent. In liver cells it is anticipated that the reverse tet transactivator protein will be expressed, but in the absence of doxycycline this will be unable to bind to the tet response element that drives the trypanosome cDNAs. Only in liver cells and in the presence of doxycycline should the trypanosome cDNAs be expressed. The cDNAs expressed are not likely to increase pathogenesis associated with trypanosome infection.

**Evaluation of foreseeable effects**

Lentiviral particles will be able to invade a mammalian cell, reverse transcribe their RNA cargo and integrate this into the genome of the host cell. This genetic element cannot be remobilised. There is a risk to human health and safety. The VSV-G pseudotype means that lentiviral particles can invade human cells via cuts in the skin or across mucous membranes. Integration into the genome of human cells could result in insertional mutagenesis (eg upregulation or disruption of normal gene expression). Precautions are in place to minimise the risks associated with this material, including appropriate PPE, minimal use of sharps (absent other than for zygote injection) and the use of biosafety cabinets. Lentiviral particles are not environmentally robust, and degrade rapidly in dry conditions. All waste from the production and injection process will be disposed as stipulated in the appropriate risk assessments to minimise further any risk to the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

GM mice will be housed in a contained mouse facility.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Lentivirus-containing waste liquids will be aspirated into a container containing Distel® though a closed aspiration system. After 24h of inactivation the container may be changed and the liquid autoclaved prior to disposal. Surface disinfection will be with 1-10% Distel. 70% EtOH is not sufficient to inactivate HIV and thus lentiviruses. All contaminated materials will be inactivated by autoclaving (100% kill) at 121°C or 134°C prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual (at least) thermocouple mapping. Each run will be monitored by both Browne TST indicator test stripes and continuous chart/digital recording of the temperature / time profile (CSU) or by digital recording only (BRF).

**Project Additional Information**
Purposes of the contained use

This project focuses on building a base of knowledge around how viruses interact with host cells in order to develop a new type of therapy where, instead of directly targeting the virus, the host cell becomes less hospitable for virus infection. Specifically, this project will identify the host ribonucleic acid (RNA) molecules that are used by respiratory viruses during their life cycles. This is a largely unexplored research area, mainly because it has been very difficult to directly identify the microscopic host RNA-virus RNA interactions that occur within an infected cell. This project will make use of a unique method established at the University of Edinburgh for isolating the protein (Argonaute) that binds to the virus RNAs-host RNA complexes and then carrying out molecular reactions to directly ligate and sequence the RNAs as a way of identifying the specific interactions that occur.

One complication of this technique is that large quantities of largely homogenous infected samples are required to gain enough power for next generation sequencing (NGS) statistical analysis. In normal infection it is difficult to determine the exact number of cells within a flask that are infected at any given time, and the viral load contained within these infected cells. We propose to use Respiratory Syncytial Virus (RSV) and Human Parainfluenza Virus (PIV3) expressing green fluorescent proteins to circumvent these restrictions. Infected cells can be identified in realtime using a fluorescent microscope, and fluorescence intensity should directly correlate with viable viral load per cell. Use of these genetically modified viruses will therefore increase both the accuracy and analytical value of our experiments, substantially advancing our understanding of host responses to infection.

Recipient or parental organism

- WT RSV cDNA (ACDP Classification 2)
- WT PIV3 cDNA (ACDP Classification 2)

Host/vector system

We propose to use RSV virus that has been already modified to express a green fluorescence protein (RSV-GFP) and PIV3 virus (PIV-GFP) that has been already modified to express a GFP. The details of these viruses and their previous construction are published (below) and no further modifications will be made.

For WT RSV cDNA: Fragment of Minigenome C41 into MP129 to create MP169 (then moved to full length RSV cDNA). Methods described in detail in Hallak et al, J.Virology p10508-10513 2000

Origin & function

We propose to use RSV virus that has been already modified to express a green fluorescence protein (RSV-GFP). Reference of the method of construction can be found at Hallak et al, J.Virology p10508-10513 2000 and Guerrero-Plata et al, Am J Respir Cell Mol Biol, p320-329 2006 and references therein. We also propose to use PIV3 virus that has been modified to express a green fluorescence protein (PIV3-GFP). Reference of the method of construction can be found in Roth et al, Antiviral Res, 12-21, 2009.

Evaluation of foreseeable effects

The inserted gene product encodes green fluorescent proteins and do not confer any selective, infectious or propagating advantage on the viruses. Therefore modified viruses and/or the genetically inserted gene product do not represent any increased risk to human health and safety over that of WT RSV or PIV3.

The modified RSV and PIV3 are WT with the exception that they express a fluorescent protein. This protein does not alter cellular or species tropism and confers no selective, proliferative or competitive advantage over WT strains as
ascertained by the producers of this virus, constructed as detailed in the journal articles referenced previously in this form. In the event of exposure of an individual to the modified virus, the response would not be anticipated to be any different to that of WT RSV or PIV3, to which individuals are exposed throughout their lifetime. It is extremely unlikely that this modified RSV or PIV3 will present any increased environmental risk over and above that of WT. The virus does not produce any significantly harmful toxins or proteins. Given that this virus has at most equal proliferative capacity, but more likely less than WT, it is extremely unlikely that in the event of public exposure this virus would result in displacement of WT strains. RSV and PIV3 are not viruses prone to recombination, mutation or alterations in either tropism or increased virulence thus in the unlikely event of infection of primary cells harbouring other pathogenic factors, accidental generation of a more pathogenic RSV or PIV3 is extremely unlikely.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All liquids and plastics containing or potentially contacting virus are treated in 5% (final concentration) Teknon Biocleanse Biocidal cleaner solution for inactivation in the microbiological safety cabinet. All liquids containing or potentially contacting virus are treated in 5% (final concentration) Teknon Biocleanse Biocidal cleaner overnight in plastic containers and disposed to drain. All plastics and reagents which contain potentially infectious virus are autoclaved using standard setting of 134 deg.C for a holding time of 5 minutes.

Project Additional Information

Purposes of the contained use

This risk assessment is intended to cover the packaging of HIV1-based lentiviral vectors containing shRNA against p53, Rb, or CDKN2A and an expression unit of the catalytic subunit of the human telomerase protein (hTERT) and subsequent transduction of target cells in vitro. Any transgene inserted into the lentiviral backbone that is known to act as an oncogene requires an additional risk assessment. These three transgene elements are known to be able to contribute to oncogenicity.

Lentiviral vectors represent a sophisticated gene delivery method that allows integration of genetic material into the genome of both dividing and non-dividing target cells. The system is composed of a number of plasmids derived from human immunodeficiency virus. Co-transfection of HEK293T cells with these plasmids results in the secretion of viral particles into the culture supernatant. Lentiviral particles can be concentrated from culture supernatant to titres of approximately 10^8-9 infectious particles per ml, when assayed on human cells. The transfer vector can carry 7-8 kb of foreign DNA and maintain stable expression once integrated into the target genome. Importantly, several safety features have been included in this system to minimise the potential of replication competent lentivirus (RCL) production, or subsequent mobilisation of the integrated transgene from the genome of the host cell. Importantly, due to the reduction of the lentiviral genome to a bare minimum for incorporation of transgenes into the target cell and expression of other factors needed for the assembly of lentiviral particles in the producer cell only, resulting in incorporation of proteins but not genomic information, these lentiviral particles are unable to form new viral particles in the target cells and are therefore unable to spread.

Recipient or parental organism

Primary cells held on site in the Roslin Institute or isolated from live animals, obtained commercially, or from collaborations. Cells may include but are not limited to lung and...
Intestinal epithelial cells, monocytes and macrophages of different origin

Primary cells from farm or companion animals will be transduced with the lentiviruses generated to immortalize them. Primary cells, which have the potential to carry unknown infectious agents and will only be used at containment 2.

Host/vector system

2nd Generation lentiviral replication system using a three plasmid vector system to generate the single-round infectious lentiviral particles used for transduction of target cells.

The second generation lentiviral system has a low risk of recombination with endogenous retroviruses due to the division of viral elements among three different plasmids. The packaging and envelope plasmids express viral proteins, which are packaged as such into the lentiviral pseudoparticle. These proteins cannot be newly synthesized in the target cell therefore the lentiviral pseudoparticle is single-round infectious.

Transgenes encoded by the lentiviruses packaged under this risk assessment may be oncogenes, and as such have the potential to have significant negative impact if accidentally transduction of the user occurs. However, all work will be carried out in a class 2 biological safety cabinet by trained users wearing appropriate PPE. Sharps (glass wear, scalps or needles) will not be used in the TC suite where lentivirus is produced or handled. Taken together the likelihood of accidental transduction of the user is considered extremely low.

The frequency of RCL generation using lentivirus vectors is considered very low and this fact, in conjunction with the ‘self-inactivating’ feature following transduction, suggests that the potential for shedding of RCL from animals is very low. Indeed, RCL have to date not been reported in association with lentiviral packaging systems (Pauwels et al 2009, Current Gene Therapy 9:459-474).

Lentivirus vectors have been shown to achieve efficient and safe transduction of the murine brain, muscle, and liver and have been used to create transgenic pigs without observable adverse side effects in viable offspring (Roslin). Indeed recent mapping studies of lentiviral vector integration sites seem to indicate that these vectors have less tendency to target dangerous transcription start sites than vectors based on MoMLV – suggesting that these vectors are much less prone to inducing insertional oncogenesis. The potential for oncogenesis as a result of insertional mutagenesis is therefore considered very low.

Origin & function

hTERT and shRNAs targeting livestock proteins TP53, Rb and INK4A will be integrated into the primary cells for immortalisation.

One of the reasons somatic cells enter a senescent state is the shortening of the telomere repeat sequence at the end of eukaryotic chromosomes. TERT (or hTERT in humans) is the catalytic subunit of the telomerase reverse transcriptase enzyme (TER). This protein is inactive in most somatic cells, whereas they still express hTERC and TP1, two telomerase-associated proteins that help to form the TER. Thus, exogenous expression of hTERT restores active TER activity in differentiated cells and has been shown to be able to extend the proliferative cell cycle, thereby immortalizing, certain primary cell types. Immortalization of cells using hTERT was also shown to change the epigenetic programming of DNA methylation and gene expression.

shRNAs targeting the tumor suppressor genes TP53, Rb, or INK4A will further enhance the proliferation and division of primary cells. Whenever possible the shRNA target sequences will be designed in an area unique to the (livestock) animal species as to not target the human gene.

Evaluation of foreseeable effects

The uncharacterized, immortalized cell lines derived from primary cells may still contain unknown pathogens and continued use at containment level 2 is advised until thorough characterization is conducted.

Genetically modified cells are not a hazard to human health. Cell lines or primary cells will not survive outside laboratory conditions and carry no additional hazards compared with those already present in the environment.

The transgenes integrated into the primary cells, once turned to immortalized cell lines, are not expected to have any harmful effects on humans.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- **Liquid waste:** Liquid viral waste will be inactivated by disinfection (HazTab for 24 hours). Liquid bacterial culture waste will be inactivated by autoclaving.

- **Plastic consumables:** Rinse with 1% Distel, contain in autoclavable bag, followed by autoclaving.

- **Re-usable Glassware:** 1% Distel with a contact time of 30min or 1% Virkon with a contact time of 1h.
  For metal parts an incubation with Distel is recommended due to the corrosive nature of Virkon.

- For autoclave procedures Browne sterilizer control tubes will be included in the load as a means of routine monitoring of treatment temperatures and time (at least 121°C maintained for 15 min). In the event that the Browne sterilizer control tubes fail to change to a green colour following an autoclave cycle then the load will be autoclaved again using an alternative machine with temperature and time monitored in the same way (eg SAH S17).

The autoclave will be subject to an annual 12 point thermocouple test on a waste cycle.

The efficiency of Distel or Virkon have been measured by independent labs contracted by the manufacturer's and were shown to have efficacy against the viruses specified (HIV). Further disinfectant’s HIV inactivation ability specified in Table 1e.

02/03/2022
Cellular regulation of and by the Hippo Pathway

The Hippo pathway has within the past two decades gained great interest as an integrator of cellular homeostasis, where it works as a nexus for diverse cellular signaling. Understanding the regulatory mechanisms of the Hippo pathway has therefore become a major focus in especially regenerative medicine. The chief biological output of the Hippo pathway centers on Yes-associated protein (YAP) and transcriptional coactivator with a PDZ-binding domain (TAZ), which are the prime mediators of the Hippo pathway, when they are active they shuttle to the nucleus and binds to and activate their cognate transcription factors.

As YAP/TAZ is deregulated in many human pathologies including a range of cancers an in depth analysis of precisely how the pathway is regulated and exactly what causes dysregulation of this pathway in human pathologies

Recipient or parental organism
- Standard lab strains of disabled E. coli (e.g. DH5alpha, BL21)
- Multiple human cell types, including cells with regenerative potential and mouse cells grown in tissue culture
- Zebrafish

Host/vector system
- Cloning vectors, siRNA, shRNA & standard expression vectors for mammalian transfection and 3rd generation virus based delivery. The virus are replication defective.

Origin & function
- We use many different targets for overexpression or knockdown. These include genes that regulate dynamic actin rearrangements, cell-cell and cell-substratum adhesion and cell migration. The genes that we introduce into cells are kinases, scaffolding proteins and transcription co-activators and transcription factors. In addition, we use probes and biosensors to identify the cellular localisation of the proteins of interest.
None of the generated cell lines will pose any risk to the environment or human health as they will not survive outside the cell incubator.

Evaluation of foreseeable effects

The E. coli (DH5alpha, BL21) that we use for propagation of DNA are disabled and do not pose any risk under normal laboratory conditions where they are handled with good laboratory practice.

Our primary mammalian target cell lines do not pose any risk nor would we expect them to survive outside their tissue culture environment. None of the generated cell lines therefore pose any risk to the environment or human health. We use a safe replication deficient virus system with immobilised vectors that also ensures these are of no risk to the environment or human health.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids (eg plasticware such as pipettes, flasks, tubes etc and agar plates) – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), or disinfect e.g. with Virkon or Trigene (1% w/v) for 30 mins or 250mg/l of NaDCC (Has-Tabs, 250mg/l gives at least 140 ppm of chlorine) for >8hrs, discharge any excess liquids to drains, dispose of solids via clinical waste stream for heat treatment or via the industrial (black bag) waste stream for landfill.

 Liquids (eg samples, culture supernatants, tissue culture media) – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), or disinfect with Virkon (1% w/v) for 30 mins or 250mg/l of NaDCC (Has-Tabs, 250mg/l gives at least 140 ppm of chlorine) for >8 hrs, discharge to drains.

Is an emergency plan required according to regulation 20?

#### Project Additional Information

**Purposes of the contained use**

Test the phenotype effect of Legionella spp. traits identified by whole genome sequence screening using genetic mutants.

**Recipient or parental organism**

Legionella pneumophila (Hazard group 2), Legionella longbeachae or other Legionella spp.  
Escherichia coli (Hazard group 1)

**Host/vector system**

Will include different types that have been developed for molecular biological purposes of E. coli and Legionella spp including pET expression vector series, pUC19, pGEM, pMAD, pE194, pTS1/2, pCu1, pT181, pSK265, pCL84, pIMAY, pKOR1, members of the pCN shuttle vector and derivatives, pMBB207, pBC-KS, pWM1007. Tn mutant libraries may be made using the vector pSRS_CM1 marked by either chloramphenicol or erythromycin resistance.
determinants. Additional novel plasmid vectors may be used as they become available.

**Origin & function**

Insertion of naturally occurring gene variants including those predicted to be non-functional due to mis and non-sense mutations. Gene variants are sourced from other strains from the same species. In order to study the effect of the presence of different variants of a target gene, strains which either lack the gene entirely or encode a variant of a gene will be replaced or complemented.

Expression of proteins such as putative virulence factors or proteins indirectly involved in pathogenesis using expression vectors (e.g. *E. coli*) for controlled expression, purification and tagging.

Natural variants or variants generated using site-directed mutagenesis of target genes will be expressed using *E. coli* vectors. The protein products will be tested to determine the effect on bacteria, host cells (e.g. macrophages) or combinations of the above.

Gene variants generated using site-directed mutagenesis where amino acid residues predicted to be in an active site are replaced with other amino acids with a different chemical property or charge.

Other inserted genes as fluorescent proteins from jellyfish and corals as well as β-galactosidase and β-lactamase genes originated from *Escherichia coli* will be used as standard reporter genes and for construction of gene fusions.

**Evaluation of foreseeable effects**

The GM microorganism is predicted to have the same capacity as other naturally occurring variants found in the environment and will be able to survive and persist if the a suitable amoebal host is present. There is no evidence that genetic determinants associated with human infection confers any advantage to survive in the environment.

Insertion of antibiotic resistant cassettes in order to select for plasmid positive strains will confer resistance to that antibiotic. However, the antibiotic resistance introduced to *Legionella* strains (to chloramphenicol, kanamycin or ampicillin) will not affect the normal treatment protocol.

Inserted gene products will be derived from existing strains of *Legionella*, and may be modified by site-directed mutagenesis. The examples of genes that will be targeted include putative virulence factors. The products of these genes are not predicted to have any inherent toxicity, carcinogenic or allergenic properties. These genes may slightly alter various phenotypes of *Legionella*, including virulence determinants. However, it is not predicted to the increase the pathogenic potential of the modified strain above that of naturally occurring strains.

For example, the introduction of an O-actylase gene is predicted to modify the LPS structure on the cell wall of the strain and this specific phenotype has also been shown to be over-represented in strains linked to human infections.

Reporter genes are non-harmful and fused genes for expression analysis will be only introduced to strains which already harbour the genes so the virulence of the host bacterium should not be affected.

The are no predicted hazards arising from the alteration of any pathogenic traits.

In some bacterial pathogens reports of ‘anti-virulence’ genes exist, whereby mutation of the gene enhances virulence. However, such loci are rare, as evidenced by screening of random mutant libraries using methods such as Tn-seq, which indicates that a very small proportion of random mutants screened in animal models are enriched relative to the inoculum following infection. Even where increased fitness of such mutants in vivo appears to exist, it does not automatically equate to increased pathology. The risks posed by engineered mutants is balanced by the risk of naturally-occurring mutation and risks are mitigated by the proposed containment measures.

The transfer of sequences could alter phenotypes in related microorganisms. However, these variants are already naturally occurring and this transfer can also occur in the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- **Disinfection** - All the working surfaces as well as all surfaces in case of a spill should be treated using a 1:10 solution of concentrate Distel. Distel is intended for the decontamination of surfaces of medical devices and is CE marked as Class IIa in accordance with the European Medical Device Directive 93/42/EEC and the 2007/47/EC amendments thereto. This disinfectant is manufactured by Tristel Solutions Ltd under approval by Lloyds Register Quality Assurance to the standards of BS EN ISO9001:2000 and BS EN ISO13485:2003 for the manufacture of disinfectant and sterilising solutions for medical, dental and veterinary use. A 1:50 solution was proven effective against Legionella pneumophila in 1996 by Bridle Microbiological Consultants (BS6471).

- **Autoclaving** - All contaminated materials will be inactivated by autoclaving (100% kill) as specified in BS 2646, Part 3, 1993 at 121°C for at least 15 minutes prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual (at least) thermocouple mapping and each run will be monitored using chemical indicators (e.g., Browne TST indicator test strips).

**Waste disposal**
- **Solids** (group C - e.g., plasticware such as pipettes, flasks, tubes, etc. and agar plates) - are autoclaved using a make safe cycle as specified in BS 2646, Part 3, 1993 at 121°C for at least 15 minutes. Any excess liquids are discharged to drains; solids are disposed via clinical waste stream for incineration or microwave treatment or via the industrial (black bag) waste stream for landfill.
- **Liquids** (e.g., samples, culture supernatants, culture media) – are contained in a secure, sealable and robust vessel as a flask. Autoclaved using a make safe cycle as specified in BS 2646, Part 3, 1993 at 121°C for at least 15 minutes and discharge to drains.
- **Sharps** (e.g., needles, scalpels) – Discarded into rigid “Sharpsafe” containers. The rigid lid should be snapped in place when first constructed and when ¾ full, the flap should be loosely adhered to the lid with autoclave tape. It should then be safely transported to the waste collection point, labelled with the location and date, and sent for autoclave treatment. The sharps container will then be sealed (by clicking the flap in place) and it will be sent for incineration. Autoclaved using a make safe cycle as specified in BS 2646, Part 3, 1993 at 121°C for at least 15 minutes.

Project Additional Information

Purposes of the contained use

Our aim is to understand the control of the life cycle of African trypanosomes at the molecular and cytological level. African trypanosomes are major pathogens in sub Saharan Africa, affecting up to 60 million people in 36 countries. They are transmitted by tsetse flies and produce a fatal wasting disease in humans and cattle. Most studies to date have focussed on Trypanosoma brucei spp. that have the potential to infect humans and animals, but this parasite is not the most important cause of livestock disease. Instead, two other species, Trypanosoma congolense and Trypanosoma vivax, are most prevalent and pathogenic.

We have identified a number of potential molecular regulators of the Trypanosoma brucei life cycle. However, the life cycle of Trypanosoma congolense and Trypanosoma vivax is different to Trypanosoma brucei and so might be their underlying molecular regulation. By analysis of their molecular expression in wild type trypanosomes and by perturbation of this in genetically modified parasites our objective is to understand how the molecular control of parasite transmission for
Trypanosoma congolense and Trypanosoma vivax operates. Our long term goal is to identify and exploit strategies that will allow parasite transmission to be disrupted, thereby preventing disease spread.

Recipient or parental organism

Trypanosoma congolense and Trypanosoma vivax are not infectious to humans and cause Nagana in domestic cattle and game animals in sub-Saharan Africa. They are classified as hazard group 2 by SAPO; they are not included with ACDP hazard groups, being non-infective to humans.

Procyclic (insect culture forms) of Trypanosoma congolense and Trypanosoma vivax are not infective to mammals. Trypanosomes do not produce toxins and do not form spores. Parasites do not survive outside of tissue culture or blood. They can only be transmitted by tsetse flies, though T. vivax is capable of mechanical transmission (see below). Infection by ingestion or inhalation is not a viable route of infection; parasites are only infective via the percutaneous route.

We expect most genetic manipulation of the parasite to reduce fitness and/or virulence: our experiments to date indicate perturbed expression of the molecules under study in our laboratory reduce virulence though other may affect development or increase virulence for example if they lose density dependent growth control.

Host/vector system

Constructs for transfection into trypanosomes are derivatives of commercially available, non mobilisable (i.e. Bom-, mob-, tra-) plasmids: pGEM series and pBluescript II. Inserted genes are not under bacterial expression control; they will only be effectively expressed in the parasite. In each case gene expression in the parasite is under tetracycline regulated control: thus, in the absence of tetracycline, gene expression is effectively silenced. Hence the vector and insert in combination present negligible risk.

Origin & function

Origins: T. congolense, T. vivax, T. b. brucei Lister 427; T. b. brucei TREU 927/4; T. b. brucei AnTat 1.1; T. b. evansi AnTat 3/3; T. cruzi (ACDP 3); Leishmania spp. (ACDP 2/3*).

Intended functions:
• Genes that are syntenic or predicted orthologues of genes already identified in Trypanosoma brucei as being involved in parasite differentiation (i.e. density dependent growth control in the mammalian bloodstream or differentiation upon stimulation to transform form bloodstream to tsetse midgut forms)
• Genes differentially expressed or with differential activity in different developmental stages of Trypanosoma congolense or Trypanosoma vivax.
• We will also express orthologous genes from Trypanosoma brucei in Trypanosoma congolense or Trypanosoma vivax. Other kinetoplastid orthologues may also be used (from T. cruzi, Leishmania spp. )

Where these genes or processes have been manipulated to date they have in each case either generated no consequence for the parasite, or have resulted in disruption of the parasite morphology, cell cycle or capacity for developmental processes.

We are also seeking molecules that interact with the above proteins or influence their function or specificity. In some experiments we will use genes from other kinetoplastids (for example Trypanosoma brucei) to functionally complement mutations in the above genes. These experiments will assess evolutionary conservation of the genes under study. Genes responsible for Trypanosoma brucei human infectivity have been identified and experimentally characterised: we will not introduce these genes into Trypanosoma congolense or Trypanosoma vivax.

Evaluation of foreseeable effects

T. congolense, T. vivax, T. b. brucei Lister 427; T. b. brucei TREU 927/4; T. b. brucei AnTat 1.1; T. b. evansi AnTat 3/3; T. cruzi (ACDP 3); Leishmania spp. (ACDP 2/3*).

We are investigating genes involved in life cycle differentiation events. Our experiments will express transgenic proteins, or mutant forms of these proteins or induce the ablation of the transcripts for endogenous trypanosome genes by RNA interference. These perturbations of normal processes in the cell are likely to have no consequence for pathogenicity and, moreover, may decrease parasite fitness though virulence may be increased if gene silencing affects density-dependent growth control. As indicated above, to date manipulation of the genes involved in the processes we study in Trypanosoma brucei have generated cell cycle arrest, lethality, morphological change and
Inappropriate developmental events. Manipulation of the genes under study will also not increase host range (the wild type parasites themselves are already infective to a wide range of mammals), and are very unlikely to confer infectivity of the trypanosomes to humans (the genes linked to human infectivity are known and experimentally well characterised).

Drugs used for selection of transgenic parasites differ from those used for clinical treatment of the disease. Trypanosomes produce no toxins or pathogenic products.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste from the CL3 laboratory in Ashworth 2, room 4.13, is transported to the autoclave in room 4.57 in the CL3 suite in Ashworth 3 in a locked yellow wheelie bin and autoclaved prior to removal for incineration. A robust leak-proof container is used for both storage and transport of waste for autoclaving. Most of the material that has come into contact with trypanosomes will be soaked for 24 hours in 2% Virkon. Thereafter, or for any items not disinfected first, the following waste disposal procedures will be used:

**Solids (e.g. plastic ware such as pipettes, flasks, tubes etc. and agar plates)** - autoclave using a make-safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or microwave treatment or via the industrial (black bag) waste stream for landfill.

**Liquids (e.g. samples, culture supernatants, tissue culture media)** – autoclave using a make-safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge to drains.

**Sharps (in sharps bin, e.g. needles, syringes, scalpels)** - autoclave using a make-safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), dispose via clinical waste stream for microwave treatment.

**Animal bedding and carcasses** – autoclave using a make-safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), dispose of carcasses via clinical waste stream for incineration and bedding via clinical waste stream for microwave treatment or via the industrial (black bag) waste stream for landfill.

Spills are contained with paper towels and treated with powdered Virkon (for larger volumes) or 2% Virkon (smaller volumes) and aerosols.

Degree of kill:

**Treatment with Virkon** - adding 1 ml of 1% Virkon to 10 ml of 1 x 106 bloodstream form T. brucei cells for at least 10 seconds effectively kills 100% of cells as no recovery is observed two weeks after treatment (Prof. Mark Field, personal communication).

**Autoclaving** - effectively 100% kill (annual validation).

Project Ref 207/18.7

Understanding the changes in mRNA processing that allow the pathogenic fungus Cryptococcus neoformans to survive stress and initiate host infection

Date Ackn'd 23/08/2018

CU2 Project Title

Tick if notifying a connected programme of work N

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use

Aim 1: To understand how sequences specify mRNA regulation in different growth states including lab models of infection by creating designed libraries of chimeric mRNAs composed of various relevant C. neoformans 5’ and 3’ regulatory sequences and mutations thereof, surrounding fluorescent reporter genes. Transform them into C. neoformans by genomic integration, quantify individual chimeric mRNAs and their protein products.

Aim 2: To understand how mRNA and protein sequences affect localization, expression, and function of native Cryptococcus proteins that regulate mRNA processing by creating recombinant proteins in C. neoformans, especially native proteins fused to epitope tags or fluorescent proteins, and mutants of RNA binding proteins, DNA binding proteins, and other proteins that regulate their binding. To test the effect of mutations on mRNA/protein localization, and expression, and downstream mRNA processing.
and cell growth.

**Recipient or parental organism**

Laboratory isolates of Cryptococcus spp., including C. neoformans strains H99, KN99a, and JEC21 (Hazard Group 2); these are Amphotericin B susceptible.

**Host/vector system**

Disabled laboratory strains of E. coli. Non-hazardous standard E.coli plasmids containing replication origins (ColE1) and selectable drug markers (Amp, Kan).

**Origin & function**

 Origins: restriction fragments or PCR amplicons from C. neoformans DNA, either using auxotrophic/antibiotic markers such as NAT /GEO for nourseothricin/G418 resistance, respectively (Chun & Madhani, Meth. Enzym., 2010; Hua et al., Clin Diagn Lab Immunol., 2000) or CRISPR/Cas9 for selection-free transformation (Fan & Lin, Genetics, 2018).

 Vectors are non-mobilisable.

 Intended functions:
 Libraries of chimeric mRNAs composed of various relevant C. neoformans 5’ and 3’ regulatory sequences and mutations thereof, surrounding fluorescent reporter genes to understand how sequences specify mRNA regulation in different growth states, including lab models of infection.

 Native proteins fused to epitope tags or fluorescent proteins, and mutants of RNA binding proteins, DNA binding proteins, and other proteins that regulate their binding and mutations thereof to test the effect of mutations on mRNA/protein localization, expression, and downstream mRNA processing and cell growth.

 Normal/expected function is fluorescence or regulation of gene expression. No known toxins or allergens will be produced. Inserts are not expected to have harmful physiological or pharmacological properties or to affect pathogenicity of cloning host or normal human defence mechanisms. Gene transfer is possible but unlikely to be hazardous. None of the proposed manipulations will introduce genes for which there is any evidence of additional harmful effects to immuno-competent humans.

**Evaluation of foreseeable effects**

None of the proposed manipulations will introduce genes for which there is any evidence of additional harmful effects to immuno-competent humans. Most deletion mutants reduce the viability and/or virulence, and deletions of less than 3% of genes increase the virulence of C. neoformans in animal models (Liu OW, et al. 2008. Cell 135: 174–188.). We plan to work only with any genes whose deletion decreases, or does not impact, virulence. The effect of GMOs on immuno-compromised individuals is expected to be similar to that of C. neoformans occurring naturally in the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Broth cultures, agar plates, absorbent disposable paper towels and infected plastic-ware such as pipette tips will be sterilised by autoclaving, at a minimum of 121ºC for 50 mins, validated by monitoring of internal chamber temperature. This method is widely acknowledged to guarantee complete killing of fungal cultures and spores. Wastes from autoclaving will be disposed of to the drains (liquids) or via the clinical waste stream.

Sharps (in sharps bin, eg needles, syringes, scalpels) – any necessary sharps will be disposed of in sharps containers, which are disposed of via the clinical waste stream for heat treatment via a university approved contractor.
The genetic modification safety committee agreed that the appropriate containment and control measures have been assigned.

### Project Additional Information

**Purposes of the contained use**

The purpose of the work is to elucidate mechanisms by which host cells respond to bacterial infection and the consequences of these responses. The aim is to improve understanding of the mechanisms used by the innate immune system to combat bacterial infections with the goal of identifying new therapies and preventive measures.

**Recipient or parental organism**

The following Class II organisms are included in this notification: Streptococcus pneumoniae, Haemophilus influenzae, Acinetobacter baumannii, Staphylococcus aureus, Klebsiella pneumoniae, Pseudomonas aeruginosa, Escherichia coli, Enterococcus faecalis and S. mitis.

All organisms are hazard group 2 pathogens.

Streptococcus pneumoniae, Staphylococcus aureus, Streptococcus mitis, Enterococcus faecalis, Haemophilus influenzae, Klebsiella pneumoniae, Acinetobacter baumannii, and Pseudomonas aeruginosa are all human pathogens.

Each organism can cause pulmonary infection or invasive disease, S. pneumoniae can also cause meningitis after colonisation of the respiratory tract. However with the exception of S. aureus and some H. influenzae, S. pneumoniae and E. coli strains these pathogens are predominantly opportunistic infections of sick patients in a hospital setting or with immune compromise.

S. pneumoniae can cause pneumonia or invasive diseases including meningitis. However, most infections are in people with medical illnesses or at the extremes of age. Preventive vaccines are available which prevent invasive disease.

Pneumococcal vaccination will be offered to all members of staff irrespective of the primary pathogen they work with.

Staphylococcus aureus can cause soft tissue infections. It colonises the skin of approximately one third of healthy individuals. It may also cause invasive disease typically spread by access to the blood, usually in hospitalised patients with cannulae or other instrumentation but sometimes in healthy patients in the community. Illness is characterised by signs of soft tissue infection or patients with invasive disease have fever and chills. There is currently no vaccine but effective antimicrobials are available against the strains we will use.

Haemophilus influenzae type b (Hib) vaccination will be considered for anyone working with on a sustained basis with Hib which can cause pneumonia and invasive disease. We however work primarily with non-typable H. influenzae which typically cause upper respiratory infections or bronchitis in patients with chronic lung disease and for which there is currently no vaccine. It is however an opportunistic infection and unlikely to cause disease in healthy patients.

All the other pathogens are primarily opportunistic infections, meaning they are unlikely to cause infection in healthy staff. *P. aeruginosa* can cause opportunistic infections of wounds, including keratitis. Lung disease would only be expected in people who are immunocompromised or with chronic lung disease. *S. mitis* is part of the normal oral flora and causes rare cases of aspiration pneumonia or invasive disease typically associated with cannulae or prosthetic materials or with poor dentition. *E. faecalis, K. pneumoniae* and *E. coli* are part of the normal bowel flora, these causes abdominal or urinary tract infections following surgical procedures or instrumentation. Pneumonia is described but very rare with enterococci and for the other organisms typically occurs in immunocompromised patients or those on a ventilator. *Acinetobacter baumanii* is an environmental micro-organism that can colonise sick patients typically in intensive care settings. It is an opportunistic infection and like most of the Gram negative bacteria listed is typically selected by use of broad spectrum antimicrobials. Infections include ventilator associated pneumonia. Infections would not be expected in healthy staff but if after investigation of febrile symptoms they were identified they would be treated with antimicrobials.

*S. aureus, S. pneumoniae* and *H. influenzae* can cause clinical symptoms of fever, respiratory tract illness or invasive
disease (signs of fever and chills). All workers will be informed about potential symptoms and to seek urgent medical
advice if they show any symptoms of ill health. All infections are effectively treated with prompt administration of
antimicrobials as outlined above. All workers will be advised to contact their GP and to ask for referral to their local
NHS admissions unit for assessment if indicated. Staff will be offered pneumococcal vaccination to prevent any risk of
S. pneumoniae meningitis and Hib vaccination if working with Hib. The other pathogens as primarily opportunist
infections are unlikely to cause any infections in healthy staff but any staff with chronic medical conditions will be asked
to have a health assessment with occupational health to assess if they should work with the pathogen. All staff will be
asked to report any health symptoms promptly to their GP or University health services promptly as above.

Host/vector system

The mutants have been created by external collaborators using techniques such as insertional mutagenesis or in
frame deletions and inactivated chromosomal genes may have been complemented by reinsertion of a copy of the
deleted gene, which may have been achieved by use of a plasmid maintained by an antibiotic resistance marker.
Inactivated chromosomal genes may or may not contain antibiotic resistance cassettes (e.g. Janus cassettes) but
where these are used they will involve antibiotics such as streptomycin, kanamycin, chloramphenicol, lincomycin,
macrolides or tetracyclines which are not the antimicrobials used as the primary treatment of these organisms, which
are primarily treated with penicillins, cephalosporins, carbapenems, or where beta-lactam resistant, glycopeptides,
lipopeptides or fluoroquinolones.
Confirmation of the genetic mutation and initial analysis of function will have been carried out in the collaborators
laboratories. Any potential further manipulation of parental or genetically modified strains will be under the direct
guidance of the primary laboratory who have created the strains.
Mutants will be of reduced virulence or will have no alteration of virulence compared to parental strains.

Origin & function

The mutants will have been created by external collaborators using techniques such as insertional mutagenesis or in
frame deletions and inactivated chromosomal genes may have been complemented by reinsertion of a copy of the
deleted gene, which may have been achieved by use of a plasmid maintained by an antibiotic resistance marker. Any
potential further manipulation of parental or genetically modified strains will be under the direct guidance of the
primary laboratory who have created the strains.
We include an appendix of several mutants we anticipate we would like to investigate as part of this study and will
update this appendix as further mutants are investigated. This outlines strains, the genes mutated and any antibiotics
resistance markers used for the mutant.
Transposon mutant libraries of strains such as S. aureus or S. pneumoniae may be accessed from collaborators or
genetic transformants of clinical S. pneumoniae on a standard laboratory strain background (TIGR4) generated.
In addition, the mutants will include deletion mutants, point mutations or complementation mutants of genes involved
in bacterial adherence, resistance to host defence strategies or cell death. And will potentially include genes in
involved in the production of capsules, cell wall constituents, surface expressed proteins, toxins, enzymes,
transporters, metabolic pathways, resistance to reactive species, proteases or peptides, iron acquisition or global
regulators (where deletion of the regulator is not anticipated to increase virulence).
In all cases, the mutants will be deemed to have no enhancement of virulence compared to the parental strain or to
the clinical strain in the case of mutant screens involving transformation. In the vast majority of cases, it is anticipated
that the GMMOs will essentially be attenuated versions of the parent strain. Whilst it is possible that insertional
inactivation of a particular gene within a locus may result in elevated virulence, if that gene (or downstream genes
within the locus) plays a role in repression of virulence factors, it is considered unlikely any such effect would raise the
containment level required above that for a hazard group 2 pathogen.
Insertional inactivation of putative virulence genes and antibiotic resistance determinants is likely to render the GMMO less virulent and/or less resistant to antimicrobials. In theory, transposon mutant screens could alter susceptibility to killing in a phagocyte but usually with associated fitness cost that will alter survival in the environment. Mutants will be of reduced virulence or will have no alteration of virulence compared to parental strains. As such the consequences of the deletions or of complementation are predictable and will produce strains that are less pathogenic or of comparable pathogenicity to the wild-type strains and will not have altered routes of transmission or host range. The most likely consequence of inadvertent exposure would be colonisation of the skin (for S. aureus), the respiratory tract (for S. pneumoniae), oral cavity (S. mitis) or gut (E. coli, K. pneumoniae or E. faecalis). However, these laboratory strains would be less likely to outcompete the individuals own strains. Other bacteria studied would be unlikely to colonise immunocompetent hosts only those with lung disease or immunocompromised. Respiratory tract colonisation for agents other than S. pneumoniae only occurs for those with underlying lung disease or in hospital and receiving broad spectrum antimicrobials and the same is largely true for H. influenzae, K. pneumoniae and S. aureus. Transient colonisation of S. pneumoniae occurs in 10-70% of the normal population, so if this were to occur it would replicate a situation that commonly occurs in normal life. If colonisation were to occur there is a small chance of invasive disease. We cannot predict the exact magnitude of this risk but since invasive disease occurs at a frequency of <1/100,000 in adults in the UK that means the risk of invasive disease is <1 in a thousand if it were to occur for S. pneumoniae. Prevalence data for S. aureus bacteraemia is also <1/1000 and rates of invasive disease with the other pathogens listed range from negligible (<1/1,000,000 to 1-10/100,000) all making these highly unlikely events.

Evaluation of foreseeable effects

Insertional inactivation of putative virulence genes and antibiotic resistance determinants is likely to render the GMMO less virulent and/or less resistant to antimicrobials. In theory, transposon mutant screens could alter susceptibility to killing in a phagocyte but usually with associated fitness cost that will alter survival in the environment. Mutants will be of reduced virulence or will have no alteration of virulence compared to parental strains. As such the consequences of the deletions or of complementation are predictable and will produce strains that are less pathogenic or of comparable pathogenicity to the wild-type strains and will not have altered routes of transmission or host range. The most likely consequence of inadvertent exposure would be colonisation of the skin (for S. aureus), the respiratory tract (for S. pneumoniae), oral cavity (S. mitis) or gut (E. coli, K. pneumoniae or E. faecalis). However, these laboratory strains would be less likely to outcompete the individuals own strains. Other bacteria studied would be unlikely to colonise immunocompetent hosts only those with lung disease or immunocompromised. Respiratory tract colonisation for agents other than S. pneumoniae only occurs for those with underlying lung disease or in hospital and receiving broad spectrum antimicrobials and the same is largely true for H. influenzae, K. pneumoniae and S. aureus. Prevalence data for S. aureus bacteraemia is also <1/1000 and rates of invasive disease with the other pathogens listed range from negligible (<1/1,000,000 to 1-10/100,000) all making these highly unlikely events.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All bacterial cultures from plates are placed in the metal buckets for autoclaving and autoclaved on a decontamination cycle to render them safe and ready for discarding. Material will be inactivated by autoclaving (100% kill) at 121°C for 20 minutes prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual (at least) thermocouple mapping and each run will be monitored by continuous chart or digital recording of the temperature / time profile. Contaminated pipettes, pipette tips, spreaders, bacteria infected liquid etc. must be soaked for at least 12 hours in 1% virkon solution to decontaminate, prior to safe disposal. Any bacterial spills will be decontaminated with a 1% virkon solution for two hours before placing in yellow bins for incineration. Animal bedding, waste from animals and carcasses that have been infected with GMMO organisms will be incinerated.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
The genetic modification safety committee agreed that the appropriate containment and control measures have been assigned.

Purposes of the contained use

We will examine how rotaviruses interact with the host cells they infect by comparing wildtype virus replication kinetics with the replication kinetics of viruses which have been modified in specific regions of the virus genome. Modification of the virus genome can be done either to alter the nucleotide sequence of the virus (i.e. synonymously) or the protein sequence (i.e. non synonymously). By identifying regions of the virus genome key for interaction between virus and host, we can identify new therapeutic candidates and vaccine targets.

Recipient or parental organism

Mammalian culture cells or organoid systems will be infected with rotavirus.

Host/vector system

Rotaviruses infect a range of organisms including man, monkeys, bovine species and chickens, and a range of strains specific to different hosts will be used.

Origin & function

The rotavirus genome comprises 11 segments of double stranded RNA. To artificially synthesise a rotavirus which we have the ability to alter the genetic sequence of, we encode the virus genome on 11 discrete plasmids, each corresponding to one segment of the virus genome, with each segment under the control of the T7 RNA polymerase promoter. All 11 plasmids are then co-transfected into BSR-T7 cells which have been engineered to express the T7 RNA polymerase, and so viral RNAs and proteins are produced. This ultimately yields the production of de novo virus particles.

Artificial synthesis of rotaviruses using this approach enables us to modify the sequence of the virus genome. To modify the sequence of the virus, the viral genome sequence encoded on the plasmid is modified. These modifications will be used to make modified viruses which we can characterise in comparison with unmodified virus.

Evaluation of foreseeable effects

Our lab is interested in investigating virus-host interactions, including how the virus interacts with the innate immune response. We are therefore interested in modifying regions of the virus genome that we hypothesise are important for downregulation/ control of the innate immune response. The impact of this would be that the virus would replicate less well.

We are also interested in identifying accessory proteins produced by the virus, and confirmation of their production by mutagenesis to remove them. Viruses encode accessory proteins to assist their replication, so modifications to this effect will again cause a fitness loss to the virus.

We are also interested in how dinucleotide composition impacts virus replication, and to investigate this we will modify the frequency of dinucleotides of interest (usually CpG) by synonymous mutation. Addition of CpGs has been shown to be detrimental to virus fitness for a range of virus (Gaunt et. al., eLife, 2016; Atkinson et. al., NAR, 2014 among others). Removing CpGs from a virus genome may cause a modest increase in fitness for echovirus 7 (Atkinson et. al., NAR 2014) but we were not able to reproduce this for influenza A virus (unpublished data). Extensive recoding of a virus genome is unlikely to cause an improved replication phenotype, due to the likelihood of inadvertent loss of packaging signals, accessory protein open reading frames etc.; therefore, there may be a small increase in virus fitness but this is not considered likely.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

RV-containing waste liquids will be aspirated into a container containing Distel® though a closed aspiration system. After 24h of inactivation the container may be changed and the liquid discarded down the sink. Surface disinfection will be with 2% Distel and 70% EtOH. Plastic waste will be soaked in 2% Distel overnight prior to being discarded through the autoclave waste stream. Distel is effective against bacteria, viruses, fungi, mycobacteria and denatures RNA and DNA (https://www.scientificlabs.co.uk/product/TR1366#tab-1). Distel is recommended for use at 1:100 dilution for normal laboratory applications.
(https://www.tristel.com/tristel-products/distel-for-labs) and so 2% is conservative. Distel has demonstrated efficacy against rotaviruses at a 1:100 dilution (https://mixmed.myshopify.com/pages/distel).

All contaminated materials will be inactivated by autoclaving (100% kill) at 121°C or 134°C prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual (at least) thermocouple mapping and each run will be monitored using chemical indicators (eg Browne TST indicator test strips).

### Project Additional Information

#### Purposes of the contained use

Define function of bacterial genes and proteins involved in pathogenesis.

#### Recipient or parental organism

- **Streptococcus pyogenes** (group A Streptococcus)
- **Streptococcus agalactiae** (group B Streptococcus)
- **Streptococcus dysgalactiae** (inc. subsp. equisimilis)
- **Streptococcus spp.**
- **Lactococcus lactis**

#### Host/vector system

Plasmids facilitating:
1. Streptococcal protein expression in streptococcal species and Lactococcus lactis
2. Streptococcal gene knockout or replacement (including mutant libraries)
3. Recombinant protein production
4. Protein interaction studies

#### Origin & function

Genetic material involved will originate from streptococcal or other bacterial species.

Functions include: antibiotic resistance markers, reporter genes, gene fusions, gene complementation, modifications to promoter sequences or amino acid residues, expression of streptococcal genes in heterologous species, deletion or functional inactivation of streptococcal genes, expression of naturally occurring alleles.

#### Evaluation of foreseeable effects

Some of the species used are human pathogens (S. pyogenes, S. agalactiae and S. dysgalactiae subsp. equisimilis), whereas Streptococcal spp. are largely pathogens of animals, which can cause humans disease.

The GMOs should be no more hazardous than the parent strains from which they were derived, indeed in the vast majority of cases strains should be less virulent. Any excess risk is related to (a) the introduction of additional antimicrobial resistance genes that may impede the efficacy of antimicrobials if required, and (b) the inadvertent but
rare genetic modification that results in unforeseen increase in virulence, for example in a regulatory gene. Hazards from antimicrobial resistance are minimised by use of antimicrobial markers that are not in clinical use.

While the production of strains more virulent than wild type is unlikely to occur, it is a possibility. Mutations in regulatory genes can occur spontaneously in nature, and are selected for during invasive infection; as such the risk of such mutations arising in nature is possibly greater than the risk that they occur in the laboratory. However, if a more virulent strain is produced, work with this modified agent will stop until the hazards and risks have been considered. While very unlikely that any additional control measures will be necessary, if required, these will be implemented, the assessment be updated and the findings be discussed with the local GM biological safety officer.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not relevant

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be autoclaved via the biohazard waste route followed by alternative treatment or incineration by our waste contractor. Liquids which have been autoclaved will be discharged to sink.

Disinfection
Please give details of disinfectant(s), method and validation including concentration of disinfectant and contact time (eg supplier's instructions or local validation).
Tristel at a 1:100 dilution with contact time of 30 secs – 5 minutes (manufacturer's guidelines for working with Streptococcal species)
https://www.tristel.com/tristel-products/all-tristel-products

Autoclaving
Please give details of autoclave method and validation.
All contaminated materials will be inactivated by autoclaving (100% kill) at 121°C or 134°C prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual (at least) thermocouple mapping and each run will be monitored using chemical indicators (eg Browne TST indicator test strips).

The genetic modification safety committee agreed that the appropriate containment and control measures have been assigned.

Project Containment
This project will test the feasibility of utilizing the eukaryotic protist Toxoplasma gondii as a vector for therapeutic protein delivery to the brain. The idea relies on harnessing T. gondii’s features as a brain parasite to enable protein replacement therapy. Using a novel method for driving constitutive secretion of heterologous proteins by T. gondii, we will (1) generate transgenic T. gondii lines that express and secrete the mammalian MeCP2 protein and (2) test this GMMO as a protein delivery system in rodent models of the neurological disorder Rett Syndrome (RTT).
**Host/vector system**

The DNA vector inserted into *T. gondii* is a *T. gondii* expression plasmid (non-viral), introduced by electroporation and integrated into the *T. gondii* genome following drug selection. The plasmid contains a selectable cassette including the gene HXGPRT (complementing a mutation in the parental line). This vector does not pose any hazards. The lab strains used in this study, corresponding to the "type II" lineage of *T. gondii*, have particularly low virulence compared to other natural strains of *T. gondii*.

**Origin & function**

Lab generated plasmid DNA encodes for fusion gene comprised of the endogenous *T. gondii* gene GRA16, fused to murine MECP2. The expression of the insert is controlled by the endogenous *T. gondii* GRA16 promoter and GRA2 3'UTR. The murine MECP2 sequence is codon optimized according to *T. gondii* endogenous codon usage to facilitate optimal protein folding and expression. Infected mice will receive *T. gondii*-derived MeCP2 protein in amounts that are not considered to be deleterious.

**Evaluation of foreseeable effects**

(1) None of the genetic modifications conducted are related to any of the existing pathogenic traits of *T. gondii*. Furthermore, in vitro, the altered *T. gondii* did not exhibit elevated virulence, resistance or growth rate, compared to the unaltered line. (2) On introduced into mice, the risks associated with the *T. gondii* infection are considered low as detailed in the accompanying RA. There is no expected novel or cumulative hazard in *T. gondii* infection of Mec2-null mice compared to wild-type animals.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

(1) Before injection, *T. gondii* will be grown in incubators in a CL-2 *T. gondii* lab. (2) All infection procedures will be conducted in the infection section of the Roslin rodent unit which is a secure unit.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

NA

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

(1+2) Plastic waste is neutralized using Distel or similar quaternary ammonium disinfectant (5% w/v solution) for 24 hours, then autoclaved. (2) Sharps will disposed of immediately into a sharps bin and thenautoclaved according to standard practice for sharps. Other items will be autoclaved and then disposed of along with other waste from the Bioresearch & Veterinary Services (BVS). Animal carcasses will be disposed of by incineration.

Project Additional Information

Purposes of the contained use

Human embryonic stem cells (H9) will be differentiated to hepatocyte-like cells, and will either knockdown or overexpress the ten-eleven translocase 1 (TET1) and 2 (TET2) enzymes, using a replication-deficient lentiviral vector. The purpose of this experiment is to interrogate the roles that TET1 and TET2 play in human fatty liver disease, by modelling fatty liver in vitro. The lentivirus will either carry a sequence to overexpress the gene of interest, or shRNA sequences to silence it. Cells will be differentiated until day 15, and then infected for 24 hours. After a further 24 hours, cells will be treated with a cocktail of lactate, pyruvate, and octanoate, to induce a fatty liver-like phenotype in vitro.

Recipient or parental organism

Human embryonic stem cell line (H9) and human embryonic kidney cell line (HEK293)

Host/vector system

The inserts coding either the human TET1 or TET2 catalytic domain, full length human TET1 or TET2 will be cloned into a pSFFV backbone (a gift to the lab). This will then be transfected into HEK293 cells alongside two packaging plasmids: pMDG and pCMVint. This will generate viruses that express genes of interest under a CMV promoter.
For the shRNA sequences, pLKO.1 plasmids carrying shRNA sequences targeting TET1 or TET2 will be purchased from Sigma-Aldrich (Catalogue # SHCLNG-NM_030625). These will be transfected into HEK293 cells alongside two packaging plasmids: psPAX2 and pCMV-VSV-G. This will generate viruses that express genes of interest under a CMV promoter.

Origin & function

We will be using the lentiviral vector to either overexpress the catalytic domain or full length sequence of human TET1 and TET2. Both genes are involved in regulation of gene expression through alteration of DNA methylation patterns. Where TET1 or TET2 are absent, a third isoform, TET3, can provide some compensation for loss of function. We will additionally use lentiviral vectors carrying shRNA sequences to knockdown TET1 and TET2 in vitro.

Evaluation of foreseeable effects

The likelihood of harm to human health is low. The role of Tet1 and Tet2 is to oxidise methylated cytosine, to 5-hydroxymethylcytosine, which is thought to be a stable epigenetic mark. Whilst TET1 and TET2 have been identified as potential oncogenes, and associated with the development of glioblastoma, it is not believed that their impact on genome methylation alone is sufficient to drive changes in gene expression.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disposable lab coats must be worn when working with high titre virus stocks and during the first 7 to 10 days after transduction. They must be autoclaved before final disposal by incineration via the yellow bag route.

All solid and liquid waste must be decontaminated/disposed of by the user at the end of every TC session.
Surfaces will be sprayed with Virkon 10% solution after use. Surfaces within the class II cabinet should not be sprayed with Virkon 10% solution as it corrodes the metal, use 1% Distal Trigene instead.

Solid waste disposal:
Stripettes
Autoclave stripettes before disposal. Double bag in clear plastic autoclave bags in a metal bucket for autoclaving then place in a yellow bag for disposal by incineration.

Plastic ware such as flasks, tubes and agar plates:
Soak in 1%w/v Virkon, or 1,000 ppm Precept (four 0.5g tablets into one litre of water) for 24 hours before discharging any excess liquid via drains. Following chemical decontamination, place all plastic ware and agar plates into the yellow bags within the tin autoclave drums, tie bag and place in the white plastic bin - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes).
After autoclaving, yellow bags are disposed of by incineration.

Liquid waste disposal
samples, culture supernatants, tissue culture media
Any liquid potentially containing virus should be collected in an autoclavable screw top plastic bottle (stored under the sink). It should NEVER come into contact with the vacuum system. The liquid waste should be chemically disinfected by soaking in 1% w/v Virkon, or 1,000 ppm Precept (four 0.5g tablets into 1 litre of liquid) for 24 hours before discharging via the drains. The container must be labelled with name, group and date.
The genetic modification safety committee agreed that the appropriate containment and control measures have been assigned.

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID
The purpose of the contained use is to produce recombinant human alpha-synuclein protein to act as a substrate for a newly developed protein aggregation assay called Real-Time Quaking Induced Conversion assay (RT-QuIC). RT-QuIC has been demonstrated to be a very sensitive and specific diagnostic test for Parkinson's Disease and Lewy body dementia.

For recombinant α-syn protein expression and purification, the host will be the E. coli BL21 Rosetta strain. Plasmid maintenance stocks will utilise the E. coli DH5 alpha strain. These are functionally disabled strains that cannot survive in the environment and do not colonise the human gut.

The vectors used will be pET and pUC type vectors such pET24a or pRSET. These vectors are non-transmissible and do not pose a risk to human health or to the environment.

The DNA for making WT human α-syn was cloned by RT-PCR from a cDNA library by Dr Gillian Cooper at the National Institute for Biological Standards and Control (NIBSC). Future genetic inserts will be cloned by RT-PCR from a commercial cDNA library by e.g. EuroFins or GeneArt. The intended use is to express and maintain recombinant protein expression in E.coli.

E. coli BL21 Rosetta strain and the E. coli DH5 alpha strain are functionally disabled strains that cannot survive in the environment and do not colonise the human gut, and as such pose no risk to human health or the environment.

The human a-synuclein recombinant protein is a monomeric protein which has been shown to be non-hazardous using both cellular toxicity assays involving SHSY-5Y cells and using inoculation studies involving mice.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All contaminated materials will be inactivated by autoclaving (100% kill) at 134oC for 30 minutes prior to disposal of waste by incineration. Autoclaves will be validated by annual (at least) thermocouple mapping and each run will be monitored by continuous chart or digital recording of the temperature / time profile.

Non-GMM

- Project notified under transitional arrangements

**Project Additional Information**
Purposes of the contained use

This project is involved in the development and establishment of a pseudotype lentivirus expression system to permit investigations of the role of viral surface glycoproteins in mediating interactions with avian hosts. It will generate pseudotype particles, which are chimeric “viruses” consisting of a surrogate virus core surrounded by a lipid envelope with the surface glycoproteins of another virus displayed on the outside of the viral particle.

By removing the genetic element of the virus being studied and replacing it with a suitable reporter, viruses, especially high-pathogenic, can be studied in this safer, single cycle system. The comparative safety of pseudotype viruses circumvents the need for restrictive, expensive, and widely unavailable high-category biosafety facilities, increasing access to research groups interested in highly pathogenic viruses. This pseudotype virus expression system will be utilised for studying avian viruses including avian influenza virus (AIV), avian infectious bronchitis (IBV) and newcastle disease (NDV), to aid vaccine development projects against these avian viruses.

Briefly, pseudotype viruses are generated via co-transfection of “producer” cells with plasmids expressing: (1) the envelope protein of a virus of interest, (2) proteins of a “core” virus, often a retrovirus, and (3) a reporter transgene. The envelope protein will enable the virus to target cells permissive to the virus of interest. During cell transduction, the reporter transgene becomes integrated into the genome of the cell (via lentivirus vector components) and is expressed, permitting quantification.

Recipient or parental organism

Laboratory adapted E. coli such as E. coli HST08 (Stellar competent cells, Takara) and JM109 (Promega) will be used for cloning and plasmid amplification. These recipient non-pathogenic E. coli used for cloning and production of the expression vectors will be laboratory adapted E. coli K-12 derivative strains so survival outwith the defined culture conditions is unlikely and they cannot survive in the human digestive tract or produce toxins. The expression vectors transformed into these E. coli strains are not designed to express in E. coli.

Packaging cells used to produce non-replicating viral particles or recipient cells to be infected with the pseudotype viruses will be established cell lines; human embryonic kidney 293T/17 (HEK293T/17), Madin-darby Canine Kidney (MDCK) and Vero cells and do not pose a significant threat to human health. Titration and serum neutralisation assays using pseudotype viruses will be conducted using cell lines, including HEK 293T/17, MDCKs and Vero cells. [Hazard group 1 for cells, Hazard group 2 for lentiviral particles].

The tropism of the pseudotype particles generated will be altered from that of the parent vector, and will be dependent on the specific glycoprotein expressed by the helper plasmid. The pseudotype particles are replication deficient and will not be able to enter the target cell type without expression of the glycoprotein under investigation or without some transfection mechanism. Using glycoproteins from avian influenza, IBV and NDV will alter, and likely reduce, the number of cell types that the lentiviral particles can enter.

Host/vector system

Host organisms:
Plasmids will be propagated in E. coli JM109, K-12 (Promega) or HST08 (Stellar competent cells, Takara). [Hazard group 2]
Lentiviral particles will be produced by co-transfection of 3 or 4 plasmids into human embryonic kidney (HEK) 293T/17 cells. [Hazard group 1 for cells, Hazard group 2 for lentiviral particles]
Titration and serum neutralisation assays using pseudotype viruses will be conducted using cell lines, including HEK 293T/17, MDCKs and Vero cells. [Hazard group 1 for cells, Hazard group 2 for lentiviral particles]

Vector systems (plasmids):
pl.18 or pcAGGIIs (expression vectors used for gene of interest) - the cDNA construct for the avain glycoprotein under investigation will be inserted upstream of a human cytomeglovirus (CMV) promoter.
pCSFLW (firefly luciferase or GFP lentiviral vector) - reporter construct which is a modified HIV-1 clone containing the packaging elements and a firefly luciferase reporter or a green fluorescent protein reporter. This is a self-inactivating vector, with a safety component incorporated through a deletion in the 3’ long-terminal repeat (LTR), this is
Transferred into the 5' LTR after one round of reverse transcription and abolishes transcription of the full-length virus after it has incorporated into a host cell. This renders the resulting lentiviral particles replication incompetent and will significantly reduce expression from the viral promoter after integration of the reporter into the genome.

pCAGGs-TMPRSS2 or pCAGGs-HAT (protease plasmids)

p8.91 (gag/pol lentiviral vector) - a modified HIV-1 clone, which lacks the retroviral Psi packaging element sequence in addition to the removal of virulence and accessory genes (env, vif, nef, vpu, and vpr genes), which are not required for viral packaging. It has a CMV promoter in lieu of long-terminal repeat (LTR)-based promotion, meaning that p8.91 will provide the necessary genes for the production of the core only.

**Origin & function**

Avian virus glycoprotein sequences will be cDNAs, selected originally from the sequence data of the avian virus under investigation. These cDNAs will be purchased as GeneART DNA fragments, they will be codon optimised and additionally synthesised with the appropriate restriction enzyme sites and kozac sequences added to ensure efficient ligation into expression plasmids and subsequent translation.

Pseudotype virus particles will be produced in HEK 293T/17 cells, a human cell line initially transformed with the adenovirus early region, also expressing the SV40 T-antigen. Virus particles are produced by the co-transfection of a 2nd generation (disabled) lentivirus vector and helper plasmids. The helper plasmids will contain avian viral glycoproteins (p1.18 or pCAGGs), proteases (pCAGGs) and firefly luciferase (pCSFLW). Using glycoproteins from avian viruses will alter, and likely reduce, the number of cell types that the lentiviruses can enter.

The lentiviral vectors are introduced to the HEK293T packaging cells by transfection to produce pseudotype viruses in the cell culture supernatant, these recipient cells will be transduced with the replication incompetent lentivirus particles for 24 hours at 37°C with the chemical transfection agent, Polyethylenimine (PEI). Lentiviral particles are generated in the packaging cells and are released into the growth media. Specifically in the experimental work proposed for AIV, endogenous recombinant neuraminidase (derived from Clostridium perfringens) will be added to the transfection culture after 24 hours to enable budding of viral particles from the cell surface. The growth media and supernatant containing viral particles will be collected after 72 hours of incubation at 37°C, filtered, aliquoted into 1ml aliquots in screw-top Eppendorf tubes and stored in a designated freezer box at -80°C in a locked room.

The pseudotype particle produced will be titrated in HEK293T cells to determine the relative luciferase units (i.e. viral titre) and then subsequently screened in serological assays (serum neutralisation and haemagglutinin inhibition assays) to assess cross-reactivity against avian serum, specific for the virus and the surface glycoprotein under investigation. Additional assays will be performed to assess the role of the viral surface glycoproteins in facilitating interactions with host cells receptors and permitting entry into avian host cells.

**Evaluation of foreseeable effects**

This pseudotype expression system to be used here is a three plasmid based system, with the components necessary for virus production split across multiple plasmids: (1) transfer vector containing transgene e.g. GFP or Firefly luciferase, (2) packaging vector and (3) envelope vector, which decreases the risk of any recombination events. Several safety features have been included in this system to minimise the potential of replication competent lentivirus (RCL) production, or subsequent mobilisation of the integrated transgene form the genome of the host cell. This is a 2nd generation lentiviral replication system displaying low risk of recombination with endogenous retroviruses due to the division of synthetic viral elements (i.e. coding sequences have been significantly altered from the original) and the vectors are self-inactivating.

Lentiviral vectors are disabled and are only able to replicate in helper cell lines. They are a well established reagent and are not considered to pose any significant health risk. The pseudotype virus to be used here will be derived from a HIV-1 clone. It will be a second generation, replication incompetent system. The majority of viral genes required for viral replication have been removed. Others (Gag, Pol and Rev) will be supplied in trans. A deletion in the 3' long-terminal repeat (LTR) allows transcription following transfection of HEK 293T cells but following reverse transcription results in a non-functional 5'LTR in transduced cells and as a result are self-inactivating vectors.

The lentiviruses will be capable of infecting human cells with the consequent insertion of the vector genome into chromosomal DNA but that will be the end of the life-cycle as the virus is replication deficient, self-inactivating, 2nd generation vector which is not carrying genetic material harmful to humans (no human oncogenes or tumour
suppressor genes). The main hazard is the possibility of oncogene activation at the site of integration and the self-inactivating lentiviruses are considered less likely to activate cellular genes near insertion sites than conventional gamma-retroviral vectors. A further potential hazard is the generation of replication-competent virus but the use of self-inactivating vectors makes this highly unlikely.

Accidental inoculation via application to cuts or via needle stick could result in the transduction of human tissue. Due to this risk, sharps will not be used during production, concentration or assays involving lentiviral pseudotype viruses. To avoid unnecessary exposure. All broken skin (cuts, dermatitis, weeping wounds etc.) will be covered with a waterproof dressing and appropriate PPE of lab coat and gloves will be worn at all times. Operator gloves will cover the cuffs of the lab coat whilst working with lentiviral particles.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids (e.g. plastic ware, pipette tips, flasks, tubes etc), which have been in contact with lentivirus plasmids or pseudotype particles will be disposed of into a designated container inside the biosafety cabinet. This container will be sealed prior to removal from the cabinet and subsequently autoclaved according to the procedure as stated below.

Lentivirus containing waste liquids will be aspirated into a container containing 10% Distel, a broad spectrum virucidal disinfectant, in a biosafety cabinet through a closed aspiration system to avoid aerosol generation. Waste media will be treated with Distel at a 1:10 dilution for 24 hours at a designated place to inactivate any remaining lentiviral particles and autoclaved prior to disposal. All waste bottles will be clearly labelled with date and content and autoclaved afterwards according to the procedure as stated below. Surface disinfection of the biosafety cabinet will be conducted with 1-10% Distel.

Autoclaving:
All contaminated materials will be inactivated by autoclaving (100% kill) at 134°C with a hold time of 10 minutes prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves are validated at least by annually by thermocouple mapping and each autoclave run will be monitored using chemical indicators (eg Browne TST indicator test strips).

The genetic modification safety committee agreed that the appropriate containment and control measures have been assigned.

Project Containment
Project Additional Information

Purposes of the contained use

Our model of infection employs adult pregnant mice to study ascending vaginal infection caused by Escherichia coli K1. We aim to use this model of infection combined with a genetically modified bioluminescent strain of E. coli O18:K1 (A192PP) to track the course the infection using an IVIS bioluminescence imager. Strain A192 (DSM. No. 10719) (Achtman, et al., 1983) was used to generate this strain. A bioluminescent derivative of E. coli A192PP has been generated by introduction of the luxCDABE operon from the nematode symbiont Photorhabdus luminescens, as performed by collaborators. The luxCDABE operon is supplied through mini-Tn5 mutagenesis using the construct pUTm.

Recipient or parental organism

ACDP hazard group: 2

Host/vector system
pUTmini-Tn5

- Plasmid can only be maintained in lambda pir+ donor strains (e.g. E. coli S17-1 lambda pir).
- Plasmid can be transferred by conjugation to other bacterial strains (pir-) and acts as a suicide vector.
- Transposon is disarmed, so forms stable integrations within recipient chromosome and cannot re-mobilise. (Winson, et al., 1998) The mini-Tn5 is also transcriptionally isolated: a in frame stop codon (TAG) was introduced 18 codons upstream of the luxC ATG.

Origin & function

The inserted transposon is the luxCDABE: lux operon from the nematode symbiont Photobdus luminescens ATCC29999 (Hb strain) (Winson, et al., 1998). With kanamycin resistance cassette (Km2). The operon provides the mechanics for bioluminescence emission from the recipient strain. Recipient strains are resistant to kanamycin (kanR) by acquisition of mini-Tn5 luxCDABE Km2.

Evaluation of foreseeable effects

The inserted transposon is the luxCDABE: lux operon from the nematode symbiont Photobdus luminescens ATCC29999 (Hb strain) (Winson, et al., 1998). With kanamycin resistance cassette (Km2). The operon provides the mechanics for bioluminescence emission from the recipient strain. Recipient strains are resistant to kanamycin (kanR) by acquisition of mini-Tn5 luxCDABE Km2.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

- Animal housing at BVS LF2 Animal Facility has individually ventilated cages (IVCs).
- Appropriate personal protective equipment (PPE) will be worn at all times for work with animals; including P2 face masks, disposable gloves, overalls, shoe covers and mob caps.
- Infection of pregnant mice will be done in downdraft hoods in SU548 to enable mice to be anaesthetised during bacterial instillation. However, only the trained operator will be in room SU548 when any work with this bacteria is undertaken.
- Infected mice will be housed in individual IVC cages and will not be touched by BVS staff after infection with this bacteria.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

70% ethanol will be used to disinfect all surfaces used in microbiology culture lab (W1.34) and animal facility (LF2). Ethanol has been show to kill E.coli following 10 seconds exposure at all concentrations between 40-100% (Tilley et al, J Bacteriol, 1926).

1% Virkon will be used for cleaning all instruments and spraying – in of materials transported into LF2.

1% Trigene will be used on bench surfaces prior to 70% ethanol as above.

W1.34 Waste:
Disposal route following standard QMRI waste disposal guidelines:
Solids (eg plasticware such as pipettes, flasks, tubes etc) – Soak in Virkon for 12-24h. Discharge any excess liquid to drains, dispose of solids via the yellow bag with yellow tag heat treatment waste stream.
Liquids (e.g., samples, culture supernatants, tissue culture media) – disinfect with Virkon for 1-24 hrs, discharge to drains.
Spills – soak in Virkon or Precept solution for at least 10 min, then soak up with absorbent towel. Discard material for incineration.

Animal Facility
- Autoclave waste will be collected by LF2 staff and will be sterilised by autoclaving for a cycle of 131°C for 30 mins.
- Autoclaved material will then be disposed of by identified trained LF2 staff.
- Mice carcasses will be incinerated and disposed of by LF2 support staff.

Sharps will be treated before use using 70% (v/v) ethanol and disposed of after use in supplied sharps-bins for incineration. Surgical scissors and other surgical instruments (e.g., tweezers) will be autoclaved after use (a designated set of surgical instruments will be used for these experiments). All staff receive training in use of sharps as part of their HO PLH training.
- Contaminated sharps will be placed in sharps bins and will be incinerated. Surgical scissors and other surgical instruments will be cleaned with 70% IMS then soaked in Virkon for at least 10 mins, then wiped with 70% IMS before autoclaving.

The purpose of this project is to interrogate normal and defective fusion mechanisms using in ovo transient transgenics and gene-edited models of candidate fusion genes in the avian eye and additional avian embryonic contexts.

The avian replication-competent retroviral vector system (RCAS: Replication-Competent ASLV long terminal repeat (LTR) with a Splice acceptor virus) will be used to deliver genes of interest to cultured cells to generate loss of function (gene deletions) and gain of function (gene over-expression) genetic tools. These tools will then be used in further cell culture and chicken embryos to test specific experimental hypotheses for understanding mechanisms of epithelial fusion.

**Recipient or parental organism**

E.Coli K12 DH5a for plasmid amplification
Genotype: F- Φ80lacZΔM15 Δ(lacZYA-argF) U169 recA1 endA1 hsdR17(rk-, mk+) phoA supE44 thi-1 gyrA96 relA1 λ-
E. coli K-12 derivatives including, DH5a are recognised as non-colonising and disabled. They are not considered pathogenic to humans or animals. They are expected to have limited survivability in the environment and have auxotrophic requirements, which are unlikely to be satisfied outside of laboratory culture. The RCAS constructs have pBR322 origin of replication for low copy number amplification in competent bacteria, and an ampicillin resistance gene for selection. They are non-mobilisable and the cloned genes are under control of eukaryotic promotors with no known activity in bacterial hosts. Replication of the construct will not confer fitness to the host nor result in any change in pathogenicity or host range. Therefore, the likelihood of expression is effectively zero and the risk to humans and/or the environment is negligible.

UMNSAH/DF-1 for producing viral titres
UMNSAH/DF-1 is an established spontaneously transformed and characterised embryonic chicken fibroblast cell line. The avian source of this immortalised cell line poses low risk to humans due to the genetic relationship (widely divergent) of the cell line to humans. Transfected RCAS plasmid constructs containing genes of interest (which may be of chicken or human origin) will drive production of virus within the host cell line for harvesting and injection into embryonic chicken tissues. The envelope gene from Avian Sarcoma and Leukemia Viruses (ASLV; the family of which RSV belongs) maintains avian-specific host range, therefore RCAS vectors will not replicate in mammalian cells and risk to humans is effectively zero.

UMNSAH/DF-1 are expected to have limited survivability in the environment and have auxotrophic requirements, which are unlikely to be satisfied outside of laboratory culture. We do not anticipate increased survivability in cells expressing the virus. Therefore the risk to the environment is low.

Chicken Embryonic tissues for study
Wild-type Hy-Line fertile chicken eggs and eggs from stable transgenic lines (e.g. memGFP) are obtained from The Greenwood Building (Roslin Institute). Specific
pathogen free (SPF) status eggs are obtained from The Bumstead Building (Roslin Institute). All eggs are incubated at 37°C until the required stage of development reached. No infected embryos will be incubated to develop past embryonic day 10. RCAS Virus will be transduced to embryos and will drive expression of the cloned genes in infected cells. Infected embryos will usually not be allowed to develop beyond 10 days of incubation and will never be allowed to hatch. Chicken embryos can only survive within the egg along with constant incubation at 37°C. It is unlikely that these conditions would be met outside the laboratory. We do not anticipate increased survivability in the embryo when expressing the virus or the genes contained within the vector, therefore the risk to the environment is low.

Host/vector system

The RCAS (Replication-Competent ASLV long terminal repeat (LTR) with a Splice acceptor) vectors are simple, replication-competent avian retroviruses derived from the avian Rous Sarcoma Virus (RSV), (previously described and is commercially available: Hughes et al., J Virol 1987 Oct; 61(10):3004-3012; https://www.addgene.org/search/advanced/?q=RCAS). This virus has been characterised and used extensively (see Morgan and Fekete, 1996. Methods in Cell Biol. 51, 185).

Like RSV, the RCAS viral DNA genome comprises genes, gag, pol and env which code assembly of new viral particles. In RCAS, the src gene, a proto-oncogene, has been deleted and replaced with a ClaI restriction enzyme site for convenient insertion of genes of experimental interest. The splice acceptor of src is retained in the virus to ensure processing of the inserted gene’s mature messenger RNA prior to translation and protein expression. Long Terminal Repeats (LTR) allow insertion of viral genetic material into the host genome, and their promoters further enhance expression.

This retrovirus is replication competent but only infects avian species, and not mammals, by direct injection or transfection. Very high viral titres are required to infect significant amounts of tissue in chick embryos and embryos from pathogen free chickens are most susceptible. The src gene that makes this virus oncogenic in chickens has been removed and replaced with a restriction site so that a transgene can be easily inserted here. Any potentially harmful effects will depend on the gene or antisense construct inserted into RCAS.

As with wild-type viruses, RCAS vectors carry out all aspects of the viral life cycle as well as encode an additional transgene. Once within the host cytoplasm, RCAS can cross the nuclear membrane and integrate in the host-genome where it then acts as a cellular gene under dogmatic control of the host. New viral particles bud from the host membrane and go on to infect neighbouring cells. Thus, once the virus is transduced to host tissues, the transgene can be spread from cell to cell within the embryo. This delivery system was engineered to reduce the number of rounds of viral replication required to produce the viral titre necessary for use, and therefore gives a stable vector with reduced opportunity for rearrangement.

The RCAS virus only replicates in appropriately chosen susceptible avian cells (usually chicken or quail, although others can be used). This work will utilise A or B envelope subgroup RCAS (A, B) and maintains avian-specific host range, therefore this RCAS vector will not infect or replicate in mammalian cells. Normally, mammalian cells lack functional receptors for any of the envelope proteins of the RSV virus and therefore the virus cannot enter mammalian cells. To overcome this barrier, mammalian cells would have to present functional RSV envelope protein receptors on the cell surface. In some cases, particular RCAS vectors will infect mammalian cells, but will not replicate. This capability involves mis-expression of cloned functional receptors in mammalian cells and has only ever been documented in the laboratory (Bates, Young and Varmus, 1993).

Further we will never attempt to express RSV envelope protein receptors in mammalian cells, nor will we generate RCAS vectors that use the envelope proteins found in mammalian retroviruses.

Origin & function

The RCAS system will artificially express novel genes of interest (that may be chicken sequences or gene sequences from other vertebrates including mouse, human or fish) in cell cultures and in vivo embryonic tissues to understand gene function during developmental tissue fusion and to identify functionally-essential protein-protein interactions. We will tag candidates with well-described epitopes (e.g. FLAG, V5, or Myc) or with fluorescent proteins (e.g. green fluorescent protein, Citrine). These tags are required to visualise and specifically isolate the gene products from infected cells during experimental analyses. We will compare the following controls to the wild-type: a truncated variant that contains only the signal peptide fused to GFP, which can be secreted but has no function; GFP-only; and empty vectors. This is to test the specific requirement for extracellular interactions between these proteins and their cognate receptors (both novel and known).
The genes that will be investigated will include genes encoding growth factors, transcription factors, phosphatases, enzymes, receptors, and other genes of so far unknown function.

**Evaluation of foreseeable effects**

**Risks to humans**
Effectively zero. The viral delivery system cannot infect humans and therefore the likely hood of harm is effectively zero. It is believed that RCAS does not cause human disease and it has a history of safe use.

**Risks to the environment**
Strains of chickens differ in their susceptibility to viruses with different envelope subgroups. Most chicken strains purchased from commercial vendors are typically resistant to viruses with E envelope subgroup, while the viruses we will be using most often have envelope subtypes A and B (Morgan & Fekete, 1996, Methods in Cell Biology 51, 185-214).

Direct injection of high experimental viral titres are required to infect embryos and generate efficient expression of inserted genes. In the case of accidental release of virus from level 2 containment facility, there would not be enough virus required to infect avian species in the environment. Furthermore, a wild avian would have to be susceptible to viruses with envelope proteins A or B.

The src gene that makes this virus oncogenic in chickens has been removed. However, integration of the viral genome assembly is effectively random and therefore insertion could occur near a proto-oncogene within the host genome. Integration is not specific or dependent upon proto-oncogenes and therefore the chance of insertion near one is low. This work specifically uses embryos that will be terminated prior to embryonic day 10 and we will never allow infected embryos to hatch.

We believe a combination of these reduces the risk to organisms in the natural environment to effectively zero upon accidental release.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Disinfection**
After use, surface disinfection will be with 1% Distel with contact time of 30mins.

Liquid waste will be collected in polythene lidded containers and treated for 24 hours with 1% Distel solution. After the disinfection period, inactivated solutions are disposed to drains with copious amounts of cold water.

Reusable surgical tools will be treated in 1% Distel for 30 minutes prior to being bagged and autoclaved.
According to manufacturer’s guidelines Distel used at 1% concentration for the recommended time is as effective as using 1.4% formaldehyde to deactivate retroviruses and results in total inactivation. Used at this concentration, Distel is considered by the manufacturer to be non-hazardous to humans (https://www.tristel.com/tristel-products/distel-for-labs).

**Autoclaving**
Solid waste will be collected in double autoclave waste bags immediately after work, sealed with a tie and subjected to autoclaving under approved conditions. 100% kill is
achieved with this procedure. All contaminated materials will be inactivated by autoclaving (100% kill) at 121°C or 134°C prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware and surgical tools. Autoclaves will be validated by annual (at least) thermocouple mapping and each run will be monitored by continuous chart or digital recording of the temperature / time profile or using chemical indicators (e.g. Browne TST indicator test strips).

Other
Extracts will be made from tissue culture cells transduced by retrovirus vectors for biochemical and cell biological procedures (e.g. microscopy). The simple act of infection inactivates much of the input virus as it becomes uncoated upon entry into the cell. When making cell extracts, residual virus will be inactivated by detergent treatment (i.e. 1% SDS or 0.5% NP40). The effectiveness of the detergent treatments will be validated by plating transduced cell extracts on indicator cells and selecting for epitope tag expression. For microscopy techniques, the transduced cells will be fixed with 4% paraformaldehyde; retroviruses can also be effectively treated with formaldehyde solutions. There will be little or no packaged virus in these infected cells, and any remaining virus should be inactivated by these treatments.

Waste disposal routes
Waste from eggs or embryo tissue infected with RCAS virus will be broken then bagged with absorbent material in a sealed clinical waste bag, along with plasticware contaminated during use of infected eggs or embryo tissue. These sealed bags will be deposited into the anatomical bins in the cold room and then collected and autoclaved to inactivate any RCAS virus vector present prior to incineration as clinical waste. Non-infected and transgenic egg waste will be treated in the same manner in accordance with local procedures.

Solid cell culture waste or plasticware that has been infected or contaminated with RCAS virus will also be sealed in a clinical waste bag, deposited into the anatomical bins in the cold room, collected for inactivation by autoclave prior to incineration as clinical waste.

Liquid waste will be collected in polythene lidded containers and treated for 24 hours with 1% Distel solutions. After the disinfection period, inactivated solutions are disposed to drains with copious amounts of cold water.

General tissue culture waste that has not been contaminated with RCAS virus will be disposed of by the biohazardous waste stream which includes inactivation by autoclave prior to onward processing.

Clostridia isolates: C. butyricum (type strain Rowett) and two newly isolated strains, one is most closely related to the aforementioned C. butyricum, and the other is most closely related to C. beijerinckii. E. coli (CL1, K12 and B derivatives)

Host/vector system
DNA from the Clostridia sp. and reintroduced will result in increased expression of genes involved in the butyrate pathway involved in the production of has (H2) and

Origin & function
DNA taken from the Clostridia sp. and reintroduced will result in increased expression of genes involved in the butyrate pathway involved in the production of has (H2) and

02/03/2022
volatile fatty acids (such as butyric acid).

DNA from Aquorea victoria (jelly fish), Vibrio vulcanifcus, Bascillus subtilis and Pseudomonas putida (all CL1) will endow the Clostridia and E. coli with fluorescence to act as reporters to facilitate ease of manipulation.

The vector systems themselves will endow the Clostridia (and E. coli) with antibiotic (chloramphenicol, thiamphenicol, erythromycin, spectinomycin, tetracycline) resistance for counter-selective purposes.

**Evaluation of foreseeable effects**

None of the introduced genetic material is expected to increase the pathogenicity or survival outside of a lab environment of the recipient organisms, or pose a threat the outside environment should accidental release occur. Furthermore as the Clostridia sp. in question is strictly anaerobic and cannot survive in air its likelihood of escape is further lessened.

The antibiotic resistance (chloramphenicol, thiamphenicol, erythromycin, spectinomycin, tetracycline) acquired by the recipient organisms are also not on the list of primary antibiotics used to treat infections of Clostridia sp. or other anaerobes.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Cultures and contaminated liquid waste containing Clostridia sp. are to killed using PRESEPT (5 g/l, 0.5% w/v) and left for 16 hours. Surfaces are also to be cleaned with this solution as well as 70% ethanol for. Resulting in near 100% killing of cells as well as >5 log10 reduction in spore number (as reported in the literature for Clostridia sp.).

To test this the biocidal ability of the aforementioned treatments, cultures can be incubated with either PRESEPT and ethanol for specific lengths of time, and colony forming units measured indicating the viability of cells after treatment. This will indicate if this is an effective method of killing.

Disposal of killed cultures, petri dishes and contaminated plastics are to be held (separate from CL1 waste) for autoclaving at either 134°C (and held for 5 mins, for plastic waste, and disposed via approved contractor) or 121°C (and held for 15 minutes, for liquid waste, and disposed to drain). Resulting in 100% kill of bacteria and spores.

**Host/vector system**

Please see next box.

**Origin & function**

**SARS-CoV-2 S pseudotyped lentivirus:**

The self-inactivating lentiviral vector will be generated using a second generation lentiviral (LV) packaging system. Vectors generated will be pseudotyped to have either the SARS-CoV-2 or Vesicular stomatitis virus (VSV-G) envelope. A bald lentiviral vector lacking the envelope protein needed for host cell entry will also be used as a negative control. The final recombinant lentiviral genome will contain a self-inactivating 3' LTR, a central polypurine tract (cPPT), the EGFP gene (under control of the elongation factor 1 alpha (EF1a) promoter), and woodchuck hepatitis virus postranscriptional regulatory element (WPRE).

Host cells capable of internalising lentiviral particles will be genetically modified by the integration of the proviral DNA into the host genome, permitting the constitutive expression of EGFP under control of the EF1a promoter. The transduction efficiency of lentiviral vectors pseudotyped with SARS-CoV-2 S will be compared to vectors pseudotyped with VSV-G. This will be done by comparing EGFP activity in exposed host cells.

Virus tropism will likely be altered in the SARS-CoV-2 S pseudotyped lentiviral vector. SARS-CoV-2 S pseudotyped virus has recently been reported to be dependent on the cellular expression of ACE2 (Hoffman et al, 2020, Cell 181, 271–280). ACE2 is known to be highly expressed in multiple tissues including the lungs, kidney, heart, and vasculature (Patel et al, Circulation Research. 2016; 118:1313–1326). Bald lentiviral particles will be used as a negative control. The transduction capability of these bald lentiviral vectors in all host cells will be nullified owing to their lack of envelope protein, as shown by Ou et al (Nature Communications. 2020; 11:620).

**Recombinant HCoV-229E:**

This 229E mutant was originally derived by Cervantes-Barragan et al (mBio, 2010, 1:e00171-10). Recombinant HCoV-229E cDNA was produced by recombining vaccinia
virus containing full-length HCoV-229E cDNA with the pHC0V-GP-EGFP plasmid containing the P-glycoprotein-EGFP (GP-EGFP) fusion protein. This recombination event resulted in the replacement of HCoV-229E accessory gene 4 (located in between the genes encoding the spike and envelope proteins) with the gene encoding the GP-EGFP fusion protein. The recombinant HCoV-229E genome will therefore contain all the components found in the wild type HCoV-229E virus except accessory gene 4. This will allow for coronavirus replication to be monitored in infected cells by monitoring GFP fluorescence.

HCoV-229E is known to utilise the human aminopeptidase N (hAPN) as its receptor on human cells (Yeager et al., Nature, 1992, 1357:420-422). hAPN is known to be expressed in numerous cell types including macrophages, stromal cells, smooth muscle cells, endothelium, and epithelium (Dixon et al., J Clin Pathol. 1994, 47:43-47). Virus tropism and host range of the recombinant virus are not expected to be altered compared to WT HCoV-229E.

Evaluation of foreseeable effects

SARS-CoV-2 S pseudotyped lentivirus:
Second generation lentiviral vector(s) will be used. Expression of Rev in trans allows the production of high-titre HIV-derived vector stocks from a packaging construct also containing Gag, Tat, and Pol. This design makes the expression of the packaging functions conditional on complementation available only in producer cells. The gene delivery system, which conserves only four of the nine genes of HIV-1 relies on three separate transcriptional units for the production of transducing particles, offering significant advantages for its biosafety. If, an exposure to humans occurred, the lentivirus is significantly disabled and replication competent free. Even if that person had a pre-existing HIV infection, the chances of recombination are extremely small. Once produced through the packaging system, the recombinant vector is stable.

Given SARS-CoV-2 S pseudotyped lentivirus particles do not contain the gene encoding the SARS-CoV-2 S protein, the chance of generating a novel HCoV-229E genome containing the SARS-CoV-2S gene is effectively zero. To further reduce the probability of a generating a novel recombinant virus, experiments using these two viruses will be timed to not overlap with each other. This reduces the chance of a cell being co-infected with both viruses to effectively zero.

Recombinant HCoV-229E:
HCoV 229E infection causes a range of symptoms and severity dependent on the context of infection. HCoV-229E has been associated with transient and self-limiting febrile and upper respiratory tract infection in immunocompetent adult patients. There is no evidence that this is associated with significant negative outcomes in the short or long term. In children HCoV-229E has a similar pathogenicity. There are cases of patients with detectable coronavirus in respiratory samples presenting with meningitis, however no causative link has been found (Dominguez et al., J Med Virol, 2009, 81:1597-60). In severely immunocompromised patients there are case reports of pneumonia, including fatal cases (Pene et al., Clin Infect Dis, 2003, 37:929-932; Gerna et al., J Med Virol, 2006, 78:938-949). HCoV 229E has been identified in hospitalised Chinese children with pneumonia and asthma (though the immune status is not mentioned) (Zeng et al, Eur J Clin Microbiol Infect Dis, 2018, 37:363-369); in children with bronchiolitis and laryngitis (Brini et al., PLoS One, 2017, 12:e0188325) and SARI (Suresha et al., J Med Virol, 2016, 88:163-5). HCoV 229E has also been identified in the blood of a child presenting with suspected arboviral infection (Bonny et al., Genome Announc. 2017 22;5.pii: e01313-17) and as a co-infection with OC43 in the respiratory tract of a child presenting with acute flaccid paralysis (Turgay et al., J Pediatr Neurosci, 2015 10:280-1).There is no effective vaccine available for HCoV-229E.Vertical transmission from mother to foetus has been suggested in a small-scale study in which 3/6 newborns from HCoV-229E positive mothers also tested positive for the virus (Gagneur et al., Eur J Clin Microbiol Infect Dis, 2008, 27:863-866). Larger scale studies are required to investigate the vertical transmission and risks of HCoV-229E during pregnancy.

Clinical transmission is thought to be through inhalation of fomites. There are no reports of HCoV-229E infection through ingestion, however this has been considered likely for other coronaviridae and should be considered a risk (Jasper et al., Clin. Microbiol. Rev, 2015, 28:465-522).

It is deemed highly unlikely that the recombinant HCoV-229E could revert to wild type HCoV-229E. However, this cannot be completely ruled out if infected individual also currently infected with wild type HCoV-229E. Similarly, the possibility a cell being co-infected with SARS-CoV-2 S pseudotyped lentivirus and recombinant HCoV-229E generating a novel recombinant virus is extremely low but cannot be completely excluded.

N/A
No derogations requested.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disinfection: All solid and liquid waste will be decontaminated/disposed of by the user at the end of every TC session. Surfaces will be sprayed 1% Trigene followed by 70% IMS after use.

Solid waste disposal:
- Stripettes. Rendered safe by autoclaving, then placed in a yellow bag with a yellow tag for disposal by incineration.
- Plastic ware such as flasks and tubes: Soak in 1%w/v Virkon, or 1,000 ppm Precept (four 0.5g tablets into one litre of water) for 24 hours before discharging any excess liquid via drains. Following chemical decontamination, place all plastic ware into the yellow bags within the tin autoclave drums, tie bag and place in the white plastic bin.
  After autoclaving, yellow bags with yellow tags are disposed of by incineration.

Liquid waste disposal
Any liquid potentially containing virus should be collected in an autoclavable screw top plastic bottle (stored under the sink). The liquid waste should be chemically disinfected by soaking in 1% w/v Virkon, or 1,00ppm Precept (four 0.5g tablets into 1 litre of liquid) for 24 hours before discharging via the drains.

Autoclaving details
All contaminated materials will be inactivated by autoclaving (100% kill) at 121°C 15 minutes prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual (at least) thermocouple mapping and each run will be monitored by continuous chart or digital recording of the temperature / time profile.

Experiments will be designed to assess competitive fitness, population dynamics and evolution of antibiotic resistance in Pseudomonas aeruginosa (hazard group 2). Strains will be cultured in isolation and co-cultured at varying densities in the presence and absence of antibiotics. Co-culturing may also be carried out with hazard group 1 E. coli strains. Population dynamics and strain composition will be quantified using standard methods such as plating, optical density and fluorescence plate reads, and flow cytometry.

Recipient or parental organism
Pseudomonas aeruginosa PA01 and PA14 laboratory strains

Host/vector system
Standard laboratory cloning vectors, such as pUC18-mini-Tn7 type suicide delivery vector and pTNS1/2 helper plasmid, carried by non-pathogenic E. coli cloning hosts

Origin & function
Fluorescent reporter genes:
- GFP originates from the jellyfish Aequorea victoria. Variants (e.g. YFP, CFP) were generated from GFP by mutations.
- DsRed originates from the cnidarian Discosoma spp. Variants (e.g. mKate, mCherry) were generated from DsRed by mutations.
- The intended function of these genes is to label bacterial strains in a manner that is detectable by devices using fluorescence (plate readers, flow cytometry, microscopy) and thus assess strain composition in bacterial populations.
Natural plasmids carrying antibiotic resistance genes:
- Plasmids such as Rms149, PAMBL1, PAMBL2 were originally isolated from clinical strains of Pseudomonas aeruginosa.
- The intended function of these plasmids is to confer resistance to specific antibiotics in the laboratory strains into which they are introduced.

**Evaluation of foreseeable effects**

We do not expect our genetic manipulations to increase the infectivity or pathogenicity of the bacteria. The introduced plasmids confer resistance to certain antibiotics in clinical usage for treatment of serious P. aeruginosa infections (particularly ceftazidime, meropenem); however, other antibiotic treatment options remain available. Serious infections are rare in healthy individuals, and individuals at elevated risk of serious infection will not be permitted to carry out this work. Infection risk will be further mitigated by strict containment and control measures.

Pseudomonas aeruginosa is widespread in freshwater and soil. In the unlikely event of release to the environment, we expect our genetically modified strains to be at a competitive disadvantage, as carriage of fluorescent reporter genes and introduced plasmids bears a fitness cost. The introduced plasmids are not expected to spread to other bacterial hosts, since these plasmids lack their own conjugative machinery and our bacterial strains do not carry other plasmids providing this machinery for mobilisation.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

University of Edinburgh School of Biological Sciences waste inactivation and disposal procedures will be followed.

- All solid and liquid waste material will be autoclaved for sterilisation.
- Consumables (mainly plasticware) - autoclave (121-125 deg. C for at least 15 minutes), discharge any excess liquids to drains, dispose of solids via the industrial waste stream.
- Liquids (e.g. bacterial cultures) - autoclave (121-125 deg. C for at least 15 minutes), discharge to drains.
- Agar plates - autoclave (121-125 deg. C for at least 15 minutes), discharge any excess liquids to drains, dispose of solids via the industrial waste stream.

Degree of kill by autoclaving is effectively 100%. Autoclaves are maintained, serviced and inspected as per the requirements of the Pressure Systems Safety Regulations 2000 and the relevant parts of the British Standard BS 2646. See University guidance Section 9.8.2

Surface decontamination in the laboratory will use 1% Virkon disinfectant or 70% v/v ethanol. Spillages will be inactivated by powdered Virkon disinfectant and mopped up with paper towels. Solid waste is subsequently disposed as per above for autoclaving.

Project Ref 207/20.3

Date Ackn'd 14/08/2020

CU2 Project Title

Generation of a BAC transgenic mouse line overexpressing a human protein that will make them susceptible to infection with a human-tropic virus

Class 2

Consent Granted

Project notified under transitional arrangements

Project Additional Information

Purposes of the contained use

The virus that we are interested in infects humans with high efficiency, but infects mice poorly. The cellular receptor for the virus is known. Mice overexpressing the human receptor from a constitutive promoter have been made elsewhere and are readily infectable. The expression pattern of the receptor in these mice is unlikely to approximate...
the spatio-temporal pattern in humans, and the existing mice are not ideal models of the disease. We aim to create a better murine model of the human disease. To do this we will insert a bacterial artificial chromosome (BAC) containing the human gene that encodes this receptor, together with appropriate regulatory elements, into a safe harbour location in the mouse genome such that the receptor is expressed in mice with a similar spatio-temporal profile to that observed in humans. This will make the mice susceptible to the virus and allow us to model disease state and treatment options.

Recipient or parental organism

C57BL/6 x CBA F1 hybrid mice

Host/vector system

BAC clone encoding the human receptor for the virus

Origin & function

BAC clone has been acquired from BACPAC Resources. We intend to integrate this BAC into the mouse genome, such that the encoded gene will be expressed in the resulting mice. This will make them susceptible to infection with our virus of interest.

Evaluation of foreseeable effects

It is anticipated that mice with BAC integrated into their genome will express the human receptor in such a way that they are both readily infectable with our virus of interest and be useful for modelling disease state and treatment options. While we do not intend to carry out infection studies on these mice within our animal facility, there is a small risk that these mice could become infected by exposure to infected animal technicians, and subsequently transmit the infection to other staff.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Mice expressing the human receptor for the virus will be housed in a secure rodent barrier facility requiring swipe card / pin access. The mice will be contained in IVCs, and cage changes will be performed within a class II biological safety cabinet. Animal technicians handling the mice will wear suitable PPE including boots, surgical scrubs, disposable nitrile gloves, N95 fluid resistant face mask and face shield. The number of individual animal technicians responsible for care of these mice will be kept to a minumum.

These measures are intended to minimise the risk of exposing the mice to the virus and subsequent onward transmission to additional animal technicians. A risk assessment (GM Ani 0520) has been performed.

Mice will not be intentionally exposed to the virus within our facility. Future experiments involving infection of the mice with the virus will be performed at CL3 by a separate collaborating organisation(s) under their risk assessments and notifications and not by the University of Edinburgh.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Both before and after cage changes the interior surfaces of the biological safety cabinet will be swabbed with a 1% virkon solution.

All contaminated materials will be inactivated by autoclaving (100% kill) at 121°C or 134°C prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual (at least) thermocouple mapping and each run will be monitored by continuous chart or digital recording of the temperature / time profile.

All carcasses and tissue waste will be disposed of by incineration (effectively 100% kill) according to the protocols set up within our animal facility. Ear clippings taken for genotyping will be disposed of as clinical waste and incinerated (effectively 100% kill).
The genetic modification safety committee agreed that the appropriate containment and control measures have been assigned.

Purposes of the contained use

African trypanosome infections of cattle represent a major restriction on economic development in some of the poorest regions across the globe, and new tools are needed to combat this constraint to cattle rearing in Africa. The primary purpose of this project is identification of the species-specific molecules whose disruption is detrimental to the parasite in the host and/or is key to interactions with the host immune system. This will be achieved through genome-wide RNA interference (RNAi) screens for loss-of-function associated with protein ablation during parasite survival during infections. The aim of a genome-wide RNAi approach is to generate a population of genetically distinct parasites, each containing an individual DNA insert to silence a specific gene upon induction with tetracycline, on a scale sufficient that the number of individual clones provide coverage to effectively knock down the expression of every gene in the trypanosome genome. This library of parasites is then injected into an animal and silencing induced, thereby enabling the testing of several thousand gene silencing events at the same time. If parasite survival in the host is impaired due to specific gene silencing, then fragments of that gene will be reduced/lost from the parasite population after induction of RNAi – detected through Next Generation DNA sequencing (NGS) of the pathogens present in the peripheral blood following induction. This gene will thus be identified as essential and targeted for subsequent development of novel drug therapies and vaccinology.

Recipient or parental organism

The organisms to be used are Trypanosoma brucei and Trypanosoma congolense. Trypanosomes are single-celled protozoan parasites, that are transmitted from host to host by arthropod vectors (tsetse flies) - the trypanosomes have been modified such that each individual cell contains an individual DNA insert that will silence a specific gene upon induction with tetracycline - sufficiently large trypanosome populations therefore provide the ability to silence every gene in the genome individually ("genome-wide library"). T. brucei and T. congolense can infect a variety of mammalian hosts (including livestock species) if inoculated by an arthropod vector or syringe, but cannot infect humans. The insect vectors required for cyclical transmission of African trypanosomes (tsetse flies) are not present in the UK, but trypanosomes can be transmitted inefficiently through mechanical transmission by biting flies (e.g. Tabanid or Stomoxys flies). Trypanosomes do not perform genetic exchange in culture or in the mammalian host. Here we aim to use a genome-wide library approach in which we can analyse the fitness of individual genes during infection to identify genes that are essential for trypanosome infection and establishment in the mammalian host.

Host/vector system

T. congolense and T. brucei have been modified such that each cell contains a single introduced segment of genetic material ("construct") that comprises genes and transcription regulatory elements that enable targeted expression of a segment of trypanosome gene, a tetracycline repressor that prevents activation of that gene expression unless tetracycline is present, and antibiotic resistance genes to enable selective growth in vitro of genetically modified parasites.

Bovine hosts (non-genetically modified) will be sourced either from the University of Edinburgh herd, or approved suppliers, and cattle will be quarantined for one week prior to parasite infection, and maintained in CL2 vector proof facilities (I Block, LARIF or Marshall Building).

Origin & function

For knockdown of genes by RNAi library, DNA fragments have been isolated from trypanosome genomic DNA by direct fragmentation and cloning. All gene fragments have been inserted into the species from which they are derived (i.e. T. congolense or T. brucei) using a DNA construct (elements defined below). The approach taken is designed to specifically identify genes whose reduction of expression results in loss of fitness; therefore, no genes are anticipated to increase pathogenicity, virulence, host range or transmission.

Construct contents: T7 RNA polymerase is derived from a bacteriophage; tetracycline repressor, Puromycin acteyltransferase, neomycin resistance gene and bleomycin resistant gene are bacterial-derived. This construct is stably integrated into the trypanosome genome and not mobile or transmissible between trypanosomes thereafter. These elements enable the expression of gene-specific double stranded RNA in a tetracycline incible fashion - this double stranded RNA then results in reduction in the target gene expression due to the cellular process of RNA interference.
Evaluation of foreseeable effects

The strains of T. b. brucei and T. congolense to be used are not infective to humans. Therefore, the risk to human health is effectively zero. There are no predicted hazards associated with the plasmid and phage vectors employed to generate the GM lines, as vector DNA was removed before insertion of exogenous genes into the genome of T. brucei and T. congolense.

This project will involve production of mutants (gene knockdown in their endogenous species) that will be either phenotypically neutral or detrimental to parasite growth. No modifications proposed are anticipated to increase pathogenicity, virulence, host range or transmission. Moreover, trypanosomes have a complex life cycle with several essential differentiated forms and it is highly unlikely that the transfer of even cryptic genes would result in increased virulence. The antibiotic resistance cassettes to be used are already widely used and have no intrinsic harmful activity. The parasites themselves do not produce toxic products or immune effectors that are linked to human pathogenicity. T. congolense and the strain of T. brucei to be used are infective to a wide range of mammalian species (with the exception of humans, great apes and some species of baboons). However, the range of potential host species or virulence is very unlikely to be changed due to the genetic modification approach being taken.

The risks of transfer to related microorganisms are negligible. While there is a trypanosome species endemic to the UK (Trypanosoma theileri) that circulates in cattle, this is a very distantly related organism, and there is no evidence or expectation that exchange of genetic material could occur between these species. Moreover, genetic exchange in trypanosomes only occurs in their cyclical tsetse fly vectors, in the case of African trypanosomes these do not occur in the UK. Additionally, all of the modifications made during this project are anticipated to be at most functionally equivalent to the wild type and would therefore confer no selective advantage to a related organism. To negate environmental transmission, between animal facility and the laboratory, infected samples will be transported under triple containment.

Trypanosomes will only survive within mammalian hosts or relevant vectors (T. brucei and T. congolense both have a developmental cycle in tsetse fly vectors – not endemic to the UK – and can survive short periods in the proboscis of mechanical vectors, e.g. Tabanid or Stomoxys flies) – they rapidly die when not in these contexts, and therefore represent minimal environmental risk. Trypanosomes are blood-borne parasites, but are not excreted into the environment in secreted/excreted bodily fluids (e.g. sweat, urine, faeces), and require transfer from animal to animal via either infected blood or infected insect vector. If inoculated into susceptible mammalian hosts by mechanical transmission (i.e. insect vector or syringe) the parasites may cause infection and consequently disease.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Derogation is requested for the following measure for the reasons provided herein:

1 – Autoclave in building

For category 2 work conducted in the Marshall Building (Dryden farm) or I Block.

Autoclaves being operated by staff routinely handling GMO/SAPO waste are not available at these locations. Secure containment of GMO/SAPO waste is achieved by transportation of waste generated at these locations to the main Roslin Institute Building where the bulk of GMO/SAPO waste is generated and its management through autoclaving is routinely performed. The distance of transfer of material from these locations to the Roslin Institute Building is short and will be conducted according to the conditions described in the risk assessment (i.e. performed by a trained and competent person in double containment, leak proof boxes clearly labelled as containing GMO/SAPO waste and accompanied with a spill kit). Where possible waste will be inactivated by chemical means (or freezing) prior to transportation to the Roslin Institute Building for autoclaving.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste associated with handling trypanosomes will be disposed of in accordance with SAPO regulations, i.e. disposed of in identified autoclave bags and the waste autoclaved and incinerated. Any infected liquid (e.g. culture medium or blood) will be mixed in >10x volume of 2% Virkon, and disposed of in the sinks in East Wing Level 2 laboratories after at least 1 hour incubation.

At the termination of experiments and to mitigate any risk of transmission by vectors, ruminant hosts will be disposed of by humane euthanasia followed by dismemberment if necessary, double bagged in sealed heavy duty plastic bags, stored at -20°C for a period of 7 days (to inactivate pathogens – the GM modifications will not impact upon the effectiveness of low temperature as a lethal measure against trypanosomes) before being disposed of as a Category 1 animal byproduct by a licensed contractor. The containment area is then subjected to thorough cleaning. All solid waste is collected into clinical waste bags, sealed and sent for incineration. The area is then swept and...
the debris placed in sealed clinical waste bags for incineration. The area is then treated with a proprietary disinfectant before washing down with a steam cleaner and being allowed to dry.

Disinfection: Any infected liquid (e.g. culture medium or blood) will be mixed in >10x volume of 2% Virkon or similar validated disinfectant, and disposed of in the sinks in East Wing Level 2 laboratories after at least 1 hour incubation. Laboratory surfaces will be disinfected by wiping with either 2% Virkon or similar validated disinfectant or by use of 70% ethanol; materials will be disposed of through laboratory waste disposal routes. After animal experiments are completed, surfaces (walls and floors) in the pen containment facility (Marshall Building, I Block or LARIF) will be cleaned using an appropriate validated disinfectant.

Autoclaving: All contaminated materials will be inactivated by autoclaving (100% kill) at 121°C or 134°C prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. In the case of contaminated materials from Marshall Building, I Block or LARIF (e.g. sharps, disposable gloves), these will be transported to the Roslin Institute building under triple containment for disposal. Autoclaves will be validated by annual (at least) thermocouple mapping and each run will be monitored by continuous chart or digital recording of the temperature / time profile.

**Project Additional Information**

**Purposes of the contained use**

The protein variants produced will be used for subsequent biophysical and biochemical analysis including, but not limited to, mass spectrometry, super-resolution microscopy, circular dichroism, and fluorescence microplate assays.

**Recipient or parental organism**

The recipient organisms are standard BL21 and DH5α laboratory strains of E.coli. Both E.coli strains to be used are attenuated in their ability to survive outside of laboratory conditions and are non-pathogenic. These are functionally disabled strains that cannot survive in the environment and do not colonise the human gut.

**Host/vector system**

The vector system used will be a commercially-available pET based plasmid, a non-hazardous carrier of genetic material. The vectors are used to express and maintain recombinant proteins in E. coli and were obtained from Invitrogen. They contain a gene which confers resistance against beta-lactam antibiotics upon the host bacterium.

**Origin & function**

Inserted gene products are human proteins and variants (single point mutations, splice variants etc). Estimated expression levels result in 2-10 mg quantities of recombinant protein produced. Each of the gene inserts used will produce recombinant α-syn in its monomeric form1 at a concentration of 1-5 mg/ml. The pathological and toxic conformers of α-syn are considered to be oligomers, protofibrils and fibrils1,2, whilst the native monomeric form of α-syn is considered to be non-toxic1. Recombinant α-syn exists predominantly as stable unfolded monomers1. The formation of oligomers and fibrils from monomeric α-syn requires specialised procedures involving prolonged shaking at 37°C and high-powered sonication3, and does not occur spontaneously. Evidence for the lack of toxicity of monomeric recombinant α-syn comes from studies using cellular toxicity assays using SHSY-5Y cells4 and inoculation studies using mice.5 The addition of recombinant α-syn to SHSY-5Y cells4 did not result in cell death as measured by the MTS colorimetric assay. Masuda-Suzukake et al injected mice intra-cerebrally with monomeric human recombinant α-syn and found that none of the mice had pathological symptoms or evidence of neuropathology related to α-syn.5 Therefore, there is evidence at both cellular level and using mouse transmission studies that monomeric recombinant α-syn is not associated with disease or toxicity. As such, there is no evidence that monomeric recombinant α-syn poses a hazard to human health.

2. Lashuel HA, Overk CR, Oueslati A and Masliah E. The many faces of α-synuclein: from structure and toxicity to therapeutic target. Nat Rev Neurosci 2013, 14(1) 38–49
Evaluation of foreseeable effects

Due to the attenuation of the E.coli strains used, they have been shown to have limited colonisation ability, therefore making them highly unlikely to colonise healthy individuals.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disinfection
Liquid waste contaminated with GMOs expressing alpha-synuclein constructs is disinfected using Virkon. For decontamination of liquid cultures, a 2% Virkon solution should be applied in a 1:1 dilution with the liquid for at least 1 hour prior to disposal.

Autoclaving
All contaminated materials will be inactivated by autoclaving (100% kill) at 121°C or 134°C prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual (at least) thermocouple mapping and each run will be monitored by continuous chart or digital recording of the temperature / time profile and/or using chemical indicators (eg Browne TST indicator test strips).

Solid waste
All solid waste contaminated with either GMOs expressing alpha-synuclein constructs or purified alpha-synuclein proteins is disposed of via the contaminated laboratory waste route. They must be autoclaved (see details above) prior to disposal.

Liquid waste
Liquid waste contaminated with GMOs expressing alpha-synuclein constructs is disinfected using Virkon. For decontamination of liquid cultures, a 2% Virkon solution should be applied in a 1:1 dilution with the liquid for at least 1 hour prior to disposal.

Liquid waste contaminated with purified alpha-synuclein protein will be collected via a designated liquid waste stream. This will then be autoclaved using the above described procedure to ensure deactivation of the protein prior to disposal.

**Project Additional Information**

**Purposes of the contained use**

The overarching goal of this project is to study bacterial host-pathogen interactions by identifying novel bacterial virulence factors in a range of respiratory pathogens using genetic screens and characterizing the mechanisms through which these virulence factors interact with host cells using three-dimensional models of the human lungs. Candidate genes predicted to be important for infection and dissemination will be disrupted through transposon insertion and site-directed mutagenesis. The resulting mutants will be characterized in three-dimensional tissue culture models that allow us to observe bacterial dissemination. Mutants that show a dissemination phenotype will
be complemented to confirm that the phenotype is related to the gene of interest. If initial characterization suggests that the bacterial genes directly interact with host factors or have host modulatory functions, those genes may be expressed in eukaryotic cells to confirm these interactions. In some cases, fluorescent or luminescent cassettes will be transformed into the bacterial strains so that they can be visualized by microscopy.

Recipient or parental organism

1) Pseudomonas aeruginosa (Wild type – strains PA01, PA14, PA ATCC2783) is an opportunistic human pathogen that is capable of causing infection in immunocompromised individuals including urinary tract infections, dermatitis and soft tissue infections, and respiratory infections. However, P. aeruginosa is unlikely to cause disease in healthy adults, and when such infections do occur they are generally mild and treatable (Hancock and Speert, Drug Resist Update. 2000 Aug;3(4):247-255).

2) Staphylococcus aureus (Wild-type- strains SA5003, SH1000, MRSA254, MSSA476) is primarily a commensal bacterium in humans that is commonly present on the skin and mucous membranes of up to 50% of healthy individuals without causing disease. However, S. aureus can also be an opportunistic pathogen most commonly associated with nosocomial infections of wounded skin and soft tissues as well as respiratory and gastrointestinal infections and septicaemia. (Lakhundi and Zhang, Clin Microbiol Rev. 2018 Oct; 31(4): e00020-18).

3) Mycobacterium smegmatis (Wild-type strain Mc2155) is a non-pathogenic strain of mycobacteria commonly found in soil, marine water, and freshwater. It does not cause disease in humans or animals.

4) Mycobacterium marinum (Wild-type strain Mc2155) is an opportunistic pathogen capable of infecting freshwater and marine fish, resulting in chronic progressive disease with significant morbidity and mortality. It is also capable of producing granulomatous lesions in other animals. However, due to strict temperature sensitivity M. marinum does not cause disseminated disease in immunocompetent individuals and there is no evidence of transmission from person to person. (Hashish et al., Vet Q. 2018; 38(1): 35–46).

5) Mycobacterium bovis BCG (disabled vaccine strain) is an attenuated strain of mycobacteria that has been used as a human vaccine against Mycobacterium tuberculosis since 1921. It has a long history of safe use in humans and a wide range of other animals including livestock. In rare cases of immunocompromised individuals, such as those who are HIV+ or have inherited immune disorders, vaccination with BCG has resulted in infections ranging from cutaneous lesions to disseminated disease, but the majority of these infections are self-limiting. (Murphy et al., Tuberculosis (Edinb). 2008 Jul;88(4):344-57).

6) Mycobacterium tuberculosis ΔRD1, ΔpanCD (Disabled laboratory strains mc26030 and mc27000) are attenuated strains of M. tuberculosis from which two distinct virulence regions responsible for disease have been disrupted. Mycobacterium tuberculosis is a hazard group 3 biological agent, but these strains are sufficiently attenuated and so highly unlikely to revert to higher pathogenicity that we believe it can be safely reclassified as hazard group 2. We therefore wish to reclassify this strain to HG2 for the following reasons based on the following evidence of greatly its reduced pathogenicity. The ΔRD1 attenuating mutation is the deletion of the RD1 virulence locus which contains the ESX Type VII secretion system. This is the same mutation responsible for loss of virulence in the BCG vaccine and deletion of this locus alone has been shown to attenuate M. tuberculosis (Lewis et al., Infect Dis. 2003 Jan 1;187(1):117-23). In addition, ΔpanCD deletion results in complete loss of the panCD locus which encodes two genes required for the synthesis of pantothenate, which alone also attenuates M. tuberculosis (Sambandamurthy et al., Nat Med. 2002 Oct;8(10):1171-4) to make reversion to wild-type and makes growth of this strain dependent on media supplementation with pantothenate. Deletion of two distinct loci further attenuates the strains and reduces the possibility of reversion to wild-type as either deletion is attenuating. This strain is highly attenuated in vivo in all animal models tested and is unable to cause disease in mouse, guinea pig, calf, and non-human primate models even at high dose. There have been no reported human infections with this strain, and it has been approved for use in Biosafety Level 2 laboratories in the USA (Sambandamurthy et al., Vaccine. 2006 Sep 11;24(37-39):6309-20; Waters et al., Vaccine. 2007 Nov 7;25(45):7832-40; Larsen et al., Vaccine. 2009 Jul 23;27(34):4709-17.) Strain mc27000 is a direct derivative of mc26030 from with the antibiotic resistance cassette has been removed resulting in an unmarked strain (Ojha et al., Mol Micobiol. 2008 May 5; 69(1) 164-74).

7) Non-pathogenic strains of E. coli K12 (disabled laboratory strains DH5- , BL21, HB101, XL1-Blue) are naturally occurring commensal bacteria that do not express virulence genes are not capable of causing disease in humans even at extremely high doses (Smith HW, Nature 1975 Jun 5;255(5508):500-2).
8) Burkholderia thailandensis (wild-type strain E264) is an environmental bacterium present in the soil and water of tropical regions including Southeast Asia and Northern Australia. It is considered non-pathogenic and does not cause disease in healthy individuals, but is capable of causing infection in mouse models (Morici et al., Microb Pathog. 2010 Jan; 48(1): 9–17.)

9) Eukaryotic cell lines may be classed as recipients if selected to stably maintain eukaryotic expression vectors by antibiotic-mediated selection for chromosomal integration. Cell lines may include A549, EaHy926, THP-1, J774, RAW264, L929 or derivatives thereof. Other similar cell lines may be used as they become available

**Host/vector system**

Give brief details of Vector(s):

1) Plasmids for gene expression in bacteria (non-integrating) will include those of the pMB-, pUC-, pACYC-, pBAD-, pBR-, pGEM-, pGEX-, pEXT-, pSET-, pBluescript-, pEC-, pLAFR, pMLBAD-, and pET- series, as well as derivatives of these plasmids that contain the origins of replication pMB1, ColE1, p15A, pSC1010, R100. pUC, FII, incW, pBRR1, RK2, oriV, or incP and standard antibiotic markers (Amp, Cm, Kan, etc.)

2) Integrating plasmids for gene expression in mycobacteria will include those of the pYUB- and pMH- series and related plasmids derived from these series containing the same mycobacteria and E. coli origins of replication. These vectors are suicide plasmids containing an integrase from the L5 bacteriophage, allowing a single copy to integrate specifically into the attP site of mycobacteria

3) Plasmids for targeted mutagenesis will include those of the pDM-, pEX-, pDONR-, pCDNA- and pKD- series and related suicide vectors produced using the same methodology expressing λRed recombinase or counter selection markers for homologous recombination to facilitate gene deletion.

4) Bacteriophage vectors including the phAE- shuttle plasmids for mycobacteria will be used for targeted mutagenesis. These phage are only capable of replicating within specific strains of bacteria and are not capable of infecting human or animal cells

5) Plasmids for the delivery of mobile elements for random mutagenesis will typically possess a λpir-dependent origin and the mobilisation region from plasmid RP4 permitting their delivery only from λpir-expressing E. coli expressing the RP4 conjugation machinery. These include the pUT-series for plasmids harbouring mini-Tn5 derivatives. Similar replicons will be used to transfer cloned and mutated fragments to recipient genomes by homologous recombination and may possess markers for positive-selection (e.g. sacBR) and antibiotic resistance.

**Origin & function**

1) Fluorescent and luminescent cassettes genes encode proteins that emit light for the purpose of visualization on a microscope or plate reader. These include the LuxABCDE bacterial luciferase locus and fluorescent proteins such as GFP and its derivatives (e.g. YFP, CFP) and dsRed and its derivatives (e.g. mCherry, tdTomato). Antibiotic resistance markers (e.g. gentamicin, chloramphenicol) are carried on the cloning vectors for the purpose of selecting transformant.

2) Random and targeted mutagenesis of bacterial genes by transposable elements will typically result in the loss of function of the gene in which the mutation occurred. Complementation of the native allele by homologous recombination, expression on a plasmid, or insertion on an integrating plasmid will be performed to restore function to the mutated strain. For these experiments, the predicted function of the majority of these genes will be bacterial dissemination or adhesion and invasion of host cells, though other related function may also be included in these studies. The inserted DNA will typically contain an antibiotic resistance cassette conferring reduced susceptibility to the relevant antibiotic.

**Evaluation of foreseeable effects**

1) Fluorescent and luminescent proteins are well characterized, have no known toxicity and are not predicted to cause pathogenicity. The antibiotic resistance markers carried on the cloning vectors confer reduced susceptibility to the relevant antibiotic (e.g. gentamicin, chloramphenicol).

2) In the majority of instances random and targeted mutagenesis of bacterial genes is expected to result in negligible effects on the overall fitness of the mutant strains

02/03/2022
during an animal infection. On rare occasions, mutations may enhance fitness in vivo or alter the tissue- or host-tropism of the recipient, which could potentially result in increased replication within some cell lines or increased growth within certain tissues in vivo. It is also possible that mutations will not alter the function of the gene which would result in a wild-type strain with no impact on virulence. Insertion of foreign DNA may have unanticipated polar effects on upstream or downstream genes. Complementation of the native allele is expected to restore function to the mutated strain. Depending on the expression system used this may result in partial or complete complementation of any defect present, and in some instances may enhance the magnitude of gene expression, or alter the timing of such, relative to that present in nature. The antibiotic resistance markers that will be introduced will confer reduced susceptibility to the relevant antibiotic.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste will be disposed of by heat inactivation via autoclave, 100% kill. Protocols for each of waste that may be generated are as follows:

1. Consumables (e.g. plastic-ware such as pipettes, flasks, tubes etc.) - autoclave at 121-1250C for a minimum of 15 minutes. Disposed via industrial (orange bag) waste route through the University approved contractor.
2. Liquid discard (e.g. samples, culture supernatants, tissue culture media) --autoclave setting at 121-1250C for a minimum of 15 minutes. Disposed to drain.
3. Agar plates - autoclave (121-1250C for at least 15 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (orange bag) waste stream for landfill
4. Sharps waste in sharps containers (e.g. needles, scalpel blades) --disposed via the clinical waste stream for heat treatment via the University approved contractor.
5. Cytotoxic waste, solid and sharps must be segregated separately into purple lidded containers for disposal - disposed via the University approved contractor.

Animal Units | Large Scale Activities | Human Clinical Applications

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

Endothelin is a potent vasoconstrictor. We seek to produce a cohort of pigs with an inducible endothelin transgene such that we can study vascular dementia associated with hypertension. To do this we will microinject a lentiviral vector encoding the transgene construct into pig zygotes. The lentiviral vector is non-mobilisable. Once integrated into the DNA of the zygote it becomes a permanent feature of the genome. Once born the transgenic pigs will not pose a higher risk to human health than non-transgenic pigs.

**Recipient or parental organism**

Pig

**Host/vector system**

Second generation lentiviral vector

**Origin & function**

We will use a second generation lentiviral vector encoding the pig endothelin 1 cDNA under the control of a tet-response element to produce transgenic pigs. This will be microinjected into the perivitelline space of pig zygotes, infect the cell and integrate into the genomic DNA.

The lentiviral vector system which we will use has several safety features included to minimise the potential of replication competent lentivirus (RCL) production, or
subsequent mobilisation of the integrated transgene from the genome of the host cell. There is a very low risk of recombination with endogenous retroviruses due to the division of synthetic viral elements (ie coding sequences have been significantly altered from the original) among three different plasmids. The packaging and envelope plasmids (psPAX2 and pVSVG respectively) express viral accessory proteins in the HEK293 packaging cell line such that the desired transgene elements, inserted between the lentiviral LTRs, are packaged into the lentiviral pseudoparticle. The endogenous HIV-1 envelope glycoprotein has been replaced with VSV-G; while this increases the tropism of viral particles, it is also toxic to cells that express it. As the psPAX2 and pVSVG plasmids do not contain the lentiviral packaging signal sequence they are not packaged into the lentiviral pseudoparticle. This feature means that the elements required for producing lentiviral pseudo particles are only present in the transfected HEK293 packaging cells and not in cells that are subsequently transduced.

2nd generation lentiviral vectors are termed “self-inactivating” by virtue of a deletion in the 3’ LTR. This deletion does not affect the transcription and packaging of the recombinant viral genome in the producer cell line, but following reverse transcription results in a non-functional 5’ LTR in the integrated genome. This feature minimises the risk of mobilisation of the integrated construct.

As a consequence the resultant particles are single-round infectious. I am not aware of any literature reporting RCL or mobilisation of the integrated transgene from 2nd generation lentiviral systems. The relevant genetic elements encoded within the lentiviral vector will be the pig endothelin 1 cDNA under the control of a tet-response element. Downstream of this there will be a ubiquitous promoter (hUBc) driving expression of the reverse-tet transactivator protein, with an IRES followed by a neomycin resistance marker gene. In the absence of doxycycline the endothelin transgene is silent. In the presence of doxycycline the conformation of the reverse-tet transactivator is altered such that it is able to bind to the tet-response element, driving expression of the endothelin transgene.

Evaluation of foreseeable effects

The transgenic pigs will not have altered toxicity, allergenicity or behaviour. We anticipate that induced expression of the pig endothelin transgene will result in a hypertensive phenotype. We do not anticipate that induction of hypertension will alter the behaviour of the pig such that it is of greater risk to humans.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Animals will be housed in secure pens which are 1.5m in height as required by the HO regulations. The pens are contained within a locked facility with access controlled by the facility manager and limited to authorised personnel only. There will always be a minimum of 2 barriers between the animal and the external environment. Animals will be cared for by experienced staff wearing appropriate PPE. All staff involved in the care of these animals will be aware that they are genetically modified. Animals will be segregated by sex at weaning and maintained in single sex groups throughout life, other than to facilitate planned breeding.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Following schedule 1 culling the GM organism can be considered as inactivated and will be disposed of by either incineration or rendering.

Disinfection

All laboratory surfaces that come into contact with tissues/cells from these animals will be wiped with a 1% Virkon solution. Culture plates and pipettes will be soaked in a 1% Virkon solution overnight before disposal.

Autoclaving

All contaminated materials will be inactivated by autoclaving (100% kill) at 121°C or 134°C prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual (at least) thermocouple mapping and each run will be monitored using digital read outs.

Is an emergency plan required according to regulation 20? Y

If yes, tick to confirm that it is attached to this form Y
The genetic modification safety committee agreed that the appropriate containment and control measures have been assigned.

**Project Additional Information**
Purposes of the contained use

To identify essential genes involved in the proliferation, survival or migration of non-human mammalian cancer cell lines in vitro.

Recipient or parental organism

Cell lines derived from dogs, cats and horses.

Host/vector system

Vector: 2nd generation lentiviral vector. This is a replication-incompetent HIV-derived vector composed of three separate plasmids (psPAX2, pMD2.G and LentiCRISPRv2), with additional safety features including self-inactivation of LTR sequences.

Host: cancer cell lines and control fibroblast cell lines derived from dogs, cats and horses; HEK293T cells and closely-related Lentiviral Production Cells (commercially available human embryonic kidney-derived cell lines) for lentiviral production and titration.

Origin & function

The genetic material introduced into the cells comprises the nuclease enzyme spCas9 (originally derived from Streptococcus pyogenes), or a catalytically inactivated version, under an EF-1a core promoter, together with a synthetic sgRNA scaffold and a pool of sgRNA sequences targeted at the host genome, under a U6 promoter, and a puromycin or blasticidin resistance gene to allow antibiotic selection of the targeted cells. The sgRNA protospacer sequences will be synthesised de novo, while the other genetic elements are from the following 3 plasmids: LentiCRISPR-v2 (Addgene plasmid # 52961), lentSAMv2 (Addgene #75112) or Lenti-(BB) -EF1a-KRAB-dCas9-P2A-BlastR (Addgene #118154). The intended function of this CRISPR-Cas9 system is to target each gene in the target genome causing either 'knockout' of the gene by nuclease activity with imperfect non-homologous end-joining repair, leading to introduction of frame-shift mutations, or to increase or inhibit transcriptional activity.

Evaluation of foreseeable effects

Lentiviral vector:
This will have the ability to infect any mammalian cell line in vitro, resulting in expression of the Cas9 enzyme and sgRNA construct, or to infect humans or other animals if exposure occurs via mucous membranes, skin wounds or blood inoculation, but not via intact skin. The virus is replication-incompetent and self-inactivating, so sustained infection or spread of infection is not possible. Expression of the CRISPR/Cas9 constructs would lead to disruption of target gene sequences or expression in cells derived from the target species, with a lower chance of effects in any non-target species such as humans (depending on sequence homology). There is a small risk of oncogenesis after exposure via a clinically significant route, either via insertional mutagenesis or via disruption of oncogenes / tumour suppressor genes.

Genetically modified target host cells:
The genetically modified host cells will comprise a mixed pool of cells in which the function of each gene in the genome is expected to be disrupted individually in a subset of the cells. These cells are expected to exhibit a range of growth characteristics in vitro. All the cells are non-infectious themselves and will not harbour any pathogens dangerous to humans, and the genetic modifications involved will not lead to production of a harmful product. The genetic modifications introduced are not likely to lead to immune evasion or to increase the risk to humans in any way.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N
**Project Additional Information**

**Purposes of the contained use**

To generate human liver cell lines from healthy and diseased human liver for in vitro experiments, with a view to minimize reliance upon rodent models, and to accurately model human liver pathology.

**Recipient or parental organism**

Primary human liver cells, from healthy individuals, and those with liver pathology.

**Host/vector system**

An MuLV (Murine Leukaemia Virus) retroviral vector system will be used to deliver SV40 Large T antigen and TERT, which are genetic inserts commonly used for cell immortalisation.

**Origin & function**

Retroviruses for delivery of Large T antigen and TERT will be generated by TransIT mediated transfection of HEK cells, in OptiMEM media. The plasmids used will be: pUMVC (packaging), pMD2.G (pseudotyping), pBABE-Zeo SV40-LT (transfer plasmid for Large T antigen), pBABE-hygro-hTERT (transfer plasmid for TERT).

SV40 Large T antigen and TERT are genetic inserts commonly used for cell immortalisation. The transformation/immortalization by SV40 LT involves the following mechanism(s): (1) activation of E2F-mediated transcription through binding with Rb-E2F complex and (2) inhibition of p53, by blocking p53-dependent transcription activation and p53-independent growth-arrest. These two mechanisms lead to overcome growth arrest, prevent apoptosis and result in cellular proliferation. Another method used to immortalise primary cell lines is overexpression of telomerase reverse transcriptase (TERT), the catalytic subunit of the telomerase enzyme. The telomerase reverse transcriptase (TERT) protein is inactive in most somatic cells, causing the length of telomeres to shorten with age, leading to senescence. Expression of hTERT prevents the telomere from being truncated during cell division, thus cells are able to avoid replicative senescence.

**Evaluation of foreseeable effects**

Since the genes required for the γ-retroviral packaging and transduction are not encoded by the transfer plasmid, but instead are provided in trans by the other plasmids, the γ-retrovirus product can transduce target cells, but the transduced target cell does not produce additional virus.

Due to the broad tissue tropism provided by VSVG, the final amphotropic, MLV retroviral vectors will be able to infect all mitotic mammalian cells, but will be replication incompetent, unless recombination events occur (with endogenous or exogenous retroviruses, or with packaging components).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Disinfection Virkon RelyOn or 70% ethanol will be used for disinfection. Virkon RelyOn will be used at a final concentration of 1% with a contact time of 10 minutes. 70% ethanol will be used with a contact time of 30 seconds. Surfaces (incl bench tops, floors, small pieces of equipment, Gilsons, samples tubes etc) will be disinfected using a 1% Virkon RelyOn solution with a minimum contact time of 10 minutes or 70% ethanol with a minimum contact time of 30 seconds.

All liquid waste in the liquid waste collection bucket will be mixed with a 2% Virkon RelyOn solution in a 1:1 ratio and left for 10 mins following the conclusion of the experiment. After 10 mins, the mixed liquid waste can be discarded down the laboratory sink.

Solid will be chemically inactivated using Virkon RelyOn as described above prior to autoclaving, given the (low) oncogenic risk posed by the virus. Following chemical inactivation, solid waste will be double bagged in autoclave bags, necks sealed with autoclave tape, clearly labelled and autoclaved at 121-124°C for a minimum of 15 minutes prior to disposal of waste in a yellow bag with yellow tag, via an external contractor.

**Project Additional Information**

**Purposes of the contained use**

To generate retroviral particles for stable transduction of a fibroblast cell line to enable the subsequent generation of mitochondria-depleted cells.

**Recipient or parental organism**

Human fibroblast cells (although any cell type/species could be used).

**Host/vector system**

Phoenix amphotropic packaging cells will be transfected with a retroviral vector on a LZRS backbone. This host/vector system separates the transfer plasmid from the envelope and packaging proteins to ensure that no single plasmid contains all the necessary components necessary to produce viral particles. Therefore, retroviral particles can only be generated following transfection of the YFP-Parkin transfer plasmid into the Phoenix packaging cell line. The viral particles produced can only infect target cells once and will not produce any new viral particles after the initial infection.

**Origin & function**

Phoenix amphotropic packaging cell lines are derived from human embryonic kidney (HEK) 293T cells. These cells contain:

- A temperature-sensitive T antigen that enables the amplification of vectors containing the SV40 ori and thereby considerably increases the expression levels obtained with transient transfection
- A construct capable of producing the gag-pol packaging element that is under control of a RSV promoter. This construct also contains an IRES-CD8 surface marker downstream of the reading frame of the gag-pol construct to monitor gag-pol production
- A construct for the codification of the envelope protein for ecotropic and amphotropic viruses, which is under control of a CMV promoter

YFP-Parkin retroviral vector has a LZRS vector backbone combined to DNA sequences for eYFP (for immunofluorescence detection) and Parkin (to induce mitochondrial depletion). Parkin is a ubiquitin ligase protein that mediates the clearance of damaged mitochondria upon mitochondrial stress.

**Evaluation of foreseeable effects**

No single plasmid contains all the components necessary to produce viral particles, which can only infect target cells once and will not produce any new viral particles after the initial infection. Following transfection of the YFP-Parkin transfer plasmid into Phoenix packaging cells, YFP-Parkin retroviral particles will be collected from the media.
supernatant and used to transduce a cell line of interest. YFP-Parkin will be stably integrated into the host genome, and upon mitochondrial stress, will mediate clearance of damaged mitochondria from the cells.

In the event of accidental exposure, it is unlikely that the GM virus would cause harm to human health because the viral vector on its own is replication incompetent and would be of minimal risk. In addition, the genetic information contained within the retroviral particles is insufficient to generate new infectious virus.

The transfer plasmid can infect cells from all commonly used mammalian species but again is unlikely to spread because the plasmid is replication incompetent. The expression of each construct in the packaging cell line is under the regulation of different promoters to minimize recombination potential and the generation of recombined viral products.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Human Clinical Applications
## Project Additional Information

### Purposes of the contained use
To use hESC/IPSC reporter lines to enhance our understanding of the haematopoietic differentiation process and ultimately increase efficiency of HPC/HSC production.

### Recipient or parental organism
Genes will be introduced into (i) human packaging cell line 293T, (ii) human embryonic and induced pluripotent stem cells (ESC and iPSC), (iii) human umbilical cord blood cells, and (iv) mouse non-haematopoietic cells.

### Host/vector system
Third generation amphotropically packaged HIV-1 derived lentiviruses; pLenti, pSico and FUGW derived expression vectors (Addgene).

### Origin & function
Reporter constructs will contain fluorescent markers eGFP or Venus, derived from the jellyfish Aequorea victoria or tdTomato or mCherry, derived from Discosoma sp sea anemone. Expression of these will be driven by human haematopoietic lineage promoters including those of the ID1, GLI1, WNT, RUNX1, VE-CADHERIN, CD43 genes; expression of the markers will report on differentiation at key points in the haematopoietic lineage. The inserted DNA will be reporting the activity of the promoter regions of specific genes only and should not have any effect on the transcribed/translated gene products of those genes.

For reprogramming constructs, a range of genes (including transcription factors or secreted factors) thought to play a role in differentiation of haematopoietic stem cells will...
be inserted. It is intended that combinations of these factors will be expressed to test for the ability to reprogram recipient cells into haematopoietic stem cells. For expression of factors for reprogramming, these will be under tight control of doxycycline inducible promoter system where expression is reliant upon the addition of doxycycline to derepress.

Evaluation of foreseeable effects

The third generation lentiviral vectors used contain a number of safety features that render them replication incompetent and once transduced the human cell lines will pose a negligible risk of transmission. Some vectors contain the woodchuck hepatitis virus post-transcriptional regulatory element (WPRE) to enhance both virus titre and expression of introduced genes. This element can enhance the yield of expressed protein product and may increase the associated risk. However the WPRE is capable of expressing part of the X protein of WHV, and may exhibit oncogenic properties. Injection of lentivirus with the WPRE into mice caused liver tumours. This suggests that the vector backbone may be inherently oncogenic, before it is manipulated to express genetic material and SACGM (2004) recommended this requires containment level 2. The expressed marker, eGFP, is not harmful per se and is not expected to change the behaviour of the cells into which it is introduced. It is not expected to change the host range or infectivity of the vectors used to introduce it into the target cells.

293FT, embryonic /IPS and mouse cells are not infectious and will not colonise a human subject and will not survive outside tissue culture facilities. Genes important for haematopoietic differentiation and genes identified in embryonic HSCs and precursors from gene-expression analysis (specific genes to be decided) but may include oncogenes are on the whole considered low risk. The transduced stem cells and their differentiated progeny cannot assemble the infectious particles. Virally encoded transgenes may be expressed in higher than normal levels because of the presence of the WPRE sequence. For expression of oncogenes if identified in expression screens of stem cells or their precursors then the risk would be thought be low in most cases as the expression is regulated by drugs (eg doxycycline). If the virus were to be introduced into human tissue it may be possible that expression of a normal gene product or oncogene could be produced at levels above that normally found and hence may present a very low but real hazard.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disinfection

All solid and liquid waste must be decontaminated/disposed of by the user at the end of every TC session.

Surfaces will be sprayed 1% Trigene followed by 70% IMS after use. Any spills outside of the hood (on any hard surface, eg. benchtop, incubator or floor) must be wiped down immediately with 1% Trigene/Chemgene then sprayed with 70% ethanol as above.

Solid waste will autoclaved after every session (as described above) before final disposal by incineration via the yellow bag route. Any liquid potentially containing virus should be collected in an autoclavable screw top plastic bottle (stored under the sink). It should NEVER come into contact with the vacuum system. The liquid waste should be chemically disinfected by soaking in 1% w/v Virkon, or 1,00ppm Precept (four 0.5g tablets into 1 litre of liquid) for 24 hours before discharging via the drains. The container must be labelled with name, group and date.

Autoclaving

All contaminated materials will be inactivated by autoclaving (100% kill) at 121°C or 134°C prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware.

Autoclaves will be validated by annual (at least) thermocouple mapping and each run will be monitored by continuous chart or digital recording of the temperature / time profile.
The genetic modification safety committee agreed that the appropriate containment and control measures have been assigned.

**Project Additional Information**

**Purposes of the contained use**

Increased understanding of pathogen biology to inform future treatment of candidiasis and other conditions caused by these organisms.

**Recipient or parental organism**

This work will use pathogenic Candida species (principally Candida glabrata and Candida albicans, and specifically not Candida auris). Strains include SC5314, CAI4, RM1000, BWP17 and SC5314 (C. albicans) and BG2 and CBS138 (C. glabrata).

These organisms are commonly present as part of human commensal flora but are opportunistic pathogens causing mucocutaneous infection of several body systems, most commonly the mouth, oesophagus and vagina. Risk factors include pregnancy, the use of intrauterine devices and oral contraceptives as well as antibiotic use and diabetes. Systemic disease only occurs in severely immunocompromised individuals. Infection by inhalation of aerosols is not known to occur.

Standard non-pathogenic laboratory Eschericia coli strains (K12 background) will also be used.

**Host/vector system**

**E coli:** pMB1-based non-conjugative plasmids. Standard ampicillin and kanamycin resistance genes, standard fluorescent protein-encoding genes (GFP, RFP etc.) adapted from ACDP 1 invertebrates. Regulatory sequences from Candida species and related yeasts, engineered inducible promoters, engineered tags (His, FLAG, etc). Standard antibiotic resistance markers (Amp/Kan) will be used.

**Candida:** Vectors for CRISPR Cas9 technology, solo system: pV1093 or pV1200. Duet System: pV1025 and pV1090 (Vyas et al. [2015] Sci Adv. 1, e1500248). Genomic integrations using PCR-amplified or restriction digested DNA. No mobilisable vectors involved. Antifungal markers Nat/Geo may be used.

**Origin & function**

Fluorescent or other standard marker proteins derived from non-pathogenic invertebrates (GFP, mScarlet). Regulatory sequences from Candida spp and related yeasts as well as engineered inducible promoters. Engineered tags (FLAG, His etc.). Selectable resistance markers for yeasts and bacteria (Kan, amp, Nat, Geo). Sequences required for CRISP/Cas9 engineering (adapted from S. pyogenes and Candida-derived guide RNA sequences).

**Evaluation of foreseeable effects**

None of the proposed manipulations will introduce genes for which there is any evidence of additional harmful effects to humans or the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All liquid waste and solid materials that have been in contact with microorganisms will be sterilised by autoclaving before disposal by the approved local routes.
The genetic modification safety committee agreed that the appropriate containment and control measures have been assigned.

CDKL5 Deficiency Disorder (CDD) in humans is a neurodevelopmental encephalopathy characterised by profound impairments, which include autism spectrum disorder (ASD), intellectual disability (ID), epilepsy, movement disorders and autonomic dysfunction. Rodent models of the disease do not develop the full range of phenotype observed in humans. We will produce pigs with altered CDKL5 in order to discover how the disease will manifest in animals with larger brains.

**Recipient or parental organism**

Pig

**Host/vector system**

CRISPR/Cas9 modification of the endogenous pig CDKL5 gene

**Origin & function**

CDKL5 Deficiency Disorder (CDD) in humans is caused by de novo genetic mutations in the cyclin dependent kinase-like (CDKL5) gene. It is a neurodevelopmental encephalopathy characterised by profound impairments, which include autism spectrum disorder (ASD), intellectual disability (ID), epilepsy, movement disorders and autonomic dysfunction. It is possible that modification of the pig CDKL5 gene will result in animals with altered temperament and/or development of seizures. These changes, if observed, may result in the animals being more aggressive.

**Evaluation of foreseeable effects**

Animals will be housed in secure pens which are 1.5m in height as required by the HO regulations. The pens are contained within a locked facility with access controlled by the facility manager and limited to authorised personnel only. There will always be a minimum of 2 barriers between the animal and the external environment. Animals will be cared for by experienced staff. All staff involved in the care of these animals will be aware of the potential for altered behaviours associated with the genetic modification.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**Project Ref 207/21.5**

- Date Ackn'd: 05/08/2021
- CU2 Project Title: Development of an induced ovine pulmonary adenocarcinoma model with both replication competent and replication deficient Jaagsiekte Sheep Retrovirus
- Class: Class 2
- CultureVolClass2: < 1 Litre
- Consent Granted

**Project Additional Information**

**Purposes of the contained use**

Ovine pulmonary adenocarcinoma (OPA) is an infectious lung tumour of sheep caused by the betaretrovirus, jaagsiekte sheep retrovirus (JSRV). OPA is widespread throughout the world and causes significant economic and animal welfare issues. The mechanism of pathogenesis in OPA is not fully understood but it has been established that the JSRV Env glycoproteins are capable of transforming fibroblasts and epithelial cell lines in vitro and therefore act as viral oncogenes. In addition, delivery of Env-coding regions to the lungs of mice and sheep in vivo, using viral vectors, results in the growth of lung tumours histologically similar to those present in...
One difficulty in OPA research is that there is no permissive culture system for propagating JSRV in vitro. An important advance in JSRV research was the development of an infectious molecular clone that generates infectious virus when transfected into 293T cells. This in vitro-derived virus causes OPA when inoculated intra-tracheally into young lambs. Importantly, this molecular clone (pCMV2JS21) can be modified to produce mutant viruses, which can be used in vivo to investigate specific aspects of JSRV biology. One derivative of pCMV2JS21 is a replication-defective virus encoding only the JSRV Env protein.

This project will utilise infectious JSRV derived from pCMV2JS21, which although derived using recombinant DNA methods is identical to naturally occurring wild-type virus is still considered a GM virus. In addition, we will use a replication-defective JSRV vector derived from pCMV2JS21. This vector is able to infect cells in a single round of infection and subsequently express the JRV Env protein, but it is unable to spread further.

In terms of lung cancer research, OPA has significant similarities in histological appearance, activation of oncogenic signalling pathways and transcriptional profiles to certain types of human lung adenocarcinomas. These findings have resulted in OPA being proposed as an excellent model to study human lung cancer.

The overriding aims of this study is to understand the infectious process of JSRV. This knowledge is essential for:
1. Developing OPA control methods which can be used in eradication programmes or assurance schemes.
2. Developing an OPA model which can be used in translational studies for human lung cancer research.

Genetically modified replication-defective JSRV (RD-JSRV) and JSRV will be produced at Moredun Research Institute (MRI), covered by their own risk assessments (work to produce the vectors at MRI has been notified to HSE (GM172/06.1)). Virus will be transferred to the Large Animal Research and Imaging Facility (University of Edinburgh) for use in this study.

Using 3–12-month-old sheep, the viruses produced at MRI will be delivered via a bronchoscope into a subsegmental bronchus. Tumour development will be monitored over a 9-month period using thoracic ultrasound and CT imaging. Blood, nasal swabs and exhaled breath condensate will also be collected during this time. The CT scan data will be used to generate 3D images indicating the size and spatial location of tumours. The concentration of JSRV/RD-JSRV in each breath condensate and nasal swab sample will be estimated as copy number/volume by RT-qPCR. RD-JSRV should be undetectable as it cannot replicate.

**Recipient or parental organism**

Wild type JSRV particles contain 2 copies of single-stranded positive sense RNA. Its genome of approximately 7,460 nucleotides contains 4 genes encoding viral proteins. These 4 genes are: gag (encoding the matrix, capsid and nucleocapsid proteins); pro (encoding aspartic protease); pol (encoding reverse transcriptase and integrase enzymes) and env (encoding surface and transmembrane envelope glycoproteins). An additional open reading frame, known as orfX, which overlaps with the pol gene, has also been identified; however, it is not required for in vitro cellular transformation or in vivo oncogenesis. Interestingly, JSRV-induced neoplastic transformation is mediated by the viral Env glycoprotein, although the mechanisms underlying this process are not completely understood. The transforming activity of Env was first shown in vitro using rodent fibroblasts, with subsequent in vivo experiments showing that the administration of viral vectors expressing Env to the lungs of mice and sheep results in adenocarcinoma formation. Env localisation at the plasma membrane may enable it to interact with other molecules such as protein kinases, leading to the activation of downstream pathways that promote cellular proliferation and survival. The Ras-MEK-ERK and PI3K-AKT-mTOR pathways are commonly activated in OPA tumours; others may include EGFR, RON-HYAL2 and heat shock proteins. Following pathway activation, it is likely that further mutations are required for tumours to develop, such as telomerase activation, the activation of other cellular oncogenes or the inactivation of tumour-suppressor genes.

**Host/vector system**

RD-JSRV, produced by co-transfection of 293T cells with 2 plasmids. The first is a vector plasmid (CJ-Env), derived from the infectious molecular clone pCMV2JS21. This vector has a deletion that removes most of the Gag and Pol coding regions, rendering the virus replication-defective. The second is a packaging plasmid that encodes the JSRV Gag-Pol coding regions only. Transfection of cells with these 2 plasmids produces vector particles capable of a single round of infection but that in the recipient cell express only JSRV Env – see next section.
Replication competent JSRV (wild type): pCMV2JS21 has the U3 region of the viral 5’ LTR substituted with the CMV-IE promoter (derived from pcDNA3 by PCR). These proviruses will be used to transfect mammalian cells (293T) in order to produce infectious virions.

Molecular clones of replication competent JSRV:

Replication competent JSRV (wild type): pCMV2JS21 has the U3 region of the viral 5’ LTR substituted with the CMV-IE promoter (derived from pcDNA3 by PCR). These proviruses will be used to transfect mammalian cells (293T) in order to produce infectious virions.

Molecular clones of replication-deficient JSRV:

The vector derives from the infectious molecular clone pCMV2JS21 and is produced by transfecting cells with two plasmids.

The vector plasmid, pCJ-Env, is a modified form of pCMV2JS21 in which the majority of the regions encoding the JSRV Gag and Pol protein have been deleted. This plasmid can therefore express only the JSRV Env protein and cannot direct the production of viral particles. This plasmid also retains elements of the JSRV genome including LTR regions and the packaging signal.

Production of viral-like particles is mediated by co-transfecting 293T cells with pCAG-JS-GP-CTE2X, a helper packaging plasmid that expresses the JSRV Gag, Pro and Pol proteins that form the JSRV capsid. This plasmid also contains two copies of the Mason Pfizer monkey virus constitutive transport element (CTE) for optimal export of unspliced mRNA and a poly A signal derived from the bovine growth hormone. This plasmid does not contain the JSRV packaging signal.

Co-transfection of these 2 constructs into 293T cells will result in the production of vector particles (RD-JSRV) capable of delivering the pCJ-Env genome into target cells in a single round of infection but incapable of replicating further. Homologous recombination to produce a replication competent retrovirus is not possible since there are no sequences in common. Therefore, spread to new cells beyond those receiving the “first hit” or between animals is not possible. Since the packaging signal (Ψ) is present, there remains a theoretical risk that subsequent (inadvertent) infection of an animal carrying the CJ-Env transgene with wild type JSRV could mobilise this vector. However, such mobilisation would not have any increased hazard above that of wild-type JSRV infection, since the env gene is encoded by wild type JSRV. In addition, the risk of cross-infection of experimental animals is negligible due to animal containment procedures.

Expression of JSRV Env in the RD-JSRV vector is controlled by the JSRV LTR thereby restricting expression to type-II pneumocytes and club cells. This means that the risk associated with this vector is no more than wild type JSRV (indeed, less so because RD-JSRV is replication-defective).

Evaluation of foreseeable effects

Hazards of wild-type JSRV to human health
Low risk. Although human lung cells have cellular receptors (HYAL2) to allow virus entry there has been no reported cases of human JSRV-induced disease and JSRV is not considered a human pathogen.

Hazards of RD-JSRV to human health

(i) Hazards associated with the recipient microorganism (e.g. bacterial host or viral vector)
Low risk. RD-JSRV is a disabled version of the wild-type JSRV. It carries the same oncogene as wild-type JSRV and utilises the same determinants (receptor and promoter (LTR)) are the same as the wild-type virus. It has the same envelope proteins and LTRs as wild type JSRV and therefore have the same tropism as wild type virus. Therefore, these vectors represent even less of a risk to human health than JSRV virions. Retroviral vectors used in this programme will not be replication competent and therefore have no risk of spreading to persons other than those directly handling the vectors.

There are no factors specific to this work that increase the risk to any one group. However, severely immunosuppressed workers should not handle transformed human cell lines and pregnant women should avoid working with sheep due to the risk that the sheep harbour other zoonotic agents.

Hazards to the environment.
Low risk. Wild type JSRV causes ovine pulmonary adenocarcinoma (OPA) in sheep and transmission is principally via the respiratory route. OPA is endemic in the UK and given the scale of the experiments it is extremely unlikely that a breach of containment would lead to a measurable increase in the incidence or prevalence of OPA. In addition, experience with infectious lung fluid from sheep with OPA, and with virus produced in vitro, indicates that the amount of virus released from sheep with experimental OPA is less than that used in the experimental inoculum (i.e., we get back less than we put in).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**Hazards of wild-type JSRV to human health**

Low risk. Although human lung cells have cellular receptors (HYAL2) to allow virus entry there has been no reported cases of human JSRV-induced disease and JSRV is not considered a human pathogen.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

**Disinfection**

Anistel (1%) has been validated for use against other enveloped viruses including HIV-1 and hepatitis B virus virus and will be used according to the manufacturer’s instructions; 1:200 with a minimal contact time for hard surfaces of 5 minutes.

Virkon® broad spectrum virucidal disinfectant used according to the manufacturer’s instructions. This disinfectant has proven virucidal efficacy against adenoviridae, parvoviridae, retroviridae and paramyxoviridae. 1% Solution will be prepared as follows: add 10 gm of powder to a litre of warm water and stir until dissolved. Once made up Virkon remains active for 5-7 days. A dye is included with Virkon which is pink in its oxidised form but becomes colourless in its reduced form – indicating that the solution should be replaced. The required minimal contact time for hard surfaces is 10 minutes.

**Autoclaving**

All contaminated materials will be inactivated by autoclaving (100% kill) at 121-134°C with a holding time of at least 15 minutes, prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual (at least) thermocouple mapping and each run will be monitored by continuous chart or digital recording of the temperature / time profile. Each run will be monitored using chemical indicators (eg Browne TST indicator test strips).

Solid laboratory waste: Autoclaved in-house.
Liquid laboratory waste: Autoclaved in-house or treated with Anistel or Virkon disinfectant and disposed in general drainage.

Animal waste: Bedding will be disposed of by composting. Previous analysis has shown that no JSRV RNA can be detected in bedding of inoculated animals using quantitative real-time PCR.

Animal carcasses will be double bagged and disposed of by rendering. Tissue retained at post-mortem will be processed and handled as laboratory waste.

Project Ref 207/21.6

Date Ackn'd: 06/08/2021

CU2 Project Title: Causes of neurodegeneration in Alzheimer’s disease, ageing, and related degenerative disorders

Date Project Ceased: 02/03/2022

Class: Class 2

Culture Vol Class 2: < 1 Litre

Consent Granted: Non-GMM

Project notified under transitional arrangements N
### Project Additional Information

**Purposes of the contained use**

In this project, we will use tissue from animal models of Alzheimer's and related neurodegenerative diseases to study the causes of brain degeneration and to test candidate therapeutic pathways. We will test the hypothesis that overexpression of a subunit of the ECM protein, Laminin, can ameliorate toxicity caused by amyloid beta which leads to loss of the connections between brain cells and eventual cell death.

**Recipient or parental organism**

Cultured mouse organotypic brain slice cultures from non genetically altered (wild type) and GM mouse pups. Example GM lines to be used include: APP/PS1, C3Ko. Hazard group 1. GM animal tissue used will pose no threat to human health and can be worked with under category 1.

**Host/vector system**

Lentiviruses will be transduced into mouse organotypic brain slice cultures. (Lentiviral vectors: VSV-G pseudotyped third-generation lentivirus). Lentiviral vectors are derived from HIV, which is a member of the retrovirus family. Wildtype lentivirus has a plus-strand linear RNA genome.

A lentiviral vector is first constructed as a plasmid in E. coli. It is then transfected into packaging cells along with several helper plasmids. Inside the packaging cells, vector DNA located between the two long terminal repeats (LTRs) is transcribed into RNA, and viral proteins expressed by the helper plasmids further package the RNA into virus. Live virus is then released into the supernatant, which can be used to infect target cells directly or after concentration.

When the virus is added to target cells, the RNA cargo is shuttled into cells where it is reverse transcribed into DNA and randomly integrated into the host genome. Any gene(s) that were placed in-between the two LTRs during vector cloning are permanently inserted into host DNA alongside the rest of viral genome. By design, lentiviral vectors lack the genes required for viral packaging and transduction (these genes are instead carried by helper plasmids used during virus packaging). As a result, virus produced from lentiviral vectors has the important safety feature of being replication incompetent (meaning that they can transduce target cells but cannot replicate in them).

**Origin & function**

The Lamb1 gene from the mouse genome will be expressed in lentivirus to cause production of the laminin beta 1 protein. This is an extracellular matrix glycoprotein. When expressed in genetically modified Drosophila, this protein protects cells from toxicity of amyloid beta, one of the key pathologies in Alzheimer's disease. Here we will test whether this also occurs in mammalian models (mouse brain slices in culture). To identify transduced cells, the virus will also express green fluorescent protein (originally derived from the jellyfish Aequorea victoria). As a control, another lentivirus will be used expressing the fluorescent protein mCherry (originally derived from a modified dsRed protein expressed in Discosoma sea anemones).

**Evaluation of foreseeable effects**

By design, lentiviral vectors lack the genes required for viral packaging and transduction (these genes are instead carried by helper plasmids used during virus packaging).
As a result, virus produced from lentiviral vectors has the important safety feature of being replication incompetent (meaning that they can transduce target cells but cannot replicate in them).

Whilst there is no known oncogenicity of the Lamb1 protein, a literature search suggested there may be a link with Lamb1 overexpression and cancer. To mitigate this small risk, the viral titre used will be very low, the virus used will be replication incompetent, and appropriate PPE/ safety measures will be taken.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

No sharps will be used other than glass coverslips (which need be used as we have no viable alternative).

Any broken glass which is likely to feature a viable GM component will be disposed of in a sharps bin and autoclaved with a regimen consistent with deactivation of GMO’s before the container is sealed and tagged for uplift.

Any broken glass with no hazardous considerations will be disposed of in a regular Haveshaps bin. All users will be made aware of potential for injury due to broken glass and disposal routes.

All contaminated materials will be inactivated by autoclaving (100% kill) at 121°C or 134°C prior to disposal of waste or cleaning and recycling of reusable laboratory equipment. Autoclaves will be validated by annual (at least) thermocouple mapping and each run will be monitored by continuous chart or digital recording of the temperature / time profile.

We will decontaminate all waste before disposal: yellow bag with yellow tag to be used.

**Project Additional Information**

**Purposes of the contained use**

Gain understanding on how fungal pathogens adapt and thrive under different stress conditions with the aim to inform future treatment of candidiasis and other conditions caused by these organisms.

**Recipient or parental organism**

This work will use pathogenic Candida species (principally Candida albicans and Candida glabrata). Strains include: SC5314, CAI4, CAI8, RM1000, BWP17, SN78 (Candida albicans) and BG2 and CBS138 (Candida glabrata) and ambient, non-GMO, strains of Candida albicans and Candida glabrata (NHS provided). All strains are HG2.

The above organisms are commonly present as part of human commensal flora but are opportunistic pathogens causing mucocutaneous infection of several body systems, most commonly the mouth, oesophagus and vagina. Risk factors include pregnancy, the use of intrauterine devices and oral contraceptives as well as antibiotic use and diabetes. Systemic disease only occurs in severely immunocompromised individuals. Infection by inhalation of aerosols is not known to occur.

Standard non-pathogenic laboratory Eschericia coli strains (K12 background) and standard non-pathogenic Saccharomyces cerevisiae strains, with a history of safe use (W303, S288C, SK1) will also be used as part of this work. These strains are HG1.
### Host/vector system

1. Specific non-mobilisable Candida spp vectors (low copy replicating and integrating vectors [YPB1, Clp10, Clp20, Clp30]; low copy replicating and integrating vectors for ectopic expression [YPB-ADHpt, pACT1]; integrating expression vectors regulated by methionine [MET3 promoter], maltose [MAL2 promoter], glucose [PCK1 promoter], or doxycycline [tet ON/OFF promoter]; CRISPR Cas9 technology. Solo System: pV1093 (Amp) or pV1200 (NAT1+Amp). Duet System: pV1025 (NAT1+Amp) and pV1090 (Amp).

2. pRS vectors, YIPlac (integration), YCPlac (centromere based), YEPlac (2-micron), PCR tagging vectors (epitope tagging).

3. Non-mobilisable E. coli vectors (pUC-derived vectors, such as: pBluescript, pGEM-T, and bacterial expression vectors: pET vectors, pGEX, pQE).

### Origin & function

Fluorescent or other standard marker proteins derived from non-pathogenic invertebrates (GFP, YFP, tdTomato). Regulatory sequences from Candida spp and related yeasts as well as engineered inducible promoters. Engineered tags (FLAG, His, etc.). Selectable resistance markers for yeasts and bacteria (Kan, Amp, Nat, Geo). Sequences required for CRISP/Cas9 engineering (adapted from S. pyogenes and Candida-derived guide RNA sequences)

### Evaluation of foreseeable effects

None of the proposed manipulations will introduce genes for which there is any evidence of additional harmful effects to humans or the environment. No known toxins or allergens will be produced as a result of insertion in E. coli, Candida albicans, Candida glabrata or S. cerevisiae and inserts will not affect the pathogenicity of any host.

Briefly, insert code for normal or mutant forms of yeast genes involved in cell cycle control, chromosome segregation or regulation of metabolism, often with short epitope tags added to enable immunological detection of expressed proteins, or GFP tags for localisation studies. These yeast genes are not expressed to have harmful physiological or pharmacological properties, or to affect pathogenicity of the cloning host or human defence mechanisms. Some examples of genes to be targeted are those of the Kinetochore complex (CHL4, MCM21, CTF3) and the cohesin complex (MCD1, SCC2) in order to generate null mutants or conditional knockouts. Deletion of those genes will render the strains less virulent than their isogenic strains. No null mutations have been described that increase the virulence of C. albicans or C. glabrata.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

### Project Additional Information

**Purposes of the contained use**

To trace and image the axons and cell bodies of neurons that provide input to layer 1 cells in the entorhinal cortex. This will inform us of the nature of the information that layer 1 cells are processing and help set up future experiments that will establish how these inputs contribute roles of the entorhinal cortex in spatial cognition and memory.

**Recipient or parental organism**

NDNF-iRES-Cre mouse line (Strain: C57BL/6JCrj) [Jackson Lab Stock No: 030757].

Neuron-derived neurotrophic factor (NDNF) is a specific molecular marker for neurons in layer 1. By driving expression of Cre recombinase from the NDNF1 promoter is is possible to target a significant portion of the entorhinal layer 1 population.
Host/vector system

EnvA-pseudotyped B19G-deleted rabies virus: pSADB19dG-mCherry
Helper Vector: pAAV-Syn-FLEX-nGToG-WPRE3

Origin & function

The helper vector is an AAV vector that mediates Cre-dependent expression of the TVA receptor, B19oG and nuclear localised green fluorescent protein. Because in the NDNF-IRES-Cre line the expression of Cre is restricted to layer 1 neurons, the gene products encoded by the AAV will be expressed only in these neurons.

SAD-B19 is a genetically engineered rabies virus that has had the B19G glycoprotein removed and has been pseudotyped with the envelope protein EnvA of the Avian Sarcoma and Leukosis virus. As a result, it cannot infect mammalian cells unless they have been modified to express the TVA receptor. Once inside the layer 1 neurons that have already been infected with the helper vector, SAD-B19 can replicate and label layer 1 cells (first-order) and their presynaptic neurons (second-order). It can not spread any further as the second order cells will lack the TVA receptor and B19oG protein.

Evaluation of foreseeable effects

SAD-B19 has been shown to be extremely stable in vivo and has been used in numerous studies without evidence of its reversion to wildtype. It is not expected to be harmful to the host organism or cause any gross phenotypic or behavioural abnormalities.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All NDNF mice will be housed in standard cages in groups of up to 4 before and after surgery. They will be kept at all times within the animal research unit in the Hugh Robson Building, which is a containment level 2 area. All staff have been trained and assessed in handling laboratory mice. Researchers have been trained and assessed by a Named Veterinary Surgeon to perform surgery safely, ensuring the trainee is competent when handling and transporting the animals.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

SAD-B19 will be disposed in sharps bins with a yellow bin, purple lid and yellow tag (for cytotoxic/static waste sharps). For animals injected with the virus, they will be sacrificed 3-4 weeks after surgery by exsanguination during a paraformaldehyde (PFA) perfusion procedure, they will then be decapitated and the brain will be extracted and kept in a PFA solution. The anatomical waste will be placed into an autoclave bag for sterilisation. Following autoclaving the bag will be transferred to yellow clinical waste bags with red tags for disposal via our clinical waste contractor.

Page 5063 of 15326
The recently emerged pathogenic SARS-CoV-2 virus continues to cause a major human pandemic. Animal models which accurately reflect the human disease would be of great value for pathogenesis studies and antiviral testing. Current animal models developed for SARS include small rodent models, such as mice engineered to express the human receptor for this virus, hACE2. Although these models demonstrate a disease state following challenge, they do not accurately reflect human disease, with mortality resulting from significant infections in the brain. Furthermore, the scale and gross anatomy of rodents is very different from humans. In contrast, the anatomy of pigs is more similar, with pig lungs equivalent to human lungs in size and structure. A transgenic pig expressing hACE2 will represent an invaluable model for Covid-19 research.

We aim to use a lentiviral vector encoding the hACE2 cDNA under the control of a cytokeratin promoter to produce transgenic pigs. The lentiviral vector will be injected into the perivitelline space of pig zygotes, which will then be transferred to recipients. Additional zygotes may be cultured to blastocyst stage for in vitro analysis. Piglets will be born and genotyped (GMAni0621). Tissues will be collected and cell cultures established at Roslin (covered in the class 2 risk assessment GM 0421). These will be assessed for infectivity by SARS-CoV-2 in the Roslin Institute Building labs under a separate risk assessment. This RA covers the transgenic pigs. It does not cover any

Work involving infection with SARS-CoV-2. Any work using SARS-CoV-2 to infect cells or pigs will be performed in a CL3 laboratory under a separate risk assessment.

Recipient or parental organism

pig

Host/vector system

Second generation lentivirus expressing human ACE2

Origin & function

We will use a second generation lentiviral vector encoding the hACE2 cDNA under the control of a human cytokeratin 18 promoter to produce transgenic pigs. This will be microinjected into the perivitelline space of pig zygotes, infect the cell and integrate into the genomic DNA.

The lentiviral vector system which we will use has several safety features included to minimise the potential of replication competent lentivirus (RCL) production, or subsequent mobilisation of the integrated transgene from the genome of the host cell. There is a very low risk of recombination with endogenous retroviruses due to the division of synthetic viral elements (i.e. coding sequences have been significantly altered from the original) among three different plasmids. The packaging and envelope plasmids (psPAX2 and pVSVG respectively) express viral accessory proteins in the HEK293 packaging cell line such that the desired transgene elements, inserted between the lentiviral LTRs, are packaged into the lentiviral pseudoparticle. The endogenous HIV-1 envelope glycoprotein has been replaced with VSV-G; while this increases the tropism of viral particles, it is also toxic to cells that express it. As the psPAX2 and pVSVG plasmids do not contain the lentiviral packaging signal sequence they are not packaged into the lentiviral pseudoparticle. This feature means that the elements required for producing lentiviral pseudo particles are only present in the transfected HEK293 packaging cells and not in cells that are subsequently transduced.

2nd generation lentiviral vectors are termed “self-inactivating” by virtue of a deletion in the 3’ LTR. This deletion does not affect the transcription and packaging of the recombinant viral genome in the producer cell line, but following reverse transcription results in a non-functional 5’ LTR in the integrated genome. This feature minimises the risk of mobilisation of the integrated construct.

As a consequence the resultant particles are single-round infectious. I am not aware of any literature reporting RCL or mobilisation of the integrated transgene from 2nd generation lentiviral systems. The relevant genetic elements encoded within the lentiviral vector will be the human ACE2 cDNA under the control of the human cytokeratin 18 promoter. It is intended this promoter/transgene combination will enrich and ideally restrict transgene expression to epithelial cells, such that epithelial cells of the respiratory tract of the transgenic pigs will express hACE2. No mammalian selection cassette is present within the integrated transgene.

Evaluation of foreseeable effects

The transgenic pigs will not have altered toxicity, allergenicity or behaviour. Through expression of the human ACE2 transgene it is anticipated that they will be more readily infected by the SARS-CoV-2 virus, and if infected are likely to shed virus. If the transgenic pig were to become infected with SARS-CoV-2 there is a possibility that it could become sick.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Animals will be housed in secure pens which are 1.5m in height as required by the HO regulations. The pens are contained within a locked facility with access controlled by the facility manager and limited to authorised personnel only. There will always be a minimum of 2 barriers between the animal and the external environment. Animals will be cared for by experienced staff wearing appropriate PPE. All staff involved in the care of these animals will be aware of the potential for altered pathogenicity associated with the genetic modification. Animals will be segregated by sex at weaning and maintained in single sex groups throughout life, other than to facilitate planned breeding.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Following schedule 1 culling the GM organism can be considered as inactivated and will be disposed of by either incineration or rendering.

02/03/2022
Disinfection
All laboratory surfaces that come into contact with tissues/cells from these animals will be wiped with a 1% Virkon solution. Culture plates and pipettes will be soaked in a 1% Virkon solution overnight before disposal.

Autoclaving
All contaminated materials will be inactivated by autoclaving (100% kill) at 121°C or 134°C prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual (at least) thermocouple mapping and each run will be monitored using digital read outs.

Project Ref 207/22.1

Date Ackn'd  25/02/2022

CU2 Project Title
Deciphering the role of secreted proteins in Toxoplasma gondii infection

Class  Class 2
CultureVol Class 2  < 1 Litre
CultureVol Class 3-4

Non-GMM  Consent Granted

Project notified under transitional arrangements  N
This work will investigate parasite proteins for their role in establishing chronic infections. By analysis of their expression in wild type Toxoplasma and by perturbation in genetically modified parasites our objective is to understand how they function in formation of the chronic cyst and parasite survival.

This work will include several arms of genetic manipulation:
1. Generating pools of parasites where each parasite has a different gene disrupted by CRISPR/Cas9. Using this method, 100s of genes can be targeted in the same parasite flask and the important genes are identified by determining which parasites grow more slowly or are unable to form a healthy cyst.
2. Targeting of individual genes of interest by generating conditional or complete gene knockout, and adding tags for localisation/biochemical purposes.
3. Inserting fluorescent or bioluminescent proteins to be able to follow parasite differentiation of infection patterns.

**Recipient or parental organism**

Toxoplasma gondii

**Host/vector system**

All vectors used are standard non-transmissible bacterial plasmids, with drug selection markers for use in bacteria and Toxoplasma. They include promoters to control expression of parasite genes of interest, or alternatively are intended to disrupt parasite genes by inserting selection markers in place of the gene.

**Origin & function**

We will be investigating novel and identified genes proposed to be involved in Toxoplasma differentiation and survival as chronic stage parasites. These genes are all of Toxoplasma gondii origin.

Additionally, fluorescent/bioluminescent proteins will be expressed for tracking parasite growth or differentiation.

Origin: Aequorea Victoria, Lampyridae

Cas9 from Streptomyces pyogenes will be used for generating mutations in parasite genes.

**Evaluation of foreseeable effects**

Alteration of parasite virulence

We are targeting genes involved in establishing Toxoplasma chronic infection. Evidence to date indicates that perturbation of these molecules in genetically modified parasites will either not alter or reduce viability. Parasites failing to form chronic cysts do not show increased virulence in mice (Waldman et al 2020, Cell 180 (2)), while parasites lacking GRA2 or GRA6 are less viable in mouse infection (Mercier et al 1998, Infect Immun 66(9)).

Some of the genetically modified Toxoplasma strains may be more virulent in mice or alter the nature of the observed response in tissue culture cells as compared to their
parent strains. Increased virulence in the mouse model could result from expressing a parasite-secreted protein in a strain that doesn't normally express it or from the disruption of a secreted protein. For example, deletion of the parasite protein GRA15 which normally dampens the immune response to the parasite, leads to a more virulent parasite (Rosowski et al 2011, J Exp Med 208 (1)). However, none of the genetically modified Toxoplasma strains will ever be more virulent than any other wild-type strain available, which vary in their expression of these secreted molecules.

This is an unusual outcome to be aware of and reduced virulence or no change is expected when altering expression of these target genes.

Alteration of drug resistance
The use of drug selection markers is required to select for the integration of DNA vectors in to the Toxoplasma genome. Wherever possible, this work will use selection markers that do not impact treatment of a Toxoplasma infection (eg. Using HXGPRT or CAT genes). When essential, the DHFR selection marker may be used (which is widely used in the research field). In this case the parasites will be resistant to standard drug treatment and potential infections will need to be treated with Atovaquone + sulfadiazine instead of the Pyrimethamine (+sulfadiazine).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
GM Toxoplasma will be used to infect wild type mice. Mice infections (intraperitoneal or oral routes) and mouse dissections will be done in a Class II MSC, within a barred CL2 designated room in a contained animal facility. For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Toxoplasma tachyzoites and bradyzoites are susceptible to killing by chlorine-based disinfectants, 70% ethanol and autoclaving (Spickler, Anna Rovid. 2017. Toxoplasmosis. Retrieved from http://www.cfsph.iastate.edu/DiseaseInfo/factsheets.php.). Evidence of killing of Toxoplasma by Virkon treatment is included in Appendix 4 of the risk assessment (provided by Dr David Smith, Moredun Research Institute).

Animal bedding and carcasses – autoclaved using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 C for at least 15 minutes or 126-130 C for at least 10 minutes or 134-138 C for at least 3 minutes). Thereafter, carcasses will be disposed of via clinical waste stream for incineration and bedding via clinical waste stream for microwave treatment.

Waste residues from cell culture or from bacterial cloning which cannot be autoclaved are inactivated by treatment with Virkon. Additionally, syringes, blunt needles, tubes etc that are contaminated with Toxoplasma culture will be disinfected in Virkon overnight before being placed in bins for autoclaving. Infected cell culture supernatants may be aspirated under vacuum into a sealed flask containing Virkon in quantities sufficient to attain 2% final concentration. Contaminated sharp needles will go directly in to a sharps bin, labelled as CL2, and autoclaved for decontamination and disposed of via the clinical waste stream for heat treatment via the University approved contractor. This applies to sharps from tissue culture and the animal unit.

1. Virkon
   1. 1% solution for:
      • Plasticware (pipettes, pastettes) with surface contamination - soak for a minimum of 2 hours fully immersed
      • Treatment of minor contamination (minimum 10 min contact time) and surface disinfection (benches and floors)
   2. 2% final concentration (overnight contact) for disinfection of liquid cultures and supernatants
   3. Powder or granules will be used to both absorb the liquid and disinfect a spillage or use with liquid waste. For spillages, allow aerosols to settle and then working from the outside of the spill, apply powdered Virkon to the liquid (minimum contact time 10 minutes) before mopping up with paper towels, wiping the area with 1% Virkon and disposing of all solid waste via the clinical (orange bag) waste stream.
Alcohols 70% v/v or Distel spray will be used for routine wiping down of Class II MSC.

The genetic modification safety committee agreed that the appropriate containment and control measures have been assigned.

This work will use pathogenic Candida species (principally Candida albicans and Candida glabrata). Strains include: SC5314, CAI4, CAI8, RM1000, BWP17, SN78 (Candida albicans) and BG2 and CBS138 (Candida glabrata) and ambient, non-GMO, strains of Candida albicans and Candida glabrata (NHS provided). All strains are HG2.

The above organisms are commonly present as part of human commensal flora but are opportunistic pathogens causing mucocutaneous infection of several body systems, most commonly the mouth, oesophagus and vagina. Risk factors include pregnancy, the use of intrauterine devices and oral contraceptives as well as antibiotic use and diabetes. Systemic disease only occurs in severely immunocompromised individuals. Infection by inhalation of aerosols is not known to occur.

Standard non-pathogenic laboratory Eschericia coli strains (K12 background) and standard non-pathogenic Saccharomyces cerevisiae strains, with a history of safe use (W303, S288C, SK1) will also be used as part of this work. These strains are HG1.

Research into reproduction and reproductive processes in vitro and in vivo using amphotropic retrovirus and lentivirus, adenovirus, human herpes simplex virus type 1 and human cytomegalovirus.

Recipient or parental organism
Bacteria: E. coli K12 (disabled)
Primary cells: derived from humans, mouse, rat and sheep
Immortalised cell-lines: HEK293 cells and derivatives BHK, HeLa, Vero cell lines (for HSV-1) HFFF2 cell lines (for HCMV)
Animal models: Sheep, marmoset, rat, and mice.

Host/vector system
Retrovirus: gag/pol = vector 1; Env = vector 2;
Delivery and cloning vector either VSV-G or MoMLV = vector 3
Lentivirus: gag/pol = vector 1 (containing WPRE); Rev = vector 2
Delivery and cloning vector VSV-G = vector 3
Adenovirus: shuttle vector containing gene of interest and adenovirus backbone

Origin & function

Genetic material will either be synthetic (PCR amplification product) or derived by cloning of cDNA or genomic material from a reproductively relevant tissue. Thus these genes will be targeted to specialised endocrine regulated tissues to assume full effect. A wide spectrum of material is being investigated, including known oncogenes e.g. c-myc and growth factors e.g. activin subunits

Some HSV-1 and HCMV modified virus will encode beta-galactosidase and green fluorescent protein as reporter proteins to monitor expression of viral genes in infected cultured cells. These sequences and their products are not associated with any health and safety risk.

Functions being investigated include; apoptosis, cell growth, cell differentiation, cellular transformation and cell communication focussing on reproductive processes, virus host interaction focusing on viral lytic cycle and post-translational regulation.

Evaluation of foreseeable effects

E. coli K12 and cell-lines are non-harmful and are unable to survive unless held in lab conditions.

Once packaged the virus particles (adeno, lent, HSV and CMV) will be capable of infecting a number of different species, including human. The GM viruses will be less fit than wild type virus, thus production of wild type virus either deliberately (HSV type 1, see below) or by recombination of the E1a gene from the HEK293 cell genome into the adenoviral genome will produce fitter virus. Stocks of adenovirus will not be repeatedly passaged to counteract the production of wild type, which is likely to occur 1 in 1x10e10.

Adverse effects for retroviruses have been reported from gene therapy trials where large numbers of virus (1x10e11) have been specifically infected into cells, selected for genomic integration using antibiotics then the proviral carrying cells injected into the immune compromised recipient. These individuals were initially immune-compromised, so it is unlikely this would happen in healthy individuals even if exposed to high titres (1x10e9/ml) since the virus would have to be injected directly into the blood stream and then viral integration would have to be specifically selected for.

If viral infection does occur then adverse effects are likely to be low. The viruses self-inactivate once integrated into the genome, and cannot re-activate due to deletion of the U3 in the 3'LTR. Thus even if infected with wild-type virus, eg an individual was carrying a latent HIV infection then the provirus cannot mobilise and propagate the vector or the inserted genetic material. Although activation of genes adjacent to the integration site is possible as discussed above, this cannot be propagated into a clonal population and instead the infected cells are likely to slough off in the respiratory tract and eye. Percutaneous injection of virus is possible, but this would require injection of large amounts of high titre virus. Since it is anticipated that viral titres will not exceed 1x10e9 per ml then the likelihood of large scale integration and oncogenic activation of cellular genes is low. Insertion of oncogenes into these viral vectors poses an additional risk since expression of these will be driven from constitutively active promoters. Adenovirus infection is most likely to occur by inhalation but again in immune competent individuals this is unlikely to generate a persistent infection, instead cells will be sloughed off.

All activities required for propagation of virus will be done wearing gloves and the production of aerosols will be minimised wherever possible and use of sharps and glassware will be avoided or minimised wherever possible. When producing high titer virus preparations eye protection will be worn.

HSV-1 is a common human pathogen for which infection occurs by direct contact with skin or eyes. Worldwide, greater than 40% of the population is seropositive for HSV-1. Accidental infection in the laboratory can occur by splashes of infected material to a mucosal surface or by viral entry through broken skin. Except in immuno-compromised individuals, HSV-1 infection is limited to epithelial cells, in the order of several million, at the infection site, resulting in the appearance of fluid filled vesicles (cold sores) and to the sensory ganglia that innervate the site. Infection of sensory ganglia leads to a life-long latent infection which is asymptomatic. Reactivation, usually triggered by cellular stress, can occur, whereby the virus travels from the ganglia to the site of primary infection and again productively infects several million cells.

Herpes infections of the eye are associated with keratoconjunctivitis and repeated recurrences can lead to scarring of the cornea. In very rare cases, approximately one in a million, herpes infection can lead to encephalitis, which if untreated, has a mortality of greater than 70% and most survivors are neurologically impaired. Herpetic whitlow is an infection caused by herpes simplex virus that affects health care workers. The source of infection is generally thought to be damaged cuticle or skin exposed to HSV infected secretions. This results in a short period of symptomatic infection and the establishment of latency. In the laboratory single acute dose exposure by accidental percutaneous injury could result in herpetic whitlow. Antiviral agents for HSV-1 are acyclovir (Zovirax), valacyclovir and famcyclovir.

HCMV is common in the population (in excess of 40% seropositive worldwide). Infection after birth is usually asymptomatic but sometimes a syndrome resembling infectious mononucleosis or glandular fever is caused by the virus. After initial infection the virus establishes a lifelong asymptomatic latent infection primarily in peripheral blood leukocytes. HCMV infection can lead to serious illness or death in immuno-compromised individuals and transplacental transmission during pregnancy can lead to severe neurological damage or death of the foetus. Infection in the laboratory could occur by exposure of cutaneous or mucosal surfaces to infected material or exposure
by percutaneous injury. The antiviral agent gancyclovir reduces or interrupts viral replication in vivo. All activities involving viral stocks and infected cell culture will be carried out in a biological safety cabinet whilst wearing gloves and avoiding the use of sharps and glassware. Genetically modified HSV and HCMV viruses, depending on the nature of the modified gene and the severity of the mutation, will have either wild type or reduced infectivity.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All GM modified animals are housed in purpose built barrier containment facilities. These facilities are kept locked and are kept secure by restricted digital swipe card access. In addition these key facilities are restricted for general access by non-essential personnel.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GM WASTE DISPOSAL

Apart from following the normal waste disposal procedures currently in practice within the building, the following rules must be observed:

(a) All solid and sealed liquid waste contaminated with GM material [eg. plastic pipettes, plates, small volumes of sealed liquid cultures, gloves, tips etc.] should be placed in a metal autoclave container lined with either a clear or blue plastic bag. The autoclave is regularly tested, and disposal of GM material via autoclaving, in a tested autoclave, meets the requirements of the GMO (2000) legislation. Autoclaving effectively gives 100% degree of kill and is validated annually. Autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or heat treatment, or disinfect with 10,000ppm available chlorine (Presept tablet: sodium dichloroisocyanurate, or Virkon at an equivalent concentration) for a minimum of 30 minutes in line with guidelines previously provided by the manufacturer. Disinfection - the concentrations and contact times used for disinfection have been shown to result in > 5 log reduction in virus titre (sodium hypochlorite - Croughan and Behbehani 1988 J. Clinical Microbiol 26, 213-215, Virkon - manufacturers data) and a 1% solution of Virkon disinfectant with a contact time of at least 20 mins gives a >99.999% kill of all viruses (data supplied by manufacturer). Discharge any resulting liquids to drains, dispose of solids via clinical waste stream for heat treatment. After autoclaving all waste MUST be placed in an ORANGE bag, and disposed of via the normal clinical waste stream.

(b) Glassware must be decontaminated by soaking in 1% w/v Virkon or 1000ppm Presept [four 0.5g tablets per one liter or four 2.5g tablets per five litres] for 1 hour before being rinsed and placed in the glasswash bucket provided for subsequent incorporation into the general washing process. Uncontaminated broken glassware should be disposed of in the glass waste containers supplied. Empty gas canisters should only be placed in the labeled bin. GM contaminated broken glassware and sharps should be placed in a sharps bin (eg needles, syringes, scalpels etc) and then autoclaved using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), dispose via clinical waste stream for heat treatment.

(c) Large volume, contaminated liquids must be rendered safe by the addition of Presept tablets to a final concentration of [1000ppm], which is 10,000ppm available chlorine (Presept tablet: sodium dichloroisocyanurate, or Virkon at an equivalent concentration) for a minimum of 30 minutes in line with guidelines previously provided by the manufacturer, then discharged to drains. Liquids (eg samples, culture supernatants, tissue culture media etc) can also be autoclaved using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge to drains.

Studies in cancer genetics and developmental genetics, that are an integral component of the concerted research programme on cancer and development genetics that is underway here at the Medical Research Council Human Genetics Unit.

These lentivirus vectors are infective to non-dividing human cells and are integrative to the genome therein, but are non-replicative, ie, self-inactivating, and so infected cells would not produce viral particles and hence pose no risk.

There is a risk of oncogene activation in infected cells due to the insertion, but the risk is low, and the risk of consequent tumourigenesis very low, as changes to several genes are required for these events to occur.

A third generation packaging system after Dull et al (1998) J. Virol 72 8463-8471 will be used, which requires genes from three different vectors for packaging into infectious particles. These vectors designed so as not to be packaged into viral particles and not recombine with each other or with the lentivirus.

These vectors transiently provide at high titre the viral functions required for packaging of the lentiviral construct.

The lentivirus vector to be used initially is LentiLox 3.7. This infects non-dividing human cells under the above circumstances, is stably integrative, but is non-replicative, ie, is self-inactivating. Vector expresses no viral functions once transduced. Thus, target cells can be infected with viral particles made in the packaging line but to infectious particles can then be made by the infected target cells. Wildtype virus does not infect mice and is rare in humans, so recombination with wildtype virus very unlikely. Airborne particles, if produced, would be at very low concentration and unstable.

We wish to include other similar lentivirus vectors to be developed in the future which have the same properties as outlined above (or properties giving lower risk) within the scope of this application.

We intend to use the lentiviral system to express the following classes of gene. Construct-specific risks will be covered in (future) GM Risk Assessments, and experiments only permitted if the GM Safety Committee here categorises the proposed work as Hazard Group 2 (or 1).

i) Expression of siRNAs against genes involved in development and tumorigenesis. siRNAs (short inhibitory RNAs) are short dsRNA molecules which can give sequence-specific knockdown of the expression of endogenous target genes, a process also referred to as RNAi (RNA interference). siRNAs will be expressed, if possible, as short hairpin RNA molecules, or otherwise as pDECAP constructs which express long dsRNA hairpins which are endogenously converted to functional siRNAs. Target genes will mainly be murine, so whenever possible the target sequences will be murine-specific. If this is not possible, such as when the target is human cells in culture, if practicable then the expression of the siRNA will be regulated by an inducible system (ie tetracyclin inducible) to further limit the potential risk of siRNA expression in humans. Examples of genes we intend to study are genes involved in testsis and kidney development and tumorigenesis, such as WT1 and its downstream target genes. Lentiviral siRNA vectors will be used to infect cell culture (murine or human), organ culture (murine) and in the generation of transgenic mice.

ii) Reporter genes, like lacZ, GFP, or its derivates. Promoters responding to endogenous cellular signals involved in tumorigenesis or development, or tissue-specific
promoters, will be cloned in front of these reporter genes and used to monitor the signalling pathways involved. These inserts pose no risk to human health. Reporter constructs will be used in cell culture (murine or human), organ culture (murine) or transgenesis (murine).

After surveying the promoter activity with reporter genes we will use these promoters to drive expression of developmental genes. These genes are predicted to affect early developmental stages and we propose to drive both the active genes and siRNAs. Genes that will be studied for example are Gli3, dHAND, Shh, and members of the Tbx, Nkx, Bmp and Fgf families.

iii) Expression of Cre or FLP recombinases. Cre and FLP are used in combination with conditional mouse models in which part of a gene is placed between loxP or FRT sites. Expression of Cre/FLP will result in deletion of the sequence between the loxP/FRT site and inactivation of the gene. By expressing the recombinases in an inducible or tissue-specific manner full control of inactivation of the target gene is possible. Expression of Cre or FOP poses no risk for human health. Lentiviral expression systems will be used in cell culture, organ culture and transgenesis, all murine.

iv) Expression of accessory genes involved in different tetracyclin responsive expression systems, like rtTA, tTA and Tet-R. These genes regulate the expression of genes the promoters of which have been extended with tet-binding elements, and the expression of the genes will be activated by the presence or the absence (depending on the system) of tetracyclin or its analogue doxycyclin. Expression of rtTA, tTA or Tet-R poses no risks to human health. Lentiviral expression of these genes will be used in cell culture, organ culture and transgenesis.

Evaluation of foreseeable effects

**RISK TO HUMAN HEALTH ARISES DUE TO:**
- Lentivirus vector infective to non-dividing human cells
- Lentivirus vector integrative
- Lentivirus vector at high titre
  - thence potential for insertional mutagenesis of body surface cells by the lentiviral vector and thence potential for oncogene activation in infected cells.

**RISK TO HUMAN HEALTH AMELIORATED AS:**
- Third generation packaging system to be used - requires three different vectors which cannot recombine with each other or the lentivirus.
  - Integration is stable.
  - Lentivirus vector is non-replicative, ie, self-inactivating - no viral function expressed once transduced
  - Tumourigenesis very unlikely
  - Wildtype virus does not infect mice and is rare in humans - recombination thus very unlikely
  - Airborne particles, if produced, would be at very low concentration and unstable
  - siRNA whenever possible will be highly specific to murine genes
  - Knockdown of the siRNA targeted genes in an adult human would not cause transformation
  - Targeted murine genes under developmental-specific and tissue-specific enhancer and although it is a very unlikely possibility, tests will nonetheless be done to ensure that the lentivirus does not become replicative by recombination

**APPROXIMATE EVALUATION OF ABOVE RISK (APPLYING BS8800:1996) TO HUMAN HEALTH:**
- Estimated likelihood = highly unlikely
- Potential severity of harm = extremely harmful
- Risk = moderate and thus control = Containment level 2 or rationalising.

According to the ACGM Compendium of Guidance (Part 2B, Annex III, paragraph 26) HIV-derived lentivirus (such as this) should be Hazard Group 3, unless there is justification for a lower classification. The vector here requires three different vectors for packaging (ie a 'third generation system') and is self-inactivating/non-replicative. Further, the probability for oncogene activation in infected cells is anyway low, and for consequent tumourigenesis is very low. We thus consider there to be sufficient justification for classification of this proposed work as Hazard Group 2, rather than 3.
AND RISK TO THE ENVIRONMENT:
Negligible - transduced cells/animals not infective (see above), all changes somatic (see Section 8), and all virus, cells and tissues/animals destroyed (see Section 12).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Any live-birth transduced mice will be entirely reared, housed and killed within our Transgenic Mouse Facility. This is a secure 'barrier' unit, and as such escape of mice or entry of exogenous rodents is almost impossible. Such animals anyway pose negligible risk to human health or to the environment, as they could not be infective with the lentivirus vector (is self-inactivating/non-replicative).

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Complete immersion in 1% Virkon for at least two hours will be used to destroy all cultures and sterilise all items. Virkon is a potent peroxygen disinfectant that will give 100% kill of all agents used, the lentivirus in particular. Virkon is known to give 100% kill of the closely related HIV (US Environmental Protection Agency). Liquid waste will then be disposed to drains. Solid waste is then routinely autoclaved and then sent for commercial incineration. Larger tissue samples/whole animals (ie mice) are routinely disposed by commercial incineration (there is no viral risk from such items anyway).

Project Containment

Four GM Risk Assessments attached. Relevant comments include the following.

Committee noted this proposed use at high titre of an integrative retrovirus that could infect non-dividing human cells. According to the ACGM Compendium of Guidance (Part 2N, Annex III, paragraph 26) this should be HG3, unless there is justification for a lower classification. It was further noted that the virus requires three different vectors for packaging (ie a 'third generation system') and is self-inactivating/non-replicative. However, the former must be considered in the context of its infectivity once packaged. Committee were mindful of the potential, albeit very low probaility, for oncogene activation consequent upon infection of and integration into the genome of a worker's cells. Nonetheless, the non-replicative nature of the construct was agreed as sufficient justification for classification of this proposed work as HG2 rather than HG3. The proposed (section 15) HG1 is not sufficient.

Committee requires, as a condition of this approval, that packaging lines are assayed by plaque formation colony assay or equivalent to ensure that the viral vector has not become replicative by recombination (although it is accepted that this is unlikely, it was considered that the high titres used might possibly increase the overall likelihood). This assay must be performed initially, and then repeated after three months of actual project work, and then after every six months of actual project work thereafter. And the acceptable result is to be zero replicative viral particles.

Project Ref 326/03.1

Date Ackn’ed: 17/02/2004

CU2 Project Title: TO DEFINE THE ABILITY OF ADENOVIRAL OR ADENO-ASSOCIATED VIRAL (AAV) GENE TRANSFER OF CANDIDATE GENES TO REDUCE BRAIN DAMAGE

Class: Class 2

CultureVolClass2: < 1 Litre

Consent Granted: Not Applicable

Project notified under transitional arrangements: N

Historical Significant Changes: GM326/03.1 transferred from GM 326 as of 30/06/2004
**Project Additional Information**

**Purposes of the contained use**

The aim of the project is to assess the ability of a number of biological active genes to reduce brain damage.

**Recipient or parental organism**

These adenoviral or adeno-associated viral vectors will be produced and characterised in Department of Medicine and Therapeutics, University of Glasgow (HSE centre number GM 397). All adenovectors to be used in this study and E1-deleted first generation adenoviral vectors based on the pJM17 system (McGrory, W. J. Bautista, D. S. and Graham, F. L.: A simple technique for the rescue of early region I mutations into infectious human adenovirus type 5. Virology 163: 614-617, 1988). In brief, adenoviruses are generated by recombination resulting in the deletion of the E1 region of the viral genome and replacement with the expression cassette. This renders the adenoviruses replication defective. However, with these first generation viruses there is still a small risk of recombination with the E1 region in 293 helper cells used to propagate the viruses. All stocks are therefore routinely tested for the presence of replication-competent adenovirus (RCA) and will be negative. All stocks will also be purified on caesium chloride gradients. E1-deleted adenoviruses cannot replicate unless the E1 function is complemented in trans. Therefore the disabled vector is considered a biological agent unlikely to cause human disease and is assigned to hazard group 1 with containment level 1 as the minimum requirement. However, all the inserted genes are biologically active. None of the transgenes are proto-oncogenes. All transgenes will be under the control of the CMV promoter. There will be a minimal risk of harmful effect of these genes in organs/tissues. If the replication-defective adenovirus is inadvertently released into the general environment, immune cells will target any infected cells. It is generally accepted that the Ad will be inactivated almost immediately by the immune surveillance cells located in the peripheral system. The recombinant adenovirus will pose less of a threat once in the cell than most expression vectors as they will definitely not replicate or integrate into the host genome. Furthermore, the natural tropism of the adenoviral vectors are not altered from wild type adenoviruses in the viruses proposed for use.

AAV vectors have received increasing attention for molecular interventions in vivo and for gene therapy applications due to their low level of immunogenicity in vivo and their ability to integrate into the genome, thus producing sustained expression of transgenes for prolonged periods of time. They also have the ability to infect both dividing and non-dividing cells.

AAV vectors used in this study are serotype 2 and replication-defective through deletion of the rep and cap genes and insertion of the recombinant gene expression cassette within the AAV inverted terminal repeats (ITRs). The AAV vectors are generated by co-transfection of the AAV vector (carrying the expression cassette) and a helper plasmid carrying the helper functions necessary for AAV packaging in trans. The cells are then infected with a replication-defective herpes simplex virus (HSV) to provide helper function for AAV replication (in place of helper adenovirus). Upon a cytopathic effect in the cells, AAV and HSV particles are harvested. The HSV is removed completely by filter sterilisation to leave recombinant replication-defective AAV particles capable of expressing the transgene. This system is published (Zhang, X, de Alwesh, M., et al. High-titer rAAV production from replicating amplicons and gH-herpes vectors) and has been used for AAV preparation in Glasgow and elsewhere (Institute of Child Health, London). All stocks of AAV vectors will be generated at the Dept of Medicine and Therapeutics, University of Glasgow. AAV vectors are replication defective. There is some recombination between plasmids that may result in wild type like virus (not fully functional as they contain deletions). However, this is usually minimal (less than 0.01% of stocks). Furthermore, wild type AAV has no known pathogenicity and therefore no harmful consequences of generating even fully wildtype virus is anticipated. None of the sequences are likely to be harmful if expressed. If, by accident, they were introduced in humans via the recombinant vector, they are unlikely to be harmful since they are either reporter genes or a functional gene which would have no effect unless expressed at very high levels. Since we are only using small quantities of replication deficient vector (below 10e9 particles) accidental exposure to the vector is extremely unlikely to result in high levels of protein being produced.

**Host/vector system**

The adenoviral vectors are generated by homologous recombination between pJM17 and shuttle vectors containing transgene expression cassette and flanking E1 sequences. Following homologous recombination in helper 293 cells (which express the helper E1 function in trans, replication-defective first generation adenoviruses are produced. This methodology has been used for many years for the development of recombinant adenoviruses.

AAV vectors used in this study are serotype 2 and replication-defective through deletion of the rep and cap genes and insertion of the recombinant gene expression cassette.
cassette within the AAV inverted terminal repeats (ITRs). The AAV vectors are generated by co-transfection of the AAV vector (carrying the expression cassette) and a helper plasmid carrying the helper functions necessary for AAV packaging in trans. The cells are then infected with a replication-defective herpes simplex virus (HSV) to provide helper function for AAV replication (in place of helper adenovirus). Upon a cytopathic effect in the cells, AAV and HSV particles are harvested. The HSV is removed completely by filter sterilisation to leave recombinant replication-defective AAV particles capable of expressing the transgene. This system is published (Zhang, X, de Alwesh, M., et al High-titer rAAV production from replicating amplicons and gH-herpes vectors) and has been used for AAV preparation in Glasgow and elsewhere (Institute of Child Health, London). All stocks of AAV vectors will be generated at the Dept of Medicine and Therapeutics, University of Glasgow. AAV vectors are replication defective.

**Origin & function**

The adenoviral vectors DNAs are standard and originated from the laboratory of Dr Graham (McGrory, W. J., Bautista, D. S. and Graham, F.L.: A simple technique for the rescue of early region I mutations into infectious human adenovirus type 5. Virology 163: 614-617, 1988). The cytomegalovirus immediate early promoter is a standard viral promoter used for gene expression studies in vitro and in vivo to generate high-level gene expression in all cells transduced by the adenovirus. The AAV system is published (Zhang, X, de Alwesh, M., et al. High-titer rAAV production from replicating amplicons and gH-herpes vectors) and has been used for AAV preparation in Glasgow and elsewhere (Institute of Child Health, London). All transgenes will be constructed from full length cDNAs obtained from other research institutes and verified in our own laboratory prior to subcloning into the relevant vectors.

**Evaluation of foreseeable effects**

There will be a minimal risk of harmful effect of these genes in organs/tissues. If the replication-defective adenovirus is inadvertently released into the general environment, immune cells will target any infected cells. It is generally accepted that the Ad will be inactivated almost immediately by the immune surveillance cells located in the peripheral system. The recombinant adenovirus will pose less of a threat once in the cell than most expression vectors as they will definitely not replicate or integrate into the host genome.

AAV vectors are replication defective. There is some recombination between plasmids that may result in wild type like virus (not fully functional as they contain deletions). However, this is usually minimal (less than 0.01% of stocks). Furthermore, wild type AAV has no known pathogenicity and therefore no harmful consequences of generating even fully wild type virus is anticipated. None of the sequences are likely to be harmful if expressed. If, by accident, they were introduced in humans via the recombinant vector, they are unlikely to be harmful since they are either reporter genes, or a functional gene which would have no effect unless expressed at very high levels. Since we are only using small quantities of replication deficient vector (below 10e9 particles) accidental exposure to the vector is extremely unlikely to result in high levels of protein being produced. Consequence of environmental exposure - ‘effectively zero’.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All measures as per HSE containment level 2 for both production of recombinant adenoviruses and AAV in the laboratory and animal experimentation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Laboratory-based experiments: during the production of replication-defective adenoviruses, all solid waste (plastics etc.) are autoclaved prior to disposal. All liquid waste from tissue culture is treated with chlorine-based disinfectants for at least 24 hours prior to disposal. The use of sharps is avoided.

Is an emergency plan required according to regulation 20?

Animal Units  Large Scale Activities  Human Clinical Applications

02/03/2022  Page 5087 of 15326
Purposes of the contained use

The purpose of the contained use is to assess whether polymorphism of the human PrP gene are controlling susceptibility and resistance to prion diseases, also known as Transmissible Spongiform Encephalopathies of TSEs. The variants in question have altered amino acid codons and have been found in individuals affected by TSEs but it remains to be proven that there is a direct causal link between the codon change and the TSE disease. The details of the study are confidential in order to protect intellectual property and a successful project may result in a patent application so commercial confidentiality is also claimed. Disclosure would adversely affect the competitive position of the Institute for Animal Health in a highly competitive area of research. Exemption from disclosure is allowed by the Environmental Information Regulations 1992 as amended in 1998 and the relevant exemption is intellectual property protection and commercial confidentiality.

Recipient or parental organism

For the laboratory cloning steps, a section of the mouse PrP gene cloned in to a pBluescript vector will be subjected to in vitro mutagenesis to introduce the required nucleotide changes. The newly created sequences will be cloned into plasmid pBluescript. All constructs will be maintained in disabled E coli bacterial cultures. Details of the constructs and cloning steps are claimed as confidential. Exemption from disclosure is allowed by the Environmental Information Regulations 1992 as amended in 1998 and the relevant exemption is intellectual property protection and commercial confidentiality.

Host/vector system

For the laboratory cloning steps, the plasmid will be pBluescript II KS+. The cloning procedures will be carried out in Stratagene XL disabled bacterial hosts.

Origin & function

For the laboratory cloning steps, the plasmid will be pBluescript II KS+. The cloning procedures will be carried out in Stratagene XL disabled bacterial hosts.
The origins of the genetic material involved are cloned sections of the mouse PrP gene already available in this laboratory from other projects. The intended function of the mutagenised cloned sequences is to make gene targetted transgenic animals expressing a single copy of the transgene under the control of the endogenous PrP gene promoter. The details of this project are claimed to be confidential exemption from disclosure is allowed by the Environmental Information Regulations 1992 as amended in 1998 the relevant exemption is intellectual property protection and commercial confidentiality.

**Evaluation of foreseeable effects**

The GMMs and human health:

Hazard identification

It would be theoretically possible for a laboratory worker to swallow the Ecoli containing human disease associated amino acid codons within the mouse PrP gene. The plasmid pBluescript II is not a prokaryotic expression vector and in combination with the fact that the inserted mouse PrP gene fragment is of large size it is very unlikely that any PrP protein is expressed in these Ecoli and therefore for this altered PrP protein to appear in the gut. If despite this assessment altered PrP protein would be produced and released into the gut, the hazard would be very low as it has been shown that recombinant PrP made in Ecoli is not infectious (Scott et al 1988 Protein Engineering 2: 69-76) Those who believe TSEs (or prion diseases) are caused by an infectious protein put this down to misfolding and non-glycosylation of the Ecoli expressed protein however recombinant PrP expressed in mouse cells (Caughey et al 1988 PNAS 85: 4657) or monkey COS cells (Scott, et al, idid) or converted in vitro to protease resistant form (Hill et al 1999 J Gen Virol 80: 11-14) are also not infectious.

Capacity to survive in the human gut.

The bacteria to be used are recombination deficient so would not be expected to transfer plasmids to other bacteria or to be able to compete successfully with wild-type bacteria.

Assessment of likelihood - low.

There are extensive measures in force at the Institute for Animal Health in Edinburgh to protect staff from any infection with TSEs. All TSEs are treated in the same way in order to make sure procedures are remembered and followed diligently. CJD and BSE in addition, are handled at containment level 3 at the moment.

The minimal containment level within the building is level 2. Some closed, locked and access restricted rooms are used for work with CJD and BSE. These are higher containment than level 2 without being full level 3.

Briefly: No eating or drinking is allowed in laboratory areas

No mouth pipetting is allowed

Protective clothing (lab coats, aprons if necessary) is worn all the time

Disposable gloves are worn, eye protection is worn

Any procedures which could generate aerosols are carried out in safety cabinets

Visors are used if splashing is possible

Closed systems are used for mixing, homogenisation, centrifuging etc

Plastic disposables are used wherever possible in preference to sharps

Waste is disposed of by treating with 20,000 ppm chloros or autoclaving at 134C for 1 hour and followed by removal in hermetically sealed waste bins for incineration

Dedicated rooms are used for procedures involving CJD and BSE infectivity.

Records are kept of all accidents.

A Quality Assurance system is being set up with IAH to closely monitor all procedures, experiments and safety controls.

Assessment of consequence - High

Although expected to be unlikely, if any infectivity is generated by Ecoli containing human disease associated amino acid codons in the mouse PrP gene, this would not be expected to infect humans because of the safety measures in place. However, the consequences might potentially be grave if it did.

Estimation of risk - low

The measures in place to protect human health and safety are well above level 2 containment standards.
The GMMs and Environmental Risk

Hazard Identification

The Ecoli used to replicate the plasmid constructs containing human disease associated amino acid codons within the mouse PrP gene inserts could be discharged from the labs through the drains or in lab waste and affect animals and people in the environment. The plasmid pBluescript II is not a prokaryotic expression vector and in combination with the fact that the inserted mouse PrP gene fragment is of large size it is very unlikely that any PrP protein is expressed in these Ecoli and therefore for this altered PrP protein to appear in the environment. If the altered mouse genes were to be expressed in the Ecoli and this could enter and colonise the gut of animals or people, it might be that the altered mouse PrP protein would be expressed in the gut as well. However, this worst case scenario is highly unlikely as the Ecoli strain used are highly disabled and unable to compete with wild type bacteria. In addition recombinant PrP made in Ecoli is not infectious (Scott et al 1988 Protein Engineering 2: 69-76) Those who believe TSEs (or prion diseases) are caused by an infectious protein put this down to misfolding and non-glycosylation of the Ecoli expressed protein however recombinant PrP expressed in mouse cells (Caughey et al 1988 PNAS 85: 4657) or monkey COS cells (Scott, et al ibid) or converted in vitro to protease resistant form (Hill et al 1999 J Gen Virol 80: 11-14) are also not infectious.

More details are presented with the risk assessment.

Capacity to survive in the environment.
The Ecoli strain used is recombination deficient and should not be able to transfer plasmids to other bacteria, nor would it be expected to survive in competition with other wild type bacteria. If, however unlikely, an infectious agent was to be generated in the Ecoli cells, it may persist in the environment for long periods.

Assessment of likelihood - low

Escape of Ecoli containing human disease associated amino acid codons in the mouse PrP gene is considered highly unlikely. All bacterial cultures are treated with 20,000 ppm chloros prior to disposal or autoclaved at 134C for 1 hour. These treatments are the reliable methods of inactivating TSE agents. All nucleic acid preparations would be considered to be non-infectious due to the use of phenol or guanidinium in the preparative procedures. Any protein preparations would not leave the building unless treated as above to inactivate any infectivity. Waste then leaves the building in hermetically sealed, tamper proof clinical waste bins for incineration.

Assessment of consequence - Low

Human TSE diseases (CJD and GSS) are very rare - worldwide incidence less than 1 in a million new cases per year. There is no evidence of contagious spread of TSEs in humans and no evidence of maternal transmission. Any bacteria which found their way out of the labs would be dead because of standard decontamination procedures. Any protein remaining within them would be at low levels as high expressing promoters would not have been used.

Estimation of risk - low

The standard measures in place will protect environmental, human and animal health and safety.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

GM animals:
Institute for Animal Health, Edinburgh is housed in a building with restricted and controlled access at the entry doors (computerised key locking system). The SPF barrier animal house is highly secure with restricted and controlled access at the entry doors. Doors to the animal house are locked with entry only via computer controlled unlocking or number coded locks. Containment of animals is routinely very high for the reason of prevention of contamination of other experiments and animals are housed in a range of facilities all with at least level 2 containment. The mouse is regarded as a closed system with regard to prion diseases but dissections are performed in safety cabinets. For the present study, animal tissues would be prepared and analysed in closed locked dedicated laboratories with higher containment than level 2 (but not full level 3). Disposal of carcases: autoclaving at 134 C for 1 hour then removal for incineration in hermetically sealed bins. Our standard inactivation procedures reduce TSE infectivity to undetectable levels and containment and decontamination procedures are monitored for compliance. IAH is at the moment in the process of setting up a QA system to cover all activities from experiments to waste disposal.

GM ES cells:
Embryonic stem (ES) cell culture is performed in a dedicated locked laboratory with access restricted to essential personnel. Work is performed using disposable plastic equipment wherever possible. All liquids are treated with 20,000 ppm chloros. Tissue culture flasks, plates and falcon tubes (15 ml or 50 ml) which have been in contact...
with ES cells (targeted or untargeted) are sealed with parafilm and placed in waste bags which are removed from the tissue culture suite by a designated operator and autoclaved at 134°C for 1 hour. The waste is then removed for incineration in hermetically sealed. Our standard inactivation procedures reduce TSE infectivity to undetectable levels and containment and decontamination procedures are monitored for compliance. IAH is at the moment in the process of setting up a QA system to cover all activities from experiments to waste disposal.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation is claimed for the cloning steps of the project using GMMs.

It is not clear to us where on this form to ask for Derogation for GMOs which are not micro-organisms, so we do so here and in the confidential section 17 which contains the details of the reasoning and the experimental design. Derogation to Class 2 containment is requested for the embryonic stem cell stage of the project and the transgenic mice. Confidentiality is claimed for the details of this request. Exemption from disclosure is allowed by the Environmental Information Regulations 1992 as amended in 1998 and the relevant exemptions are intellectual property protection and commercial confidentiality.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All bacterial cultures are treated with 20,000 ppm chloros prior to disposal or autoclaved at 134°C for 1 hour. These methods kill E. coli bacteria. These treatments are also reliable methods of inactivating TSE agents to undetectable levels. All nucleic acid preparations would be considered to be non-infectious in terms of TSE infectivity due to the use of phenol or guanidinium in the preparative procedures which inactivate protein (Rowher RG (1991) Current Topics in Microbiology and Immunology 172: 195-232). Any protein preparations would not leave the building unless treated as above to inactivate any infectivity. Bacterial culture plates, ES cell plates and mouse carcasses are autoclaved at 134°C for 1 hour prior to disposal. Waste then leaves the building in hermetically sealed, tamper proof clinical waste bins for incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

This proposal was discussed in detail during 2 separate meetings of the GM safety committee and the proposers provided relevant additional information as requested. The committee members were concerned about various procedures to ensure they were sufficiently contained. The committee members were happy that all safety measures were in place for other projects already. The local NPU Safety officer is part of the GM committee. Staff are entitled to join a union and are represented by appropriate safety officers. Full details of the GM committee deliberations are presented in the confidential sections of this form. Confidentiality is claimed on the grounds of intellectual property protection and commercial confidentiality. These exemptions are allowed under the Environmental Information Regulations 1992 as amended in 1998.

The study of oligodendrocyte differentiation, and the oligo-axonal interactions involved in myelination, so as to develop new strategies to enhance repair in Multiple Sclerosis. This project aims to induce the expression of adhesion molecules involved in multiple phases of oligodendrocyte development in myelinating oligodendrocytes. A second objective is to inhibit the expression of candidate genes hypothesized to regulate axo-glial adhesion and myelination using short hairpin RNA’s. The use of viral expression is necessary for these investigations, because myelination occurs over multiple weeks, and the duration of gene expression or repression required is greater than what can be attained using conventional transfection methods.

**Recipient or parental organism**

DH5alpha E.coli (disabled) and other common disabled E.coli K12 strains. LinX or equivalent packaging cell line for retrovirus, and HEK293 FT or equivalent for lentivirus. Cells to be infected are rodent oligodendrocyte and other precursors, neurons, neurospheres or oligospheres.

**Host/vector system**

Bacterial cloning vectors (eg. pUC based vectors). Retroviruses including pSM2 and LMP (Open Biosystems), lentiviruses including pLenti6.2v5 and ViralPower Packaging mix (a mixture of pLP1, pLP2 and pLP/VSVG plasmids; Invitrogen).
The objective of our studies is the knock-down of gene expression by the use of virally expressed small interfering RNA’s, and/or disruption of protein function by virally expressed dominant negative isoforms, resulting in the inhibition of adhesion signalling pathways implicated in myelination, leading to alterations of myelin-forming capacity or the generation of myelin-forming cells.

DNA clones for expression (encoding wild-type or dominant negative forms of adhesion and related signalling molecules) will be obtained from collaborators, or generated by standard molecular biology techniques from DNA libraries held within the laboratory. Short-hairpin RNA sequences will be obtained from Open Biosystems Inc. Or will be designed using software such as "shRNA Retriever" from RNAi Central and then synthesised commercially and inserted into the vectors described above.

**Evaluation of foreseeable effects**

is will cause serious harm to the researcher is very low as the decrease in gene expression could not spread beyond the small number of cells directly exposed to the virus, either within the individual or to other individuals. Similarly, the ectopic expression of wild-type or inactive forms of oligodendrocyte proteins such as integrins may likewise alter the function of cells that are infected. The risk this poses will be minimised in two ways. First, the great majority of proteins expressed or knock-down to study myelination will have no effect on cell proliferation - an entirely different cellular process. In those cases were proteins implicated in myelination have been shown to have secondary effects on proliferation, the constructs used will be designed to express proteins that inhibit or prevent cell proliferation. Second, the very small number of cells affected by any contact of a researcher with the (replication-incompetent) viruses would limit the consequences of such an accident.

c) The vector (LMP) is derived from a mouse stem cell retrovirus (MSCV) vector, and while replication competent, cannot be packaged without viral gag, pol, and env genes, which it does not contain. pLenti contains a deletion in the 3’ long terminal repeat (LTR) that results in self-inactivation of lentivirus after transduction of the target cell, resulting in the virus being replication-incompetent. In both cases, once integrated into the transduced cell, the virus cannot longer be packaged.

The potentially harmful effects to the environment are effectively zero because

a) Genetic material will not have any outside target mammalian cells, and in the case of the small interfering RNA's will be species-specific.

b) The donor micro-organisms are disabled and will therefore not cause environmental harm by transfer to other organisms.

c) The vectors are replication-incompetence that will prevent dissemination or transfer to other organisms.

d) The resulting genetically modified micro-organism are extremely susceptible to dessication and will only survive a few hours at room temperature. Taken with the non-oncogenic nature of the genetic sequences to be used, the specificity of the vectors for mammalian hosts and their replication incompetence the resulting GMM poses no effective risk to the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid waste will be decontaminated by chlorine bleach and solid waste by autoclaving.

Email received, Dept. of Pathology ACGM dated May 16th 2007.
"The Dept. of Pathology ACGM has approved your risk assessment entitled:“The use of lentiviral and retroviral expression vectors to influence gene expression and cell signalling in myeliating oligodendrocytes” as a class 2 project. Moreover the committee had no substantive comments so the risk assessment can be used as is”.

Project Additional Information

Purposes of the contained use

Identified proteins enriched in particular stages of the trypanosome life cycle will be expressed or their genes manipulated in cultured insect or bloodstream forms of the parasite. This will allow investigation of the development of Trypanosoma brucei spp. through its life cycle at the cellular and molecular level. Our aim is to improve understanding of the function and regulation of these molecules, which it is expected will be clarified by these experiments. This may identify strategies to control the
Transmission of these parasites in Africa.

Recipient or parental organism

GMO: Cultured insect or bloodstream forms of the parasite. Insect forms are non-pathogenic, non-transmissible. Bloodstream forms require tsetse fly transmission. These are only indigenous in Africa. No tsetse fly colonies are maintained at the University of Manchester. Trypanosome do not produce toxins and we expect most genetic manipulation of the parasite to reduce fitness and therefore virulence.

Host/vector system

Parental organism: Trypanosoma brucei spp. blood and insect forms
Vector system: pGEM or pBluescript based bacterial shuttle vectors engineered to enable parasite gene expression or modulation in the parent organism using a tetracycline regulated inducible expression system. These are non mobilisable shuttle vectors. Specific vectors are pET series, pGem, pGemT-easy, pLew100, pZJM, pBluescript II, p2T7, pHD541 and pHD430

Origin & function

1. T. brucei spp. genes or proteins displaying specificity, enrichment or implicated in the involvement in particular life cycle stages of the parasite. Their function is expected to be in progression of the parasite through its developmental cycle and, potentially, parasite metabolism.
2. Reporter gene expression to allow selection of transgenic parasites or detection of the expression pattern or location of those proteins described in (1). This will include genes for resistance to antibiotics used for parasite selection and green fluorescent protein gene fusions for protein localisation.

Evaluation of foreseeable effects

Where gene expression of particular molecules implicated in life cycle regulation are expressed we anticipate differentiation phenotypes to be observed. Specifically we will use markers for each life cycle stage to detect reduced ability to initiate differentiation, enhanced differentiation rates of failure in the programme of differentiation events at particular points. Transgenic parasites harbouring regulatory molecules with specific mutations to enable the isolation of interacting partner molecules (for example substrate-trapping mutants) or which generate altered differentiation phenotype will be used for protein isolation or examined for altered pattern of gene/protein expression. In each case transgenic bloodstream and insect form parasites will be used and differentiation between these stages examined. However, it is not possible to differentiate parasites from the insect form back to the bloodstream form in the absence of the tsetse fly vector. Therefore the life cycle cannot be completed in the laboratory. These genes will be expressed using a tetracycline inducible expression system. Therefore, in the absence of tetracycline the genes are effectively silenced. Antibiotic resistance genes used for selection of transgenic parasites are not those used for clinical treatment of the parasite and will otherwise have no foreseeable effect. Reporter genes (e.g. green fluorescent protein) are for localisation and assay of expression pattern for particular parasite genes or sequences. There is no foreseeable consequence of this.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

T. brucei spp. does not produce spores. They are rapidly killed outside of the culture vessel or blood by desiccation osmotic shock (washing with water, detergents) and cannot penetrate unbroken skin. Parasite genes are expressed or perturbed using a tetracycline inducible expression system and will be effectively silenced outwith the culture vessel. Tsetse flies are required for transmission and completion of the life cycle; these are indigenous only in sub Saharan Africa. Thus the parasites, whilst mammal infective as the bloodstream forms are effectively deficient in mobilisation capacity. The wild type bloodstream form parasite is mammal infective and virulent. It is highly unlikely that genetic modification will enhance this; rather gene manipulation is likely to reduce virulence and transmissibility.

We request derogation from Containment class III to containment class II for specific containment measures.

CONTAINMENT MEASURE:
1. Isolation. The laboratory is separate from other laboratories in the building being fully contained within a locked laboratory, with access restricted to authorised lab personnel.

2. Laboratory sealable for fumigation. The trypanosome cell line used has a contained use regulation level of 3 but the containment recommended by the COSSH assessment is level 2. Therefore the containment applied will be level 3. However, we request derogation to allow relaxation of the requirement for sealability for fumigation.

4. Entry via airlock. Trypanosomes can only be transmitted by blood-blood contact or by skin puncture. They cannot survive in air and do not form spores. We request derogation as risk assessment does not indicate a requirement for this measure.

5. Negative pressure. The trypanosome cell line used has a contained use regulation level of 3 but the containment recommended by the COSSH assessment is level 2. Therefore the containment applied will be level 3. However, we request derogation to allow relaxation of the requirement for airflow.

6. Filtration of extract and input air. Trypanosomes do not form spores and cannot undergo airborne transmission. Handling of bloodstream form parasites is most commonly as in vitro cultured forms. These are opened only in a microbiological safety cabinet with HEPA filtration. We request derogation to level 2.

7. Microbiological safety cabinet. Trypanosomes do not form spores and cannot undergo airborne transmission. Handling of bloodstream form parasites is most commonly as in vitro cultured forms although purification of parasites from blood is not practical in a safety cabinet. However there is no generation of aerosols. The laboratory is self contained providing containment. We request derogation to level 2.

8. Autoclave in the laboratory suite. There is a central sterilisation facility in the Stopform building, but no autoclave facility within the laboratory. However, all parasites, and material that has come into contact with parasites is rendered non-infective by soaking in 2% Virkon for 12h prior to transport to the autoclave facility. Transport is in sealed containers. Therefore we request derogation to level 2.

11. Shower. Trypanosomes are only transmitted by blood-blood contact or by inoculation. Skin penetration of the naked parasite is not possible. Parasites cannot survive in the external environment. Therefore we request derogation to level 2.

REQUEST FOR DEROGATION OF ANIMAL FACILITIES
The School of Biological Sciences BSU operates as a first class animal containment facility. Laboratory rodents infected with Trypanosoma brucei spp. will be contained in accordance with the regulations defined for Containment level III. However we request derogation to containment level II for specific regulations:

1. Isolation. The BSU is separate from other laboratories in the building being fully contained within a locked laboratory, with access restricted to authorised BSU personnel.

2. Laboratory sealable for fumigation. The trypanosime cell line used has a contained use regulation level of 3 but the containment recommended by the COSSH assessment is level 2. Therefore the containment applied will be level 3. However, we request derogation to allow relaxation of the requirement for sealability for fumigation because trypanosomes do not produce spores, cannot be transmitted in an airborne form, or by aerosol. Blood:blood contact is required.

4. Entry via airlock. Trypanosomes can only be transmitted by blood-blood contact or by skin puncture. They cannot survive in air and do not form spores. We request derogation as risk assessment does not indicate a requirement for this measure.

5. Negative pressure. The trypanosome cell line used has a contained use regulation level of 3 but the containment recommended by the COSSH assessment is level 2. Therefore the containment applied will be level 3. However, we request derogation to allow relaxation of the requirement for airflow.

6. Filtration of air. Trypanosomes do not form spores and cannot undergo airborne transmission. Transmission can occur only by blood-blood contact or inoculation. Standard operating procedures minimise risk of aerosol. We request derogation to containment level II with respect to HEPA filtration of the animal enclosure.

7. Microbiological safety cabinet. Trypanosomes do not form spores and cannot undergo airborne transmission. Operating procedures limit the possibility of aerosol. The BSU is self contained providing containment. We request derogation to level 2.

11. Shower. Trypanosomes are only transmitted by blood-blood contact or by inoculation. Skin penetration of the naked parasite is not possible. Parasites cannot survive in the external environment. Therefore we request derogation to level 2.

14. Control of disease vectors. Trypanosomes can only complete their life cycle in the tsetse fly. These are not indigenous in the UK, or outside sub Saharan Africa. There are no tsetse flies maintained at the University of Manchester.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

A laboratory scale project employing good microbiological practice and good occupational safety and hygiene.
Disenfection with 2% aqueous Virkon solution according to University Policy and Guidance document. Material that has come into contact with parasites is inactivated by soaking in hypochlorite (1:500) for 24h.

Liquid waste and solid waste (other than sharps and animal waste) is sterilised in an autoclave maintained and validated by the manufacturer's service organisation for the destruction of clinical waste prior to transfer by a licensed operator to a commercial incinerator site authorised to treat GM waste. Sharps and animal waste are transferred directly to the incinerator for destruction.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

The University GM committee, at a meeting held on 29.4.97, endorsed the decision of the local GM committee (dated 16.4.97) and the two outside experts from other local committees that this project requires Containment Level 2 facilities that are available in laboratories 2.681 and 2.682 of the Stopford Building. No special problems were identified that could not be contained by Good Microbiological Practice. It was noted that Group II organisms were involved and that HSE approval was required before work could start.

- Non-GMM: Consent Granted
- Project notified under transitional arrangements

### Project Additional Information

**Purposes of the contained use**
- Introduction of methyl transferase genes, via retrouiral infection, into murine es cells.
### Recipient or parental organism
Murine embryonic stem cells, E14 line.

### Host/vector system
**DH5α**: Host

Non mobilisable plasmids, pLNCX-Derives: vector.

Replication - incompetent retrouirus production in PT67 cells.

### Origin & function
Genetic material derived from non-mobilisable pLNCX plasmids and containing commonly used reporter and marker genes together with one of the following three genes.

1. De Novo Methyltransferase 3A.
2. De Novo Methyltransferase 3B.
3. Methyl Binding Domain 2B.

The vectors enable study of these gene functions in cell culture.

### Evaluation of foreseeable effects
The genetic elements and vector system are well characterised and frequently employed. The proximal aim is to generate replication. Incompetent viral particles for the purpose of infection of murine ES cells and the study of the phenotypic effects of the above-named genes. Since the viral particles will be incapable of autonomous propagation (due to the absence of structural genes) and since the plasmids themselves are non-mobilisable, there are no significant foreseeable environmental or health concerns arising from this experiment.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
**Effective containment and control measures:**

1. Non-mobilisable plasmids.
2. Replication - incompetent viral particles.
3. Use of a Level 2 containment facility.
4. Use of a Level 2 tissue culture hood.
5. Chemical and heat inactivation of waste material.
6. Confirmation of inactivation using appropriate methods.
7. Autoclaving of all equipment before removal from facility.
9. Regular inspection of facility and hood.
10. Regular confirmation of satisfactory autoclaving.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste management measures:

1. Pipette aspiration of biological cell culture material.
2. Chemical and heat neutralisation of cells and viral particles.
3. Chemical and heat neutralisation of bacterial cultures.
4. Confirmation of 100% neutralisation by demonstration of absolute sterility post treatment.
5. Monitoring of methods using Browne’s steriliser tubes.
6. Removal from facility in appropriate labelled bags for incineration.

Project Additional Information

Purposes of the contained use
Introduction of Epsien-Barr virus genes into human antigen presenting cells using Vaccinia virus as a vector.

Recipient or parental organism
Recombinant Vaccinia viruses are thymidine kinase negative and consequently less virulent than wild type Vaccinia.
Manipulated human antigen presenting cells are not known or thought to be any risk to the operator of the environment.

Host/vector system
DH 5a Host
Vectors will be non-mobilisable plasmids.
Vaccinia virus will be propagated in TK-143 cells.
All Epstein-Barr virus genes are derived from the phototype B95.8 strain of EBD. The gene products will be used to stimulate an immune response against cells latently infected with EBV, as with some tumour cells.

Evaluation of foreseeable effects

EBV is carried out by nearly all individuals in any community, therefore, the effect of any exposure to a single EBV gene product is likely to be effective zero. Vaccinia virus has been used on a wide scale to immunise people. Vaccinia virus Recombinant strains carrying Rabies Virus genes have also been used in non laboratory settings, notably in Belgium where virus infected meat was used to immunise foxes in the wild.

Plasmid vectors are of the non-mobilisable type. Thus, these should be incapable of passing genetic material to wild-type bacteria.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All cultural aspirates pass into concentrated Presept. Aerosols will be contained with an 'in line' 0.22mu filter. All solid and liquid waste will be autoclaved after chemical inactivation. All bacterial cultures will be chemically treated and its effectiveness monitored by regualr culturing to test for viability. The autoclave is regularly monitored by use of Browne's tubes and a temperature recorder. Removal of waste after treatment to the clinical waste stream.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The maximum culture released at one time is 5 litres.

All liquid waste is autoclaved prior to disposal via the drain. All solid waste is autoclaved and then incinerated off site by an external contractor.

The autoclaves are routinely serviced and calibrated (every 6 months or year). Thermographic measurement vials are added weekly to check the required temperature is being reached.

Project Ref 208/07.1

Date Ackn'd 15/02/2007

CU2 Project Title Development of a idiopathic pulmonary fibrosis (IPF) model to facilitate the design of more effective medical treatments to treat IPF in humans.

Class 2

Culture Vol Class 2 1-50 Litres

Non-GMM Consent Granted Not Applicable

Consent Granted

Project notified under transitional arrangements N

Withdrawn N

Tick if notifying a connected programme of work N

Historical Significant Changes

Historical Date of Additional Info
**Project Additional Information**

**Purposes of the contained use**
The contained use aims to develop a model for the human disease idiopathic pulmonary fibrosis to facilitate the design of more effective medical treatments.

**Recipient or parental organism**
A variety of routinely used cell lines and experimental models will be used.

**Host/vector system**
Recombinant replication deficient adenoviruses [AdTGF-beta-1 & AdTGF-beta-1 223/225].
- AdTGF-beta-1 expresses inactive porcine TGF-beta-1.
- AdTGF-beta-1 223/225 contains a mutation of cysteine to serine at positions 223 & 225, rendering the expressed TGF-beta-1 biologically active.
- Both vectors contain a deletion in the E1 region which makes them replication deficient.

**Origin & function**
**Origin of material**
Material is cDNA of the full length porcine TGF-beta-1, isolated from the Okayama and Berg cloning vector and plasmid pPK9A, by digestion with restriction endonucleases KpN (TGF-beta-1) and BamH1 (TGF-beta-1 223/225).
Fragments subcloned into shuttle plasmid pACCMV.PLP.ASR(+) which contains the left end of the human adenovirus type 5 genome (0-17 mU) and a human cytomegalovirus promoter, a multicloning site and an SV40 polyadenylation signal inserted into the E1 region. After spontaneous homologous recombination between the plasmids, recombinant replication-deficient adenoviruses AdTGF-beta-1 & AdTGF-beta-1 223/225 were rescued.

**Intended function of genetic material**
- AdTGF-beta-1 expresses inactive porcine TGF-beta-1
- AdTGF-beta-1 223/225 contains a mutation of cysteine to serine at positions 223 & 225, rendering the expressed TGF-beta-1 biologically active.

**Evaluation of foreseeable effects**
**Vector**
The adenovirus vectors used are replication deficient which limits the chance of survival and transmission. Expression in the lining of the respiratory epithelium declines with time and is limited to ~ 2 months (part 2B-Annex III, HSE compendium of guidance).

**Inserted sequences**
Inserted gene is only recognised by specific receptor. Binding of TGFB1 to receptor in lung triggers events leading to fibrosis. Induction of fibrosis would require large quantities of adenovirus to be delivered to lung and potentially repeat inoculations.

**Control measures in place**
Minimise the risk of development of fibrosis in laboratory workers.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
A variety of engineering and operational controls appropriate to containment level 2 activities will be implemented to ensure effective containment and control of the proposed activities involving genetically modified organisms.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogations applied for.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid and liquid waste (wherever possible) will be sterilised on site by autoclaving at 121°C for at least 20 mins in autoclave that are regularly maintained and UKAS validated. Degree of kill is regarded at 100%. Each autoclave load is monitored with suitable indicators (e.g. autoclave tape, indicator tubes).

All sterilised solid waste will then be disposed by off-site incineration. Asterilised liquid waste will be disposed of via drain.

If necessary small quantities of liquid waste will be disinfected with commercially available, efficacious disinfectants e.g. Virkon. All use will be as directed by the manufacturers guidelines.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment

NHRC biological safety committee (includes responsibility for genetic modification) recommended that the risk assessment be modified to restrict the amplification cycles in 293 cells to < 10 for approval at category 1.

Designation as a class 2 activity was considered appropriate for associated work activities.

All media and material in contact with GM material, as well as GM cultures, are autoclaved prior to disposal. Small volumes of media are sterilised by bleach.

GM plants are grown in growth cabinets and containment glasshouses. GM plants are bagged and autoclaved. Soil used with GM plants is bagged and either autoclaved or steam heat treated according to a Standard Operating Procedure.

Validation of deactivation is carried out using indicator tape and temperature gauges of the equipment. Autoclaves and steaming equipment are regularly inspected.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Please enter comments of the GM safety committee on the risk assessment
### Project Additional Information

#### Purposes of the contained use

Plants will be inoculated with modified ACMV DNA. The modified ACMV lacks a viral coat protein.

#### Recipient or parental organism

Test plants (Nicotiana benthamiana) will be inoculated with modified ACMV DNA. The modified ACMV lacks a viral coat protein and thus is unable to form a viral particle and thus will not be insect transmitted. ACMV symptoms on his host, Manihot esculenta, a non-UK crop, are mild. Its insect vector Bemisia tabaci is not found in the UK. No genes which are toxic or allergic to humans or animals will be cloned in ACMV. Hazard arising from these experiments is negligible and the risk effectively zero.

#### Host/vector system

- **Host**: Nicotiana benthamiana
- **Vector**: ACMV genome A based constructs in piC19H

#### Origin & function

Plasmid with ACMV-specific sequences obtained from Dr J Stanley, John Innes Centre, Norwich Research Park, Colney Lane, Norwich NR4 7UH, UK.

Constructs will be used to express foreign gene sequences as inoculated plants.

#### Evaluation of foreseeable effects

ACMV with or without foreign gene insertion is unlikely to be harmful to humans or animals. The modified ACMV genome on inoculated plants is likely to be less fit than wild type.

ACMV is not transmitted by seed or pollen. Its natural host Manihot esculenta is not grown in the UK and its insect vector Bemisia tabaci is not found in the UK.

ACMV clones lack the coat protein gene, so it cannot be insect trasmitted. Genes cloned in the vector are not toxic or allergenic to humans or animals.

The likelihood of hazards arising is negligible.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

- Inoculation of host plants will take place in a secure, closed growth room. Access to the growth room will be restricted to authorised personnel.
- A limited number of plants (<50) will be grown in compost in pots on waterproof trays. A limited amount of water will be used in watering. Routinely, there will be no run-off. If run-off occurs, it will be contained.
- The growth room is insect free.
- Transport of waste material will be in secure closed containers and autoclaved.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

all material in contact with GM materials, including GM cultures, plants and growth media will be placed in identified containers and autoclaved prior to disposal. The autoclave is routinely serviced and checked for temperature and pressure.

Project Ref 212/01.2

Date Ackn’d 03/08/2001

CU2 Project Title

THE USE OF TOBACCO MOSAIC VIRUS (TMV) AS A TOOL FOR THE EXPRESSION OF FOREIGN GENES IN PLANTS

Date Project Ceased

Project notified under transitional arrangements N
**Project Additional Information**

**Purposes of the contained use**

Plants will be inoculated with modified TMV RNA containing differing plant genes.

**Recipient or parental organism**

Test plants (*Nicotiana benthamiana*) will be inoculated with modified TMV RNA. TMV with or without modification is unlikely to be harmful to humans or animals. TMV is present in the UK. Disease symptoms caused are moderate and vary in differing hosts such as *Nicotiana tabacum*. TMV is not transmitted by insects or pollen. TMV is transmitted by mechanical inoculation, grafting contact between plants and occasionally seeds (via the testa). No genes that are toxic or allergenic to humans or animals will be cloned in TMV. Hazard arising from the experiments is negligible and risk effectively zero.

**Host/vector system**

*Host: Nicotiana benthamiana*  
*Vector: TMV cDNA with a duplicated coat protein promoter clone in pUC19*

**Origin & function**

Plasmid with TMV-specific sequences obtained from Dr W O Dawson, University of Florida, Lake Alfred, FLA 33850, USA.  
Constructs will be used to express foreign gene sequences as inoculated plants.

**Evaluation of foreseeable effects**

TMV with or without a foreign gene insertion is unlikely to be harmful to humans or animals. The modified TMV genome inoculated on test plants is likely to be less fit than wild type.  
TMV is not transmitted by insects or pollen. It is mechanically transmitted and occasionally (via the tests) seed transmitted.  
Genes clones in the TMV vector will not be toxic or allergenic to humans or animals.  
The likelihood of hazards arising from this work is negligible.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Inoculation of host plants will take place in a secure, closed growth room. Access to the growth room will be restricted to authorised personnel.  
A limited number of plants (<50) will be grown in compost in pots on waterproof trays. A limited amount of water will be used in watering. Routinely, there will be no run-off. If run-off occurs, it will be contained.
The growth room is insect free.

Transport of waste material will be in secure closed containers and autoclaved.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Project Ref  212/01.3

Date Ackn'd  03/08/2001  CU2 Project Title  GENE EXPRESSION IN PLANTS USING POTATO VIRUS X (PVX) AS AN  Class  Class 2  Culture Vol Class 2  <1 litre  Culture Volume Class 3-4
Project Additional Information

**Purposes of the contained use**

Plants will be inoculated with modified PVX RNA containing differing test genes.

**Recipient or parental organism**

Text plants (Nicotiana benthamiana) will be inoculated with modified PVX RNA. PVX with or without modification is unlikely to be harmful to humans or animals. PVX is present in the UK, but is often not considered a pathogen. PVX is only mechanically transmissible. No genes which are toxic or allergenic to humans or animals will be cloned in PVX. Hazard arising from these experiments is negligible and the risk effectively zero.

**Host/vector system**

Host: Nicotiana benthamiana.
Vector: pP2C2S bacterial plasmid containing a PVX genome with duplicated viral coat protein promoter.

**Origin & function**

Plasmid with PVX-specific sequences obtained from Dr D Baulcombe, John Innes Centre, Norwich Research Park, Colney Lane, Norwich NR4 7UH, UK.

Constructs will be used to express foreign gene sequences as inoculated plants.

**Evaluation of foreseeable effects**

PVX with or without foreign gene insertion is unlikely to be harmful to humans or animals. The modified PVX genome on inoculated plants is likely to be less fit than wild type.

PVX is not transmitted by seed or pollen. It is only transmitted by mechanical inoculation.

Genes cloned in the vector are not toxic or allergenic to humans or animals.

The likelihood of hazards arising is negligible.

Project Ref 212/02.1
**Project Additional Information**

Purposes of the contained use

The aim of the proposed experiment is to test the ability of cloned MBV to replicate in transfected protoplasts of Agaricus bisporus and Coprinus cinereas in vitro.

Recipient or parental organism

Protoplasts of Agaricus bisporus or Coprinus cinereas will be transfected in vitro by plasmid DNA containing MBV or cDNA. MBV is unlikely to be transfected using virions or viral RNA. Experiments will be carried out in vitro. It is unlikely that MBV cDNA will infect wild mushrooms outside tissue culture facilities.

Host/vector system

Host: Agaricus bisporus and Coprinus cinereas

Vector: MBV cDNA in pVC19

Origin & function

Plasmid with MBV-specific sequence (MBV variant tester) MBV with or without foreign gene insertion is unlikely to be harmful to humans or animals. The virus is unlikely to be transmitted by mechanical inoculation of virions or RNA. Experiments will be carried out in vitro using protoplasts unlikely to survive in the environment. Likelihood of hazards arising from this work is negligible.

Evaluation of foreseeable effects

Inoculation of protoplasts will take place in vitro in a contained laboratory.

All material arising from the experiments will be placed in secure containers and autoclaved.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Date Project Ceased 02/03/2022
The purpose of the project is to use the plant viruses, Potato virus X (PVX) and Tobacco mosaic virus (TMV), as tools for the expression of foreign genes in plants, with the aim to investigate potential of the PVX and TMV vectors as tools for foreign protein production.

Both PVX and TMV are endogenous viral pathogens and neither is considered to have any serious consequences on infected plants. Both viruses are transmitted in nature by mechanical means, generally plant-plant contact and neither virus is known to be transmitted by arthropod or nematode vectors. In the unlikely event of release of the modified virus to the environment a rapid selection for "wild-type" virus is observed and recombinant viral progeny lacking foreign genetic sequences rapidly arise and dominate quickly dominate the viral population.

The modified PVX and TMV cDNA's with a duplicated viral coat protein subgenomic promoter is cloned in plasmid pBluescript KS (M13-) for propagation in suitable Escherichia voli K12 strains. Nucleic acid sequences of interest will be inserted into the vector using standard molecular biology procedures. Gene expression will be under the control of the coat protein promoter and the expression level will not exceed that of the viral coat protein.

The gene encoding the human endostatin protein will be inserted into cDNA copies of the PVX and TMV viral genomes in such a way that infection of plants with invitro synthesized viral RNA transcripts will permit the infection of host plants and production of recombinant endostatin. Endostatin is a protein that acts as a negative regulator of angiogenesis and therefore has a potentially important role as a therapeutic agent to prevent rumour growth and metastasis.

Evaluation of foreseeable effects

Endostatin is normally produced in humans and animals (eg during wound healing processes) and therefore neither endostatin-coding sequences nor endostatin are considered to pose any health threat to humans and animals. It is unlikely that introduction of the endostatin gene into the PVX or TMV genome will alter the routes of viral vector transmission.

The modified PVXs or TMVs are likely to be less fit than wild type. It is unlikely that expression of human endostatin, a protein that is not normally expressed in plants, will make PVX or TMV pollen or seed transmissible. It is also very unlikely that the modified PVX or TMV will become a vector transmissible (eg by insect, mite, fungal or nematode vectors) and that the host range of the modified PVX will be altered. Therefore, the genetically modified PVX or TMV will not be any more harmful than its parent.
Inoculation of plant material will be performed in a Unigro GroDome. The construction method means that the facility is virtually airtight. The compartments can be negatively pressurised (to approx 40 pascals) to ensure that insects or pollen do not escape and an air exhaust bag filter will be used. The method of construction also means that the steel superstructure and polycarbonate dome can withstand winds up to 120mph and resist impact from flying objects produced by such winds.

Close adherence to standard operating procedures, training of staff, and rigorous implementation of containment measures should protect the environment. Furthermore, the isolated location of the growth room inside a building in the middle of a very large field of perennial fruit crops (which PVX or TMV is not able to infect), should prevent the modified viruses from escaping to infect any susceptible natural host plants.

Gene expression vectors based on PVX and TMV have been used for well over a decade in the UK under containment conditions that are inferior to those of the GroDome without any evidence of escape to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Infection of whole plants with modified PVX will be undertaken in a compartment of the Unigro Grodome Containment Facility. This facility is designed to meet containment level II and is therefore suitable for the proposed research. Access to the facilities (growth room) will be restricted to authorised personnel only.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

In the laboratory all media in contact with GM materials as well as GM cultures and plants will be placed in identified containers and autoclaved prior to disposal.

Infected plants will be grown in compost in pots in waterproof trays in a containment growth room inside a building. Only a limited amount of water will be used daily for watering plants. There will be no run-off water. Accidentally contaminated water will be contained.

Plant material and other solid waste will be transported from the Unigro GroDome compartment in secure closed containers, for autoclaving and disposal.

Following recommendation from Defra Plant Health Division, liquid waste and condensate from the cooling coils will be collected, treated with Virkon to give a final concentration of 1% (or another suitable disinfectant at an appropriate concentration) and then autoclaved.

Is an emergency plan required according to regulation 20? Y

Please enter comments on the GM safety committee on the risk assessment

The GMSC was convened to discuss this notification, and agreed recommendations have been incorporated into the section above.
Use of pseudomonas syringae pv moresprunourn to deliver Pseudomonas effector genes into plant cells

Historical Significant Changes
Historical Date of Additional Info
Significant Change ID
Date of Significant Change

Project Additional Information

Purposes of the contained use
The project will explore the genetic basis of host specificity by using strains that cause bacterial canker on Prunus species. Comparative genomics will be used to compare the pathogenicity factors of these strains to try and find genes important for infecting Prunus species and closely related strains isolated from other plant species.

Recipient or parental organism
Wildtype strains of Pseudomonas syringae/savastanoi (these species names are used interchangeably) from the pathovars morsprunorum, syringae, avellanae, aquilegia, tomato and phaseolicola. These strains were isolated from diseased cherry, plum, hazelnut, aquilegia, tomato and bean plants. All Pseudomonas moresprunorum strains derive from the UK and are only known to cause disease on cherry and plum. Another strain, isolated from Aquilegia vulgaris, will also be used, again isolated from the UK.

Host/vector system
Strains of E.coli (principally DH5a and S17) will be used to store vectors and used for conjugation of the vector into Pseudomonas.
Gene candidates possibly involved in host specificity including secondary metabolite biosynthesis genes and effectors will be cloned and transformed into E. coli and then moved into different strains of Pseudomonas in order to elucidate their functions and if they are targeted by plant resistance. Knockout strains in which some of these genes are deleted may also be produced to further determine function. Cloning will be primarily focused on finding avirulence genes (genes that reduce pathogenicity) so will involve moving candidate avirulence genes from non-pathogens into pathogens to see if they effect virulence. Knock-outs will also focus on reducing virulence. Therefore, GM strains are likely to have reduced virulence on their host, rather than an expanded host range.

### Evaluation of foreseeable effects

The genes involved will function in pathogenicity of the isolate for example effector genes which suppress the plants immune system or secondary metabolites that kill plant cells. In the highly unlikely event of establishment or dissemination, the microbes will likely have reduced virulence compared to wild-type clones and therefore be evolutionarily unfit and unlikely to persist. Were they to do so they would contribute to the already high levels of bacterial canker that are currently present in the wider environments, due to the susceptibility of most cultivated cherry material.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The inserted genetic material will include secondary metabolite biosynthetic genes and effectors from the pathogen. They will be expressed in their active form. The inserted material will never intentionally leave the laboratory due to the use of containment protocols, restricted access protocols and the use of licensed, contained rooms. In the highly unlikely event of establishment or dissemination, the microbes will likely have reduced virulence compared to wild-type clones and therefore be evolutionarily unfit and unlikely to persist. Were they to do so they would contribute to the already high levels of bacterial canker that are currently present in the wider environments, due to the susceptibility of most cultivated cherry material. It is unlikely that transmission would be altered, as this is primarily through mechanical wounding and tissue localisation is unlikely to be altered in a detrimental way (to the plant) due to the ability of the pathogen to already infect multiple major tissue types.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All material in contact with GM materials including GM cultures, plants and growth media will be placed in identified containers and autoclaved prior to disposal. The autoclave is routinely checked for temperature and pressure.

### Project Additional Information

#### Purposes of the contained use

The purpose of the project is to use the plant virus, Strawberry Mild Yellow Edge Virus (SMYEV), a relative of the potexvirus Potato virus X (PVX), as a tool for the expression of foreign genes in plants, with the aim to investigate potential of the SMYEV vector as a tool for protein production for the purposes of screening pathogen-derived avirulence genes.

#### Recipient or parental organism

The host of the virus is disarmed Agrobacterium tumefaciens which will then be infected into Fragaria x ananassa.

#### Host/vector system

The SMYEV is the vector system. SMYEV is a potexvirus and is present in the UK. The disease symptoms caused are mild, and SMYEV is often considered not to be a plant pathogen.
The genes to be expressed in using SMYEV will be reporter genes to show that the system works including β-glucuronidase (GUS), a protein which is not normally expressed in plants. When the expression system is working effectively genes involved in disease resistance including effector genes and resistance genes will be expressed using the viral system.

Evaluation of foreseeable effects

The modified SMYEVs are likely to be less fit than wild type. Evidence from Tobacco Mosaic Virus has shown that potexviruses usually lose their transgenic component during the natural infection process and therefore will have reverted to wild type after several passages (see Virology 172:285-292 1989). However, the chimeras may have novel properties, which could alter pathogenicity. It is unlikely that expression of a reporter gene, a protein which is not normally expressed in plants, will make SMYEV (or other potexvirus) pollen or seed transmissible. In future, when using genes from pathogens and genes involved in disease resistance and signalling process it is also unlikely that these genes will increase the fitness of the virus for the same reasons. Potexviruses have small genomes and no virus has been found with a >6.5kb genome. Therefore it is highly unlikely that a transgenic protein could be sustained in the viral genome. It is also very unlikely that the modified SMYEV will became a vector transmissible from plant to vector (e.g. by insect, mite, fungal or nematode vectors) and that the host range of the modified SMYEV will be altered. Therefore, the genetically modified SMYEV will not be any more harmful than its parent.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Although SMYEV is not considered to be a serious pathogen, protection of the environment is still the primary concern. Close adherence to standard operating procedures, training of staff, rigorous implementation of containment measures will protect the environment. Furthermore, the isolated location of the growth room inside a building (Bioassay Basement B) will prevent the modified viruses from escaping to infect any susceptible natural host plants. The growth room is free from insects, so transmission via this route is unlikely. Although SMYEV is transmitted insect vectors, it cannot be acquired from infected plants. Therefore cautious insect control is in place in the growth room, and the facilities will afford secure containment. Transport of waste from the facilities will be in secure closed containers. Compliance with the requirements set down by DEFRA for the parental virus will provide satisfactory environmental protection. The likelihood of hazards arising is therefore negligible and the risk is effectively zero.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All material in contact with GM materials including GM cultures, plants and growth media will be placed in identified containers and autoclaved prior to disposal. The autoclave is routinely checked for temperature and pressure.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N
This risk assessment is aimed at using a strawberry virus as a tool for expressing genes in planta. This risk assessment was considered to be of negligible risk to human health and low risk to the environment. The containment measures will effectively reduce the risk to zero. As the research is using a plant pathogen the overall classification of the GM material has to be Class 2 and the HSE informed.

The committee approved this GMRA and subject to HSE approval this work can proceed.

### Project Ref 212/16.3

- **Date Ackn’d**: 17/03/2016
- **CU2 Project Title**: Investigating the pathogenicity of fungal vascular wilts *Verticillium* sp and *Fusarium* sp
- **Class Culture Vol**: Class 2 | ≤ 1 Litre
- **Consent Granted**: Non-GMM | Consent Granted

- **Withdrawn**: N
- **Tick if notifying a connected programme of work**: N

### Historical Significant Changes
- **Historical Date of Additional Info**: 02/03/2022

### Project Additional Information

- **Purposes of the contained use**: The fungal vascular plant pathogens *Verticillium dahliae* and *Fusarium oxysporum* have an extremely broad host range, and they are widely known for causing wilt. They are soil-borne pathogens, which can live in the soil for long periods of time making the control methods very challenging. The aim of the study is to characterize the
mechanisms of infection, revealing the effector gene repertoire and its influence on pathogenicity. Therefore, effector genes will be inserted and deleted from the fungal organisms to study their function. This will be done by cloning the constructs into E.coli and then transferring the vectors into Agrobacterium tumefaciens which will be used to transform the fungal species.

In addition, circadian clock studies will be performed towards assessing how pathogenicity is affected by the circadian rhythm. This will be carried out in Verticillium dahliae, by knocking out putative clock genes and adding promoter reporters (Luciferase) and fluorescent proteins (e.g. Green Fluorescent Protein).

**Recipient or parental organism**

Verticillium sp (causative of verticillium wilt)
Fusarium sp (causative of fusarium wilt)

**Host/vector system**

E.coli (principally DH5a)
Agrobacterium tumefaciens disarmed (EHA105; GV3101)

**Origin & function**

The cloned genes from Verticillium sp or Fusarium sp are involved in pathogenicity (effector genes which suppress the plants immune system). For knockouts, the inserted DNA will be 500-1000bp upstream and downstream of genes of interest. FP and reporter genes will allow the fungi to fluoresce under a microscope or luminesce the presence of a substrate.

**Evaluation of foreseeable effects**

Some strains of Verticillium dahlia and Fusarium oxysporum are present in the environment. Although care must be taken to avoid their release. Some isolates come from abroad, and they present a risk for the environment since they could be significant if released. Therefore, these strains are to be kept at containment level 2 and are treated as licensed pathogens.

Expression of the effectors genes from pathogens: could increase the fitness of the pathogens. Expression of the reporter genes: will not cause any harm for the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Transformed organisms with effector genes could have altered pathogenicity on plant species and they could cause an increase of virulence. Appropriate containment of these pathogens will be taken (containment level 2).

Transformed organisms with fluorescent proteins, reporter genes or gene knockouts will be no more hazardous than the untransformed fungi.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

none requested

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All material in contact with GM materials including GM cultures, plants and growth media will be placed in identified containers and autoclaved prior to disposal. The autoclave is routinely checked for temperature and pressure.

**Is an emergency plan required according to regulation 20?**

N

If yes, tick to confirm that it is attached to this form

N
The risk assessment investigating the pathogenicity of fungal vascular wilts Verticillium sp and Fusarium sp was considered to be of negligible risk to human health and low risk to the environment. The containment measures will effectively reduce the risk to zero. As the research is using a plant pathogen the overall classification of the GM material has to be Class 2 and the HSE informed. The committee approved this GMRA and subject to HSE approval this work can proceed.

### Project Additional Information

**Purposes of the contained use**

Genetically modified Giardia will be produced to study the evolution of the mitochondrion, an energy-generating cellular organelle central to the origins of all extant eukaryotic organisms. The project will also investigate the physiological role of mitochondrially-derived genes and their encoded proteins.

**Recipient or parental organism**

Wild-type Giardia intestinalis, pathogenic.

**Host/vector system**

Non-mobilisable, pUC-derived plasmid vectors will be used to introduce DNA into Giardia by electroporation. Transfectants will be selected on the basis of their acquired marker genes. Acquired episomal or chromosomal foreign DNA is lost from Giardia in the absence of selection.

**Origin & function**

The genetic manipulation of Giardia will entail the introduction of well studied genes with no known harmful or toxic properties to human health or to the environment. Homologous Giardia genes encoding mitochondrial functions (eg cpn60, hsp70) as well as standard reporter genes (eg firefly luciferase, B-galactosidase, neomycin resistance) will be expressed in Giardia. The source of DNA will be the laboratory strain WB (ATCC # 30957) and conventional strains of Escherichia coli.
**Evaluation of foreseeable effects**

Members of the genus *Giardia* parasites a wide variety of vertebrates, including humans, and cause diarrheal disease worldwide, particularly in children. *G. intestinalis* is transmitted in nature as waterborne infective cysts, it is a non-invasive pathogen and secretes no known toxin. About half of infected people are asymptomatic and the infection frequently resolves spontaneously. Under standard laboratory conditions, *Giardia* is cultured as the non-infective trophozoite form. Cultured trophozoites are sensitive to desiccation, detergents, and changes in temperature, pH and osmolarity, and do not survive passage through the stomach. However, infective cysts can be experimentally generated in culture and these may be environmentally transmitted. The most likely route of transmission to people in the laboratory is by oral ingestion. This possibility will be minimised by the use of automatic pro-pipettes and disposable gloves. Further, efficient anti-giardial drugs exist for the treatment of giardiasis (Wolfe MS. 1992. Giardiasis. Clin Microbiol Rev 5, 93-100). The proteins to be expressed are not involved in pathogenicity, so it is unlikely that GMMs will be more harmful to humans than either the host or wild-type *Giardia*. All culture work will be carried out in a class II microbiology safety cabinet. Access to the culturing facility will be restricted.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All cultures and contaminated waste will be treated with 5% chloros and autoclaved prior to disposal as conventional solid/liquid waste. No GMOs are viable after such treatment.

Project Additional Information

Purposes of the contained use

The project forms one component of a multi-site Medical Research Council (MRC) funded Co-operative Group (CoG) whose remit is the "Rational Development of an HIV/AIDS Vaccine". Other components of the (CoG) are based at Kings College London, Imperial College School of Medicine, St George's Medical School, University of Oxford and University of Reading. While drug complex drug therapies are available to stabilise HIV/AIDS, it is widely accepted that development of effective vaccines is to tackle populations, such as in sub-Saharan Africa where incidence of HIV infection is very high and growing. Studies at RHUL will involve production of genetically modified bacteria, cultured mammalian cells, and replication-defective adenoviral vectors (rAds) which contain partial DNA sequences of the HIV genome. In addition parallel studies will be conducted on the simian immunodeficiency virus (SIV) an organism which infects certain classes of primates but not humans. However, no intact infectious HIV or SIV will be handled. The GMMs will be used in experiments to configure, develop and optimise rAd-based vaccines for preventative and therapeutic immunisation against HIV. It is worth noting that a 1st generation of rAd-based HIV vaccines are already in human clinical trial. The HIV/SIV genomes contains some 10 genes and a range of control sequences, all of which are required to constitute an infective and pathogenic viral particles. In the work at RHUL, individual HIV/SIV gene sequences, or combinations of several sequences be cloned and manipulated in bacteria, and then introduced into rAds: so-called 1st generation [E1/E3-deleted] and 2nd generation [E1/E3/E2 (terminal protein and viral DNA polymerase)-deleted]) rAds of serotypes 5, 11 and 35 will be constructed. These rAd GMM will be able to transduce a range of mammalian cell types (including human) and will then be tested for effective gene delivery and effective production of the putative immunogenically-protective HIV/SIV protein components in a range of cultured human and mouse cells.

Recipient or parental organism

Cultured Escherichia coli K12 derivatives will be genetically modified.
Cultured human and murine cells will be genetically modified.
Adenovirus will be genetically modified (in all cases in replication-defective format).

Host/vector system
Hosts are described above. Non-mobilisable plasmids vectors are derived from pBR/pUC plasmids, and from M13 bacteriophage. Replication-defective adenovirus vectors will be produced and propagated in HEK-293 and 911 cells.

Origin & function

HIV/SIV genetic elements will be derived from cloned fragments of HIV Clade B and C, and SIVmacJ5 isolates produced elsewhere and imported into the containment lab in plasmid form. No intact infectious HIV or SIV genetic isolates or molecular clones will be handled.

The HIV/SIV genomes contain some 10 genes and a range of control sequences, all of which are required to constitute an infective and pathogenic viral particles. In the work at RHUL, individual HIV/SIV gene sequences, or combinations of several sequences be cloned and manipulated.

Evaluation of foreseeable effects

Summary of major risks identified:

(i) GM adenoviral vectors expressing the HIV/SIV nef gene were considered to present the highest level of risk to human health.

(ii) Naturally occurring fully-infectious adenoviruses are mild pathogens designated at level 2 by the Advisory Committee on Dangerous Pathogens (ACDP). Adenovirus infection in humans can cause mild influenza-like illness, gastro-intestinal upsets and/or conjunctivitis, and generally pass without referral to a GP. Some 80-90% of the human population has already been infected/encountered adenovirus and are protectively immunised as a result.

(iii) GM adenoviral vectors produced in this project will be highly attenuated and replication-defective. This means they can infect human cells and thus provide an immune stimulation but cannot replicate and spread.

(iv) GM adenoviral vectors will be genetically-modified to carry several HIV/SIV genes. No infectious HIV/SIV virus is involved. However one product of these genes (the so-called nef gene) has been shown to be toxic when present at high levels in special experimental circumstances ie. widely overproduced in transgenic animals. Thus one of the GMMs being created in the project must be considered as potentially harmful to human health and thus classified as a Group II GMM as defined by HSE.

(v) Volume of production in the project will be limited to low-level, non-industrial, research scale of activity ie. Type A as defined by HSE.

(vi) Potential risks may thus exist of exposure of lab workers or members of the public to GMMs should a breach of contained use occur. Specific operational risks include (i) ingestion, inhalation or topical contact with GMM aerosols, (ii) needlestick injury with GMM contaminated sharps, (iii) inadequate waste transport and/or disinfection procedures.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disinfection Procedures and Waste Management.

(i) Chemical disinfectants will be validated under working conditions (eg. high protein concentrations in culture media) against the GMMs being handled either in practice or via manufacturer's specification. Disinfectants will be solutions of hypochlorite (5000 ppm chlorine) or Virkon (2%) or ethanol (70%).

(ii) Autoclave inactivation of GMMs (121 degrees C, 22psi, >30 minutes) will each time be validated by internal thermolog (sensitivity-strip) procedures and outcome
logged. Two thermocouple-certified large autoclaves are available, in case one should malfunction. Bagged waste will be transported to this room in a designated large, wheeled bin with a closely fitting lid, that is labelled 'GMM waste'.

(iii) GM waste containers will be clearly marked until disinfection/inactivation is complete.

(iv) Liquid waste will be discharged to sewer after disinfection by a validated procedure.

(v) Solid waste will be discharged to the domestic refuse after disinfection and/or autoclaving by a validated procedure.

Extract from the Minutes:

10.12 Report on risk assessment submitted
(NB: Consideration of this RA was chaired by JT as Deputy BSO)

a) Section 3, 3.3: Revise re emphasise hazard of nef gene

b) Section 5, 5.1: Noted that adenovirus is a level 2 ACDP pathogen but that replication-defective adenoviral vectors carry much lower if any intrinsic risk.

c) Section 5, 5.11: This paragraph was included in error and should be deleted. No animal vaccination will occur at RHUL. (Now deleted in attached RA)

d) Section 6, 6.4: This paragraph was included in error and should be revised. No animal vaccination will occur at RHUL. This paragraph to be deleted. (Now revised in attached RA).

e) Consider production of an SOP document to minimise the risk of inadvertent sero-conversion.

Recommendation: Provided changes satisfy the Deputy BSO, passed at containment Level 2 for GMMs. (NB: This Project requires CU2 notification to HSE).

Project Ref 214/11.1

02/03/2022
Project Additional Information

Purposes of the contained use

This programme of work is designed to develop and evaluate gene and cell therapy models and strategies to potentially treat inherited and acquired diseases including severe combined immunodeficiency, spinal muscular atrophy, stroke, Parkinson disease and others. A range of genes will be manipulated in prokaryotic (plasmid and phage) and eukaryotic (plasmid and replication-defective viral) gene transfer vectors, and these vectors used to transfer genes into target cells for the purpose of modelling disease and assessing potential therapeutic benefit.

Recipient or parental organism

BACTERIA
K12 derived E. coli strains such as: TOP10, SURE, JM109, DH5 and other such disabled E.coli strains.

REPLICATION-DEFICIENT VIRAL VECTORS
Retroviral vectors derived from Moloney murine leukaemia virus.
Lentiviral vectors typically derived from Human Immunodeficiency virus-1 (HIV-1).
Adeno-associated virus vectors (typically derived from AAV-2).
Adenovirus vectors (typically derived from AdV-5).

RECIPIENT MAMMALIAN CELL LINES
Laboratory cell lines like human embryonic stem (ES) cells, induced pluripotent stem (iPS) cells, BJ foreskin fibroblasts (ATCC-CRL-2522).
Established cell lines like NIH-3T3 fibroblasts, HT1080, HeLa and HEK293 cell variants, mouse ES cells, L-cells, embryonic carcinoma (e.g. Ntera 2), C6 glioma and N2A neuroblastoma cells, myoblasts (e.g. C2), rat PC12 pheochromocytoma, African green monkey COS7, lymphoid, mieloid and other standard laboratory cell lines.

RECIPIENT MAMMALIAN PRIMARY CELLS
Such as rodent motor neurons, neurons, glial cells, microglia, myoblasts, haematopoietic cells, fibroblasts and other primary cells.
Primary human cells, mostly fibroblasts from skin biopsies, but also those obtained from other tissues.
CLONING VECTORS
Non-mobilisable vector systems e.g. lambda gt and charon-based bacteriophage vectors and pUC/M13mp-based plasmid, filamentous phage or phagemid vectors, unable to replicate outside bacterial cells. For cloning and prokaryotic expression of recombinant DNA sequences, disabled E. coli K12 derived bacterial host strains (e.g. TOP10, SURE, JM109, DH5, etc) will be used.

MAMMALIAN EXPRESSION PLASMIDS
Such as pSV2, pCMV or pVAX plasmid families, or similar. Typically used on cell lines like HEK293T, HeLa, HT1080, L cells or similar. Transfer plasmids used for the production of viral vectors (please see below) also contain mammalian cell expression cassettes.

RETROVIRAL VECTOR SYSTEM (MOLONEY MURINE LEUKAEMIA VIRUS-BASED)
Transfer plasmids: such as pWZL, pBabe, pMIG families or similar.
Packaging plasmids: pGagPol(M57), pEnv(K73-Eco) ecotropic envelope, or similar.
Producer cells: HEK293 variants, or similar.
Packaging cells: Cell Biolabs' HEK293-based Platinum Retroviral Packaging Cell Line E (PlatE, ecotropic), PlatA (amphotropic) or similar. Miller's NIH 3T3 murine fibroblast-based PT cell series (amphotropic), or similar.
Characteristics: In the plasmid form able to replicate only in bacterial cells and, if plasmid backbone contains SV40 ori/enhancer, transiently in T-antigen-expressing cells like HEK293T. In the disabled retroviral vector form unable to replicate in the absence of helper virus, or in non-murine cells when using ecotropic envelope. The vectors are sensitive to inactivation by human complement. These systems are attenuated by the removal of the pol and env genes and partial deletion and repression of gag translation. Self-inactivating (SIN) mutations in the 3' LTR considerably decrease the risk of insertional mutagenesis. Absence of gag, pol and env sequences in the vector, and the use of split function packaging systems (either three-plasmid transient transfection or split-function packaging cells), make extremely unlikely the generation of replication competent retrovirus through recombination events.

LENTIVIRAL VECTOR SYSTEM (HIV-1-BASED, PERHAPS OTHERS FROM NON-HUMAN HOSTS)
Transfer plasmids: such as pHR, pRRL and pCCL families or similar.
Producer cells: HEK293 variants, or similar.
Characteristics: In the plasmid form able to replicate only in bacterial cells and, if plasmid backbone contains SV40 ori/enhancer, transiently in T-antigen-expressing cells like HEK293T. HIV-1 vectors will be generated by transient co-transfection of three (second-generation) or four (third-generation) plasmids into the producer cells. These standard lentiviral vectors are sensitive to human complement. These vectors will be replication defective (pol, env and partial gag deletion). Second-generation packaging plasmids are also vpr, vif, nef and vpu-deleted; third-generation plasmids are additionally tat-deleted. Lentivirus vectors will also have an additional 3'LTR self-inactivating (SIN) deletion, resulting in the loss of promoter/enhancer functions in the 5'LTR in the transduced target cells. The absence of packaging signal, psi, in the plasmids encoding the structural or accessory proteins will prevent the packaging of these sequences into infectious virions. The generation of a replication competent lentivirus will require multiple recombination events, making this extremely unlikely. Integration-deficient lentivector variants are mutated in the catalytic active site of integrase, preventing significant chromosomal integration of provirus and leading to the formation of increased levels of episomal vector circles; this results in highly reduced risk of insertional mutagenesis.

ADENO-ASSOCIATED VIRUS (AAV) VECTOR SYSTEM (TYPICALLY BASED ON AAV-2 GENOME)
Transfer plasmids: such as pAAV and pscAAV families, or similar.
Packaging plasmids: second-generation pAdDeltaF6 and p5E18-VD2/9, or similar.
Producer cells: HEK293 variants, or similar.
Characteristics: In the plasmid form able to replicate only in bacterial cells and, if plasmid backbone contains SV40 ori/enhancer, transiently in T-antigen-expressing cells like HEK293T. This second-generation AAV-2 genome-based production system does not require helper adenovirus. It is based on transient transfection of three plasmids
in HEK293T cells and effectively prevents adventitious appearance of replication-competent derivatives during vector production. Resulting vector is replication-defective. Use of different vector serotypes may alter vector tropism. We will use several serotypes, including AAV9 capsid protein, known to cross the blood-brain-barrier in at least young mammals.

ADENOVIRUS VECTOR SYSTEM (TYPICALLY BASED ON Ad5)
Transfer plasmids: Shuttle plasmid pDeltaE1sp1A, or similar.
Packaging plasmids: pBHG10 (deltaE1, delta psi, deltaE3), or similar.
Producer cells: HEK293 variants, or similar.
Characteristics: In the plasmid form able to replicate only in bacterial cells and, if plasmid backbone contains SV40 ori/enhancer, transiently in T-antigen-expressing cells like HEK293T. These will be replication defective vectors with deletions in the E1 and E3 region. Vectors may also have additional deletions in the E2 and/or E4 regions of the viral genome, or be “gutted”. E1 is the primary early gene transcription factor triggering the replicative gene expression cascade of other early genes, which then leads ultimately to expression of so-called late, or structural genes of the virus. Vectors are produced in E1-transcomplementing 293 cells. Over 90% of individuals are seropositive for Ad5.

PRODUCER AND RECIPIENT CELLS FOR VIRAL VECTORS
Human and other mammalian tissue culture cell lines or primary cells, as described in previous section, producing disabled retroviral, lentiviral, AAV or adenoviral vectors or transduced with them. These cells are unable to colonize humans, unable to survive outside specialised tissue culture conditions and show no evidence of innate ability to secrete transmissible agents. Producer or transduced cell cultures may contain viral vectors resulting from production process or remaining from transduction procedure, with their corresponding potential hazards.

VECTORS
Prokaryotic cloning and expression vectors.
Eukaryotic expression plasmids containing eukaryotic promoters and termination signals (of viral and mammalian origin).
Plasmids encoding retroviral, lentiviral, AAV and adenoviral vectors.
Retroviral, lentiviral, AAV and adenoviral vectors, including HIV-based vectors.

SOURCE OF INSERTS
Human and other mammal, mainly rodent (e.g. BDNF, GDNF, etc.), bacterial (beta-galactosidase, selectable markers, non-toxic C-terminal domain of tetanus toxin or TTC) or Jelly Fish, Aequorea victoria (GFP, CFP, YFP, RFP), or similar.
Non-hazardous inserts may include reporter genes, selectable genes, gene correction (by homologous recombination) cassettes, cDNAs encoding survival of motor neuron (SMN), its paralogs and other non-toxic genes, or similar.
Potentially hazardous inserts have the following functions:

TRANSGENES ENCODING MEGANUCLEASES, ZINC-FINGER NUCLEASES, SITE-SPECIFIC INTEGRASES, TRANSPOSASES AND OTHER DNA-CUTTING AGENTS.
Meganucleases are DNA endonucleases with recognition sites of at least 12-bp. They determine the homing mechanism used by a range of mobile genetic elements. The archetypical enzyme is I-SceI, and a range of artificial variants have been produced. Zinc-finger nucleases (ZFNs) are chimeric enzymes designed to have DNA endonuclease activity on similarly large target sites. ZFNs result from the fusion of zinc-finger domains (endowing site-specific DNA binding) and a non-specific endonuclease domain from a restriction enzyme. Meganucleases and ZFNs are in practice naturally or artificially designed to recognise and cut at rare DNA target sites. Similar effects could be expected from other enzymes or agents able to effect low-level DNA cutting. These DNA-cutting transgenes will be used mostly in the context of mammalian expression plasmids, lentiviral and adenoviral vectors.

NATURAL AND CHIMERIC NEUROTROPHINS, GFLs, CYTOKINES AND OTHER REGULATORS.
Expression of complementary cDNA genes encoding a variety of natural neurotrophins (e.g. brain-derived growth factor, BDNF), GDNF family ligands (GFLs, e.g. glial cell line-derived neurotrophic factor, GDNF), cytokines (e.g. cardiotrophin-1) and other regulatory proteins has shown therapeutic potential in a variety of disease models, including nervous system disorders. Additionally, these proteins can be endowed with retrograde and trans-synaptic transport properties by fusion with the non-toxic C-terminal domain of tetanus toxin (TTC), which may enhance their therapeutic potential. We will mostly use these transgenes in mammalian expression plasmids, lentiviral and AAV vectors.

**TRANSGENES AFFECTING DEVELOPMENTAL AND DIFFERENTIATION PATHWAYS, AND ONCOGENES.**

Human, mouse and perhaps other induced pluripotent stem (iPS) cells with properties similar to embryonic stem (ES) cells can be generated from skin fibroblasts and other cells by co-expression of various combinations of transgenes (for instance OCT4, SOX2, NANOG and LIN28; or OCT3/4, SOX2, KLF4 and c-MYC). These ES and iPS cells can subsequently be induced to differentiate into lineages of interest by transgene expression and/or drug treatment. cDNA sequences originating from humans or other eukaryotes will be used for this purpose. As well as "wild type" sequences, we may include sequences that are known to be mutated (either by deliberate genetic manipulation or by use of cDNA derived from cell lines harbouring known mutations). We will use a range of such cDNAs with the main goals of deriving iPS cells, inducing specific lineage differentiation of ES and iPS cells, or inducing immortalisation (overexpressing TERT) to facilitate tissue culture, mostly using retroviral and lentiviral vectors.

**SMALL INHIBITORY RNAs (siRNAs).**

Small inhibitory RNAs (siRNAs) are double-stranded RNA segments complementary to endogenous mRNA sequences which result in their specific degradation or inhibition. Synthetic siRNAs and gene transfer vectors encoding a variety of siRNAs to mRNAs of interest will be constructed. These siRNA vectors will be transferred into mammalian cells to inhibit gene expression. Target genes may include p53, PARP1, CYCD1 and others, mostly using lentiviral vectors for cassette delivery.

**PROMOTERS AND OTHER REGULATORY AND/OR STRUCTURAL SEQUENCES.**

Genomic sequences originating from humans or other eukaryotes and viruses will be cloned into the plasmid and viral vectors. These sequences are regulatory or structural in nature and include locus control regions (LCRs), chromatin opening elements (e.g. UCOE), insulators, promoters, scaffold/matrix attachment regions (S/MARs), post-transcriptional regulatory elements and others. As well as "wild-type" sequences, we may include sequences that are known to be mutated (either by deliberate genetic manipulation or by use of DNAs derived from cell lines harbouring known mutations). With the exceptions noted below, these elements will be used in mammalian expression plasmids, retroviral, lentiviral, AAV and adenoviral vectors.

Many lentiviral (and perhaps some retroviral) vectors used in the study will contain wild-type or mutated versions of an enhancer of gene expression derived from woodchuck hepatitis virus (WHV) called the woodchuck post-transcriptional regulatory element, WPRE. The wild-type element is capable of expressing part of the X protein from WHV. The truncated or full-length hepadna virus X-proteins may have oncogenic properties. We will treat this as a potential risk in accordance with the recommendations of HSE SACGM. However, it should be noted that HIV vectors containing wild-type WPRE have an excellent safety profile in a tumour-prone animal model and have been extensively used in animal experiments world-wide.

S/MAR sequences can lead to episomal maintenance of circular double-stranded DNA molecules by endowing them with replication and segregation capabilities in mammalian cells. S/MARs are being explored in the context of mammalian expression vectors to study their efficiency to induce such episomal maintenance. Successful episomal maintenance would imply replication of the episome. We are exploring S/MARs in the context of mammalian expression plasmids, lentiviral and AAV vectors.

**Evaluation of foreseeable effects**

**ACCIDENTAL CONTAMINATION OF WORKERS IN THE LABORATORY**

LIKELIHOOD: LOW; CONSEQUENCES: MODEST; OVERALL RISK: MEDIUM/LOW.

Bacterial hosts are attenuated for growth in the absence of special growth media, and the ability to adhere to the gut lining. Viral vectors are replication-deficient, and those with integration capability are human complement-sensitive with the standard viral envelopes. Established and primary cells are unable to colonize immunocompetent human hosts and show no evidence of innate ability to secrete transmissible agents.

Possible effects of accidental exposure of laboratory workers

The main hazard in the project is deemed to be the potential transduction of a laboratory worker with an integrating vector (retroviral or lentiviral) encoding a pro-oncogenic
transgene or element (i.e. growth factor, oncogene and the like). The route of exposure could be accidental injection, ingestion, inhalation, skin lesions or mucosal surfaces. Biological barriers and class 2 measures are in place to minimise the likelihood of such an event. In any case, as all viral vectors are replication-defective and retrograde transport and blood-brain barrier crossing are inefficient processes, transduction would essentially be limited to the cells directly exposed to the vector, most likely to be differentiated cells lacking extensive proliferative capacity. The likelihood of the integrating vector additionally causing insertion mutagenesis (disruption or over-activation of endogenous gene at integration site) is extremely low at the doses that could be received by accidental exposure. Crucially, given that tumorigenesis is a multi-step process thought to require several genetic alterations, accidental exposure to a single hazardous vector would not be expected to cause cancer but at the most to lead to a cancer-prone state in the affected cells.

**ACCIDENTAL ESCAPE INTO THE ENVIRONMENT**
**LIKELIHOOD:** NEGLIGIBLE; **CONSEQUENCES:** NEGLIGIBLE; **OVERALL RISK:** EFFECTIVELY ZERO.
Bacterial hosts are attenuated for growth in the absence of special growth media, and the ability to adhere to the gut lining; all manipulations with bacteria take place at containment level 1. All viral vectors are replication-defective, and manipulations with viral vectors, their packaging or producer cells, as well as their primary and established cell targets will take place at containment level 2. Retroviral and lentiviral vectors are sensitive to desiccation and have a half life of only 5-8 hours under optimum laboratory conditions. AAV and adenoviral vectors are relatively stable and could potentially survive for protracted periods in the environment, but they are non-replicating and essentially non-integrating. Cells are unable to survive outside the laboratory environment. Procedures are in place to deal with accidental spillage. All waste material is dealt with as described under section 12. The laboratories are kept secured when not in use.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity.  (*Measures & Justification*)

The handling of primary human cells and viral vectors that contain potentially hazardous sequences will be restricted to containment level 2. However, vectors that do not encode such potentially hazardous elements, or cells genetically modified by such vectors, may be used at containment level 1.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste – All contaminated waste is autoclaved in a dedicated Departmental waste autoclave used at 121° C, 22 psi, for >30 minutes (100% kill). Temperature validation provided by means of an internal thermolog. The autoclave is serviced every six months and documentary evidence of correct function stored on site. The resultant sterile waste is then placed in the College’s general waste disposal system.

Liquid Waste – All liquid waste is inactivated with solutions of either hypochlorite (5000 ppm chlorine), Virkon (2%) or ethanol (70%) for at least 1 hour after which it is disposed down the designated sinks.

**Is an emergency plan required according to regulation 20?**  N

**If yes, tick to confirm that it is attached to this form**  N

**Tick to confirm that you have attached a risk assessment to this form**  Y

**Tick if you are claiming exemption from disclosure for section of the risk assessment**  N

**Please enter comments on the GM safety committee on the risk assessment**
The risk assessment was assessed by our Genetic Modification and Biological Safety Group and the group agreed that this was Class 2 work. Following advice from several members of the group, the risk assessment underwent minor modification and was then approved, subject to receipt of CU2 form by HSE.
The laboratory is developing mucosal vaccines to *c. difficile* (see www.cdvax.org). As part of this work it is necessary to identify suitable antigens from *C. difficile* that are suitable for use in vaccine formulation. This, in turn requires analysis of genes in *C. difficile* by insertional inactivation and the study of mutants. To achieve this targeted insertional mutation is the most efficient method and requires the construction of GMMs.

The parental organism is *Clostridium difficile*, a Gram-positive bacterium. This microorganism is a defined as hazard.
group 2 in the ACDP list of pathogens. This bacterium is strictly anaerobic and short exposure to air will kill it. However, it can form spores which are dormant, heat resistant, desiccation resistant and easily dispersed in air. This organism can produce infection in animals and humans. This almost always occurs in the elderly and those in hospital and who have been treated with antibiotics which precipitates the germination of spores, outgrowth and production of a potentially fatal infection. Control of disease is mediated by antibiotic therapy. C. difficile is unable to produce infection in healthy people who are not under antibiotic therapy but a risk for dispersion is possible. In animals the disease is not controlled and in livestock which are being treated with antibiotics incidents of C. difficile gastroenteritis is common but no control measures are in place.

Host/vector system

The parental strain used for genetic manipulation is derived from the strain referred to as 630. Strain 630 is an 012 ribotype and was isolated from an infected patient. It is used by the research community as a laboratory strain for genetic manipulation. The strain is resistant to erythromycin but for cloning a erythromycin sensitive strain is used (630Derm) that has the natural erm gene deleted. For genetic manipulation the intended purpose is to delete genes in C. difficile, that is, to create knockout mutations. To achieve this appropriate plasmids are constructed using the pMLT8000 (obtained from Pro N. Minton (Nottingham) and then introduced from E. coli to C. difficile by conjugation. Introduced DNA is recombined into the C. difficile chromosome by a double crossover recombination with positive selection using erythromycin resistance. As a double crossover occurs the integration is stable and cannot excise, moreover, no autonomously replicating plasmids are introduced.

Origin & function

To delete DNA of C. difficile it is necessary to construct a plasmid (derived from the pMLT8000 plasmid series) that carry segments of C. difficile DNA flanking an antibiotic resistant gene (typically erytrhomycin resistance). When introduced into C. difficile this DNA recognises self DNA, a recombination event occurs and in the process DNA is deleted from the host genome. There are various ways in which this can occur but in every case no heterologous DNA is introduced other that the ermR gene and segments of non-functional plasmid DNA. Thus, the resulting host genome will not express foreign proteins and, when compared to the host strain will be devoid of one or more C. difficile genes and therefore potentially less 'fit' than its parent.

Evaluation of foreseeable effects

a) accidental escape into the environment
Potential risk when transporting or moving live cultures.
The risk will be minimised by all work being conducted in a level 2 containment facility with robust hygiene and air sterilisation (Medixair UV units). Spills will be contained by Virkon sterilisation and disposal of waste in double sealed bags and autoclaving. When samples are moved to the animal facility sealed chambers (snap lid boxes) will be used and moved on trolleys.

b) bodily contact or ingestion
Low risk since users will always wear appropriate microbiological coats and gloves at all times. The risk of ingestion would be essentially zero since all pipetting uses battery operated pipettors or manual pipettman within an anerobic chamber. Should exposure occur the user will wash hands with appropriate antibacterial soaps. No user will be allowed in the unit who is on antimicrobial treatment or has been (including 2 weeks post termination of treatment).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

nla
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All work with bacteria will be conducted in a class 2 designated lab in the Sch Bioi Sciences (rm 4-32).
Solid waste will be double bagged and sealed then autcolaved (121 degreesC 30min at 15 psi). This is sufficient to kill all bacteria.
Liquid waste will be either sterilised by autcolaving (as above) in sealed containers or inactivated using immersion in Virkon (minimum 1 h) which is sufficient to kill spores of C. difficile.
Laboratory spills where they occur will be disinfected using Virkon spray and wipes. Wipes are then bagged and autoclaved as solid waste.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

GMBSG were satisfied with the risk assessment and assignment to class 2. subject to HSE CU2 approval. Only minor amendments were required. approved by the Biological Safety Officer, chairman of the GMBSG.

Project Additional Information

Project Ref: 217/03.1

Date Ackn'd: 03/01/2003

CU2 Project Title: USE OF LENTIVIRUS VECTORS TO STUDY CELL GROWTH CONTROLS

Class: Class 2

Culture Vol: < 1 litre

Non-GMM Consent Granted: not applicable

Project notified under transitional arrangements: N

Historical Significant Changes: Project transferred to GM77

Project Additional Information

02/03/2022
**Purposes of the contained use**

Deregulation of cell controls affecting proliferation and apoptosis is a sine qua non of cancer development. This programme of work will use lentivirus vectors to aid analyses of the functions of cellular and viral genes involved in cell cycle regulation and cell survival. The lentivirus vector system will enable the efficient transduction of human and murine cells grown in tissue culture with either cDNAs encoding cellular and viral genes or cassettes encoding short interfering RNAs (siRNA).

**Recipient or parental organism**

The lentivirus vectors to be used in this programme of work are severely disabled derivatives of human immunodeficiency virus type 1 (HIV-1). A number of genes required for HIV-1 replication and virulence have been deleted from the lentivirus sequences contained in the vector. The virus vectors are propagated as plasmids in E. coli strains. Packaged virus able to infect human, mouse and other animal species are produced by cotransfection of the lentivirus vectors with other plasmids which provide proteins required for packaging in trans. Although the packaged lentivirus is able to transduce efficiently genes cloned in the lentivirus vector plasmid, the virus is totally unable to replicate in these cells. No infectious virus can therefore be produced.

**Host/vector system**

The standard vectors to be used are based on deleted/mutated HIV-1 genomes, pseudotyped with a vesicular stomatitis virus (VSV) envelope (VSV-G) allowing infection of a broad range of cell types. In some cases these recombinant HIV-1 will encode a green fluorescent protein (GFP) from a bicistronic transcript allowing the identification of infected cells by fluorescence microscopy or flow cytometry. In other cases the vector will encode a gene for drug resistance (e.g., Neomycin or Hygromycin). The delivery systems to be used involve three separate plasmids that are transiently cotransfected into the human 293T cell line to produce pseudotyped, packaged viruses. One plasmid encodes the HIV-1 derived vector, one encodes the VSV-G and one provides functions in trans for packaging. Two very similar systems will be used which only differ in the details of generating infectious virus:

**SYSTEM A PLASMIDS**

1. pAG131 - the HIV-IRES-GFP expression construct from which env, vif, vpr, vpu genes have been deleted and the tat gene is inactivated by inverting its open reading frame. These deletions and inversion make the resulting recombinant virus completely incapable of replication in the absence of helper proteins encoded by additional plasmids. The AG131 plasmid still encodes HIV-1 Gag and Pol and will include the cDNA of interest or encode the siRNA.
2. pME-VSV-G - this is a plasmid encoding the VSV-G envelope protein for pseudo-typing the lentivirus.

**SYSTEM B PLASMIDS**

1. pAB286 or pHOX-GFP or pHOX with GFP replaced by the siRNA cassette from pSUPER plus target sequence [see Brummelkamp et al. (2002) Science 196, 550-553.] or a cDNA. These plasmids all encode self-inactivating (SIN) lentivirus with a 400-nucleotide deletion in the 3' LTR. This deletion abolishes all LTR promoter activity and therefore the vectors are incapable of replication. The HIV-1 Vpr, Vif, Vpu, Nef and Tat genes are also deleted in the vector.
2. pRD1274 (pMD.G). This plasmid encodes the VSV-G envelope for pseudotyping the lentivirus.

**Origin & function**

The cDNAs carried by the lentivirus vectors will comprise two classes: (1) cellular and viral genes encoding proteins that promote cell proliferation and/or decrease apoptosis - such genes are generally, but not exclusively, oncogenes and (2) cellular and viral genes encoding proteins that inhibit cell proliferation and/or promote apoptosis - such genes are generally, but not exclusively, tumour suppressor genes. The siRNA cassettes will also comprise two classes: (3) siRNAs directed against cellular and viral genes encoding proteins that promote cell proliferation and/or decrease apoptosis and (4) siRNAs directed against cellular and viral genes encoding proteins that inhibit cell proliferation and/or promote apoptosis. These are described in more detail below:

(1) Lentiviruses carrying cellular and viral cDNAs encoding proteins that promote cell proliferation and/or decrease apoptosis.
Only single growth-promoting (for example EBNA-2, EBNA-3C, LMP1, RUNX1, RUNX3, Id2 and B-myb) and anti-apoptotic genes (for example Bcl-2) will be transduced in this programme of work. As cancer development is a multistep process, transduction with such genes will not transform the infected cells. This programme of work will not include viral oncogenes which have multiple oncogenic activities such as the SV40 T antigen, nor will it include clusters of genes such as HPV16 E6-E7. Genes encoding toxins will not be included in this work.

(2) Lentiviruses carrying cellular and viral cDNAs encoding proteins that inhibit cell proliferation and/or promote apoptosis.

These genes, which include tumour suppressor genes (for example p53, ASPP, RB, P130) and pro-apoptotic genes (for example Bax, Bik and Bad), are expected to inhibit cell growth.

(3) Lentiviruses encoding siRNAs directed against cellular and viral genes encoding proteins that promote cell proliferation and/or decrease apoptosis.

Short interfering RNAs (siRNA) are designed to ablate expression of a specific gene target. Ablation of oncogene expression, for example, would in many instances inhibit cell cycling or promote cell death. Expression of this class of siRNA (for example siRNAs directed against EBNA-2, EBNA-3C, LMP1, RUNXI, RUNX-3, Id2, iASPP, mdm2, RAS and B-myb), would be equivalent to that outlined in (2) above. That is, cell growth is likely to be inhibited. It is noted that siRNA sequence specificity is very precise, and generally there is insufficient homology between the mRNA target sequences of mouse and human genes for cross-species interference to occur. For example, siRNAs directed against mouse genes are unlikely to affect growth of human cells.

(4) Lentiviruses encoding siRNAs directed against cellular and viral genes encoding proteins that inhibit cell proliferation and/or promote apoptosis.

Expression of siRNAs which ablate tumour suppressor gene function has the potential to promote cell growth. Lentiviruses expressing siRNAs directed against, for example, p53, ASPP, RB and p130 may predispose cells to further oncogenic events, but would not by themselves transform the cell. This programme of work will be restricted to expression of a single siRNA directed against this class of genes, or the expression of multiple siRNAs which affect the same regulatory pathway. Examples of the latter include the p53 pathway (eg ablation of p53 or ASPP would be expected to have similar consequences) and the RB pathway (eg ablation of RB and p16 INK4a is likely to be equivalent).

Evaluation of foreseeable effects

Lentivirus vectors are designed to infect efficiently both actively proliferating and resting cells of many different species and lineages. The two major foreseeable effects are accidental transduction of laboratory personnel and animal species such as mice. In this respect, it should be noted that these vectors are replication-defective and the risk is therefore limited to cells accidentally transduced with the packaged vector. The consequences for animal species are therefore negligible, since even in the extremely unlikely event that mice were exposed to the packaged vector, the virus could not propagate.

Exposure of laboratory personnel to packaged vectors containing growth promoting genes such as oncogenes or anti-apoptotic genes (see (1) above) could result in some growth advantage of transduced cells. Similarly, transduction with lentiviruses encoding siRNAs directed to growth inhibitory genes such as tumour suppressor genes and pro-apoptotic genes (see (4) above) could also result in a growth advantage. It should be noted, however, that the single genes targeted in these studies can not by themselves result in cell transformation, even in highly responsive rodent cells. Targeting of combinations of genes with the potential to cause cell transformation has been specifically excluded from this programme of work. It should also be noted that with the scale of production to be used, it is extremely unlikely that accidental transduction will occur in stem cells at risk of carcinogenic development.

Accidental exposure of laboratory personnel with packaged vectors carrying genes that inhibit cell proliferation and/or are pro-apoptotic (see (2) above) is very unlikely to have any consequence. Similarly, transduction with lentiviruses encoding siRNAs directed to growth promoting genes such as oncogenes and anti-apoptotic genes (see (3) above) would only inhibit the growth of the cells infected. In principle, transduction of stem cells could inhibit their growth and prevent them participating in tissue maintenance. In practice, it is unfeasible that sufficient stem cells would be affected in this way to have any consequences for human health.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be collected in double autoclave waste bags and subjected to autoclaving under approved conditions. 100% kill is achieved with this procedure.

Liquid waste will be collected in polythene contains and treated for 24 hours with 1% Chloros. This achieves 100% kill.

Small laboratory spills will be treated with 70% ethanol; high concentrations of alcohol effectively kill enveloped lentiviruses (van Engelenburg et al., 2002, J. Hosp. Infect. 51:121-125). Larger spills will be cleaned with 1% Chloros. Contaminated paper towels are treated as solid waste.

Extracts will be made from tissue culture cells for biochemical and cell biological procedures (eg microscopy). The simple act of infection inactivates much of the input virus as it becomes uncoated upon entry into the cell. When making cell extracts, residual virus will be inactivated by detergent treatment (ie 1% SDS or 0.5% NP40). Studies have shown that HIV is very sensitive to inactivation even with non-ionic detergents (Ukkonen et al., 1988 Eur. J Clin. Microbiol. Infect. Dis. 7:518-523). The effectiveness of the detergent treatments will be validated by plating transduced cell extracts on indicator cells and selecting for antibiotic resistance carried by the vector. For flow cytometry and microscopy techniques, the transduced cells will be fixed with 70% ethanol or 4% formaldehyde or 4% paraformaldehyde. These treatments achieve 100% kill.

It was unanimously agreed that Containment Level 2 was appropriate in view of the slight theoretical risk to human health of tranasducing genes designed to alter cellular growth controls. It was noted that other groups working with lentivirus vectors had also designated their work as a Class 2 Activity.

### Project Additional Information

#### Purposes of the contained use
The generation of bacterial artificial chromosomes (BAC) containing entire herpesvirus genomes allows the use of powerful bacterial cloning strategies to introduce precise modifications into the virus. These modified herpesvirus BACs can be transfected into mammalian cells to study the impact of these mutations in the context of the entire genome. By stimulating the lytic cycle, infectious virus can also be recovered from these transfected cells.

#### Recipient or parental organism
Sequences comprising the Epstein-Bar virus (EBV) and herpesvirus saimiri (HSV) A11-S4 genomes will be inserted into BAC vectors, which will then be cloned and propagated in attenuated E. coli strains DH5 and DH10. Modified BAC constructs will be transfected into mammalian cell lines to generate virus stocks. It is envisaged that HEK 293 cells will be used initially to generate EBV stocks. Replication-defective EBV will be propagated in a 293 line containing an integrated full-length EBV genome to provide replication factors in trans. HSV will initially be propagated in either owl monkey kidney cells or marmoset embryonic fibroblasts, in which the virus is spontaneously lytic. In principle, infectious virus can be generated in any mammalian cell line if the replication cycle is stimulated, and other lines may be used to propagate virus as they become available.

#### Host/vector system
BAC vectors are F-factor-based plasmids which are conjugated-deficient, and are therefore extremely unlikely to transfer to bacteria in the environment. The HVS A11-S4 genome has already been inserted into a BAC vector at the University of Leeds (White et al., J. Gen. Virol., in press). This HSV strain is attenuated and lacks the stpA gene required for oncogenic transformation. Details of the proposed HVS modifications are given in the accompanying risk assessment. EBV sequences to be cloned include the entire wt sequence and derivatives with modifications of immortalisation genes, insertion of non-hazardous marker genes and viral genes as specified in GM217/99.2.
The nature of modifications to be introduced to the EBV genome using BACs are broadly the same as those reflected in previously approved protocol GM217/99.2, namely the deletion or alteration of immortalising genes, the insertion of non-hazardous marker genes or sequences and the construction of viruses that conditionally express defined viral genes. Because modifying herpesvirus BACs does not require full viral function, we will also modify or delete viral genes or structural DNA regions involved in virus latency, replication and packaging, and in the co-ordination of the viral transcription programs. The aim of our work with HVS is to identify the viral genes and DNA motifs involved in the latent and lytic replication and packaging functions of HVS, and to develop the virus as a gene delivery system. This will be achieved by 1) deletion (and subsequent complementation) of genes involved in these processes. 2) in situ modification of these genes (eg fusion to GFP or other tags; mutation of putative domains) to dissect their function. 3) Addition of marker genes (eg antibiotic resistance, luciferase) driven by various promoters to identify differences in gene expression between integrated and episomal expression systems. 4) Tagging the viral episome and arrays of Tet operator repeats to allow the visualisation of the episome in live cells. 5) Cloning human and mouse genetic loci to study expression and regulation of mammalian genes in their natural context. Such work will initially comprise analysis of MHC and immunoglobulin gene loci, but may be extended to other gene loci, however, this work will exclude cloning of oncogenic or other potentially harmful genes.

Evaluation of foreseeable effects

Propagation of BAC-transformed attenuated E. coli strains is not expected to have any adverse effect. The BAC plasmids would be exceedingly difficult to transfer to wt E. coli and other bacterial species, and in any case viral genes would not be expected to be expressed in these bacteria. Generation of virus in transfected mammalian cell lines will give rise to recombinant virus that potentially will be able to replicate in certain primate species, including man. Both EBV and HVS are gammaherpesviruses, which have a restricted host range and grow slowly in vivo. Pathogenesis associated with A strains of HVS have not been observed in man, and the A11-S4 strain to be used has been further attenuated by removal of the transforming stpA gene. EBV is normally transmitted through exchange of saliva, and it is therefore unlikely that the virus would be transmissible under Containment Level 2 conditions. As outlined above, in the event that the recombinant EBV or HVS viruses to be used in this project were accidentally transmitted to laboratory workers, the pathogenicity of the viruses would be no greater, indeed probably less, than the wt viruses.

Release of the recombinant viruses into the environment would have no adverse effect, as both infect only primates.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be collected in double autoclave waste bags and subjected to autoclaving under approved conditions. 100% kill is achieved with this procedure.

Liquid waste will be collected in polythene containers and treated for 24 hours with 1% Chloros. This achieves 100% kill.

Small laboratory spills will be treated with 70% ethanol, which effectively kills enveloped herpesviruses. Larger spills will be cleaned with 1 Chloros. Contaminated paper towels are treated as solid waste.

Extracts will be made from tissue culture cells for biochemical and cell biological procedures (eg microscopy). The simple act of infection inactivates much of the input virus as it becomes uncoated upon entry into the cell. Any residual virus will be inactivated by detergent treatment (ie 1% SDS, 0.5% NP40) when extracts are made. The effectiveness of detergent treatments will be validated by plating transduced cell extracts on indicator cells and staining for virus plaques or viral antigens. For flow cytometry or microscopy purposes, virus-transduced cells will be fixed with 70% ethanol, 4% formaldehyde or 4% paraformaldehyde. These treatments achieve 100% kill.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N
It was unanimously agreed that work on manipulating EBV and HVS sequences in BAC vectors in E. coli could proceed at Containment Level 1. Generation of recombinant EBV and HVS viruses by transfection of mammalian cells will be a Class 2 activity. Similarly, infection of mammalian cells in culture with the recombinant viruses will be carried out at Containment Level 2.

Disinfection by immersion
Disinfection by immersion in either hypochlorite solution (2,500 ppm available chlorine by dissolving Haz-Tabs in water) or Verkon (1%) is utilised for overnight treatment of glassware. Hypochlorite or Verkon is also utilised to disinfect suspensions infected with GMMs by incubation overnight. Disinfected liquid is then discarded in the sluice. It is unlikely that more than 5 litres of disinfected sample will be released at any one time.

Disinfection procedures are validated and monitored by a trained member of technical staff using the "in Use" test (Collins, 1983) which assesses survival.

Autoclaving to Destroy
GMM contaminated glassware is autoclaved using the Labclave on the glassware autoclave to destroy cycle at 121 degrees C for 35 minutes. GMM contaminated plastic disposable consumables including all tubes, petridishes, microtitre plates, tips, ependorfs, cuvettes and pipettes are sealed in autoclavable bio-hazard bags and stored in lined bins in a separate waste disposal room (T120) for autoclaving. These are then autoclaved using the Labclave on the Plastic discard autoclave to destroy cycle at 134 degrees C for 35 minutes. Laboratory coats are also autoclaved before being sent to the laundry.

The autoclave to destroy cycles are validated and monitored by a trained member of technical staff using spore suspensions (Sterikon-Bioindicators, Merck) and testing for survival.

CU2 Project Title DEFINING THE AUTOGRAPHA CALIFORNICA NUCLEOPOLYHEDROVIRUS (ACMNPV) GENES IMPORTANT IN BACULOVIRUS TRAFFICKING WITHIN INSECT CELLS, VIRUS TRANSMISSION BETWEEN CELLS AND PERSISTENCE WITHIN INSECT CELLS

Class CultureVolClass2 CultureVolumeClass3-4

Class 2 < 1 litre

Non-GMM Consent Granted not applicable
Project Additional Information

Purposes of the contained use

To contain the viruses and virus-infected cells and larvae to be used in the above project.

Recipient or parental organism

For insect cells and larvae the parental organism will be Autographa californica nucleopolyhedrovirus (AcMNPV) C6 strain (Possee, 1986)* containing an intact polyhedrin gene. This is a wild-type baculovirus found in the natural environment. As the accompanying risk assessment indicates, baculoviruses have a long and safe history of use in many countries as a natural biological control agent (Entwistle and Evans, 1985). The AcMNPV virus has also a long and safe history of use as an expression vector for the production of recombinant proteins in insect cells (King and Possee, 1992)*.

* See risk assessment.

Host/vector system

Vector: For insect cells and larvae the vector will be Autographa californica nucleopolyhedrovirus (AcMNPV) C6 strain (Possee, 1986)* containing an intact polyhedrin gene.

Host: The host organisms for these studies are either insect cell lines maintained in vitro: Spodoptera frugiperda Sf9 and Sf21, Trichoplusia ni (TnHi5, Tn368) or laboratory-reared insect larvae (Trichoplusia ni) maintained on simi-synthetic artificial diet (King and Possee, 1992)*.

* See risk assessment.

Origin & function

Origins and functions of the modified viruses.

In this project we intend to make recombinant AcMNPV in which selected AcMNPV genes (ie self genes) are replaced by modified versions. These modified versions will be either (a) tagged with a fluorescent marker protein (eg green fluorescent protein) to make it possible to trace virus infection within cells and larvae or (b) subjected to partial or complete deletions to test gene function in the virus replication cycle in cells or in larvae. [Note: The modified genes will be made by standard cloning techniques in disabled E. coli host strains and are therefore classified as Risk Assessment Level 1. Note: This risk assessment has been approved as Level 1 by OBU ACGM and is, therefore, not part of this submission]. Within the AcMNPV, the normal virus gene will be replaced by the modified gene by homologous recombination in insect cells in culture (a process that is used routinely to make recombinant baculovirus expression vectors; King and Possee, 1992)*.
Details of genes to be tagged or modified
The fluorescent protein tags to be added to the C- or N-terminus of the virus genes are commercially available (green, red and yellow fluorescent protein gene constructs are all from Clontech Ltd), and have been used extensively by us and others in similar studies using polyhedrin-negative baculovirus vectors (Grasela et al., 2000; unpublished data). These studies have shown that the tagged virus proteins behave in the same manner as the unmodified protein. The His (variety of commercial sources) and Flag (Sigma Ltd) tags are also commercially available and are routinely used in many studies to identify and purify the tagged protein from a background of non-tagged proteins.

The virus genes that we intend to modify in one or more of the ways described above include: polyhedrin, p10, chinatinase, p35, IAP1, IAP2, gp64, cathepsin, capsid polyhedron envelope protein, ORF 1629, GP37, GP64, EGT, all late expression factors (lefs), viral capsid associated protein (vp78), actin-rearrangement inducing factor (Arif-1), nuclear matrix associated phosphoprotein (pp31), ODV-E66, GP41, viral capsid associated protein (p95), p26, p74 (Ayres et al., 1994).

* see risk assessment.

Evaluation of foreseeable effects

With respect to human health:
The recipient organism for the AcMNPV vector will either be established insect cell lines maintained in laboratory culture or an established laboratory culture of T. ni larvae which are maintained in a contained facility. The insect cells are not capable of surviving outside of the laboratory culture conditions and pose no known threat to human health (the cells contain no known adventitious agents nor are they known to have transforming properties; even if they were found to contain these agents/properties it is highly unlikely that they would be infectious to human cells) (King and Possee, 1992). The larvae are insects found in the natural environment and pose no known threat to human health (ie do not carry human diseases).

Baculoviruses have a long history of safe use in the environment as natural bio-control agents (Entwistle and Evans, 1985; Carter, 1989). They are highly specific for insect species and although they have recently been shown to be capable of entering human cells by non-specific means under artificially imposed laboratory conditions, there is no virus gene expression and virus replication does not occur. The viruses are found in the natural environment and many studies have shown that they pose no threat to human or other animal health (Entwistle and Evans, 1985). The modified AcMNPV used in this project contains only modified virus genes (ie self genes) that may be deleted, partially deleted or tagged with auto-fluorescent proteins or small peptides. We do not expect or predict that the modifications we intend to make to the specified virus genes will modify baculovirus host-range in respect to hazards to human health.

All genes to be cloned are insect virus in origin. The genes may be tagged with fluorescent protein sequences derived from other sources (these have an established history of safe use as reporter proteins, eg Jelly-fish green fluorescent protein and its colour derivatives). Expression of any genes is strictly limited to insect cell systems because the promoters to be used (natural baculovirus promoter for the specified gene) are insect cell specific (reviewed in King and Possee, 1992; Miller, 1997; Grasela et al., 2000). There is therefore no anticipated or expected harm to human health from the GMMs.

To the environment
ACMNPV contains a polyhedrin gene that encodes a stable protein matrix (polyhedra) that enables the virus to survive in the environment (Granados & Federici, 1986). The GMM will contain a polyhedrin gene and, therefore, has the potential to survive in the environment. However, containment measures (see below) will be used to prevent the GMM being exposed to the environment.

The AcMNPV is specific for a few species of lepidopteran insect and does not infect other animals or humans (see comment above about risk to human health). Therefore the only animals at risk from the GMM are a limited number of species of lepidopteran insects (Huber, 1986; Cory et al., 1994)*. The modifications made to the virus are modifications to virus (self) genes (deletions, partial deletions, tagging with fluorescent proteins or peptides). These modifications are not expected nor predicted to alter host range or virus replication (other than to inhibit replication).

If the GMM (modified virus or larvae infected with modified virus) is released to the environment (Oxford Brookes University Gipsy Lane Campus), it is highly unlikely that it will encounter other baculoviruses/susceptible insects to permit the transfer of genetic material, but it is theoretically possible. The risk to the environment will be reduced by effective control measures, which are listed below.
In assessing our protocols and methods we have identified the following as foreseeable risks in allowing the possible and accidental release of virus or virus-infected cells or larvae:

1. Release of virus through human transfer (hands, clothing)
2. Release of virus through the drains via liquid waste
3. Release of virus through waste disposal of solid waste
4. Release of virus-infected larvae by escaping caterpillars.

We have put into operation the following procedures and regulations to reduce the risk of accidental release of virus or virus-infected larvae as follows:

1. Release of virus through human transfer (hands, clothing)
   All operations with Category 2 recombinant viruses will be carried out in either T110 or T111. All researchers will wear designated laboratory coats, which are autoclaved after use. Coats will be collected in designated bio-hazard bags and transferred to the autoclave for sterilising prior to being sent for routine cleaning. Hands must be washed before leaving the laboratory and sinks with hands-free operated ('magic') taps are located at the exit points of both laboratories.

   All researchers are issued with standard laboratory procedures, which include the washing of hands when leaving the laboratory and the wearing of laboratory coats. All new staff are given an induction programme by the Laboratory Manager for the Insect Virus Research Group.

   The autoclave (Boxer 400/400V (Vacuum)) was new in 2001 and is maintained on a regular service and maintenance contract, which includes annual validation tests to ensure that the cycles we use for the sterilisation of all waste and laboratory coats meets HSE guidelines.

2. Release of virus through the drains via liquid waste.
   Liquid waste containing recombinant virus is generated after infection of insect cells in culture with recombinant virus. All procedures that generate virus-contaminated liquid waste (cell culture medium, reagents, solutions) will be carried out in a designated Class II Safety Hood. All liquid waste will be collected in screw-top glass bottles or tissue-culture growth vessels inside the Class II Hood. The bottles of liquid waste will be transferred to stainless steel autoclave bins and the waste will be autoclaved prior to disposal into the drains. Any sterilised glassware will be recycled using our normal laboratory washing-up procedures.

   The autoclave was new in 2001 and is maintained on a regular service and maintenance contract (with Lab 3), which includes annual validation of our destruct cycles to ensure that the cycles we use for the sterilisation of all liquid waste meets HSE guidelines (121 degrees C for 15 min in the centre of the maximum load). The Class II Safety Hood (UniMAT-BS) complies with BS 5726 and is services and tested twice yearly in line with HSE guidelines.

3. Release of virus through waste disposal of solid waste
   Solid waste containing recombinant virus is generated after infection of insect cells in culture with recombinant virus and after infection of insect larvae. All materials used in the handling of infectious virus are disposable (culture flasks, pipettes, dishes, insect diet pots). All waste is put into bio-hazard bags and these are sealed prior to autoclaving on the solid waste destruct cycle (121 degrees C in the centre of the maximum load). This cycle is validated once per year by Lab 3 as part of their service and maintenance contract.

   The autoclave (Boxer 400/400V (vacuum)) is also insurance inspected on an annual basis (Zurich Insurance). Each individual destruct cycle is monitored by a chart print out of the steam, time and temperature.

4. Release of virus-infected larvae by escaping caterpillars.

   Infected larvae will be maintained in sealed 'polypots', placed in trays (1 larva per pot) and incubated in T111 or a lockable warm incubator room. All larvae transfers will be
carried out on trays with benchkote surrounded by layers of sticky tape to prevent escape of larvae accidentally dropped between culture box and polypot. All polypots are inspected everyday as part of the experimental protocol and the chances of larval escape from the polypots is virtually nil. However, the trays in which the polypots are stored will be lined with benchkote and edged with sticky tape to prevent any escapes from the tray.

All polypots (inc. larvae), benchkote etc. will be sterilised by autoclaving (see above) prior to disposal.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

| Not applicable. |

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

| None |

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

#### Management of liquid waste

Liquid waste containing recombinant virus is generated after infection of insect cells in culture with recombinant virus. All procedures that generate virus-contaminated liquid waste (cell culture medium, reagents, solutions) will be carried out in a designated Class II Safety Hood. All liquid waste will be collected in screw-top glass bottles or tissue-culture growth vessels inside the Class II Hood. The bottles of liquid waste will be transferred to stainless steel autoclave bins and the waste will be autoclaved prior to disposal into the drains. Any sterilised glassware will be recycled using our normal laboratory washing-up procedures.

The autoclave (Boxer 400/400 vacuum) was new in 2001 and is maintained on a regular service and maintenance contract (with Lab 3), which includes annual validation of our destruct cycles to ensure that the cycles we use for the sterilisation of all liquid waste meets HSE guidelines (121 degrees C for 15 min in the centre of the maximum load). The Class II Safety Hood (UniMAT-BS) complies with BS 5726 and is services and tested twice yearly in line with HSE guidelines.

#### Management of solid waste

Solid waste containing recombinant virus is generated after infection of insect cells in culture with recombinant virus and after infection of insect larvae. All materials used in the handling of infectious virus are disposable (culture flasks, pipettes, dishes, insect diet pots). All waste is put into bio-hazard bags and these are sealed prior to autoclaving on the solid waste destruct cycle (121 degrees C in the centre of the maximum load). This cycle is validated once per year by Lab 3 as part of their service and maintenance contract.

Laboratory coats are also autoclaved prior to washing.

The autoclave (Boxer 400/400V (vacuum)) is also insurance inspected on an annual basis (Zurich Insurance). Each individual destruct cycle is monitored by a chart print out of the steam, time and temperature.

#### Management of (potential) escaping caterpillars

Infected larvae will be maintained in sealed 'polypots', placed in trays (1 larva per pot) and incubated in T111 or a lockable warm incubator room. All larvae transfers will be carried out on trays with benchkote surrounded by layers of sticky tape to prevent escape of larvae accidentally dropped between culture box and polypot. All polypots are inspected everyday as part of the experimental protocol and the chances of larval escape from the polypots is virtually nil. However, the trays in which the polypots are stored will be lined with benchkote and edged with sticky tape to prevent any escapes from the tray. All polypots (including larvae), benchkote etc. will be sterilised by autoclaving (see above) prior to disposal.

The expected degree of kill that the inactivation procedures will achieve.

It is expected that the destruct cycles described above, for both solid and liquid waste, will achieve 100% kill.
The local ACGM committee met on October 31st 2002 to discuss the proposal. The question of whether an emergency plan was necessary was discussed and the committee concluded that it was not. No foreseeable accident would affect the health and safety of persons outside the premises since no accident could be foreseen that could result in release to the environment because all work is contained within the designated laboratory areas and no GM material leaves these areas. The criteria for containment level 2 were each considered. Records of staff training will be put in place for this activity.

The committee was informed that the proposal had been discussed in some detail with HSE when a representative visited Brookes in May 2002 and that they had visited the facilities and been satisfied with the facilities and the containment procedures which will be in place for this project. The committee was further informed that a draft of the risk assessment for this project had been sent to HSE and that they had been satisfied with the risk assessment and the final level of containment. He made two minor points concerning the presentation of the risk assessment, both of which had been incorporated into the final version presented to the committee.

Non-GMM Consent Granted

Project notified under transitional arrangements
### Purposes of the contained use

Research to understand how the shape of Leishmania cells is formed. This work will include culturing the cells and manipulation of their gene expression using standard deletion and overexpression techniques. Outcome of genetic manipulation will be assessed by microscopy to identify changes in the cell shape.

### Recipient or parental organism

- Leishmania mexicana
- Leishmania major

### Host/vector system

1. a series of vectors to provide constitutive expression of transgenes

   References:

2. a series of vectors are designed to provide templates for the PCR generation of amplicons for the introduction of genetic tags or knocking out of specific genes either by direct electroporation or in conjunction with CRISPR/Cas9 system.

   References:

### Origin & function

The main focus is on cytoskeletal genes that are likely to be important in constructing cell shape, motility and cell division. Usually these genes will be tagged to provide epitope or other marking of the expressed proteins. Portions of genes and flanking sequences will be PCR amplified from Leishmania mexicana and Leishmania major genomic DNA and inserted into plasmids for the generation of knock out and tagging vectors.

### Evaluation of foreseeable effects

**Risk to human health**

i) Hazards associated with the recipient organism

Leishmania mexicana and Leishmania major are listed by ACDP as hazard category 2 pathogens. The organisms do not form spores, are rapidly killed outside the culture vessel (or blood) by desiccation, osmotic shock or treatment with 0.2 % Trigene or 2% Virkon solution for 1 hour and the vector required for transmission and completion of the life
cycle is not naturally present in the UK. The organisms cannot penetrate unbroken skin. Genetic modification will likely reduce pathogenicity and most transformations will result in lethality. The organisms will only be maintained in culture form in a category 2 laboratory using a class II microbiological safety cabinet. The laboratory is restricted by swipe card access to authorised personnel only. Dedicated laboratory coats must be worn at all times and gloves must be worn whilst handling Leishmania cultures. Gloves and lab coats must be removed prior to exit.

ii) Hazards related to the vector system
None expected.

iii) Hazards related to the donor/insert sequence
None expected.

v) What is the overall likelihood that, in the event of exposure, the GMO would cause harm to human health?
Low

Risk to the environment
i) What is the capacity for the GMO to survive, establish or disseminate with and/or displace other organisms?
Leishmania mexicana and L. major is cultured in controlled conditions. The organism does not form spores, is rapidly killed outside the culture vessel (or blood) by desiccation, osmotic shock or treatment with 0.2 % Trigene or 2% Virkon solution for 1 hour and the vector required for transmission and completion of the life cycle is not naturally present in the UK.

ii) What is the ability to cause harm to animals?
L. mexicana and L. major - cultured in controlled Cat 2 conditions to prevent this and the vector required for transmission and completion of the life cycle is not naturally present in the UK. The organism cannot penetrate unbroken skin.

iii) What is the ability to cause harm to plants?
No interaction of GMO is expected.

iv) What is its ability to cause harm to micro-organisms?
No interaction of GMO is expected.

v) What is the potential for transfer of genetic material between the GMO and other organisms?
None, as vectors are non-mobilisable.

vi) What is the overall assessment of risk to the environment?
effectively zero

This work has been assessed and passed by the ACGM committee at Oxford Brookes University.

Attached are the full standard operating procedures (SOPs) and are outlined below.

Receipt and transportation of Leishmania mexicana and L. major will be carried out following appropriate regulations. See attached SOP L 1 for more details.

Culturing of the organism carried out in a Cat 2 designated laboratory at Oxford Brookes University in a Class II tissue hood all cultures are disposed of in 2% virkon overnight before autoclaving in an autoclave that is situated in the building. See attached SOP L02 and L03 for more details.

Storage of Leishmania mexicana and L. major will be in liquid nitrogen, which is stored in a secure room that only authorised personnel have access to. See attached SOP L04 for more details.

The culture laboratory and tissue culture hoods will be routinely. See attached SOP LOS for more details.

The waste generated during the culture of Leishmania mexicana and L. major will be treated with 2% virkon overnight before autoclaving. The autoclaves are located in the same building as the tissue culture facilities. See attached SOP L06 for more details.
A set of emergency procedures have been drawn up in case of spillages, accidents involving the organism and breaches of security. Please see attached SOP L07 for more details.
A series of general rules for the culture laboratory have been written, which everyone will adhere to and in doing so reduce the risks involved in culturing this organism. Please see attached SOP LOa for more details.
A set of SOPs have been drawn up for the intended experiments using Leishmania mexicana and L. major. Please see attached SOPs LOg - L 15.
Work involving Leishmania mexicana and L. major will only to be carried out by fully trained staff who will be trained by the supervisor who has 10 years experience culturing this organism.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

| n/a |

| n/a |

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1. Liquid waste in volumes greater than 100ml must be placed in the 1 litre Duran bottle in labelled “waste”. Virkon powder or 20m l concentrated Trigene should be added to the waste to give a final concentration of 2% or 0.2% respectively and the bottle should be autoclaved prior to disposal down the sink.
2. Close the lids of contaminated sealable plastic-ware (e.g. tissue culture flasks) tightly within the microbiological safety cabinet and place in the autoclave bag in bucket.
   The contents of non-sealable plastic-ware, eg tissue culture plates, should have 2% virkon or 0.2% Trigene added to each well and these should be then left to soak overnight in the designated area. The contents should be emptied the next day into the white waste pots and the empty plates should be discarded into the buckets.
3. Waste from the aspirator will remain in the liquid trap overnight, prior to disposal in a duran bottle (such as that detailed in point 1 above) containing sufficient concentrated trigene or virkon powder that the final concentration is 0.2% or 2% respectively. The bottle should be autoclaved prior to disposal down the sink.
4. Once metal buckets are full, fold the internal bag over loosely and put on the lid.
5. Contaminated stripettes should be immersed in a vessel containing 2% Virkon or 0.2% Trigene and left overnight, prior to placing in the metal buckets.
6. Small items such as Gilson tips and microfuge tubes are decontaminated by immersing in the white tubs containing 2% Virkon or 0.2% Trigene overnight prior to autoclaving. Syringe bodies are placed in a sharps bin.
7. Waste is autoclaved at 134°C for a minimum of 3 minutes in an annually validated autoclave in the Oxford Brookes University sterilisation unit, prior to disposal via a contracted waste disposal company.
   A 100% degree of kill is expected from these measures.
   See attached SOP L06 for more details

Comments from the ACGM committee meeting held on 21 June 2017.
The committee is satisfied that there are the infrastructure and expertise to carry out this work and maintain the required containment measures that are already in place at Oxford Brookes University. The CATII work will take place in a suite of laboratories that are already designated for CAT II work and the staff have shown the correct level of training to carry out this work. The GMO part of the work is using very well established and well characterised procedures and we are satisfied that all the risks have been adequately dealt with and containment is organised correctly.

Purposes of the contained use

To conduct in vitro expression tests to evaluate the possibility of protecting islet cells from damage during transplantation by expressing protective genes using a baculovirus vector.

Recipient or parental organism

Autographa californica multinucleopolyhedrovirus (AcMNPV), an insect baculovirus

Host/vector system

The vector is a recombinant baculovirus expression vector (based on AcMNPV) in which the natural polyhedrin gene promoter has been replaced with the cytomegalovirus early gene promoter to enable expression of recombinant proteins in mammalian cells (termed BacMam). The vector has a number of gene deletions that mean it is unlikely to survive in the environment; the vector cannot produce polyhedrin and so cannot protect virus particles within polyhedra.

The host cells are human primary islet cells isolated from donated pancreas under Research Ethics Approval at the University of Oxford and held at Oxford Brookes under Research Ethics approval for maximum 48 hour incubation.

Origin & function

Manganese superoxide dismutase 2 (SOD) catalyzes the dismutation of superoxide into oxygen and hydrogen peroxide. It out-competes damaging reactions of superoxide, thus protecting the cell from superoxide toxicity. As such, it is an important antioxidant defense in nearly all cells exposed to oxygen. Over-expression of SOD2 has been shown to significantly extend the lifespan of flies and mice.

B-cell lymphoma 2 (Bcl-2) is a member of a family of anti-apoptotic proteins that govern mitochondrial outer membrane permeabilization (MOMP). It is linked to a number of cancers through decreased apoptosis and is involved in resistance to conventional cancer treatment. However, over-expression of Bcl-2 in normal breast cells has not been shown to induce tumor formation.

XIAP - X-linked inhibitor of apoptosis gene encodes a protein that belongs to a family of apoptotic suppressor proteins inhibiting apoptosis, as well as inhibiting caspases involved in cell death. Overexpression of XIAP was shown to prevent beta-cell apoptosis in islet cell transplantation and protect islet cells in mice, enabling the acceptance of graft.

IkBalpha is a cellular protein that acts as a natural inhibitor of Nuclear factor kappa B (NF-KB) by binding and retaining it in the cytoplasm. After exposure to certain cytokines like TNFa and IL-1 b, IkBa is rapidly phosphorylated and targeted for ubiquitin-mediated degradation, which then releases NF-KB to travel to nucleus where it induces proinflammatory genes. However, a mutant version of IkBa that is non-phosphorylatable and non-degradable was shown to be promising in protecting human islet cells in vitro, which can potentially facilitate successful islet transplantation.

SOD-2 and Bcl-2 will be PCR-amplified from commercial plasmids (GeneArt®, Life Technologies Ltd), XIAP, IKBalpha and IKBalpha mutant will be outsourced for gene synthesis by Genewiz. Once the target genes are obtained, they will be inserted into baculovirus BacMam vectors for the transduction of mammalian cells.

These genes have all been over-expressed and published in the literature. The other genes to be expressed are reporter genes (EGFP, LacZ), which also have a history of safe use.

Evaluation of foreseeable effects

The modifications made to the insect viruses are not predicted to change host range or pathogenicity in either the vector system, insect or mammalian cells. The viruses are modified to delete genes that allow them to survive and infect insects in the environment.
The primary human islet cell samples are screened for pathogens as they are cells harvested for human transplantation and only if deemed insufficient in quality or quantity are they released for research purposes. These samples will be used for limited experiments at OBU (transduction with BacMam viruses up to 48 hours) and will not be sub-cultured. All handling of cells will be performed under category 2 level containment controls, with the samples posing no greater risk than other mammalian cells used within the laboratories.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Sterilisation is by chemical disinfectants (freshly made 1 % Virkon, DuPont) and autoclaving.

Liquid waste containing recombinant virus is generated after infection of insect or mammalian cells in culture with recombinant virus. All procedures that generate virus-contaminated liquid waste (cell culture medium, reagents, solutions) will be carried out in a designated Class II Safety Hood. All liquid waste will be discarded to 1 % Virkon solution inside the Class II Hood. The bottles of liquid waste will be left for at least one hour prior to disposal into the drains. Liquid waste can also be collected in glass screw top bottles and autoclaved prior to disposal to drains. Any sterilised glassware will be recycled using our normal laboratory washing-up procedures.

Solid waste generated after infection of insect or mammalian cells in culture with recombinant virus. All materials used in the handling of infectious virus are disposable (culture flasks, pipettes, dishes). All waste is put into biohazard bags and these are sealed prior to autoclaving on the solid waste destruct cycle (at least 121°C in all parts of the maximum load for 15 min). This cycle is validated once per year by (LSS Ltd) as part of their service and maintenance contract. The autoclave is also insurance inspected on an annual basis (Ashdale Engineering). Each individual destruct cycle is monitored by a chart print-out of the steam, time and temperature.

A 100% degree of kill is expected from both of these measures.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The ACGM committee noted that whilst recombinant BacMam GMO were normally classified for use at Containment level 1, the combination with primary human islet cells was assessed at containment category 2.

### Project Additional Information

**Purposes of the contained use**

The construction of PrP vectors.

**Recipient or parental organism**

E.coli JM109 cells are the recipients of modified plasmid vectors containing recombinant Prnp gene sequences.

**Host/vector system**

The host is the E. coli strain JM109, which is non-colonising and non-pathogenic to humans. The vector, which is non-mobilisable, is a modified Bluescript II plasmid containing a large portion of the mouse Prnp gene locus.

**Origin & function**

The plasmid vector contains a large portion of the gene locus encoding the mouse Prnp gene. Modifications are made to the DNA sequence of the plasmid vector so that Prnp gene inserts derived from sheep, cattle and kudu are incorporated. The recombinant plasmid vectors are propagated in E.coli cells. Appropriate DNA sequences are prepared for microinjection procedures.

**Evaluation of foreseeable effects**

The recombinant plasmid vector is non-mobilisable, which means that the potential for transfer of genetic material between the GMO and other organisms is unlikely to occur. The host E.coli cells are non-colonising and non-pathogenic to humans, and are therefore not likely to represent a serious hazard to the operator. In addition, the E.coli strain used is auxotrophic, thus its capacity for survival and dissemination in an open environment is limited and is not likely to be significant. Furthermore, as procedures are carried out in a GM-designated level 2 containment laboratory, with the addition of negative air pressure and HEPA filtration of extract air, there is not likely to be a threat of contamination to the outside environment. Waste materials produced in the containment laboratory, which may be contaminated with E.coli or recombinant E.coli organisms, are sealed in two layers of autoclave bags and sealed again within autoclave tins before leaving the containment laboratory for autoclaving and incineration.

The risk to an operator of accidental self-injection of biological material from this project is always present but is likely to represent an unlikely or remote possibility. During handling procedures, protective latex gloves are worn by operators in order to eliminate skin contact with biological materials. As the vast majority of the work involves the use of plasticware, including plastic tips for manipulation of biological materials, accidental self-injection of material is not expected. In the event of accidental ingestion of
biological materials, and in particular transgene DNA, by an operator, it is probably unlikely that the latter would passively recombine with human DNA. However, the actual likelihood of this occurring is unknown. It should be noted that the modified PrP genes under study in this project do not contain polymorphisms analogous to those in human disease, and are very closely related to naturally occurring animals PrPs.

If the mouse PrP plasmid vector, i.e. foreign PrP, was expressed in an operator e.g. following accidental exposure, the consequence of hazard could be severe. However, it is also possible that the consequence may not be severe. This is because, and it should be emphasised that, expression of foreign PrP protein would not itself represent the prion agent. Thus, expression of foreign PrP per se may not lead necessarily to prion pathology or to infectious prion disease.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

NB  Negative air pressure is incidental to the location of the work and is not essential for this project.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- Disposable equipment: autoclaved, then incinerated.
- Solid culture plates: autoclaved, then incinerated.
- Culture supernatants: treated with chloros overnight, then disposed.
- Reusable equipment: autoclaved, washed then recycled.
- Plasticware containing chemicals such as phenol or flammable liquids (e.g. ethanol incinerated.)

# Project Additional Information

**Purposes of the contained use**

Identification of virulence and colonisation factors of campylobacter jejuni.

**Recipient or parental organism**

**Host/vector system**

The host Campylobacter strains to be used are the laboratory adapted strains 81116 and 11168, and other wild type C. jejuni strains from veterinary, environmental and clinical sources. Laboratory adapted E.coli strains (DH5a, HB101, TOPO10F') will be used for cloning and expression studies, all of which are auxotrophic and non-pathogenic. Vectors reported for use in Campylobacter will be used, such as the shuttle vector pUOA18 (Bleumink-Plyum et al., 1999. Microbiology 145: 2145-2151) that replicates in both E.coli and Campylobacter, and suicide vectors that only replicate in E.coli and are also used routinely as standard cloning vectors e.g. pBluescript (Stratagene), pCRScript (Stratagene), pUC18, pCRTOPO (Invitrogen). The vector used in the cosmid library is pLA2917 (Fry et al., 1998. Microbiology 144: 2049-2061) and the transposon delivery plasmid is pOTHM (Golden et al., 2000. Infect. Immun. 68: 5450-5453).

**Origin & function**

All genetic material will be from Campylobacter jejuni strains 81116, 11168 and other strains from human and poultry environments. DNA to be targeted will be that which has similarity to other known virulence factors such as invasins, adhesins, fimbrial genes, genes for colonisation factors or genes that encode proteins which might be...
surface exposed. The exact function of the genetic material is as yet unknown, however this will be investigated in this project by creating mutations in the targeted genes and testing these mutants in tissue culture assay systems and animal models. It is intended that by identifying virulence/colonisation associated genes it might be possible to use them to distinguish between pathogenic and non-pathogenic campylobacters (e.g. by PCR detection). Also an understanding of the mechanisms of pathogenesis and colonisation is essential in order to develop control strategies to reduce the numbers of campylobacters in the human food chain.

Evaluation of foreseeable effects

Wild type C. jejuni is pathogenic to humans however it is a commensal in most animals and birds. C. jejuni is a foodborne zoonotic organism and human infection usually arises from the consumption of contaminated meat, particularly poultry meat, however other sources including pets, water and milk have also been implicated. All GMMs that result during this project will have either a reduced ability to colonise animals and/or birds, or a reduced virulence in humans due to the insertion of antibiotic cassettes into the genes responsible for colonisation and/or virulence in humans. If a GMC jejuni were to escape from the laboratory, it might survive in the environment for a short time, particularly in a moist environment. It is, however, unlikely to grow due to its fastidious growth requirements and the fact that it is thermophilic (optimum growth temperature of 42°C). Should the GMM come into contact with animals or birds, it may be able to colonise the gut asymptomatically, but it may not be able to displace the already established gut flora. There is no evidence to suggest that DNA transfer occurs between strains of C. jejuni in vivo and so it is unlikely that transfer of the antibiotic cassette which is chromosomally located will get transferred to other organisms. If the organism does get into the human food chain it is unlikely to cause serious illness at those genes important in virulence will have been targets for insertional inactivation. Laboratory attenuated GM E. coli strains that are used for cloning purposes are likely to survive for only a short time in the environment as they are auxotrophic. If they do carry C. jejuni genes, these genes are unlikely to be expressed at very high levels, if at all, due to the differences in DNA content and codon usage between the two genera.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated waste is autoclaved prior to incineration. All re-usable equipment is autoclaved, washed then recycled. Disposal equipment is autoclaved prior to incineration.

Is an emergency plan required according to regulation 20? Y

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

All GM project risk assessments are approved by the local GM Safety Committee prior to work commencing. This assessment has been approved.

Project Containment
**Project Additional Information**

**Purposes of the contained use**

(98NPO2EAV) Generation and selection of candidate virulent/non-virulent biological clones of equine arteritis virus (EAV).

(01/01) Generation of an infectious clone of bovine viral diarrhoea virus.

**Recipient or parental organism**

Equine Arteritis Virus (Bucyrus Velogenic Strain) taken from pleura fluid isolate of an EAV infected horse in the USA in 1971 (William McCollum's Lab. USA)

EAV is an arterivirus in the family Togaviridae and is a positive strand RNA virus.

**Host/vector system**

Experimental vector system E.coli.

**Origin & function**

The genetic material is a chimaera of EAV which involves the insertion of a small region of the ORF-5 (taken from the Velogenic Bucyrus strain of EAV) into the Leiden
strains (a much less virulent strain of EAV) to give a chimaera. This chimaera should function as a more virulent form of EAV.

**Evaluation of foreseeable effects**

This new Chimaera should function as an infectious clone of EAV and may be as virulent/pathogenic as the original Velogenic Bucyrus strain of EAV in the USA. This clone should produce a more severe form of the disease in the horse than the Leiden strain which only causes a mild form of the disease. The horses are expected to make an effective immune response and make a full recovery.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid waste - autoclaved prior to incineration.
Liquid waste - autoclaved prior to disposal.

Date of Significant Change

**Project Additional Information**

**Purposes of the contained use**
To develop a novel vaccine based on DNA for the protection against swine influenza.

**Recipient or parental organism**
Selected influenza viruses

**Host/vector system**
Host: competent rec A, end A E.coli strains INVXF and DH5X. COS7 (African green monkey) cells and PEK (porcine embryo kidney) cells.
Vector: PCR2.1 prokaryotic vector.
    pcDNA 3.1 eukaryotic expression vector (Invitrogen).

**Origin & function**
Original - ‘avian-line’ swine H1N1 influenza virus.

Intended function - Expression of the viral proteins in mammalian cells.

**Evaluation of foreseeable effects**
As only two out of a required eight genes will be used, there will be no adverse biological effects. However, the genes used are, singularly capable of initiating an immune response in the host.

Through vaccination of pigs with the construct it is proposed that viral proteins will be expressed in the pig cells, which will be immunogenic.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid and liquid waste and equipment are autoclaved prior to incineration or cleaning or discard.

Human Clinical Applications

Project Ref 221/03.1

Date Ackn’d 02/07/2003

CU2 Project Title

THE INVESTIGATION OF THE MOLECULAR BASIS OF ANTIGENIC VARIATION AND IMMUNOREACTIVITY OF THE GENE PRODUCTS OF BORRELIA SPP.

Date Project Ceased

Class 2

CultureVolClass2 1-50 litres

CultureVolumeClass3-4

Non-GMM not applicable

Consent Granted

Project notified under transitional arrangements N
**Project Additional Information**

**Purposes of the contained use**

Cloning of genes and construction of sub-genomic library.

**Recipient or parental organism**

Nucleic acid origin: DNA from relapsing fever Borrelia (B. recurrentis and B. duttonii) outer membrane protein genes derived from PCR.

Outer membrane genes enable antigenic variation involved in immune evasion in their host.

**Host/vector system**

The host organism is Escherichia coli. Commercially available disabled hosts will be used including recombination deficient (recA) or endonuclease A (endA) deficient E. coli K12 derived strains (such as TG-1, XL1-Blue MRF; HB101; TOP10; TOP10F; DH5; JM109, SG13009[pREP4] and M15[pREP4]).

Prokaryotic vectors will have the following features: a bacterial promotor (eg T7) to direct expression of inserted genes. Where genes are inducible, the responsible genes for induction will also be in the plasmid. An antibiotic resistance gene to permit selection of transformed bacteria will also be present in the vector. Sequences encoding fusion tags such as GST or 6-His may be included in the vector to assist in purification of expression proteins. Vectors meeting these requirements include pBluescript; pGEM; pUC; pRSET; pTrcHis, pGEX6T, pQE-30 series; pQE40; pET, pGEX, pcDNA3.1 and pcDNA4.

**Origin & function**

Origin: DNA from relapsing fever Borrelia (B. recurrentis & B. duttonii) outer membrane protein genes derived from PCR.

Intended function: Outer membrane genes enable antigenic variation involved in immune evasion in their host.

**Evaluation of foreseeable effects**

Other researchers have reported difficulties in gaining expression of borrelial outer membrane proteins which can be lethal to host organisms. Consequently, we would predict that resulting GMOs will be less likely to survive outside their growth medium or outside the laboratory.

Dunn et al. Outer surface protein A (OspA) from the Lyme disease spirochete, Borrelia burgdorferi: high level expression and purification of a soluble recombinant form of OspA. Protein Expr Purif. 1990 Nov; 1(2): 159-68.

As the work will involve use of libraries that contain as yet un-characterised genes, it is not possible to predict the effect that these inserts will have on the host. For this reason, manipulations of live material will be done in a class 1 biological safety cabinet located in the containment level 2 laboratory.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid contaminated waste will be placed in autoclave bags within autoclave tins. The bags will not be taped or tied to allow sufficient penetration of steam. Appropriate checks of autoclave efficiency will be made. The cycle conditions will be 121 degrees C, 15 pounds per square inch for 15 minutes. Once autoclaved, waste will be sent for incineration. Procedure for collection and disposal documented in CBU143 and autoclave operation in CBU135.

Liquid waste will be placed into Duran bottles (not to exceed half full), placed in autoclave tins with loose lids and autoclaved as above. Alternatively, this will be disinfected with 5% fresh solutions of either clearsol, lysol, chloros or virkon and left overnight before disposal.

General rubbish will be collected and sent for incineration.

Project Ref  221/04.1

Date Ackn'd  02/03/2022

CU2 Project Title  Class  CultureVolClass2  CultureVolumeClass3-4
THE GENOTYPIC AND PHENOTYPIC COMPARISON OF VIRULENT YERSINIA ENTEROCOLITICA FROM HUMANS AND ANIMALS.

Purposes of the contained use

To identify genotypic markers of virulence and human pathogenicity in Yersinia enterocolitica. This will involve mutation and complementation of potential, host-specific colinsation factors identified via an ongoing comparative microarray project.

Recipient or parental organism

Laboratory strains of E. coli such as DH5α, S17.pir will be used for cloning purposes as they are easy to use, readily available, and well defined. S17.pir may be used as a donor strain to perform conjugational transfer of suicide vectors. A variety of wild type Yersinia enterocolitica strains identified as harbouring candidate genes will be used as hosts for knockout mutations if they permit uptake of DNA and recombination events.

Host/vector system

Various standard cloning vectors such as pUC18, pACYC184, pBAD18. Other suicide vectors for allelic exchange such as pPERFORM, pKNG101 (Woodward, M. J. et al 2003. JMM. 299-308), pB307 (Roe, A. J. et al 2003. Infect & Immun. 5900-5909), or pKOBEG (Derbise A et al 2003. FEMS Immun & Med Micro. 113-1156). All the above vectors have been reported in the literature, are easy to use, and readily available.

Origin & function

Wild type Yersinia enterocolitica strains from human and animal environments will provide the genetic material involved. Specific genes are as yet unknown, though genes with similarity to other known virulence factors such as toxins, adhesins, fimbriae, as well as regulatory elements are most likely to be investigated. The intended function of the genetic material is to investigate the role of these factors as potential virulence or host specific colonisation factors in Y. enterocolitica. In the majority of cases the genes will be insertionally inactivated in Y. enterocolitica and the resultant phenotype studied. In some instances non-coding regions upstream of the gene may be used to study expression of the factors via a reporter gene.

Evaluation of foreseeable effects

Wild type Y. enterocolitica is present in the environment, principally as a coloniser of pigs, but also colonises sheep and cattle, as well as domesticated wildlife such as dogs. The organism can also survive in water, soil etc. The infectious dose is relatively high, and whilst Y. enterocolitica is pathogenic to humans. It colonises animals asymptotically. Genetically modified Y. enterocolitica strains will be assumed to have a reduced ability to colonise animals due to mutations in potential...
colonisation/virulence factors. Safety procedures observed in the laboratory should make it unlikely for GM organisms to enter the food chain. Also, classically Y. enterocolitica is divided into 3 distinct families. Biotype 1b strains are considered the major human pathogens, whilst biotype 2-4 strains are considered as opportunistic human pathogens, and biotype 1a strains are classified as non-pathogenic. The cloning to be performed during this project will exclusively involve Biotypes 1a, and 2-4, with the possible exception of one Biotype 1b strain which is non-invasive in in vitro tests.

The E. coli strains that are used for cloning are all auxotrophic and so long term survival in the environment is unlikely. The plasmids used are non-mobilisable, and are readily lost from organisms in the absence of antibiotic selection pressure, with the exception of pKNG101 which requires the .pir protein present in E. coli S17 in order to replicate.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For solid contaminated materials, all contaminated waste is placed in autoclave bags inside autoclave tins and the lid secured with tape on 2 opposing sides, though not fastened, to allow steam entry, before the tin leaves the laboratory. Waste tins are autoclaved (134 degrees C for 1 hour) prior to incineration.

Liquid waste is collected in glass bottles and placed in an autoclave tine, in sub-500ml volumes. Waste tins are then autoclaved (134 degrees C for 1 hour) prior to incineration.

All general uncontaminated waste is disposed of separately from contaminated waste and disposed of by incineration.

Thorough disinfection procedures are carried out in the event of any spillages, using 2.5% lysol or 70% ethanol. Laboratory floors and surrounding corridors are disinfected regularly. All contaminated waste is autoclaved and no contaminated waste is disposed of in the drainage system without sterilisation.

02/03/2022
Can detection and typing of brucellosis in animals be further improved?

Purposes of the contained use

An "ORFeome" of Brucella genes has been created, consisting of open reading frames (ORF) of the Brucella melitensis 16M and Brucella suis 1330 genomes. A total of 3091 ORFs were cloned into Gateway™ pDONR 201™. This project intends to manipulate selected clones from the ORFeome for the generation of Gateway™ system/E.coli based organisms capable of expression of the encoded Brucella specific recombinant proteins, for use in diagnosis.

Recipient or parental organism

E.coli K12 derivative strain: E.g.: JM109, TOP10, TOP10F', DH5a.

Host/vector system

A number of Gateway™ destination vectors may be used in this project. Each vector will contain a T7 promoter element and a choice of N-terminal fusion tags. Examples of such vectors include pDES™ 15 (N terminal Glutathione S Transferase Tag), pDES™ 17 (N terminal Histidine Tag), pDES™ 14 (without the tag)- All vectors are provided by Invitrogen (www.invitrogen.com)
The ORFs to be used in this project will be obtained from the Brucella ORFeome. The host organisms of the ORFeome are E.coli strain DH5 a-T1rMAX containing the Gateway TM pDNOR 201 TM vector carrying individual ORFs for the entire genome complement of the Brucella melitensis 16M and Brucella suis 1330 strains. These GMMs cannot express the encoded ORFs. They are considered GM class 1 organisms following risk assessment approval by the VLA GMLSC. In this project the ORFs (of Brucella spp., origin) will be transferred to a Gateway TM vector and alternate host cell which is capable of expression of the inserted ORF, under controlled conditions. The expression capable GMMs will be used to generate recombinant proteins that will be used in research projects to develop novel diagnostic tests.

Evaluation of foreseeable effects

The host organisms of the original ORFeome are considered GM class 1 organisms following risk assessment approval by the VLA GMLSC. The original ORFeome consists of a library of E.coli strain DH5 a-T1r MAX containing a single ORF derived from Brucella spp., in the Gateway TM p DNOR 201 tm VECTOR. These GMMs are not capable of expression. Each GMM to be created in this project will also contain a single Brucella ORF, but in a Gateway expression vector system. The E.coli host strains selected for this project are disabled strains requiring defined culture conditions for propagation and survival. The vectors selected (Gateway TM pDES TM) contain the necessary promoters and regulatory sequences for expression of the inserted ORF, therefore these organisms are capable of generating Brucella specific proteins. Since some of the ORFs that could be used may have putatively assigned functions relating to invasion or adhesion, or be of unknown function, it is possible, although unlikely, that the expression of these genes by the E.coli host strain could confer elements of an invasive or adhesive Brucella specific phenotype to the cells. It is more likely that the proteins will not have any biological activity in the E.coli and that the presence of fusion tags will abrogate any activity, or that induced expression of the Brucella protein will be toxic to the host cells and cause their death. Overall the presence of a plasmid bearing and expressing a single Brucella gene is extremely unlikely to significantly alter the virulence/pathogenicity of these attenuated host cells. The genome sequence of Brucella melitensis (DelVecchio, V.G., et al., 2002) was used to generate the original host ORFeome and this data indicates that there are no classical virulence factors or any toxins encoded in the Brucella organism and therefore these are not present in the ORFeome. The underlying mechanism of Brucella virulence is not fully elucidated but seems largely related to the ability of the organism to establish a persistent replicative niche within the acidified phagosome of the host macrophage. This ability to survive in the macrophage is not fully elucidated but it is known to be complex and multifactorial (S. Kohler et al, 2003). For this reason it is very unlikely that the presence and expression of a single ORF can transfer the virulence or pathogenicity of the Brucella to any E.coli host. However, as the exact function of the ORFs to be selected are unknown at this point, we cannot rule out the possibility of the production of a protein that could alter the host strain E.coli phenotype. For this reason we propose that these organisms are designed as GM class 2 pathogens.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Lab waste, which has had contact with GM organisms is processed through incineration. General practice in this laboratory involves the manipulation of all bacterial cultures (Hazard Group 2 and below) in the class II microbiological safety cabinet. Solid waste (Agar plates/Absorbent paper/plastics etc) are all disposed of through autoclaving (15 minutes, 121 degrees C and 15 lbs in -2 pressure), followed by incineration. Liquid cultures/spent culture media samples are sterilised through O/N disinfectant treatment in 5% hycolin. Treated liquids can be safely discarded down the sink with copious amounts of water.

General safe working practices, including restricted laboratory access and good cleaning/sterilisation procedures will prevent the organism from entering the environment. No additional special measures are necessary.

N

Purposes of the contained use

To generate live recombinant B. subtilis vaccine candidates, which will be able to illicit a protective immune response in poultry against C. perfringens mediated necrotic
enteritis, when administered orally.

Recipient or parental organism

*bacillus subtilis* PY79.

Host/vector system

Plasmid based suicide vectors with regions of homology to the Bacillus subtilis chromosome.

Origin & function

All genetic material will be derived from either the Bacillus subtilis genome or the Clostridium perfringens genome.

It is intended that GM Bacillus subtilis strains will be able to illicit a protective immune response in poultry against necrotic enteritis.

Evaluation of foreseeable effects

No adverse effects are envisaged. Despite the fact that both Bacillus subtilis and C. perfringens are environmentally ubiquitous organisms, all work will be carried out by trained personnel, in line with safety regulations for Hazard Group 2 pathogens.

GM Bacillus subtilis strains will not be modified to express any substance which is known to be harmful to any organism or the environment. Furthermore, the proposed GM Bacillus subtilis strains will have either one or two native chromosomal genes knocked-out. Although these genes are non-essential to survival, their disruption is likely to attenuate the proposed GM Bacillus subtilis strains.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All laboratory waste (solid or liquid) will be autoclaved, then incinerated, in line with current risk assessments (VLA Weybridge). Autoclaving is for 60 minutes at 134 degrees C and 16 psi (NB: Autoclaves have been validated for efficacy against Bacillus subtilis spores - validation report of 01/10/02).

Where autoclaving is not possible, waste will be contained and incinerated immediately. Surface etc. which can not be autoclaved or incinerated will be disinfected with Virkon S (or other suitable bactericidal disinfectant) after use.

### Project Additional Information

**Purposes of the contained use**

Insert DNA capable of expressing antisense RNA to target genes will be amplified and cloned into a vector capable of stable replication within *Mycoplasma*. Expression of antisense RNA will be initiated from an inducible vector promoter allowing controlled regulation of target genes.

**Recipient or parental organism**

*Mycoplasma* species including *Mycoplasma mycoides* subspecies *mycoides* small colony type and *Mycoplasma bovis*, *M. c. capripneumoniae*, *M. agalactiae*, *M. c. capricolum*, *M. mycoides* subspecies *mycoides* large colony type, *M. gallisepticum*. 
Host/vector system

pBlueScript (+) (stratagene)
pIVT-1 (University of Alabama)

Origin & function

M. m. m. SC oriC DNA generated through PCR amplification using previously published primers. Antisense RNA generated through PCR amplification of appropriate Mycoplasma genomic sequences. OriC and antisense RNA generated through PCR amplification of Mycoplasma specific DNA sequences. The expression of antisense RNA sequences allowing downregulation of specific genes. Antisense RNA molecules function by hybridising to complementary RNA transcripts. Downregulation occurs through (I) inhibition of translation, (ii) Rapid degradation of mRNA by duplex specific Rnases or (iii) Inhibition by premature termination of transcription. Technology can be rapidly implemented and since gene function is not knocked out it eliminates the production of lethal mutants allowing the study of essential genes.

Evaluation of foreseeable effects

The production of antisense RNA will be induced under laboratory conditions. In addition although gene expression will be reduced it will not be eliminated so should not significantly affect the pathogenicity of these organisms. We will essentially be creating exotic strains and will therefore follow procedures of containment set out in ACDP and SAPO guidelines.

Evaluation of foreseeable effects

02/03/2022
The majority of genes involved in cell wall synthesis in mycobacteria are unknown. One of the reasons for this is that conventional methods of making targeted gene knock-outs are extremely difficult in mycobacteria due to the lack of efficient homologous recombination in this organism. A more efficient method for obtaining cell wall mutants of mycobacteria is to perform transposon mutagenesis, whereby transposons insert randomly into the chromosome, then to screen these mutants for alteration in cell surface structures using appropriate antibodies.

Mycobacterium bovis BCG, an attenuated strain of mycobacteria derived from virulent M.bovis and can be handled at Containment Level 2. It is the vaccine strain for tuberculosis.

Recipient or parental organism

Mycobacterium bovis BCG, an attenuated strain of mycobacteria derived from virulent M.bovis and can be handled at Containment Level 2. It is the vaccine strain for tuberculosis.

Host/vector system

EZ::Tn system (Epicentre). An EZ::TN Transposome is the complex formed by incubating an EZ::TZ Transposon with EZ::TN™Transposase in the absence of Mg2+. EZ::TN Transposomes are stable so they can be introduced into cells by electroporation. Once in the cell, the EZ::TN Transposome is activated by Mg2+ and the EZ::TN
Transposon can then randomly insert into the host's genomic DNA. This system has previously been shown to work successfully in M. bovis BCG (Stewart, G. et al., poster presentation at "Tuberculosis: Integrating Host and Pathogen Biology", Whistler, Canada, April 2-7, 2005).

Origin & function

The EZ::TN system will be used to deliver the hygromycin resistance gene from Streptomyces hygroscopicus as a selectable marker. The hygromycin resistance gene is ~1.4kb in size and can be expressed in M. tuberculosis complex organisms to confer resistance to hygromycin. The aim of using this vector::insert combination is to randomly disrupt genes in the chromosome of M. bovis BCG to generate mutants which can be selected on the basis of hygromycin resistance. The mutant bank will then be screened for recombinants with defects in cell wall synthesis.

Evaluation of foreseeable effects

Inactivation of genes in BCG will not lead to an increase in its virulence for humans. Recent work (Mol Microbiol. 2002 Nov;46(3):709-17; Proc Natl Acad Sci 2003 Oct 14;100(21):12420-5) has shown that the deletion of the RD1 locus from BCG was one of the key reasons for the attenuation of the vaccine strain during its derivation. As there are no examples of horizontal transfer of DNA in the M. tuberculosis complex, BCG cannot regain this locus; this explains why BCG has never reverted to virulence and is safe to use in humans. A subset of mutants are anticipated to be cell wall mutants, which is the focus of this project. Modification of cell wall components of virulent mycobacteria has been shown to attenuate the recombinants (Nature. 2004 Sep 2;431(7004):84-7); there are no examples of modification of cell wall components leading to increased virulence of the recombinant. Trained workers, minimising the risk to personnel or accidental environment release, will carry out the manipulations described in this Risk Assessment in a dedicated containment level 2 laboratory.

Project Additional Information

Purposes of the contained use

This project aims to identify and express proteins for use in diagnostic assays. Having identified suitable targets, using transposons mutagenesis, those genes will be clones into E. coli vectors for protein expression analysis.

Recipient or parental organism

Mycoplasma species including Mycoplasma mycoides subspecies mycoides small colony type and Mycoplasma bovis, M. c. capripneumoniae, M. agalactiae, M. c. capricolum, M. mycoides subspecies mycoides large colony type, M. gallisepticum will be subjected to Tn mutagenesis to identify cloning targets. Laboratory manipulation of these organisms is governed by ACDP and SAPO guidelines. Cloning and expression studies will be carried out in E. coli hosts: E. coli K-12 derivative strains (eg. JM109, CDJ64/D14, NovaBlue (DE3)), E. coli B derivative strain BL21 (DE3), developed at Brookhaven National Laboratories and E.coli XL10 gold.

Host/vector system

Suicide plasmids containing Tn4001 or Tn916. Cloning and expression studies will be carried out using E. coli vectors including: pG8PLO, pAff8c, (Swedish Institute collaboration), pGEM-T easy and pGEM-T (Promega), plasmids of the pET system (Stratagene).
Tn916 is a class V transposon originally detected within S. faecalis. It was the first element of this group to be discovered and has been extensively studied. Tn4001 is a composite class 1 transposon originally detected within the plasmid pSK1. Following Tn mutagenesis target Mycoplasma DNA will be PCR amplified. The identity of specific inserts are unknown at this stage but are likely to include surface proteins suitable for use in diagnostic assays. Introduction of Tn to mycoplasma genomic DNA causing disruption of open reading frames. Introduction of target DNA to E. coli to carry out expression analysis and produce Mycoplasma proteins for use in diagnostic assays.

**Evaluation of foreseeable effects**

Tn mutagenesis will cause loss of gene expression through disruption of genomic DNA. This may result in the expression of alternative pathogenicity factors within cells. Genetic manipulation within the laboratory will result in the production of exotic strains. All work will be carried out in class 2 containment according to SAPO guidelines and restrictions already in place. Tetracycline resistance will be conferred within GM strains to enable the selection of transformants. Since these organisms are not human pathogens this will not compromise treatment using this antibiotic. Should these organisms be released from laboratory containment the likelihood that they will survive is low. Mycoplasma are host dependant microorganisms unable to synthesise many essential molecules. They are under selective pressure to maintain a reduced genome size. In addition they lack a cell wall making them vulnerable to lysis. The E. coli hosts for expression studies are disabled strains, unable to survive in the environment and requiring complex media and growth conditions. DNA within expression vectors will be under the control of vector promoters. E. coli expression strains BL21 (DE3) and NovaBlue (DE3) have been engineered to contain a genomic insert capable of expressing T7 polymerase. This gene is under the control of a lac promoter and expression is induced on addition of IPTG. In the presence of T7 polymerase expression is induced from T7 promoter sequences within the transformed vector (pAff8c or pET plasmid). This leads to expression of insert DNA. Expression of vector DNA inserts within the suppressor strain CDJ64/D14 from pG8PLO is under the control of a lac promoter and is directly induced by addition of IPTG. It is unlikely that these fragments will be expressed within these strains outside laboratory conditions. It is very unlikely that the level of expression observed within the laboratory will be transferred to wild type hosts in the environment. Only single open reading frames will be transferred to host cells where they will be expressed in isolation from other mycoplasma proteins. It is extremely unlikely that the expression of one mycoplasma protein within a disabled E. coli host strain would be capable of altering virulence and, since mycoplasma lack a cell wall, it is unlikely that these proteins would be surface expressed within the host. Mycoplasma species used in this study are covered by SAPO and as a result of this live mycoplasma and modified E. coli will be maintained and manipulated under class 2 containment conditions.

**Origin & function**

Project Ref 221/05.3

Date Ackn'd: 26/08/2005
CU2 Project Title: CONSTRUCTION OF AND EFFICACY OF AN AROA VACCINE AGAINST SALMONELLA ENTERICA NEWPORT

Class: Class 2
CultureVolClass: < 1 Litre
Consent Granted: Not Applicable

Historical Significant Changes
Withdrawn: N

Project Additional Information

Purposes of the contained use
Construction of aroA vaccine Salmonella enterica Newport and characterisation in in vitro and in vivo models.

Recipient or parental organism
Laboratory strains of E. coli such as DH5a, S17pir. A characterised S. Newport strain confirmed as fully antibiotic sensitive will be used for mutagenesis studies.
Host/vector system

Standard cloning vector pCR 2.1 TOPO. Suicide vector for allelic exchange will be pKNG101.

Origin & function

A Salmonella Newport fully sensitive cattle isolate will be used. The aroA gene and the genes immediately upstream (unknown function) and downstream (serC) will be amplified, allowing deletion of the aroA gene. To allow construction of the region without the aroA gene, resulting in an auxotrophic mutant unable to survive in the absence of supplemented aromatic amino acids.

Evaluation of foreseeable effects

The use of an aroA mutant in vaccine strain construction has been well documented, and benefits from the fact that the GMO is highly auxotrophic, and rapidly dies in the absence of supplemented aromatic amino acids. Due to this the threat to the environment from the GMO is negligible. Due to the emergence of S. Newport as a zoonotic agent we have opted for an isolate sensitive to antibiotics, and have opted for an unmarked mutant, ensuring minimal impact if the organism was released. The E. coli strains that are used for cloning are well auxotrophic and so long term survival in the environment is unlikely. The plasmids used are non-mobilisable, and are readily lost from organisms in the absence of antibiotic selection pressure, with the exception of pKNG101 which requires the lpir protein present in E. coli S17 in order to replicate.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste - disposal is by autoclaving or incineration in line with current risk assessments. Autoclaving is for 60 minutes at 134 degrees C after which solid waste is put into bags for incineration. All bedding from animals and carcasses from post-mortems will be double bagged and then disinfected with FarmFluid S and immediately incinerated. The post-mortem facility will be disinfected with FarmFluid S and then fumigated after each post-mortem.

Liquid waste - disposal is by autoclaving in line with current risk assessments. Autoclaving is for 60 minutes at 134 degrees C after which waste is incinerated. Liquid waste from animal excrement will be soaked up with shavings, treated with FarmFluid S and then incinerated. Any liquid waste draining from animal rooms will be disinfected with FarmFluid S and heat treated in holding tanks.

General rubbish - all general rubbish will be double bagged and disposed of by incineration in line with current risk assessments.

Thorough disinfection procedures are carried out in the event of any spillages, using 2.5% lysol, FarmFluid S or 70% ethanol. Laboratory floors and surrounding corridors are disinfected regularly. All contaminated waste is autoclaved and no contaminated waste is disposed of in the drainage system without sterilisation. Formaldehyde fumigation together with Virkon and FarmFluid S disinfection will be used in all animal accommodation. All waste will be double bagged disinfected and immediately incinerated. Environmental monitoring will be carried out routinely.

N

**Project Additional Information**

Purposes of the contained use

* Generation of targets by PCR from Coxiella burnetii genomic DNA.
* Insertion of the PCR amplicon into separate constructs enabling downstream sequencing.
Expression of the bacterial protein in-vitro using inducible E. coli cultures to produce potentially useful diagnostic antigens.

**Recipient or parental organism**

The host organism is Escherichia coli. Commercially available disabled hosts will be used including recombination deficient (recA) or endonuclease A (endA) deficient E. coli K12 derived strains (such as TG-1; XL1-Blue MRF; HB101; TOP10; TOP10F; DH5.; JM109, SG13009[pREP4] and M15[pREP4]. The host organism, E. coli, is not considered harmful (ACDP class 1) and the strains used will be disabled reducing their ability to survive within the environment. No adverse effects are anticipated from expression of these genes in E. coli as expression of any single Coxiella gene, intragenic spacer or portion of a gene in the E. coli host is extremely unlikely to alter the virulence of the host strain.

**Host/vector system**

Prokaryotic vectors will have the following features: a bacterial promoter (eg T7) to direct expression of inserted genes. Vectors meeting these requirements include pBluescript; pGEM; pUC; pRSET; pTrcHis, pGEX6T, pQE-30 series; pQE40; PET and pGEX. The host organisms are disabled with reduced ability to survive outside the laboratory. The host organisms are not pathogens of plants or animals. The genetic inserts are linear DNA and the vectors are not mobile.

**Origin & function**

DNA will originate from Coxiella burnetii genomic preparations being derived from PCR. Various genes, intragenic spacers or other targets with likely value for detection and typing Coxiella burnetii will be selected from in silico analysis of genome data and will be amplified by PCR. Cloning will be used to obtain material for sequencing studies where it has been possible to produce sufficient template using PCR alone. Additionally, expression of antigens of potential diagnostic value consequently alleviating the need to utilise virulent CL3 pathogens for this purpose.

**Evaluation of foreseeable effects**

The host organism, E. coli is not considered harmful (ACDP class 1) and the strains used will be disabled reducing their ability to survive within the environment. No adverse effects are anticipated from expression of these genes in E. coli as expression of any single Coxiella gene, intragenic spacer or portion of a gene in the E. coli host is extremely unlikely to alter the virulence of the host strain. Although the detailed pathogenesis of these microbes is not yet fully elucidated, it is known that this is a complicated, multi-factorial process involving multiplication of C. burnetii within the acidified phagolysosome, and likely to be dependent on multiple gene products. Consequently, isolated genes or portions of genes, are unlikely to confer pathogenic properties to their recipient hosts. As the work may involve use of as yet un-characterised genes, it is not possible to predict the effect that these inserts will have on the host. For this reason, manipulations of live material will be done in a class 1 biological safety cabinet.

The strains used (E. coli) are viewed as safe and are well characterised for DNA production. The host organisms are disabled with reduced ability to survive outside the laboratory. The host organisms are not pathogens of plants or animals. The genetic inserts are linear DNA and the vectors are not mobile. If the organisms were able survive, expression of the Coxiella genes can only occur from the prokaryotic expression constructs (pRSET, pTrcHis, and pGEX6T), under certain inducible conditions. It is extremely unlikely that these conditions would be recreated outside a laboratory environment. Furthermore, Coxiella burnetii is considered endemic to Europe and consequently already occurs naturally and therefore already exist in the environment. Given the low likelihood of release beyond the confines of the laboratory together with the reduced ability to survive within the environment and lack of pathogenicity in animals or plants and the lack of vector genetic mobility, the overall risk is considered to be low.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Solid waste: Solid contaminated waste will be placed in autoclave bags within autoclave tins. The bags will not be taped or tied to allow sufficient penetration of steam. Appropriate checks of autoclave efficiency will be made. The cycle conditions will be 121 degrees C, 15 pounds per square inch for 15 minutes. Once autoclaved, waste will be sent for incineration.

Liquid waste: Liquid waste will be placed into Duran bottles (not to exceed half full), placed in autoclave tins with loose lids and autoclaved as above. General rubbish: General rubbish will be collected and sent for incineration.

Date of Significant Change

Project Additional Information

Purposes of the contained use

In this project PrP genes (open reading frame and regulatory regions) will be amplified by PCR. The PrP inserts will then be sub-cloned into different mammalian expression vectors. Transfected mammalian cell lines will be exposed to certain types of stress, including oxidative stress, in order to try to induce the pathogenic conformation of PrP. In addition, attempts will be made to infect cells with the BSE and scrapie agent whilst under stress to assess whether they become more or less susceptible to infection.

Recipient or parental organism

The recipient organism for expression vectors will be mammalian cell lines including; Bovine kidney (MBDK), Rabbit kidney (RK13), Sheep choroid plexus (SCP), Rat pheochromocytoma (PC12), Mouse neuroblastoma (N2a), Mouse differentiated neuronal (GT1). Increased transient or stable PrP expression is expected, this is not expected to be pathogenic, however if expressions levels are very high this is a possibility, as seen in PrP over-expressing transgenic mice.

Host/vector system

Expression vector systems include Clontech pLP-IRESneo with CMV promoter giving constitutive expression, Clontech pTet-On or pTet-Off with tetracycline responsive promoter allowing inducible expression, or Clontech pd2EGFP promoterless vector where the PrP promoter can be inserted to drive the expression of a green fluorescent protein (GFP) reporter protein.

Origin & function

The PrP open reading frame (ORF) is contained in a single exon (exon 3) and is approximately 900 bps long. It codes for a GPI anchored protein of ~ 250 amino acids. PrP is normally expressed in many mammalian cells but primarily in the peripheral and central nervous system. The PrP locus is approximately 20Kb in length depending of the species, promoter activity has been reported upstream of exon 1 and within intron 1.

Vector inserts will include PrP ORF (of naturally occurring genotypes) from mammals such as bovine, ovine, mouse, deer, kudu, dog and cat species derived from PCR amplification of genomic DNA. This will allow the study of how PrP genotype and species variation affects susceptibility to TSE infectivity or cellular stress. Alternatively, regulatory segments of the PrP gene such as the promoter or untranslated region (UTR), which may include exon 1 and 2, from mammalian species will be amplified from genomic DNA using PCR. The regulatory regions will be used to drive the expression of a reporter protein so that variation of expression can be assessed under different conditions.

Evaluation of foreseeable effects

The natural function of the PrP protein has not yet been fully determined although it is thought to be implicated in copper transport (Paul & Harris 1998) and may have some superoxide dismutase activity (Brown et al 1999). High level expression of PrP in mammalian cell lines has not been reported to cause spontaneous disease although
there are not many examples available. High level PrP expression in transgenic mice has been reported to lead to an increase in susceptibility to TSE and a reduction in incubation times. Only PrP of naturally occurring, non-human genotypes will be used.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste will be placed in autoclave bags then in tine sealed with tape and placed in autoclave bags before being taken to building 105. All GM cells will be autoclaved for 30 mins at 136 degrees C, 2.2 bar. All TSE infected GM cells will be autoclaved for 30 mins at 136 degrees C, 2.2 bar with the exception of strains infected with 301V mouse BSE which will be autoclaved for 1 hour at 136 degrees C 2.2 bar. All sterile waste will then be incinerated.

All liquid waste will be prepared and autoclaved as above prior to disposal down drains.

General waste is autoclaved as above prior to disposal by incineration.

Project Ref    221/07.2
Development of novel TB vaccines protecting humans or animals is a major research priority. Defra has been funding research into bovine TB vaccines for cattle for almost a decade, and one objective is to determine protective efficacies in cattle of vaccines developed during the human TB vaccine development effort. In particular, we are contracted by Defra to test the human TB vaccines that have entered, or about to enter human clinical trials. The recombinant Mycobacterium bovis BCG aureC::Hly::Hyg (VPM1002) is one such vaccine with human clinical trials scheduled to begin in Germany in late 2007. This vaccine has in small animal models provided superior protection against M. tuberculosis than wild type BCG (Grode et al 2005 JCI 115(9)2472-9). Our objective is to vaccinate cattle with BCG and VPM1002, and to compare protection against M. bovis challenge using well-established protocols (e.g. Vordermeier et al, Inf. Immun 70:3026-32, 2002).

Mycobacterium bovis BCG

BCG is an attenuated strain of mycobacteria derived from virulent M. bovis and is the only TB vaccine in routine use in humans, and is also part of the most novel TB vaccine strategies. The recombinant version subject to this assessment is further attenuated and has therefore been down-graded from P2 to P1 in Germany, by the German authorities.

Host/vector system

The plasmid VEP::Hly::Hyg is integrated in the bacterial chromosome. The chromosomal shuttle vector pMV306hyg0Hly was used which employs the L5 mycobacteriophage attachment site for integration.

Origin & function

The tuberculosis vaccine Mycobacterium bovis bacilli Calmette-Guerin (BCG) was modified to express the membrane-perforating listeriolysin (hly) of Listeria monocytogenes and the system used to deliver the hygromycin resistance gene came from Streptomyces hygroscopicus as a selectable marker.
The aim of using this vector is to express listeriolysin to disrupt the phagosomal membrane to release mycobacterial antigens into the cytosol for better induction of the immune response towards Th1. The plasmid has been integrated into the bacterial chromosome of M. bovis BCG that then can be selected based on Hygromycin resistance.

**Evaluation of foreseeable effects**

Inactivation of genes in BCG like the ure-C deletion in VPM1002, will not lead to an increase in its virulence for humans. As there are no examples of horizontal transfer of DNA in the M. tuberculosis complex, BCG cannot regain genes; this explains why BCG has never reverted to virulence and is safe to use in humans.

Construction of the VPM1002 clone will not lead to an increase in its virulence in its virulence in humans. Recent work (grode et al 2005 JCI 115(9)2472-9) has shown that the inserted hly gene showed reduced virulence in immune compromised SCID mice. Current toxicology studies with SCID and IFN-y k.o mice underlined the first results and show improved or equal safety profile compared to BCG (Grode et al, personal communications). Trained workers, minimising the risk to personnel or accidental environmental release, will carry out the manipulations described in this Risk Assessment in a dedicated containment level 2 laboratory.

It is extremely unlikely that the mutants of BCG will be released from the laboratory since the bacilli will be stored, analysed and dispensed in a Containment Level 2 laboratory by trained workers. Furthermore, the inoculi will then be transported in secure containers to the CL2 cattle accommodation where the vaccinations will take place. Once inoculated (subcutaneously), the vaccinated animals will serve essentially as primary containment as due to the vaccination route (subcutaneously), which is likely to maintain bacteria within the lymphatic system, makes excretion into environment highly unlikely. Syringes, needles, unused inoculi etc. used for the inoculations will be disposed of by incineration as will be the animals at the end of the experiment. Bacilli to be dispensed in class 1 cabinet.

No data exists on the ability of BCG to persist in the environment. However, the pathogen Mycobacterium bovis, from which BCG was derived, can survive in soil for up to 6 months and on pasture for at least 49 days (Maddock (1933). J Hyg 33:103-17). It is possible that due to its attenuation, BCG is further disabled in its capacity to survive outside of a host organism. However since this has not been established, for the purposes of this assessment it shall be assumed that BCG has the same survival characteristics as parental M. bovis. Environmental species of contrast, long-term persistence of M. bovis requires frequent passage through an animal host. The genetic lesions present in BCG render the organism unable to persist or cause disease in immunocompetent animal hosts (including humans) so it is unlikely that BCG would be able to establish, disseminate or displace other environmental organisms to a significant extent. The greatest hazard associated with exposure of animals to BCG is that cattle infected with BCG become positive for the tuberculin skin test. Although BCG does not persist in cattle and causes no disease, animals that become tuberculin positive through exposure to BCG would be deemed tuberculous by the current TB screening measures in GB and would be slaughtered as a result (please note that cattle held at VLA for experimental purposes are not subject to this routine TB surveillance). The greatest hazard is therefore an economical one for cattle kept on potential farms surrounding the VLA site. However, there are now commercial cattle holdings in close contact to the to the CL2 and CL3 cattle accommodation at VLA Weybridge, which likely hound not result in faecal, aerosol or nasal BCG shedding necessary for such an event to occur. The materials post-mortemed and incinerated, thus preventing any exposure of the environment due to BCG persisting in lymph nodes, or other internal organs. Animals will be housed in Bldg. 268 prior to post-mortem and therefore do not have to be transported to the PM room (270). Pm room to be decontaminated as per instructions for PM. M. bovis infected cows (BACC0001/01).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All work is conducted in containment level 2 laboratories or animal accommodation by highly skilled personnel. All manipulations of recombinant BCG are performed within a safety cabinet (class 1), with personnel wearing suitable protective clothing. Unused inoculi and consumables used to vaccinate cows (e.g. syringes) will be incinerated at the end of experiment following housing in Building 268 and PME in Bldg. 270. As these buildings are interconnected also with the incinerator building, no transport of animals is necessary. Bldg 270 to be decontaminated as described in BAAC0001/01.

Laboratory waste is transported to an autoclave within building in a closed metal tin. Decontamination is conducted by autoclaving for 1 hour at 135 degrees after which
waste is put into bags for incineration. Animals will be euthanized and incinerated at the end of the experiment. Waste occurring during the inoculations (needles/ syringes) to be placed in sharps containers, sealed, double-bagged and incinerated.

Laboratory waste is transported to an autoclave within the building in a closed metal tin. Decontamination is performed by autoclaving for 1 hour at 135 degrees after which waste is put into bags for incineration. Waste during the inoculations (left-over inoculi) to be double-bagged and incinerated.

Waste is transported to an autoclave within the building in a closed metal tin. Decontamination is performed by autoclaving for 1 hour at 135 degrees after which waste is put into bags for incineration.

Date Project Ceased

02/03/2022

Project notified under transitional arrangements N
Probiotics are defined as ‘live micro organisms which when administered in adequate amounts confer a health benefit to the host’ (Nomoto, 2005). Probiotics are typically lactic acid producing bacteria, such as Lactobacillus Bifidobacterium and Enterococci. As a result of anaerobic metabolism probiotics bacteria can produce volatile fatty acids (VFA’s), such as acetic, butyric, propionic and valeric acid. Recent studies have illustrated that butyric acid can down regulate the Salmonella pathogenicity island (SPI-1) by activation of the bacterial adaptive response (BarA) I Salmonella invasion regulator (SirA) pathway (Lawhorn et al., 2002; Teplitski et al., 2003). This system senses the VFA environment of the gut and directly regulates Salmonella invasion (Van Immerseel et al., 2006). In response to short chain fatty acids (SCFA) the Salmonella two component regulator system BarAlSirA, directly effects the expression of the SPI-1 transcriptional regulator, Hyper Invasive Locus A (hilA). HilA is directly linked to the invasive potential of Salmonella. The carbon storage regulators are regulatory RNA’s (csrB/C) and the protein (csrA), which are involved in the Salmonella signal transduction pathway and have been linked to hilA expression (Lawhorn et al., 2002; Teplitski et al., 2003). Studies proposed here aim to deduce the effect of VFA’s on promoters (hilA, barA, sirA, csrA, csr8 and csrC) in the Salmonella BarAlSirA pathway. In order to monitor gene expression, reporter fusion mutants will be constructed in the BarAlSirA pathway and therefore used to create a ‘biosensor Salmonella strain’ that can be utilised to probe various environmental conditions that may reduce the invasion of Salmonella into epithelial cells by directly affecting genes in the BarAlSirA pathway. Quantification of green fluorescent protein (GFP) expression from BarAlSirA pathway reporter fusion mutants will be measured by constructing a GFP transcriptional fusion with the relevant promoter. Expression of GFP under various environmental conditions will be undertaken to elucidate the invasive potential of Salmonella test strains under differing conditions. In addition, studies will be extended to GFP tagging of wild-type Salmonella strains for subsequent analysis by confocal microscopy. The tagging will be undertaken with the aid of plasmids (pFPV25.1 or pGP704K) donated by collaborators. Once electroporated into Salmonella strains, these plasmids express GFP under the control of the ribosomal subunit promoter rpsM (RPSM ribosomal subunit) and therefore produce constitutive (constant) fluorescent signal, which is essential for imaging by confocal microscopy. Salmonella strains transfected with rpsM-gfp fusion constructs or other promoter fluorescent protein fusions, will be evaluated by in vitro assays only. These assays will consist of adhesion and invasion tissue culture assays and fermentation batch culture systems.

Recipient or parental organism

Method 1. E. coli K12 DH5α/INVctF’ are standard bacterial cloning hosts and enable the replication of gene constructs in the cloning vector plasmids. E. coli K12 is a non-pathogenic E. coli strain which can be cultured quickly and easily in the lab, however, is unable to survive readily in the environment.

Method 2. The plasmids pKD4 and pKD46 are not cloning plasmids, but either act as host for the kanamycin resistance gene (pKD4) or facilitate recombination (pKD46) as recommended by Datsenko & Wanner (2000).

GFP tagging of wildtype Salmonella isolates. E. coli K12 DH5cz will be used as the cloning host and for amplification and storage of the plasmid pFPV25.1 and R-plasmid containing the rpsM-gfp fusion. The reason for use is as stated above for method 1 with the addition that E. coli K12 DH5ct can accept plasmids containing GFP fusion constructs for use in Salmonella, without any unforeseen perturbations of growth or cellular phenotype.

Host/vector system

02/03/2022
Method 1. Standard commercially available high copy number cloning vectors such as pUC18 or pCR2.1 (Invitrogen). pPERFORM series of suicide vectors - non-replicating in A. pir Salmonella enterica strains.
Method 2. Only the plasmid pKD4 and pKD46 as either a template or facilitator plasmid are used.
GFP tagging of wildtype Salmonella isolates. Only the plasmid pFPV25.1 and R-plasmid containing the rpsM:gfp fusion will be used.

Origin & function
Salmonella enterica and plasmids as follows: green fluorescent protein (gfp) on pWM1007 :AF292556, yellow (yfp) on pWM1008 AF292558, cyan fluorescent protein (cfp) on pWM1009: AF292559 (Miller et al., 2000).
The first rpsM-gfp fusion was constructed by making an rpsM:gfp fusion which was inserted into pGP704K (oriR6K- mob-aph) Vazquez-Torres (1999).
The second plasmid was constructed by the addition of an rpsM-gfp fusion which was introduced into the plasmid Schierack et al (2005) Salmonella enterica promoters, hilA barA, sirA, csrA, csrB and csrC. Salmonella Typhimurium with rpsMgfp/pGP704 inserted into an R-plasmid and pFPV25.1 which is a high copy number derivative which is under the control of the promoter rpsM.
Chromosomal complementation of the hilA promoter, with a hilA-gfp fusion. The purpose of this fusion is to elucidate the effect of various probiotic, prebiotic and symbiotic combinations on the invasiveness of Salmonella Typhimurium SL1 344 in a batch culture fermentation system by measuring the GFP signal intensity from the different promoter fluorescent protein fusions. The mutants will also be used in adhesion and invasion assays on the porcine jejunal cell line IPEC-J2. Where the effects of probiotics and prebiotics can be linked to the effect on hilA expression, the in vitro tissue culture assays. This can be quantified by confocal microscopy and automated fluorescent microtitre plate readers. Subsequently, further fluorescent reporters or fusion proteins could be constructed using the PCR SOEing method already indicated. These would consist of barA, sirA or csrA/B/C promoter-fluorescent protein fusions. The purpose of these reporter gene fusions would be to further elucidate how the probiotics are affecting the BarNSirA pathway.
GFP tagging of wildtype Salmonella isolates. Electroporation of pFPV25.1 or the R-plasmid containing the rpsM:gfp fusion, will enable transformants used in tissue culture aminoglycoside protection assays to be visualized using confocal microscopy. This will reduce the need for the use of antibodies for this work.

Evaluation of foreseeable effects
All experiments involving wild-type and GMO organisms will be conducted in line with safety regulations relevant dealing with the Hazard Group 2 pathogens (refer to risk assessment 8A311 culture).
The hilA-gfp transcriptional fusion will be used to assess different probiotics, prebiotics and various volatile fatty acids for their inhibitory effect on hilA transcription. This will manifest by altered gfp intensity for the Salmonella hilA promoter gfp transcriptional fusion. This transcriptional fusion is chromosomal and is expected to be be extremely stable, which should limit any horizontal transfer of the transcriptional fusions.
The inactivation of putative virulence determinants is unlikely to increase the virulence of test isolates because virulence is a multifactorial process involving many genes. The addition of a hilA promoter gfp fusion is unlikely effect virulence. E. coil K12 is a standard cloning host and has successfully and safely been used in molecular biology for a number of years. In addition E. coil K12 is unable to survive in the environment for long periods time.
The rpsM-gfp fusion is intended to produce a stable GFP marked Salmonella strain which can be quantified in batch culture or tissue culture studies. This plasmid is medium copy number and has been used in multiple publications. Enumeration of Salmonella Typhimurium in batch culture is essential due to the lack of suitable fluorescent in situ hybridization probes.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
none

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All studies will be performed at Containment Level 2. Thorough disinfection procedures will be carried out in the event of any spillages, using 10% Virkon S or 70% ethanol. 10% Virkon S will be used in the event of large spillages (>10ml), whereas 70% ethanol will be used for small surface spillages <10 ml. Laboratory floors and surrounding corridors are disinfected regularly. Environmental sampling of laboratories and surrounding areas is carried out routinely. All contaminated waste is autoclaved. No contaminated waste is disposed of in the drainage system without prior sterilisation.

Below is a table which describes the waste disposal procedures which will be used for different types of waste, which will be generated during this project.

Solid contaminated materials (cultures, disposables, Disposal by autoclaving in line with current risk etc) assessments. Autoclaving is carried out in the same building (a requirement of GM Class II) for one hour at 134°C. All solid waste is subsequently incinerated on site.

Liquid waste (broth cultures, supernatants, etc) Disposal by autoclaving in line with current risk assessments. Autoclaving is carried out in the building (a requirement of GM Class II) for one hour at 134°C after which liquid waste is tipped down the sink.

General rubbish Disposal by incineration on site in line with current risk assessments.

<td>Development and analysis of lyssavirus pseudotype viruses using retroviral vectors.</td>
<td>Class 2</td>
<td>&lt; 1 Litre</td>
<td></td>
</tr>
</tbody>
</table>
The objective of this project is to develop an alternative serology assay for assessing neutralising antibody responses to vaccination against or infection with lyssaviruses (e.g. rabies virus). This approach would take advantage of pseudotyped virus technology where glycoproteins from one virus are expressed on the surface of a non-infectious retrovirus particles. These can then be used as a surrogate target in a neutralisation assays without the need for category 3 containment.

The project will be conducted in collaboration with the Department of Immunology and Molecular Pathology, University College London (UCL), who have cloned G-protein cDNA sequences from the Rabies virus (Challenge Virus Standard-II, CVS-I), European bat lyssavirus type-I and -2 (EBLV-I and -2) (at VLA under GM RA 06-02) and expressed (at UCL) as a HIV based pseudotype in human epithelial cells.

The virus particles are generated by co-transfection of a cell-line with three plasmids that encode the target glycoprotein, the retrovirus structural genes and a reporter gene (e.g. green fluorescent protein, GFP) flanked by long-terminal repeats that mediate integration into the target cell DNA). The resulting vector genomes do not code for viral structural genes and viral proteins are provided in trans from the first two plasmids. These vectors are therefore replication incompetent. Details of the constructs, demonstration that they do not give rise to replication competent viruses and lack of pathogenicity in a murine model have been published (Zufferey et al. 1997). The viral supernatants will be used to infect HIV-I susceptible human cells, which will then be checked rigorously for the absence of replication competent helper virus using assays for HIV-I gag protein and reverse transcriptase.

This risk assessment only covers the work planned to take place at the VLA i.e. currently restricted to HIV and MLV based vectors with lyssavirus glycoprotein genes (representatives from all available genotypes) or the glycoprotein of VSV (non-lyssavirus rhabdovirus used as control). The recovered pseudotypes will be assessed for their usefulness in serum neutralisation assays to replace the current virus neutralisation assays performed under high containment (ACDPIII, SAPO4).

Recipient or parental organism

Cell lines: HEK 293T, NP2, BHK-21, TE671, N2A
Bacterial cells e.g. E. coli- strain TOP 10 or similar for lyssavirus plasmid construction (under RA 06/02)

Host/vector system

The human immunodeficiency virus type I (HIV-I) gag-pol construct pCMV-A8.91 (Zufferey at at, 1997) and green fluorescent protein (GFP) reporter construct pCSGW (pHR_SINcPPT-SGW; (Demaison et at, 2002) or firefly luciferase reporter construct (pCSLW, where the luciferase gene has been cloned into pCSGW in place of GFP. Murine leukaemia virus (MLV) gag-pol construct pCMVi (Towers at at, 2000) and GFP reporter construct pCNCG (a LNXC plasmid (CLONTECH) encoding enhanced GFP with CMV driving expression of the RNA) or firefly luciferase
**Origin & function**

Origins: PCR amplicons of the glycoprotein genes of lyssaviruses and VSV

Intended Function: The recovered pseudotypes will be assessed for their usefulness in serum neutralisation assays to replace the current lyssavirus neutralisation assays performed under high containment (ACDPIII, SAPO4). Pseudotypes have three major advantages over live virus neutralisation tests: (1) they can be handled in low biohazard level laboratories; (2) the use of reporter genes such as GFP or β-galactosidase will allow the assay to be undertaken at low cost in laboratories worldwide; (3) each assay requires <10μl of serum. The implementation of robust pseudotype microassays will improve our understanding of the protective humoral immunity current rabies vaccines confer against emerging lyssaviruses, and will be applicable to surveillance studies thus helping control the spread of rabies.

**Evaluation of foreseeable effects**

The MLV and HIV based vectors are molecular clones which when expressed as a pseudotype virus particle are capable of binding and entering a cell. Once within the cell the particle nucleic acid, consisting of the reporter gene only, integrates in to the target cell DNA allowing expression of the reporter. However, the vector genomes do not code for viral structural genes and viral proteins are provided in trans from at least two separate plasmids during particle production. These vectors are therefore replication incompetent and incapable of producing progeny.

Pseudotyped particles are non-pathogenic in mice so would not be expected to be so in humans should accidental exposure occur. The major risk associated with retrovirus vector production and subsequent transduction is the occurrence of replication competent, recombinant viruses (RCR). Although a minimum of 3 recombination events are necessary to produce RCR in these systems, this possibility cannot be totally excluded. While RCR derived from MLV based vectors are unlikely to be more harmful than a wild type virus which is not known to infect humans, RCR derived from HIV vectors may cause harm for humans (HIV is ACDP Hazard Group 3).

The recovery and use of these engineered pseudotype viruses will thus be restricted to GM containment level 2 (Bldg 64, Room 44E) and infected tissue culture cells will be handled in the Class II safety cabinet.

Risk to the environment: Low.

Laboratory measures are in place to reduce the risk of release of any GMO from the designated category II laboratory in which all work will be carried out. Protective clothing (laboratory coats, disposable gloves and overshoes) will be worn by staff working with GMO’s. All waste will be autoclaved prior to incineration. Infected cell culture will be handled in the Class II Safety Cabinet.

Overall Risk: Low

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- **Solid waste:** will be autoclaved (134°C, 1 hour) prior to disposal by incineration.
- **Liquid waste:** will be autoclaved (134°C, 1 hour) prior to incineration. Liquid waste from live virus manipulations will be discarded into 1% Virkon within the Class II cabinet prior to autoclaving. General rubbish: will be treated as solid waste and autoclaved (134°C, 1 hour) prior to incineration.
- **Work:** will be carried out in dedicated category II laboratories. Antibiotics used in selection of recombinant plasmids will be limited. All material incorporating antibiotics (i.e. culture agar) will be autoclaved and incinerated.
- **Operators:** performing recombinant virus handling and manipulations will adhere to the strict procedures and risk assessments necessary for all live virus work within a Class II safety cabinet. Wearing of laboratory specific PPE (lab coat, gloves, overshoes) will be required at all times. Whilst this work is being undertaken, only rabies-vaccinated staff will be permitted to enter the laboratory.
- **The viral supernatants:** will be used to infect HIV-1 susceptible human cells, which will then be checked rigorously for the absence of replication competent helper virus using assays for HIV-1 gag protein and reverse transcriptase (expertise at UCL).

Project Additional Information

Purposes of the contained use

In order to understand the role of amino acid transporter genes and sdiA related genes I metabolism, pathogenicity and epidemicity of Salmonella Enteritidis, genes will be activated individually and the characteristics of wild type and mutant strains will be compared.

Recipient or parental organism

Salmonella enterica strains with inactivated target genes (amino acid transporter genes and SdiA regulated genes) are unlikely to be more virulent than wild type strains. K12 strains harbouring single target genes which frequently are a single component of an operon are unlikely to increase the virulence of K12 strains.

All wild type strains to be used have already been typed by molecular methods to ensure traceability.

Host/vector system

Host: 1. E.coli K12 (DH5α or INVαF, S17-1λ pir)
2. The final recipient organism: Salmonella Enteritidis strains

Vector: 1. Standard high copy number cloning vectors such as pUC18 or pCR2 (Invitrogen). PERFORM series of suicide vectors -non-replicating in λpir Salmonella enterica strains.
2. Plasmid -pKD4 (Datsenko and Wanner, 2000) will be used as PCR template to create replacements of gene with kan cassette. Plasmid pKD46 (Datsenko and Wanner, 2000) expresses λ red system - y β and exo genes under the control of the P arab promoter. Contains ampicillin® marker. This plasmid contains the red system, whereby Gam inhibits hosts RecBCD exonuclease V so that Bet and Exo gain access to DNA ends and promote homologous recombination.

Origin & function

Origins: Salmonella Enterica

Intended functions of the genetic material involved: Chromosomal insertional inactivation of genes of interest: amino acid transporter genes SEN1417-1419, SdiA regulated genes srgC and rck. The purpose of these genetic modifications is to characterise these amino acid transporter genes and sdiA related genes functions and understand the role of these genes in metabolism, pathogenicity and epidemicity of Salmonella Enteritidis. The characteristics of wild type and mutant strains will be compared. Studies such as in vitro phenotype studies (phenotype array, Biolog), biofilm formation, survival within chicken models and tissue culture models will be conducted.

Evaluation of foreseeable effects

Salmonella enterica strains with inactivated target genes (amino acid transporter genes and SdiA regulated genes) are unlikely to be more virulent than wild type strains. K12 strains harbouring single target genes which frequently are a single component of an operon are unlikely to increase the virulence of K12 strains.

### Project Additional Information

**Purposes of the contained use**

- Insertion of the LLO protein coding amplification into pTriEx-1.1 Neo
- Propagation of the recombinant bacterial plasmid. The host is a general cloning host. It is transformable using standard methods.
- Expression of the proteins in a bacterial host under inducible T7 RNA polymerase.
- Assessment of protein expression in bovine cells.

**Recipient or parental organism**

- E. coli DH5α which is a derivative of E. coli K-12 (Cloning Host).
- E. coli BL21 or Rosett (DE3) (Bacterial Expression Hosts)
- Bovine cells (primary dendritic and skin fibroblasts)

**Host/vector system**

- pTriEx-1.1 Neo. (Novagen)

**Origin & function**

The complete open reading frame encoding LLO will be supplied in the pBlusscript plasmid from collaborators in the USA. The LLO insert will be subcloned into pTriEx-1.1 Neo. A his-tagged protein will be expressed and purified from E. coli using Nickel affinity chromatography. The biological activity of the recombinant protein will be confirmed using a sheep erythrocyte lysis bioassay. The protein will then be used in a series of in vitro experiments to assess whether LLO facilitates the cytosolic delivery of antigen to the cytosol of bovine cells resulting in enhanced MHC class I antigen presentation.

To assess the biological effects of endogenously synthesised LLO in bovine cells, cells will be transiently transfected with pTriEx-1.1 Neo expressing LLO.

**Evaluation of foreseeable effects**

The LLO protein has the ability to form pores in the membrane of the phagolysosome of mammalian cells, allowing release of the phagosomal contents into the cytosol of the host cell. LLO also has lytic activity on red blood cells. Whether recombinant E. coli expressing LLO will exhibit enhanced pathogenicity is unknown. However, given that E. coli is not able to grow intracytoplasmically and LLO is only active at acidic pH (optimal pH 5.5) it may be speculated that it is unlikely to do so. In vitro experiments showed that macrophages efficiently phagocytosed and killed recombinant E. coli expressing LLO, and that the LLO was functional and still allowed cytosolic delivery of antigen.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid cultures will be autoclaved for 45 minutes at 134 degs, 31.9 psi (2.2bar) pressure, prior to disposal by incineration.
Liquid waste will be autoclaved for 45 minutes at 134 degs C, 31.9psi (2.2bar) pressure prior to disposal down the drain.
Alternatively liquid waste will be treated overnight with a minimum of 1 part sodium hypochlorite (5-16% available chlorine) to 100 parts of waste liquid before disposal down the drain.
General waste will be autoclaved for 45 minutes at 134 degs C, 31.9psi (2.2bar) prior to incineration.
All methods are designed to kill 100% of bacteria

Project Ref 221/09.3

Date Ackn'd 07/07/2009
CU2 Project Title Production of a gfp mutant in Salmonella species
Date Project Ceased

Class CultureVolClass2 CultureVolumeClass3-4
Class 2 < 1 Litre
Non-GMM Consent Granted
The aim of this work is to generate a reference control strain of Salmonella enterica that contains a green fluorescent gene (gfp) in the chromosome that is constitutively expressed. The strain will be used as a positive control to improve the validation of microbiological tests and media for isolation of Salmonella and avoid the reporting of false positive results that arise due to cross contamination. The marked strain can be identified either by monitoring expression of the GFP in the presence of UV light (a commercially available plate reader) or by PCR based methods targeting the gfp gene.

The GFP mutants will be constructed by one of two methods, or possibly be both methods, and these two methods are outlined briefly below:

**Method 1**
The plasmid incorporates a transposon which is used to carry the gfp gene into the chromosome of the recipient bacteria.

* Perform filter mating of suitable Salmonella recipient strains with the donor strain (E.coli S17-1 λ pir) that has the suicide plasmid containing the gfp gene and transposon.
* Select for transconjugants that are kanamycin resistant but ampicillin sensitive (indicating presence of the gfp gene but loss of the suicide plasmid pAG408 –Noah et al., 2005).

**Method 2** (Datsenko & Wanner, 2000)

* PCR gene of interest from recipient (Salmonella) using primers with homology to gene of interest and to region of plasmid pkD4.
* Incorporate gfp gene into modified pkD4.
* Electroporate helper plasmid pkD46 into the recipient bacteria of choice to aid homologous recombination.
* Electroporate the gfp:kan construct into the recipient containing pkD46 and screen for kanamycin resistance which will indicate that homologous recombination has occurred.

**Recipient or parental organism**
Recipient organism is a strain of Salmonella enterica.

**Host/vector system**

**Method 1:**

Host- E.coli K12 (DH5α or INVαF, S17-pir)
Vector - gfp gene which is located on a suicide vector pAG408 (Surez et al., 2007 and Murphy et al., 2007)
Method 2:

Host - Final recipient Salmonella strain

Vectors

a) Plasmid pKD4 Plasmid can only be maintained in E.coli BW25141 (1633) Contains ampicillin® and kanamycin® marker

b) Helper plasmid pKD46.

Maps of both the above 2 plasmid can be found in the paper by Datsenko and Wanner (2000)

Origin & function

The gfp gene originates from the jellyfish Aequorea Victoria.

For method 1 - the gfp gene and kanamycin cassette are located on suicide vector pAG408 which is carried on chromosome of E.coli K12. A map of the plasmid pAG408 can be found in the paper by Suarez et al. (1997).

For method 2 - the gfp gene with its own promoter will be purchased from a suitable company such as Invitrogen. Plasmid pKD4 will also be used as described earlier. Plasmid pKD46, although used, will be lost when the constructs are grown at 37° C.

The intended function of the genetic material is to produce a traceable bioluminescent Salmonella strain outlined in more detail earlier.

Evaluation of foreseeable effects

All experiments involving these organisms will be conducted in line with safety regulations relevant for dealing with the Hazard Group 2 pathogens and this will limit any risks.

The suicide plasmid donor strain for method 1 (E.coli K12) contains a small plasmid unlikely to increase the virulence of the K12 strain. In addition E.coli K12 is unable to survive in the environment for long periods of time.

The gfp gene itself poses no increased risk of infection as the gfp gene does not confer pathogenicity.

Method 1 will insert the gene in an unknown area and may alter gene function. The area into which the gene has inserted will be monitored using appropriate genetic tests such as PCR, sequencing, southern hybridisation or signature tag mutagenesis to check that a virulence gene could not be upregulated.

Method 2 will disrupt gene function. There is no evidence from chicken studies when the gfp gene was inserted into the marRAB locus of Salmonella Typhimurium that the gfp gene in Salmonella strains affected pathogenicity (Randall et al., 2001). Other studies have also shown that disruption of the ompX or ompW genes does not increase the ability of Salmonella to adhere to and invade tissue culture cells (unpublished observations) and aroA mutants are attenuated (Trebichavsky et al, 2006).

The stability of modified strains will be evaluated by serial passage in broth for 10 days and previous studies have shown such mutants to be stable (Randall et al., 2001, Suarez et al, 1997). The phenotype of modified strains will be evaluated by phenotype micro-array (BIOLOG) and growth characteristics will be performed for parent and mutant strains in rich and minimal media.

Field strains exposed to UV light in checking for the presence of the gfp gene may subsequently be stored for further analysis. However, brief exposure to light is not envisaged to produce mutations in these strains and UV based bacterial identification tests based on fluorescent substrates is in regular use in commercial labs.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All studies will be performed at containment level 2 in line with relevant safety guidelines and risk assessments (FES7/1-Culture, Handle and Disposal, FES7/3-Disinfection, FES7/5-Centrifuges, FES7/85-Use of Safety Cabinets). Disinfectant used to treat small spills of any bacterial culture is 70% ethanol, disinfectant to treat larger spills is Interkokask.

Laboratory floors and surrounding corridors are disinfected weekly alternatively with the disinfectants Tegador and TASKI San to eliminate any selection of resistance by using only one disinfectant.

Environmental sampling of laboratories and surrounding areas is carried out monthly. No contaminated waste is disposed of in the drainage system without prior sterilisation/autoclaving.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

# Project Additional Information

## Purposes of the contained use

We propose to create a mutant library in Mycoplasma bovis (M. bovis) to study such processes as cell adhesion and biofilm formation.

## Recipient or parental organism

We will transform field strains of M. bovis with a suicide plasmid, part of which will integrate into the mycoplasma chromosome. The transposable element that is integrated into the chromosome carries a gene for gentamicin resistance as a selective marker but doesn't carry the transposase gene, thus preventing the re-excision of the element and therefore making stable mutants.

The strains chosen for this study will be good biofilm formers and the mutants will be screened for biofilm formation. Any mutant that does not produce a biofilm or produces a biofilm significantly better than the wild type will be selected and the position of the transposon within the chromosome defined. This will help us to understand the process of biofilm formation in mycoplasmas.

## Host/vector system

The hosts are: (1) E.coli K12 derivative strain, for example TOP10 cells. (2) Mycoplasma bovis, field strain that is not naturally gentamicin resistant, from SEB5 culture collection.

The Vector is: pMT85 - A suicide plasmid with a gentamicin resistance selective marker and transposon 4001.

## Origin & function

Plasmid originally from Staphylococcus. The plasmid also contains Transposon Tn4001 is a composite class 1 transposon originally detected in the Staphylococcus aureus plasmid pSK1 (Mahairas et al, 1989). The tranposase gene has been altered by site directed mutagenesis so that a TGG (Trp) codon was changed to a TGA (stop) codon. This means the gene is prematurely terminated in Eubacteria (such as E.coli) and results in a truncated protein which has no activity (Zimmerman et al, 2005).

(1) The E.coli host strains selected for this project are disabled strains requiring culture conditions for efficient propagation and survival. The presence of the pMT85 plasmid will confer gentamicin resistance to the host cell but will have no effect on the virulence of these bacteria. These would normally be designated as class 1 organisms.

(2) Transformation of M. bovis with the plasmid and its integration into the mycoplasma chromosome is more likely to give a disadvantage to the cell in comparison to the wild type. The integration of the transposable element and the inactivation of genes is unlikely to increase the virulence or persistence of the bacteria.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

02/03/2022
The objective of this project is to generate Classical Swine Fever Virus (CSFV) pseudotyped viral particles representative of different CSFV genotypes. CSFV can only be propagated under Defra Containment Level 3 (SAPO III containment), thereby limiting the types of experiments that can be conducted. Pseudotype virus technology allows the generation if non-infectious reporter virus particles that incorporate the surface coat proteins of a virus of interest (such as CSFV) under the direction of non-infectious retrovirus genetic elements that only require GM Class 2 containment.

Our studies will involve use of CSFV pseudotype particles in reporter assays to quantitatively measure rates of cellular uptake of different viral strains, to investigate which primary pig cells are permissive for CSFV and to screen for compounds or antibodies able to inhibit CSFV uptake. Usefulness of CSFV pseudotypes for replacing wild-type virus in serum neutralisation assays will also be assessed.

Recipient or parental organism

Pseudotype particles will be produced by transfection of pig or human tissue culture cell lines with three separate plasmids, one to express CSFV coat proteins, the second to provide retroviral proteins required for virion assembly and a third plasmid to allow expression of packageable RNA encoding a reporter gene such as green fluorescent protein (GFP), luciferase or β-gal.

A theoretical risk associated with pseudotype virus production is the occurrence of replication competent, recombinant (RCR) viruses. A minimum of 3 recombination events to place five genetic elements in the correct spatial orientation would be necessary to produce RCR. This possibility, however improbable with a three plasmid system, cannot be totally excluded. Nevertheless, risks to laboratory workers and animals are minimal as all accessory proteins required for viruses to be infectious are deleted from the system so in the improbable event of recombination occurring, any RCR produced would be non-infectious and would not produce progeny.

Pseudotype particles will be used to non-productively infect pig cell lines and primary cells.
Cell specificity is conferred by the surface coat protein, which, in this project will be derived from CSFV - a virus which is restricted to the porcine host. Once within a cell, the nucleic acid contained in the pseudotyped particle, encoding the reporter gene only, integrates into the target cell DNA allowing expression of the reporter and the process is arrested at this stage. The reporter nucleic acid does not encode viral structural genes and viral proteins are provided in trans from at least two separate plasmid to enable particle production and pseudotyped particles are therefore replication incompetent, non-infectious and do not generate progeny particles.

<td>Pig: Porcine cell lines such as pig kidney PK15 and SK6, and the pig aortic endothelial AOC cell line.</td>
<td></td>
</tr>
</tbody>
</table>

**Origin & function**

PCR amplicons of coat protein coding sequences from different CSFV strains will be cloned into pCAGGS (Riken Center for Developmental Biology).

Pseudotype virus particles will be generated by co-transfection of three plasmids:

1. The coat protein-expressing plasmid described above.
2. A plasmid supplying proteins to allow pseudotype particle assembly. The murine leukemia virus (MLV)-based gag-pol core protein construct, CMVi or the human immunodeficiency virus (HIV)-based plasmid, pCMV-Δ8.91, will be used. These plasmids are safe to use as they contain minimal viral genetic elements and all viral accessory proteins are deleted.
3. A reporter plasmid: Reporter constructs for use with pCMVi are pCNCG (a LNCX plasmid (CLONTECH) encoding GFP or pMLV-luc firefly luciferase reporter construct. Reporter constructs for use with pCMV-Δ8.91 are GFP reporter construct pCSGW (pHR_SINcPPT-SGW); or reporter constructs pCSGW-L, -RL or -β-gal where the luciferase, renilla luciferase or B-gal genes respectively have been cloned into pCSGW in place of GFP.

Human embryonic kidney 293T cells will be used to test protein expression and may be used for production of Pseudotyped particles as they are amenable to transfection and very efficient at expressing exogenous proteins. Porcine cell lines will be used for work with pseudotype particles as they will contain CSFV coat surface proteins and CSFV is restricted to porcine hosts.

**Evaluation of foreseeable effects**

There are minimal foreseeable effects from working with the three-plasmid system as the reporter plasmid does not encode any viral structural genes and viral proteins required for pseudotype production are provided in trans from two separate plasmids. As stated above, a theoretical risk associated with pseudotype virus production is the occurrence of replication competent, recombinant (RCR) viruses. A minimum of 3 recombination events to place five genetic elements in the correct spatial orientation would be necessary to produce RCR and it is highly unlikely that this could occur.

Work with the resulting pseudotype particles has few associated risks as these particles lack the accessory proteins needed for formation of infectious virus and are therefore replication incompetent and non-infectious.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not Applicable
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste generated by this project will be completely inactivated by autoclaving (134°C, 1 hour) prior to disposal by incineration.

Liquid waste will be completely inactivated by discard into 1% Virkon prior to autoclaving (134°C, 1 hour) and incineration.

General rubbish will be treated as solid waste and autoclaved (134°C, 1 hour) prior to incineration.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Project Ref 221/09.6

Date Ackn’d 01/09/2009
CU2 Project Title
Assessment of risk associated with handling (storage and culture) of genetically modified ACDP Hazard Group 1 and 2 bacteria sent from other institutions

Date Project Ceased 02/03/2022

Class 2
CultureVolClass2 < 1 Literature
CultureVolumeClass3-4
Non-GMM Consent Granted
Project Additional Information

Purposes of the contained use

The Phengenix program launched by FES offers the expertise in genotyping and phenotyping of bacterial and eukaryotic cells to the wider research and commercial community. The technologies are applicable to wild type and genetically modified organisms, this risk assessment therefore covers the handling, storage and culture of ACDP Hazard Group 1 and 2 bacteria at the VLA.

Recipient or parental organism

Constructs of genetically modified bacterial species will be supplied by collaborative institute. NO Modifications to be carried out at VLA.

There are several different methods employed to create mutants in a bacteria. The one employed will depend on the purpose of the studies and species of bacteria. Creation of mutants typically relies on the introduction of mutated non-replicating DNA (e.g. in suicide plasmids, transposons, bacteriophages or PCR product), which may or may not be integrated into the chromosome. Where complete ablation of gene function is required, the mutated DNA may contain a copy of the target gene disrupted by a selectable marker e.g. antibiotic resistance genes. However, with modern approaches to mutagenesis, the wild type allele is often replaced with a mutant allele without leaving any antibiotic resistance gene in the cell.

Host/vector system

This application will include the use of any ACDP Hazard Group 1 or 2 bacterium. The bacterium chosen will depend on the nature of the primary studies undertaken at the collaborating institute. Typically bacteria are chosen due to interests of the groups involved e.g. pathogenesis, biochemistry, epidemiology etc. A variety of vectors are available for use in different bacterial species. These are usually non-mobilisable or mobilisation-defective vectors from commercial or academic sources.

Origin & function

DNA sequences are usually obtained from the organism of interest by PCR methods. These sequences may include promoter sequences, encoding and/or non-coding sequences. Mutations are often selected for by the replacement of sequence of interest with a selectable marker (e.g. antibiotic resistance cassette) or reporter gene (e.g. beta-galactosidase, luciferase or fluorescent protein).

The purpose of manipulation of genetic material is to characterise and understand the effect of DNA sequences on the metabolism, pathogenicity and/or epidemiology of the organism of interest. Comparisons will be made with the activities of the progenitor strains to assign DNA sequence function. The studies offered at the VLA will be in vitro phenotypic characterisation to include central metabolism, effects of stress and metabolic effectors.

Evaluation of foreseeable effects

All experiments involving these organisms will be conducted in line with safety regulations relevant for dealing with ACDP I and II bacterial species (refer to risk assessment FES7/1 and FES7/127).
Bacterial strains in which DNA sequences have been manipulated are unlikely to be more virulent than the wild type strains. The GMO is likely to be less virulent than its pathogenic progenitor and can therefore be handled at the ACDP category relevant to wild type. Nevertheless, the specific risk assessment for the organism to be studied will be obtained from the collaborator and any additional risk (if any) will be carefully considered before the work commences at the VLA.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disposal:
Solid contaminated materials: Following acceptance of phenotyoping results by customer, wild type and GMO stocks will be destroyed according to local procedures. Disposal by autoclaving (in building 4 room 3 or 36) and incineration in line with current risk assessments (FES7/4) - One hour and 10 minutes at 134°C. All solid waste is subsequently incinerated onsite. Liquid waste: Disposal by autoclaving and incineration in line with current risk assessments (FES7/4) - One hour and 10 minutes at 134°C after which liquid waste is tipped down the sink. General Rubbish: Disposal by incineration on site in line with local procedures.

Special measures necessary to protect the environment: A restricted access laboratory has been assigned in which all studies will be carried out. All live culture work will be prepred in class II safety cabinet that will be regularly fumigated (FES7/75 & FES7/85). All studies will be conducted in line with relevant safety guidelines and risk assessments (FES7/1-Culture, Handle and Disposal, FES7/3-Disinfection, FES7/5-Centrifuges, FES7/85-Use of Safety Cabinets). Disinfectant used to treat small spills of any bacterial culture is 70% ethanol, disinfectant to treat larger spills is Interkokask. Laboratory floors and surrounding corridors are disinfected weekly alternating between 2 disinfectants to avoid any selection of resistance by using only one disinfectant.

Is an emergency plan required according to regulation 20? Y

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

02/03/2022
Project Additional Information

Purposes of the contained use

Protein misfolding cyclic amplification (PMCA) is used in research and diagnosis of animal transmissible spongiform encephalopathies (TSE’s), such as BSE in cattle and Scrapie in sheep. PMCA is a technique akin to PCR in that it amplifies very low levels of product, in this case and the abnormal (disease associated prion protein (PrPSc), to detectable levels. To achieve this, the test sample is mixed with a high abundance of normal (cellular) prion protein (PrPC) and treated with cycles of sonication and incubation over a period lasting for several days/weeks. At regular intervals (currently daily) the PMCA mixture is replenished with fresh PrPC for further conversion/amplification. Currently PrPC is supplied as a tissue homogenate derived from ovine brains, however, there are inherent limitations using this as a source of PrPC. The tissues have to be taken within 30 minutes of post mortem and processed within 45 minutes for the tissue to be suitable for the support of amplification and even then this is not guaranteed. In addition, the ethical issue of using animal derived tissues for what we hope to become an 'off- the-shelf' diagnostic test is questionable (a single sheep brain will support 400-500 tests).

Recent advances in rodent PMCA technology using recombinant PrP (rPrP) (Atarashi and others 2007) is the first step towards a brain free substrate approach. There are a number of advantages for the transfer of this technique to detection of sheep scrapie. Recombinant PrP of different genotypes can be manufactured in milligram quantities. This line of approach would also facilitate the control of the conversion/amplification conditions.

The aim of the project is to determine if recombinant PrPC can be used as a replacement for brain derived PrPC in the PMCA technology.

We will acquire from two research establishments (IDEXX Laboratories and ADAS UK), E.coli strains that have been transformed through the insertion of the PrP gene.
The transformed E.coli will be grown up and recombinant protein expression induced. After induction cells will be lysed and protein extracted from inclusion bodies. Extracted protein will be purified and refolded as required for use in PMCA experimentation.

Recipient or parental organism

The E.coli host strains selected for this project are disabled strains requiring precise culture conditions for efficient propagation and survival. These would normally be designated as class 1 organisms (see SACGM Guidance notes). The vectors selected contain the necessary promoters and regulatory sequences for expression of the inserted gene, therefore these organisms are capable of generating recombinant proteins. The vectors themselves are considered to be non-mobilisable. The foreseeable effects of this GMM relate largely to the 'insert', in terms of the intrinsic properties of the protein of interest and the effect such a protein would have on the virulence and pathogenicity of the host strain.

The production of the prion protein by the modified E.coli host is not expected to alter the pathogenicity or virulence of the E.coli host. The E.coli host is a K12 or B strain derivative, and such is considered disabled. Production of the prion protein is not expected to alter the ability of this E.coli host strain to survive in the environment or become invasive. The vectors used for delivery of the gene of interest to the E.coli host and to drive expression of the protein are non-mobilisable, and thus gene transfer is dependent upon accidental encounter with organisms that can complement the lack of mobilisation function. This is considered unlikely as measures to prevent the release of the organism from the lab are in place.

Host/vector system

The following laboratory adapted E.coli strains have been used:

E.coli K12 derived strain Novablue(DE3)™, E.coli B derived strain BL21 (DE3)™, E.coli Rosetta strain™.

The E.coli K12 hosts allow stable propagation of the recombinant plasmids and, depending upon the vector, inducible expression of the recombinant protein. These E.coli are RecA, EndA deficient and considered 'disabled'. They are amongst the most frequently used bacterial host and are considered to have a good safety profile (see SACGM Guidance notes). These organisms do not possess or express known virulence factors (Muhldorfer and others 2006, Muhldorfer and Hacker 2004, Kuhnert and others 1997 & Bachmann - Strain derivatives and mapping 1996)

E.coli Novablue DE3 strain is a K12 derivative.

E.coli B derivatives are EndA deficient but have intact RecA function. Nevertheless, these strains are recognised as non-pathogenic. (see SACGM Guidance notes, Muhldorfer and others 2006, Muhldorfer & Hacker 2004, Kuhnert and others 1997 & Bachmann - Strain derivatives and mapping 1996).

E.coli Rosetta™ host strains are Tuner™ derivatives designed to enhance the expression of eukaryotic proteins that contain codons rarely used in E.coli (see web based data from vector suppliers - Invitrogen, Sigma Aldrich, Promega & GE life sciences) Tuner™ strains are lacZY deletion mutants of the BL21 (B derived) strain.

Vector

The following expression vectors have been used:

pET-41a and pET-22b(+), both of which are commercially available from Novagen.

pET vectors have a modified pUC origin and are therefore lacking in the Bom and Nic sequences necessary for mobilisation. pUC series and derivatives are non-mobilisable.

Origin & function

The nucleic acid insert will compromise amino acid residues 23-231 of the prion protein gene encoding naturally occurring sheep genotypes and Syrian hamster PrP.

GM recombinant plasmids containing the nucleic acid inserts will be used to produce recombinant proteins in E.coli. Production of the transformed E.coli will be done for us
by external research establishments.

**Evaluation of foreseeable effects**

Very low risk.

The vectors used are impaired in their ability to pass on genetic material to other bacteria. Furthermore, if gene transfer to environmental bacteria was to occur it is unlikely to have any notable effects as the foreign gene is not known to encode proteins that promote any selective advantage or contribute to virulence and pathogenicity.

Release of the cloned genes/plasmids into the environment will have little impact. The vector/plasmid is non-mobilisable and non-conjugative and genetic transfer to other organisms requires the presence of specific helper plasmids under specific conditions (Lebaron and others 1997). This event is considered unlikely. Furthermore, plasmid DNA released into the environment will be naturally degraded by ubiquitous nucleases.

In the unlikely event that transformed E.coli is released to the environment where appropriate conditions exist for its survival and growth, gene transfer to other host species, prokaryotic and eukaryotic is very unlikely.

Many research groups have tried to develop infectious rPrP (Mehlhorn and others 1996 and Hill and others 1999) and been unsuccessful. One group has been able to develop infectious rPrP (Legname and others 2004) but only under strict unusual conditions involving a short 55 amino acid peptide with a mutation at residue 101 (p101L) treated with 3M urea at 37°C before intracerebral inoculation. The risk of our rPrP becoming infectious on release to the environment is extremely low. The genetic sequence we intend to insert into the E.coli does not contain the P101L mutation. It would also be very unlikely to be released in an environment where urea is present at a concentration of 3M and at a temperature of 37°C. The resultant GMM is considered equivalent to ACDP hazard group 2 due to the unknown expression levels of recombinant ovine and hamster PrP, which could be potentially toxic and/or pathogenic at higher concentrations.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Derogation is required for the siting of the autoclave used for this project. Due to the high temperature required for destruction of Prion proteins an alternative autoclave to that within the building is required. This will involve transporting the waste from the building to another no more than 50 metres away across a level (no steps) car park.

Appropriate documentation to support this derogation is provided with this application.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All work with the GMM will be carried out within containment level 3 with derogation (no negative pressure, no requirement for fumigation) laboratory dedicated for work involving TSE's. All work involving GMM's except for incubation of E.coli in growth media will be carried out in a dedicated class 1 safety cabinet up to the point where the E.coli have been lysed using a Bugbuster. Incubation of E.coli in growth media will be carried out in large capped bottles within an integrated shaking incubator with lid. Reusable labware will be treated with either 2M sodium chloride or sodium hypochlorite (20,000ppm free chlorine) to kill any E.coli and deactivate any abnormal prion protein, before removal from the laboratory for cleaning. The safety cabinet will be cleaned with ethanol on a daily basis and with sodium hypochlorite weekly.

Solid waste (Agar plates, absorbent paper, plastics etc) will be disposed of through autoclaving (134-137°C for 30 minutes) followed by incineration. The higher temperatures used for autoclaving are required for deactivating abnormal prion protein. (Transmissible spongiform encephalopathy agents: safe working and the prevention of infection: Publication of revised guidance. June 2003. Department of Health).

Large volume liquid waste cannot be autoclaved using existing equipment used for autoclaving TSE waste. Alternative measures for handling large volume TSE waste have been devised and have been in use for many years. Small volume GMM waste can be absorbed onto tissue paper and treated as for solid waste. Large volume GMM waste (50mls plus) produced in these experiments will be mixed with equal volumes of sodium hypochlorite (40,000ppm free chlorine) for one hour to kill any organisms and deactivate any aggregated PrP, then disposed of by incineration. See attached SOP for waste transport procedures.

Contaminated or potentially contaminated rubbish should be placed in black plastic sacks and disposed of by incineration using general waste management.

Project Ref 221/10.2

Storage, use and culture of luminescent (lux) ACDP hazard group 2 bacteria

Class 2 Culture Volume Class 3-4

Project notified under transitional arrangements N
Project Additional Information

Purposes of the contained use
To identify the sites of colonisation for Leptospira interrogans and Campylobacter jejuni within the insect model; Galleria mellonella

Recipient or parental organism
1) Leptospira interrogans L495 and E. coli DH5alpha
2) Campylobacter jejuni ATCC 33291 and E. coli DH5alpha

Host/vector system
1) L. interrogans: pAL615 (contains lux genes, pflgB promoter)
2) C. jejuni: pSB377 (contains lux genes), pRY107 (shuttle vector) and pflaA (ATCC 33291).

Origin & function
Photorhabdus luminescens (formerly called Xenorhabdus luminescens) is a Gammaproteobacteria belonging to the family Enterobacteriaceae. It is a bioluminescent bacteria found in terrestrial environments.

• Lux CDABE reporter system - commonly used reporter gene system (Murray et al., 2010; Allen and Griffiths., 2001)
• flaA σ28 promoter - From the test strain ATCC 33291 (Allen and Griffiths, 2001)
• flgB promoter from Borrelia burgdorferi (provided by M. Picardou; pasteur Institute (Murray et al., 2010))

Automatically distinct internal structures of the Galleria larvae were successfully identified through the use of histopathology in a previous project SC0243. However, histopathology failed to identify the colonisation sites within the Galleria. A LUX tagged Campylobacter and Leptospira will provide traceable luminescent bacteria to study tissue tropisms and elucidate sites of colonisation using an In Vitro imaging System (IVIS).

Evaluation of foreseeable effects
No adverse effects are envisaged. All experiments involving these organisms will be conducted in CL2 laboratories in line with safety regulations relevant for dealing with hazard group 2 pathogens (refer to risk assessment FES7/1). The lux operon from Photorhabdus luminescens (formerly called Xenorhabdus luminescens) poses no increased risk of infection as the lux genes do not confer pathogenicity; the genes product's function is to emit light which is not known to be harmful to any organism or the environment (Van Dyk and Rosson, 1998). The luxCDABE fusion has been stably inserted into the chromosome and therefore is unlikely to be lost (Murray er al., 2010; Allen and Griffiths, 2001).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Disposal of bacterial waste and/or infected Galleria will be destroyed using local procedures (autoclaving and incineration). Live, infected Galleria will be frozen at -20°C for at least 16 hours before being autoclaved. Waste and frozen Galleria will be disposed of by autoclaving (Building 4; room 2, Stewart Stockman; room SE.110) and incineration in line with current risk assessments (FES7.4); 70 minutes at 134°C and 15 psi. All solid waste is subsequently incinerated on site.
All organisms are ACDP hazard group two and all manipulations will be carried out in our collaborative institutes and do not require any further modifications at VLA. However, wild type strains will be used as well as the genetically modified strains.

All studies will be carried out in a Class II safety cabinet (FES7/85) as required and always within a containment level two laboratory. All studies will be conducted in line with departmental risk assessments (FES7/1, FES7/3, FES7/5, and FES7/85) and the relevant safety guidelines. Small spills (<20ml) of bacterial culture are treated with 70% ethanol; larger spills (>20 mls) Interkokask or Superkill. Laboratory floors and the surrounding corridors are disinfected weekly with Tegador and TASKI (weekly rota applied) to eliminate any selection of resistance by using one disinfectant. All bacterial waste will be disposed of by autoclaving (134°C, 15 psi for 70 minutes) before incineration.

Transfer of any live ACDP hazard group two cultures will occur in a sealed vessel e.g. a bio bottle or any other container with a sealable lid (Refer to risk assessment FES7/133).

<td>Expression of retroviral gag protein in cell lines already expressing exogenous PrPc</td>
<td>Class 2</td>
<td>&lt; 1 Litre</td>
<td>Non-GMM</td>
</tr>
</tbody>
</table>

02/03/2022
The work aims to express the gag gene from Maedi-visna virus in cell lines already expressing ovine and bovine PrPC. There is growing evidence that co-infection of animals with lentivirus enhances the detection of scrapie in sheep (Salazar et al., 2010), and co-infection has also been shown to increase infecton in cell models (LeBlanc et al., 2006). More recently the co-expression of just gag protein from HIV has been shown to increase sensitivity up to 100x in a cell model of Chronic Wasting Disease (CWD) (Bian et al., 2010).

We have previously generated a series of cell lines based on the rabbit kidney cell line, RK13, constitutively expressing either ovine or bovine PrPC and have shown permissiveness to infection with a subset (7 out of 30) of scrapie field cases (Neale et al., manuscript in preparation). We now aim to co-express the gag protein from Maedivisna virus in these cell lines, as well as the individual proteins that comprise the gag protein - the gag protein once expressedin the cell is cleaved by proteolytic action into three main proteins - matrix, capsid and nucleocapsid. It is proposed that the co-expression of the gag gene from Maedi visna virus in cell lines currently permissive to scrapie infection will increase their sensitivity. Additionally it is hoped that expression of the gag gene, or its component parts, in cells expressin bovine PrP will render them susceptible to infection with BSE. By expressing the 3 major components of the Maedi visna virus gag gene separately it may be possible to elucidate whether one of these componenets is required for increased sensitivity or whether it is a co-ordinated effetct of all the products of the gag gene.

Recipient or parental organism

1. Laboratory adapted E. coli strains:
   - e.g. E.coli K12 derivative strains, e.g. JM109 (Promega), TOP10, TOP10 F'; DH5α (Invitrogen)
   - e.g. ccdB Survival 2 T1R strain (Invitrogen, Cat# A10460).

2. Mammalian cell lines based on the RK13 cell line constitutively expressing ovine or bovine PrPC (covered by GMRA 02/07)
   - The E.coli K12 hosts allows stable propagation of the recombinant plasmids. These E. coli are RecA and EndA deficient and considered 'disabled'. They are amongst the most frequently used bacterial host and are considered to have a good safety profile (anon, 2007). These organisms do not possess or express known virulence facotrs (Muhidorfer et. al., 1996; I Muhldorfer and J. Hacker, 1994; Kuhnert et. al., 1997; Bachmann 1996).
   - The ccdB Survival 2 T1R strain (Invitrogen) is used as it is resistant to the toxic effects of the ccdB gene and may be used to propagate and maintain vectors containing the ccdB gene (e.g. pcDNA-DEST40). It is RecA and EndA deficient. (www.invitrogen.com).

The RK13 cell lines expressing ovine PrPC have been shown to be permissive to scrapie infection (Neale et al., manuscript in preparation), the addition of the gag protein...
expression will hopefully increase sensitivity towards scrapie and BSE inocula with low infectious titres.

Host/vector system

The vector will be the commercially available:

pCI (Promega) + linear puromycin selection (Clontech), pIRES-puro3 (clontech) or pBI-CMV1 (Clontech)

The PrPC expressing cell lines have been generated using either a neomycin or hygromycin antibiotic selection (Neale et al., manuscript in preparation), therefore a different antibiotic selection is required in this case puromycin.

The pCI vector does not contain any mammalian antibiotic selection (Promega Technical Bulletin #TB206) and has to be co-transfected with either a linear antibiotic selection marker or a second plasmid containing antibiotic selection, in this case the linear puromycin selection marker from Clontech will be used.

If the pCI expression vectors do not establish stable expressing cell lines, pIRES-puro3 contains the internal ribosome entry site (IRES) of the encephalomyocarditis virus (ECMV), which permits the translation of two open reading frames from one messenger RNA. After selection with puromycin, nearly all surviving colonies will stably express the gene of interest, thus decreasing the need to screen large numbers of colonies to find functional clones. The expression cassette of pIRESpuro3 contains the human cytomegalovirus (CMV) major immediate early promoter/enhancer followed by a multiple cloning site (MCS) that precedes stop codons in all three reading frames, a synthetic intron known to enhance the stability of the mRNA, the ECMV IRES followed by the puromycin gene, and the polyadenylation signal from SV40 (Clontech Protocol no. PT3646-5, version no. PR8532553).

If there is a requirement to express two of the components of the gag gene in cell line at one time a bi-directional expression vector such as pBI-CMV1 (Clontech) will be employed. The pBI bidirectional vectors are designed to constitutively express two proteins of interest at similar levels (unlike IRES vectors, in which the expression of the proteins that are upstream and downstream of the IRES sequence varies). In the pBI bidirectional vectors, expression is driven by constitutively active human cytomegalovirus promoters (PminCMV). The gene(s) of interest must contain an initiation codon and a stop codon (Clontech Protocol no. PT4440-5).

Origin & function

The gag gene from Maedi-visna virus. No handling of Maedi-visna will take part at the AHVLA - expression vectors for the gag polyprotein (pN3-GAG) will be acquired from Department of Veterinary Medicine, University of Cambridge. The Matrix, Core, and nucleocapsid constituents of the gag gene will be cloned into the appropriate expression vectors as described above.

The gag gene is being supplied in the pN3 vector (Reina et al 2008 Vaccine 26, 4494). The gag gene is from the EV1 strain of Maedi visna virus (GenBank:S51392.1 bases 314-1848). The full length gene will be PCR amplified with appropriate restriction enzyme overhangs to be cloned into the pCI and pIRES-puro3 vectors.

The individual sequences for the Matrix (nucleotide 506-937), Core (nucleotide 938-1594) and Nucleocapsid (nucleotide 1595-1849) (nucleotide positions from Sargan et al., 1991) constituents will also be PCR amplified with the insertion of peptide tags for ease of identification once expressed in the mammalian cell lines (Matrix-Myc tag, Core-HA tag, Nucleocapsid-VSV-G tag).

Additional sequence added

Myc tag - 5' GAACAAAAACTTATTTCTGAAGAAGATCTG
HA tag - 5' TACCCATACGACGTCCCAGACTACGCT
VSV-G tag - 5' TACACTGATATCGAAATGAACCGCCTGGGTAAG

Expression vectors will be produced with the peptide tags on either the N or C terminal (2 expression vectors for each component).

Evolution of foreseeable effects

Published evidence suggests that the co-infection of animals or cells with Maedi visna virus increases the sensitivity of the organism to scrapie infection (Salazar et al.,...
Further to this expression of the gag gene from HIV increases the sensitivity of cell lines to CWD (a prion disease infecting cervids) (Bian et al., 2010). It is proposed that the co-expression of the gaga gene from Maedi visna virus in cell lines currently permissive to scrapie infection will increase their sensitivity. Additionally it is hoped that expression of the gag gene in cells expressing bovine PrP will render them susceptible to infection with BSE. By expressing the 3 major components of the Maedi visna virus gag gene separately it may be possible to elucidate whether just one of these components is required for increased sensitivity or whether it is a co-ordinated effect of all the products of the gag gene.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid waste generated in R66, B64 will be autoclaved at 136°C, for a minimum of 1 hour prior to incineration.

Solid waste generated in R26, B63, which may include TSE contaminated waste, will be placed in autoclave bags, loosely sealed then placed in autoclave tins sealed with tape and taken to B150 for autoclaving for 30 mins at 136°C, 2.2 bar. Use of autoclave in building other than where work carried out agreed with HSE (letter 26 September 2006 Ref. GM221). This autoclaved waste is then incinerated.

Liquid waste generated in R66, B63 will be autoclaved 136°C for a minimum of 1 hour and then incinerated if contained in single use plasticware or disposed of to drains if containers are recycled, maximum volume 200ml per bottle.

Liquid waste generated in R26, B63 is placed in a glass bottle in a solution of Chloros (final concentration 20%) and left in the safety cabinet overnight (minimum 16 hours). This waste is then transferred to a dedicated liquid waste plastic container. When the container is at 50% capacity it is sealed, placed in a heavy duty black sack and placed in the dedicated liquid waste pick-up bin located in the locked gas cylinder storage cage at the side entrance to B107. It is collected from this point and incinerated.

**Is an emergency plan required according to regulation 20?**

**Project Containment**
Purposes of the contained use

Salmonella enterica is a zoonotic enteric pathogen of warm blooded animals that is a major cause of food poisoning and typhoid fever in the developing world. Subspecies enterica serovars are frequently isolated from livestock production in the UK. Some serovars are isolated from a particular subset of livestock species. S. Mbandaka an emerging serovar, is commonly isolated from cattle, chickens and soya based animal feed. This distribution is very different to that of S. Derby which is predominantly isolated from pigs and turkeys (AHVLA2010). These trends have been maintained over decades and between continents. Thus this would suggest that the mechanisms of persistence and colonisation are pathogen specific and may be an attribute of the interaction between the host and pathogen. It is the aim of this study to better understand the bacterial mechanisms that maintain these distributions.

Comparative functional genomics and phenotypic analysis has shown that S. Mbandaka possesses various adaptations for persistence in the environment, including biofilm formation at ambient temperatures, adhesion to abiotic surfaces and the ability to utilise a wider range of metabolites. Whereas, S. Derby of porcine origin has been shown to be highly invasive and have a higher level of antibiotic resistance and the ability to produce mannose binding type 1 fimbriae at 37°C.

Furthermore, a new genomic island has recently been discovered at the AHVLA in S. Derby, Salmonella Pathogenicity Islands 23 (SPI-23), comprising of 42 open reading frames (ORFs) of which 16 are unique to S. Derby amongst S. enterica SPI-23 contains several type IV pilin genes and four potential effector proteins. In addition five genes are absent from Salmonella pathogenicity island 1 (SPI-1) of S. Derby, one of which has been identified as a novel type three secretion system effector protein.
The studies outlined in this RA aim to further characterise SPI-23 and the unique SPI-1 region through knock-in and knock-out mutants in isolates of both serovars. Introduction and removal of DNA at specific locations will be achieved through allelic exchange (Datsenko and Wanner 2000) using GeneBridges technology. The phenotypic effects of these mutations will be studied in in vitro assays including porcine jejunum (IPECs-J2) cell culture and in vitro organ cell culture (IVOC) to assess the contribution of SPI-23 and SPI-1 to pathogenesis. Expression analysis in the knock-in mutants will also be tested by reverse transcription quantitative real time PCR, to compare mutant expression levels with wild-type isolates containing SPI-23.

Recipient of the plasmid constructs and hosts of targeted mutagenesis are wild-type Salmonella enterica serovars Derby D1 and D2 and Mbandaka M1 and M2. E. coli K-12 derivatives will be used as hosts for plasmid constructs containing SPI-1 and SPI-23.

TOPO TA cloning dual promoter kit (Invitrogen) will be used to produce a non-mobilisable plasmid containing all SPI-23 genes under the control of a T7 and SP6 promoter. The plasmid contains kanamycin and lacZ blue/white screening systems, to select for and maintain transformed isolates.

Through bioinformatical analyses it is believed that SPI-23 is a putative pathogenicity island, with type 4 pili, used in adhesion and type three secretion system effector proteins used during invasion and intracellular survival. In the same study a region of SPI-1 has been identified as containing a putative type three effector protein (Hayward et al., unpublished).

Evaluation of foreseeable effects

Knock-out mutants of SPI-1 and SPI-23 will most likely be less pathogenic compared to wild-type, unmodified Salmonella enterica. Whereas SPI-23 knock-in mutants of S. Mbandaka will be potentially more pathogenic than unmodified environmental isolates. SPI-23 naturally occurs in S.Derby isolates and will be introduced into avirulent isolates of S. Derby D4, D6, D8 lacking the island. The SPI-1 region from S. Mbandaka being introduced into S. Derby is naturally occurring in the closely related non-typhoidal (ACDP category 2) serovar S. Cholerausuis (Chiu et al., 2005). All experiments involving these organisms will be conducted in line with safety regulations relevant for dealing with ACDP hazard group 2 bacterial species (refer to risk assessment BAC2/1 and BAC2/127). All individuals entering the Containment level 2 laboratory where the strains are stored must wear laboratory coats and must wash hands with anti-bacterial soap before exiting the laboratory. Laboratory benches are sprayed down with 70% ethanol after each use. To avoid aerosol production, air conditioning is shut off before isolates are handled in a class II microbiological safety cabinet (MSC).

Disposal by autoclaving in line with current risk assessments (BAC2/4). Autoclaving is carried out in the same building (a requirement of GM Class II) for one hour at 134°C (30 PSI). All solid waste is subsequently incinerated on site.
Disposal by autoclaving in line with current risk assessments (BAC2/4). Autoclaving is carried out in the building (a requirement of GM Class II) for one hour at 134°C (30 PSI) after which liquid waste is tipped down the sink.

Disposal by incineration on site in line with current risk assessments (BAC2/4)

### Project Additional Information

#### Purposes of the contained use

The goal of the study using a rescued recombinant virus, offered from St Andrews University, to assess the pathogenicity of a viral clone compared to the genetically heterogeneous material currently used for in vivo experiments in sheep.

#### Recipient or parental organism

The parental virus is a bovine field isolate of SBV from Germany that was rescued at the Univ of St Andrews as described recently (Elliott, R. Bakqori, G. van Knippenberg, I., Koudriakova, E., Li, P. McLees, A. Shi, X and Szemiel, A. M. Establishment of a reverse genetic system for Schmallenberg virus, a newly emerged orthobunyavirus in Europe. J Gen Virol Published ahead of print December 19, 2012, doi:10.1099/vir.0.049981-0). Briefly the rescued virus is genetically identical to the parental strain used.

#### Host/vector system

Due to the fact that we will obtain the rescued virus from collaborators, there is no host/vector system to be used in this study at AHVLA.

#### Origin & function

The genetic material used is a full-length virus. One segment of the genome encodes the nucleocapsid protein, one the viral polymerase and one the glycoproteins.

#### Evaluation of foreseeable effects

The hypothesis is that individual variants of the rescued virus will be equally or less pathogenic than the mix of quasi-species generated by in vivo passage of the wild type only. Based on its genetic identity with the parental strain we presume that it will behave similarly, if not identical to the wildtype virus.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n.a

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The virus has not been classified as SAP or ACDP. Based on current knowledge and failed attempts to demonstrate Abs in humans (Ducomble T, Wilking H, Stark, Takla A, Askar M, Schaade L, et al. Lack of evidence for Schmallenberg virus infection in highly exposed persons, Germany, 2012. Emerg Infect Dis. 2012 Aug. http://dx.doi.org/10.3201/eid1808.120533)SBV remains ACDP unclassified. CL2 has been proposed for GM work with such non-zoonotic Orthobunyaviruses before. However, we will utilise negative pressure, sealable containment facilities with insectocutors, to minimise any vector (midge) associated risks.
Due to the identity of the recombinant virus with its parental strain, we will treat material possibly containing the GMO identically. In brief, solid waste such as animal tissues, animal waste and bedding is collected and ultimately incinerated. Bagged waste will be decontaminated with FAM30 (1:240) or 1% Virkon (contact time 30 minutes) before transfer to tins and subsequent autoclaving (134°C for a minimum of 30min at 30 psi.) or incineration. Liquid effluent from animal facilities will be subjected to heat treatment (effluent is treated by heating to a minimum of 80° C for two hours before release). Smaller volumes from the laboratory will be autoclaved as described above.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Project Ref 221/13.2

Date Ackn'd 31/05/2013

CU2 Project Title Recombinant knockout Mycobacterium bovis BCG

Class CultureVolClass2 CultureVolumeClass3-4

Class 2 < 1 Litre

Non-GMM Consent Granted

Project notified under transitional arrangements N
### Project Additional Information

#### Purposes of the contained use

Mycobacterium bovis is the causative agent of bovine tuberculosis in cattle. Our aim is to vaccinate groups of cattle with laboratory developed genetically modified knockout strains of Mycobacterium BCG and to evaluate whether they are more protective than unmodified BCG against M. bovis challenge. In these strains, the inactivation of the gene will have been achieved either by allelic exchange using homologous recombination or by transposon mutagenesis.

The construction of the Mycobacterium bovis BCG knockout strains will not be done at AHVLA. The strains to be used will be supplied ready for injection by our collaborators.

#### Recipient or parental organism

The recipient of the BCG knockout strain is the cow.

#### Host/vector system

The host is the cow and the vector is a Mycobacterium bovis BCG knockout strain.

#### Origin & function

For knockout strains generated by homologous recombination, mycobacterial genomic DNA such as that prepared from BCG, M. bovis or M. tuberculosis are used as templates for the generation of PCR products. For those generated by transposon mutagenesis, the transposon is delivered into the chromosome of BCG by the temperature sensitive, kanamycin resistance expressing phage MycoMarT7.

The BCG knockout strain will be introduced into cows to induce an immune response that protects them against challenge by virulent M. bovis.

#### Evaluation of foreseeable effects

BCG is an attenuated strain that has been used as a live vaccine against TB in humans and cattle for over 80 years. It has been shown to be safe both in immunocompetent humans and cattle and produces no detrimental side effects. BCG can, however, cause a disseminated disease ('BCG-osis'), which is often fatal, in severely immunocompromised humans, such as those infected with HIV. As a precaution, pregnant women must not be allowed to work with BCG, although no harmful effects have been observed on the foetus where vaccination has been given.

The original M. bovis BCG was first used in 1921 and was derived from virulent M. bovis by serial passages on potato skins. Today, several substrains exist (e.g. BCG Danish, Tokyo, Pasteur) that differ in regions of genomic deletions, antigen expression levels, immunogenicity, and protective efficacy. A single 9.5 kb deletion, known as RD1, common to all substrains and is thought to be primarily responsible for their attenuation. The possibility of reversion of BCG to a virulent phenotype is considered unlikely as the RD1 mutation is a large multi gene deletion and the organism shows very low rates of lateral gene transfer. In addition, complementation of BCG with a clone containing the RD1 region does not fully restore virulence to that of the parent M. bovis, implying that other recombination events are required for restoration of full virulence. There are no recorded instances where BCG has undergone reversion to virulence.
The BCG knockout strains that will be tested are expected to have the same or lower level of virulence than that of non-recombinant BCG. There are no recorded instances where deletion of a gene(s) in BCG has led to an increase in virulence.

It is intended to vaccinate cattle (DBT R23). No detrimental effects are foreseeable in the vaccinated animals as the BCG knockout strains are predicted to have the same or lower levels of virulence than non-recombinant BCG. It is however expected and intended that the knock out strain may give a greater level of protection than BCG, or if protection is equal or lower than wild-type BCG that it will impart other beneficial effects such as the avoidance of skin test reactivity which would be of major benefit as it would allow continuation of tuberculin-based test and slaughter policies alongside vaccination. Vaccine efficacy will be tested by the application of appropriate immunological and microbiological techniques. Again, neither the immune responses generated nor the sampling schedule are expected to have detrimental effects on the animals.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The CL2 large animal accommodation, such as buildings 417, 418 or 419 at Coomnlands farm have good ventilation and a barrier control system to prevent access to rodents and other small animals. Access to the building is controlled through a swipe card system.

When applied via the subcutaneous route, our data demonstrated that cattle did not shed BCG (please see appendix 1 on the accompanying GMRA) Once inoculated, the vaccinated animals will restrict bacteria within their own lymphatic system; this makes the chance of excretion into the environment negligible (see RA 23). However, to provide for the unlikely event that during the inoculation procedure BCG would be released all solid waste including PPE waste (disposable overall, boots, gloves, face masks, needles, syringes unused inocula etc) will be bagged and incinerated immediately after inoculation as will be bedding during the first 24 h post-vaccination. Waste generated during the 24 h post vaccination period, will be classed as low level waste and disposed according to local ASU SOPs. At the end of the experiment, the animals will be incinerated.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste:
Laboratory waste is contained within a closed metal tin and transported to an autoclave with the aid of a trolley. The service lift must be used to transport waste from the CL2 laboratory located on the ground floor of building 7 to the autoclave located on the first floor. Decontamination is conducted by autoclaving for 1 hour at 135°C after which waste is put into bags for incineration.

Animal accomodation: Needles and syringes, to be disposed of into sharps container, which is then placed into plastic bag, which is then decontaminated with FAM30 (1:20), left for at least 1h and then removed for incineration.

Liquid waste:
Laboratory waste is contained within a closed metal tin and transported to an autoclave with the aid of a trolley. The service lift must be used to transport waste from the CL2 laboratory located on the ground floor of building 7 to the autoclave located on the first floor. Decontamination is performed by autoclaving for 1 hour at 135°C after which waste is put into bags for incineration. Waste occcurring during the inoculations (left-over inoculi) to be double-bagged and incinerated.

Liquid waste in animal contaminated material, see above). Liquid waste after vaccination: see section 4.2.

General waste:
Laboratory waste is transported to an autoclave within the building in a closed metal tin. Decontamination is performed by autoclaving for 1 hour at 135°C after which waste is put into bags for incineration.

Waste associated with animal work: place into appropriate plastic bag, spray/dunk into FAM30 solution (1:20) and after at least 1 hour contact time remove for incineration.

### Project Additional Information

#### Purposes of the contained use

Synthetic antisense oligonucleotides (SAO) will be generated and used to silence the expression of target genes in the first instance a beta-lactamase. These experiments will be conducted in either bacteria (the GMO) transformed with a recombinant plasmid or in a cell free expression system using this recombinant plasmid.

#### Recipient or parental organism

The parental organism will be an E. coli bearing a plasmidic CTX-M beta-lactamase gene. The parental strain will have been isolated from veterinary sources (e.g. cattle) from field studies of a UK farm.

#### Host/vector system

A range of hosts may be used including:

1. E. coli K12, DH5α
2. AS19 (a derivative of strain B)
3. BL21
4. BK21 (DE3)
5. E. coliDH10b (F-mcrA Δ(mrr-hsdRMS-mcrBC) φ80lacZΔM15 ΔlacX74 recA1 end A1 araD139 Δ(ara, leu)7697 galU galK λ-rpsL nupG
6. Commercially available strains such as One Shot ® TOP10 (Invitrogen)

Vector:
Commercially available expression/cloning vectors such as pUC11, pUC18/19, pMQAK or similar will be used.

#### Origin & function

PCR products amplified from E. coli strains bearing beta-lactamase plasmids which will include the sequence of the gene (CTX-M beta lactamase) of interest as well as the untranslated region immediately upstream of the start codon (5'UTR) and in some instances the promoter of the target gene may also be included.

A short sequence ~ 200bp from around 50bp upstream of the CTX-M gene and a luciferase or GFP reporter gene will either be commercially synthesised or amplified by PCR and inserted into a suitable plasmid vector.

#### Evaluation of foreseeable effects

Synthetic Antisence Oligonucleotides (SAOs ) will be directed towards the gene of interest (CTX-M) and associated sequence, and will be only homologous with target genes, thus reducing the risk of off-target effects in both bacterial cells and humans. The SAOs are comprised of a nucleic acid base with a modified backbone structure which is resistant to immediate degradation. The safety of SAO use in humans has been demonstrated, they will eventually undergo enzymatic degradation. Presence of bacterial containing CTX-M genes are common in farm animals and as such if plasmid containing a CTX-M gene were released into the environment it would not pose a health risk above that which already exists. Bacteria containing the CTX-M gene alone are treatable with non-penicillin antibiotics.

All experiments using these organisms will be conducted in CL2 laboratories, in line with safety regulations for ACDP Hazard group 2 organisms. Appropriate PPE (Lab coats and gloves) will be worn at all times. A class II safety cabinet will be used for all aerosol generating activities the risk of aerosol spread.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disposal of bacterial waste will be inactivated using local procedures (autoclaving and incineration). Waste will be disposed of by autoclaving (70 minutes at 134° and 15 psi. Building 4; room 2) and incineration in line with current risk assessments (BAC2/4); All solid waste is subsequently incinerated on site.

Disposal of liquid waste is by autoclaving and incineration in line with current risk assessments (BAC2/4); 70 minutes at 134°C, 15 psi. Autoclaving using dry cycle for up to 100 ml volumes of liquid cycle for 500ml volumes (validated by probe). Liquid waste will be inactivated with an equal volume of Virkon S (1% w/v; contct time > 30 min) prior to autoclaving.

Date Project Ceased 02/03/2022

This project assessment has been approved by the AHVLA Biological Safety Committee.
**Purposes of the contained use**

We propose to use reverse genetics techniques to manipulate the influenza genome to create novel viruses altered specifically in one or more genes. This will also include whole gene replacements. Subsequent in vitro & in vivo infections will demonstrate the effect of specified genetic changes on viral phenotype, eg pathogenicity and host adaptation. The effectiveness of vaccine construct generated by reverse genetics will also be studied in pigs and ferrets.

**Recipient or parental organism**

Influenza A virus

**Host/vector system**

**Host:**
1. E. coli K12 derivative strains will be used for the transformation and amplification of plasmid DNA. Examples are DH5 alpha derived (e.g. NEB 5 alpha or similar) or DH10 beta derived (e.g. TOP10 or similar) or similar strains.
2. Human 293 T cell line, other eukaryotic cell cultures eg MDCK, BHK, Vero, chick embryo fibroblasts (CEFs), chick embryo liver (CEL) cells and swine cell cultures (eg NPTr, NSK).
3. Nine to eleven day old embryonated fowls’ eggs.
4. The recovered viruses will be used to infect mammalian, including pigs and ferrets and possibly avian hosts, including chickens, turkeys and ducks for in vivo studies. This will also include ex vivo organ explants (e.g. trachea, bronchi, lung, turbinates)

**Vector:**
1. pCR-XL-TOPO (Invitrogen).
2. Poll vectors (derivatives of the pcDNA3 vector, non-mobilisable, Invitrogen) and Helper plasmids (with CMV driven promoter to express the 4 polymerase proteins and NP from the A/Victoria/75 H3N2 virus, Invitrogen) - 12 plasmids system (Howard et al., 2007).
3. pHW2006; pHW2000 (with CMV driven promoter) - eight plasmids system (Hoffmann et al., 2000b)

**Origin & function**

All genetic material will be derived from influenza A virus strains. The genetic material will be used to generate infectious viral progeny by reverse genetics. The progeny viruses will then be studied for altered phenotype in in vivo and in vitro models.

All eight full-length (890-2341bp) genes of the influenza genome:
1. Polymerase basic 2 (PB2) (Internal protein)
2. Polymerase basic 1 (PB2) (Internal protein)
3. Polymerase acidic (PA) (Internal protein)
4. Haemagglutinin (HA) (Surface protein)
5. Nucleoprotein (NP) (Internal protein)
6. Neuraminidase (NA) (Surface protein)
7. Matrix (M) (Internal protein)
8. Non-structural gene (NS) (Internal protein)

Viruses will be generated where whole genes or point mutations will be derived from Influenza A virus strains such as:

1. Seasonal Human Influenza isolates - ACDP2/SAPO unclassified
   - H1N1 pandemic
   - H3N2 subtype

2. Ancestral Human Influenza Isolate - ACDP2/SAPO unclassified
   - A/Puerto Rico/8/34 (PR8) H1N1 [commonly used as the virus backbone in RG (reverse genetics) derived vaccines]
   - Genes of the polymerase complex from A/Victoria/75 (human H3N2 isolate) (to provide helper function in the 12 plasmid reverse genetics system)

3. Swine Influenza isolates
   a) Endemic Strains - ACDP2/SAPO unclassified - Avian-like H1N1 subtype
      - H1N1 pandemic
      - Classical H1N1 subtype
      - H1N2 subtype
      - H3N2 subtype
   b) Natural /wild type reassortant strains - ACDP2 or advisory 3/SAPO unclassified
      - A(H1N1)pdm/09 reassortant viruses e.g. A(H1N1)pdm/09 & H1N2, A(H1N1)pdm/09 & H1N2 TRIG, A(H1N1)pdm/09 & avian-like H1N1 A(H1N1)pdm/09 & H3N2 and A(H1N1)pdm/09 & H3N2 TRIG or equivalent viruses.

In some cases, viruses generated by reverse genetics procedures will be supplied to the AHVLA by collaborators. These are likely to include:
- H9N2 & A(H1N1)pdm/09 reassortant viruses e.g. Imperial College London, NIMR, HPA Colindale, NISBC.
- A(H1N1)pdm/09 & H3N2 reassortant viruses ACDP2/SAPO unclassified Kansas State University (Qiao et al., 2012)
- A(H1N1)pdm/09 & H3N2 reassortant viruses ACDP2/SAPO unclassified e.g. Imperial College London, NIMR, HPA Colindale, NISBC,
- PR8 internal with different HA-NA (e.g. H1, H2, H3, H5*, H7*, H9, N1, N2, N3, N7, N9) combinations-routine vaccine candidates. These viruses, and the plasmids encoding the genes of these viruses, exist in many CL2 labs worldwide e.g. UK - Imperial College London, NIMR, HPA Colindale, NIBSC - GMO2/3.
  * Including viruses where the multi-basic cleavage site has been removed to render them equivalent to low pathogenicity avian influenza viruses.

**Evaluation of foreseeable effects**

The reverse genetics system will be used to produce a range of infectious mutants of diverse pathogenicities which will result in viruses that may have altered (i.e. increased, equivalent or reduced) virulence. The mutations to be introduced using the system include those observed in viruses isolated from the field and known to affect infectivity and/or pathogenesis in mammals including humans. Therefore the production of these mutants will allow further understanding on the role of mutations essential for promoting infection and transmission in livestock and humans, the latter using the pig and the ferret as human model of disease. The generation of re-assortant viruses including genes from different species will be representative of potential field re-assortant viruses [e.g. A(H1N1)pdm/09], promoting a better understanding on the role of the pig as a potential mixing vessel and the ability of the virus to cross the species barrier. There is no intention to produce avian and mammalian influenza chimeric viruses similar to those produced and published from the labs of Kawoaka (Imai et al., 2012) and Fouchier (Herfst et al., 2012).

No genetic sequences of SAPO4 influenza viruses will be used to generate organisms by reverse genetics.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

1. All waste, solid contaminated materials, cultures & disposables produced in the designated SAPO unclassified/ACDP2 laboratory is sealed in autoclave bags, decontaminated by spraying with 1% Virkon S (contact time of 10 min), contained in an autoclave tin and autoclaved at 134°C for 60 minutes before incineration.

2. All manipulations with GMOs viruses that are also classified as advisory ACDP3 viruses will be done in ACDP3/SAPO3 or SAPO 4 facilities that have regular inspections by the HSE. Waste disposal from these facilities is strictly controlled in accordance with SAPO the main features are as follows:
   a) Effluent is sterilised by a procedure known to kill the pathogen, heat treatment for 95°C for 2 hours, and this procedure is confirmed as having operated satisfactorily before the effluent is discharged to the public sewer. This includes all liquid waste from the building eg from sinks, toilets, showers.
   b) All biological waste material is sterilised at 134°C for 60 minutes before removal from the containment facility through a double ended autoclave. The functioning of autoclaves is monitored to ensure that time/temperature cycles are completed. The load is then taken immediately to an incinerator on site.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form  

Tick to confirm that you have attached a risk assessment to this form  

Tick if you are claiming exemption from disclosure for section of the risk assessment

The project assessment has been approved by the AHVLA Biological Safety Cabinet.

### Project Ref 221/13.5

Date Ackn'd 02/03/2022  
CU2 Project Title  
Class  
CultureVolClass2  
CultureVolumeClass3-4
The aim of this work is to prepare DNA libraries and screen them for expressed functions (e.g. antibiotic resistance or production of antimicrobial compounds).

The libraries will be prepared from DNA extracts of the total microbial content (the metagenome) of various sample types, e.g. faeces, and saliva, that may be of human and animal origin; soil, water and other environmental sites. The resulting clones will therefore contain different fragments of the metagenomic DNA and represent the microorganisms present in the sample. There is a very remote chance of animal or human DNA being cloned into the vectors but any such clones will become apparent upon sequencing, following functional screens. However, it is important to stress that the eukaryotic protein have a low probability of being expressed in bacterial systems due to differences in codon usage and expression.

The library created in this manner will be employed in activity-based screens. The library will be transformed into a heterologous host, e.g. commercially available E. coli cells (e.g. EPI300; Epicentre) or a Gram-positive bacteria of ACDP hazard group 1 or 2 e.g. Streptomyces lividans (Courtois et al, 2003) or Bacillus subtilis (Kaneko et al, 2005) or Straphylococcus aureus (Williams et al, 2006) provided by collaborators e.g. University College London. The transformants will then be cultured under selective pressure to screen for a desired biological activity (phenotype). For example, libraries can be screened for the ability to grow in the presence of antibiotics or the ability to inhibit the growth of an indicator organism. Clones with the desired phenotypes will be recovered, propagated and the insert DNA sequenced to determine the underlying genetic mechanism responsible for antibiotic resistance or inhibition.

The advantage of this activity-based screening approach is that functional genes can be recovered without prior knowledge of their sequence. Consequently, the technique can enable the identification of new genes and it has been successfully employed to identify a range of novel enzymes (for a review see Ferrer et al., 2009), including antibiotic resistance genes (Sommer et al., 2009). Drawbacks of this approach are that it requires that the cloned genes are expressed and the gene products active in the heterologous host, and factors such as codon usage, promoter sequence and interactions with other proteins can all influence the recovery of clones.

Recipient or parental organism

Laboratory adapted E. coli strains:
Commercially available E. coli K12 derivative strains such as EPI300, JM109, TOP10, or DH5a (available from e.g. Epicentrel, Promega and Invitrogen). These strains are routinely used in relevant laboratories at the AHVLA.
Gram-positive bacteria (ACDP hazard group 1 or 2): e.g. Streptomyces lividans, Bacillus subtilis or Staphylococcus aureus.

Both gram-negative and -positive strains will be employed as heterologous hosts, to enable activity-based screening in these two main bacterial divisions. The E. coli K12 hosts allows stable propagation of the recombinant plasmids and, depending upon the vector, inducible expression of cloned genes. K12 derived E. coli are recA, endA deficient and considered 'disabled' (i.e. non-pathogen). They are amongst frequently used bacterial host and are considered to have a good safety profile (anonymous, 2007). These organisms do not possess or express known virulence factors (Muhldorfer et al., 1996; Muhldorfer and Hacker, 1994; Kuhnert et al., 1997’ Bachmann et al., 1996). The E. coli strains used in this work have a long history of safe use and can be safely handled at containment level 1 (Commander, 2008; Anonymous, 2008).

EPI300 cells (Epicentre) will be used as the copy-number of clones with an oriV origin of replication is under the tight control of an inducible promoter linked to the trfA gene, making them ideal for use with the cloning vector pCC1BAC (see3.2.3 below)

EPI300 genotype: F- mcrA Δ(mrr-hsdRMS-mcrBC) Ф80lacZΔM15 ΔlacX74 recA1 araD139 Δ(ara, leu)7697 galU galK l- rpsL (StrT) nupG trfA dhfr.
Gram-positive heterologous hosts will be strains of Streptomyces lividans, Bacillus subtilis or Staphylococcus aureus (Courtois et al, 2003; Kaneko et al, 2005; Williams et al, 2006). These will be provided by collaborators e.g. University College London. The Gram-positive strains were derived from the John Innes Culture Collection or are characterised laboratory strains that have been previously published (Kaneko et al, 2005; Williams et al, 2006). They are well characterised, ADP hazard group 1 or 2 (ibid).

Libraries will be created in a several different vectors according to experimental needs, specific examples include:

- pCC1BAC (Epicentre); chloramphenicol resistance selectable marker (see Epicentre link in references).
- pUC18 (many suppliers, e.g. Thermoscientific); ampicillin resistance selectable marker. (see Thermoscientific link in references).
- pUC19 (many suppliers, e.g Thermoscientific); ampicillin resistance selectable marker. (see Thermoscientific link in references).
- pZE21 MCS 1 vector (Expessys); kanamycin resistance selectable marker. (see Expressys link in references).
- pBEST310 (Kaneko et al, 2005; laboratory collection); neomycin resistance selectable marker. (see publication details in references).
- pLEW6832 (Williams et al, 2006; laboratory collection); ampicillin, streptomycin selectable marker. (see publication details in references).

Other vectors may be employed if experimental need dictates. These will be selected from the list of non-mobilisable or mobilisation defective plasmid vetors given in the guidance documents "The generation and use of GM E. coli (K12 or B strain derivatives) for the purpose of recombinant protein production" that is maintained by the SHaW unit on livelink (http://vla43/index/business/safety-intro/safety-gmos.htm).

Origin & function

The nucleic acid insert used for library preparation will be derived from the metagenome (i.e. the total DNA content of a microbial population) of various sample types, e.g. faeces, saliva, and soil. Samples from both humans and animals may be employed in this study. All samples, before usage will be assessed for their metadata i.e. any accompanying information on the health of animal, farm etc. to ensure low risk/hazard samples are used.

Nucleic acid extracts will not be prepared form samples that have been demonstrated to contain ACDP hazard group 3 or 4 organisms.

The cloned genetic material will be used in activity-based screens in which a selection for phenotypes of interest (see section 2.1) will be undertaken. Clones with the desired phenotypes will be recovered, propagated and the insert DNA sequenced to determine the underlying genetic determinant responsible.

The E. coli heterologous hosts selected for this project are disabled strains requiring precise culture conditions for efficient propagation and survival. Thes E. coli are normally designated as containment level 1 organisms (Anonymous, 2007; Commander, 2008; Anonymous, 2008)

Evaluation of foreseeable effects

The Gram-positive heterologous hosts selected for this project are designated as containment level 1 or 2 organisms (Courtois et al, 2003, Kaneko et al, 2005, Williams et al, 2006))
The vectors selected for this work are considered to be non-mobilisable. pZE21 MCS 1 and pBEST310/pLEW6932 contain the necessary promoters and regulatory sequences for expression of the inserted nucleic acid, therefore in these organisms the transcript may be translated to produce a functional polypeptide. The transformation of the vectors employed, when they do not contain an insert DNA sequence, into the heterologous hosts used in this study is not considered to change the host cell ACDP hazard group, as they do not alter the virulence and/or pathogenicity of the host cells. Therefore E. coli transformed with an empty vector will remain at ACDP hazard group 1 and the Gram-positive heterologous hosts (B. subtilis, Saureus, Slividans) will remain at ACDP hazard group 1 or 2. As with all DNA libraries, the exact nature of the nucleic acid insert of each clone cannot be defined at the start of the experiment. Only clones that successfully pass through the function-based screening will be retained for further study. Any clone studied extensively will be characterised by sequencing of the cloned DNA. It should be noted that the creation of DNA libraries is a standard molecular biological technique (Sambrook and Russell, 2006) that has been undertaken safely for many decades. To minimise the potential for inadvertently creating pathogenic clones, no metagenomes from samples known to contain ACDP hazard group 3 or 4 organisms will be used in this work. Additionally, any clone revealed to contain high risk pathogenic gene post sequencing (e.g. the shiga toxin gene) will be transferred to CL3 facilities, in accordance with local procedures (see RA BA2/001).

The GM organisms produced in the work covered by this risk assessment are considered to be ACDP hazard group 2 and GM class 2.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1. Solid contaminated materials: cultures, disposables, etc: Disposal by autoclaving (in an autoclave bag in a sealed tin) for one hour and 10 minutes at 134°C (Building 4, Room 2 or 36; Building 63 Room 21) and incineration in line with current risk assessments (BAC2/4). All solid waste is bagged and subsequently incinerated on site.

2. Liquid waste: broth cultures, supernatants, etc: Disposal by autoclaving (in an autoclave bag or container/duran in a sealed tin) for one hour and 10 minutes at 134°C (Building 4, Room 2 or 36) after which liquid waste is tipped down the sink, in line with current risk assessment (BAC2/004).

3. General rubbish: Disposal by bagging and subsequent incineration on site in line with local procedures

Project Containment

02/03/2022
Continued TB vaccine development: Improving BCG and developing non-sensitising vaccines for cattle

**Project Additional Information**

**Purposes of the contained use**

Development of novel tuberculosis (TB) vaccines protecting humans or animals is a major research priority. Defra has been funding research into bovine TB (Mycobacterium bovis) vaccines for cattle for almost a decade. These include objectives to: develop vaccination strategies that improve the duration of immunity of the BCG vaccine; identify biomarkers of vaccine induced protection; and to screen novel vaccine candidated. As a valuable tool for this means an established mouse model is also utilised to directly inform the cattle model. The full remit of work proposed here is currently funded through Defra ROAME-projects, such as SE3266.

Towards this central goal of vaccine development, one fundamental aspect is understanding the mechanisms of protection induced by the only human TB vaccine BCG, so that an improved vaccine or vaccine strategy can be developed. Here we propose the use of recombinant strains of BCG as a valuable tool to facilitate this.

In mice, our recent data showed that the live BCG vaccine bacilli persist, at a low level and without causing any clinical disease, for at least 16 months (Kaveh, et al., submitted). Following antibiotic abbreviation of these persisting BCG we have observed two distinct mechanism of immunity. One that is independent of, and one dependent on, the presence of persistent BCG. We hypothesis that the first is due to the induction of long term immunological memory by as yet undetermined CD4 T cells; and the second is due to the constant priming of medium term CD4 effector memory T cells which we are currently characterising. One approach to further analyse immunological memory in the absence of persisting BCG is through the use of metabolically limited (auxotrophic) recombinant BCG Knock-Out (KO) strains that, unlike the...
parental strain, are unable to survive in vivo. Another approach is in the identification of the rare T cells that convey long term immunity. Present at very low frequencies, they are typically beyond the limits of detection of conventional analyses. Through the use of adoptively transferred cloned donor T cells all specific for a defined innocuous foreign protein (e.g. Chicken Ovalbumin, OVA), these cells can be accurately tracked throughout an immune response in a normal recipient mouse immunised with a recombinant BCG Knock-in (KI) strain expressing this protein. Other potential areas of investigation, may track the trafficking of BCG bacilli in the vaccinated host, for instance through the use of recombinant BCG KI strains expressing fluorescent proteins (e.g. GFP). Some strains may also represent promising vaccine candidates and require screening in the mouse model.

The recombinant strains have or will be sourced from external laboratories through collaborations. These will be stored and prepared for immunisation in Bovine TB Research Containment level 2 (CL2) laboratory. Mice will be immunised and housed in high security animal accommodation, cared for by Animal Services staff (ASU), and maintained at CL2. Tissue samples will be transferred to the Bovine TB research CL2 laboratory for immunological or bacteriological analysis.

Recipient or parental organism

The recipient organisms is Mycobacterium bovis bacille Calmette-Guerin (BCG) The construction of recombinant BCG strains will not be done at AHVLA. The strains to be used will only be supplied by our collaborations in UK, EU and North American institutions ready for in vitro culture and immunisation. Only strains that have already been evaluated by external researchers will be used who must supply confirmation that their hazard group is no greater than HG2. No strains that have a known or likely increase in virulence will be used.

Host/vector system

Laboratory mice (e.g. strains BALB/c and C57BL/6) will be immunised with these BCG strains at AHVLA. Cells from these mice will also be stimulated in vitro with these BCG strains. The mouse is a well-established model for the study of bovine TB. Mouse experiments can be carried out faster, in larger numbers and in a cheaper fashion than in the target species. They also allow for a more in depth analysis due to the extensive reagents, methodology and ease of manipulation. For instance, providing the ability to undertake adoptive transfer and analysis of T cells of defined antigen specificity to study immune memory development. Thus, experiments in mice will inform those in the target species, cattle.

Origin & function

BCG Knock-out (KO) strains

Individual targeted genes will be inactivated in these strains to either:

i) Prevent in vivo metabolism, for example by creating auxotrophs that can only grow with the addition on an exogenous source of a specific nutrient only available in vitro.

ii) Alter the presentation of BCG antigens to the immune system in order to induce a superior protective immune response.

BCG Knock-in (KI) strains

The addition of nucleic acid to allow expression of proteins/peptides that will be limited to harmless additions that do not increase the virulence of the organism. For instance:

i) Innocuous proteins foreign to Mycobacteria used only to evaluate a normal BCG induced immune response by providing the ability to track a distinguishable specific response against this defined surrogate BCG antigen. E.g. Ovalbumin from Chicken, which contains an antigenic peptide epitope which is well characterised and used in mouse immunology studies.

ii) Fluorescent proteins/probes that allow the BCG bacilli to be tracked in vivo. E.g. green fluorescent protein GFP is a fluorescent protein from the jelly fish Aequorea Victoria and is used extensively in research to allow detection of cells.

Recombinant strains may also contain the addition of an antibiotic resistance cassette to allow The in vivo selection of successful recombinants only. These will be limited to
Kanamycin or Hygromycin, which are not used for anti-mycobacterial therapy in humans.

**Evaluation of foreseeable effects**

BCG is an attenuated strain that has been used as a live vaccine against humans and cattle for over 80 years. It has been shown to be safe both in immunocompetent humans, cattle and mice, producing no detrimental side effects. BCG can, however, cause a potentially fatal disseminated disease ('BCG-osis') in severely immunocompromised humans, such as those infected with HIV. The original BCG was first used in 1921 and was derived from virulent M. bovis by serial passages on potato skins. Today, several substrains exist (e.g. BCG Danish, Tokyo, Pasteur) that differ in regions of genomic deletions, antigen expression levels, immunogenicity, and protective efficacy. A single 9.5 kb deletion, known as RD1, is common to all substrains and is thought to be primarily responsible for their attenuation. The possibility of reversion of BCG to a virulent phenotype is considered unlikely as the RD1 mutation is a large multi gene deletion and the organism shows very low rates of lateral gene transfer. In addition, complementation of BCG with a clone containing the RD1 region does not fully restore virulence to that of the parent M. bovis, implying that other recombination events are required for restoration of full virulence. There are no recorded instances where BCG has undergone reversion to virulence.

The recombinant BCG strains that are proposed here are expected to have the same or a lower level of virulence than that of a non-recombinant BCG. There are no recorded instances where deletion of a gene(s) in BCG has led to an increase in virulence. All the proposed alterations to BCG are unlikely to increase the risk of a subsequent hazardous mutation.

Mice vaccinated with recombinant KO or KI BCG will induce no foreseeable detrimental effects. Mice are monitored twice daily as part of their standard husbandry and so any unexpected effects that could be detrimental to the mice, would be observed quickly and the animals euthanised. Auxotrophic KO BCG strains will induce a self-limiting infection on immunisation, as opposed to wild type BCG which has been shown to persist for at least 16 months. This will be confirmed by bacterial culture on first evaluation. Immune responses, evaluated as the main aim of all these studies, will also help identify any potential increase in virulence.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste is placed directly into an autoclavable bag (liquids first in a sealed bottle) and then closed inside an autoclave bin/tin and transferred by trolley to an autoclave located in the building. Waste is autoclaved on a cycle that has been shown to maintain a minimum of 121°C for 1 hour. All autoclaved waste is incinerated as standard for the site. The autoclaves are temperature profiled and calibrated every 6 months to ensure cycle criteria are maintained.

After working with the strains or immunised animals, surfaces are disinfected with 70% ethanol, as internally validated removal of items from the lab/animal room

Date of Significant Change

Project Additional Information

Purposes of the contained use

To determine the efficacy/duration of immunity in pre-vaccinated chickens of the recombinant herpevirus of turkey after challenge with NDV.

Recipient or parental organism

Young chickens.

Host/vector system
Herpesvirus of turkeys (strain FC-126).

**Origin & function**

The F gene of a non-pathogenic strain of NDV (lentogenic vaccine strain Clone 30) and the VP2 gene of IBDV (strain F52/70) 
The fusion (F) protein in NOV is involved in attachment and entry into host cells and is the major antigen responsible for immunity against NOV infection.

VP2 protein is a major structural protein and the major host protective immunogen of IBDV, containing epitopes responsible for the induction of neutralising antibodies.

**Evaluation of foreseeable effects**

It is recognised that the insertion of foreign genetic material coding for proteins associated with the attachment and entry of virus to host cells into HVT may result in novel pathogenic properties. As NOV is associated with mild conjunctivitis and influenza-like symptoms in man it may therefore possible that the presence of the F protein in the virus envelope could result in transmission to man. HVT however is typically cell associated and, although small quantities of infectious cell-free HVT has been detected in the feather dust of chickens vaccinated with HVT, it is considered unlikely that human infection is possible, although it cannot be categorically discounted.

The VP2 protein does not have features like a signal sequence or transmembrane anchor region such as F from NDV or most of the glycoproteins from herpesvirus and is therefore not expected to be exposed on the cell surface. The risk of hazards arising from alteration of the existing traits of the HVT vector is considered low.

There have never been reports of the recombination of HVT with other related herpesviruses of poultry, e.g. virulent if. (serotype 1) MOV or serotype 2, and the possibility of recombination with a virus capable of infecting humans is therefore considered extremely small. Genetic transfer to other organisms in the environment has never been described for herpesviruses, and is therefore considered to be unlikely.

Chicken to chicken spread has been reported with the parental HVT, however the Sponsor's experience with the recombinant viruses is that chicken to chicken transmission does not occur, although chicken to turkey and turkey spread has been seen. Virus replication (in terms of viraemia and organ isolation) is found in chickens but this is predominantly cell-associated virus, mature cell-free virus is only shed in extremely small quantities from the feather follicles. No adverse reactions have been seen with recombinant vi-uses expressing either the F protein or VP2.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not Applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not Applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Chickens will be vaccinated with the GMM as 18-day-old embryos at the Sponsor's premises (premises number: GM391) and transported to APHA in transport boxes with integral dust filtration. Transport of birds will be under the control of the Sponsor, by a licensed carrier with adherence to all relevant legislation and animal welfare
considerations. This approach has been approved by the Sponsor's own local GM Committee.
Animal waste. Transport boxes, animal carcasses and bedding will be double bagged, and placed in a steri-bin which will be surface disinfected (1% Virkon S for 10 Minutes) prior to being autoclaved and incinerated. Laboratory waste. Sharps associated with the challenge of birds will be placed in a designated sharps box which will be surface disinfected (1% Virkon S for 10 Minutes) and subsequently autoclaved prior to incineration. Autoclave cycle P4 (134°C for 30 mins) as specified in local SOP ASU202 will achieve a 100% kill of the GMM. Any animal liquid waste will be discharged into the effluent treatment plant where it will be heated and held at a temperature of 96°C for two hours, cooled to 38°C and then discharged to the main drainage system.

Project notified under transitional arrangements N
**Project Additional Information**

**Purposes of the contained use**

To determine the immunogenicity and/or protective efficacy against bovine tuberculosis (bTB) of recombinant herpesvirus-vectored vaccines expressing mycobacterial antigens in a cattle model of bTB.

**Recipient or parental organism**

Bovine. The cow is the target species for bTB and therefore represents the ideal model for the testing of vaccines against the disease.

**Host/vector system**

BoHV-4. Recombinant BoHV-4 has been shown to be immunogenic and proposed as a vector for veterinary vaccines.

**Origin & function**

Synthetically produced mycobacterial DNA sequences from BCG, M. bovis or M. tuberculosis.

- **Rv0287 (TB9.8):** Esat-6 like protein. May be involved in virulence. Component of esx-3 secretion system. Well recognised by T cells from M. bovis infected cattle. It has been part of previous subunit vaccine that provided protection for vaccinated cattle when used in conjunction with adenovirus-vectored vaccine (Dean et al., 2014).
- **Rv0288 (TB10.4):** Esat-6 like protein. May be involved in virulence, but frequent vaccine target antigen. This antigen is well recognized by bovine T cells post-infection and has been demonstrated to protect in murine models against M. tuberculosis and M. bovis challenge. Component of esx-3 secretion system. It has been part of previous subunit vaccine that provided protection for vaccinated cattle when adenovirus-vectored (Dean et al., 2014).
- **Rv1733:** Unknown function, recognized by T cells from M. bovis infected cattle.
- **Rv2389:** Promotes resuscitation and growth of dormant, non-growing bacteria. Also recognized by T cells from M. bovis infected cattle.
- **Rv3620:** Putative ESAT-6-like protein, recognized by bovine T cells post- M. bovis infection.
- **Rv3804 (Ag85A):** Involved in cell wall mycolation. Required for biogenesis of trehalose dimycolate necessary for maintaining cell wall integrity. Demonstrated as protective antigen in TB animal models, and cattle (e.g. delivered as adenovirally-vectored subunit to boost BCG-primed calves).

**Evaluation of foreseeable effects**

Recombinant protein(s) will be expressed in mammalian hosts.
Due to gene targeted deletion of ORF73, the BoHV-4 vector is unable to establish latency and can only infect animals transiently. In addition to this characteristic, the inserted bTB genes have no known toxic effects. Vaccinated animals as the viruses are non-persistent in vivo. It is however expected and intended that the inserted mycobacterial proteins will be expressed and an antigen-specific immune response generated (i.e. the virus will serve as vaccine delivery system). Vaccine efficacy will be tested by the application of appropriate immunological and microbiological techniques. Again, neither the immune responses generated nor the sampling schedule are expected to have detrimental effects on the animals. A clinical monitoring system will be applied by the animal care and veterinary staff involved in the experiments to detect unforeseen adverse effects (including change in behaviour/demeanour, loss of appetite, increased temperature). The monitoring protocol will be also discussed with the involved staff at the pre-start meetings to be held prior to the start of any experiment.

The risk of infection in humans is minimal based on in vitro analysis of replication in human cell lines (Gillet et al., 2004). The use of GFP-marked wild-type BoHV-4 to screen 21 different human cell types showed that human lymphoid and myeloid cells are not susceptible to infection, whereas epithelial-derived cells are susceptible to virus entry (range: 72% to 7%), but only poorly permissive for replication (range: 3% to 0.1% based on viral gene expression). No human cases of BoHV-4 infection or disease have been reported to date and, as such, no detrimental effects on exposed humans are foreseeable. Exposure monitoring by e.g. serological testing of animal carers etc. is therefore not necessary. Although BoHV4-TB1 is regarded as safe, immunocompromised individuals shall not handle this vector or be exposed to it via vaccinated cattle.

The risk to rodents as possible transmitters of virus in the environment is also minimal based on in vivo experimental infection studies in mice and rats. Following in vivo inoculation of mice with Luc-expressing BoHV-4, the virus was shown to home specifically to the liver with persistent expression of Luc in only the liver and no other organ. Viral DNA was not detected in any organ other than liver following at 2 days post-infection (tested kidney, spleen, lung, heart, blood and lymph nodes). No clinical symptoms and no replicating virus were detected in liver at 7 day post-infection (Franceschi et al., 2014). The inoculation of mice with BoHV-4 vectors expressing pathogen target antigens, from blue tongue virus or monkeypox, was not associated with any overt clinical signs, detrimental effect or pathology (Franceschi et al., 2011, Franceschi et al., 2015). In adult rats inoculated with GFP-labeled BoHV-4, expression of GFP was only detected in liver endothelial cells, but not parenchymal cells. No infectious virus was recovered from blood, spleen or liver confirming the lack of replication in vivo (Donofrio et al., 2006).

Solid Waste:
From laboratory: Place in plastic autoclave bag, double bag in second autoclave bag, spray with 70% ethanol, 10 minutes contact time, then autoclave and incinerate.
Self-life of the 70% ethanol is 1 week.
Autoclave conditions: minimum 15 PSI at 121°C, 30 min.
From animal facilities waste: All solid waste including bedding and PPE must be discarded into a plastic bag which is then decontaminated with FAM30 (1:20) for at least 1 h and removed for incineration. Needles and syringes must be
disposed of into sharps container before bagging and processing as before.

Liquid waste:
From laboratory: No cultures performed. Therefore, liquid laboratory waste will be virus stocks or diluted vaccine preparations. Place containers (plastic tubes or cryovials) into plastic bag inside class II MSC, place bag into second bag, spray outside with 70 % Ethanol (leave for 10 minutes), then remove from cabinet for autoclaving and incineration.

Autoclave conditions: minimum 15 PSI at 121°C, 30 min. Volumes to be autoclaved will be less than 10 mL.

From animal facilities: Liquid waste in animal accommodation occurring during vaccinations will be contained in syringes and disposed as part of solid contaminated material (see section 5.1). To prevent liquid animal waste, contaminating the drains, during the first 14 days after inoculation drains will be blocked and liquid discarded by adsorption into solids (straw or bedding) that will be disposed of as described in section 5.1. At the end of the experiment, animal accommodation will be cleaned with FAM30 (1 :20 diluted), contact time 1 h, including drain covers before drains can be opened again. Water troughs will be drained on straw/bedding and this disposed as solid waste.

General rubbish:
Waste associated with animal work: Place into appropriate plastic bag, spray/dunk into FAM30 solution (1 :20) and after at least 1 hour contact time remove for incineration.

This project assessment has been approved by the APHA Biological Safety Committee.

Project Ref 221/19.1
Cattle challenge with a transposon mutagenised Mycobacterium bovis library

This is a collaborative research project under the EradbTB funding scheme that includes three institutions: Royal Veterinary College (RVC), London School of Health and Tropical Medicine (LSHTM) and Animal & Plant Health Agency (APHA). SK (RVC) is the overall PI of the project.

The overall goal of this project is to identify the bacterial genetic determinants for survival of Mycobacterium bovis (M. bovis) in cattle in vivo. In order to do this we will use Transposon Directed Insertion Sequencing (TraDIS methodology). This approach, which has been used successfully in other bacteria (i.e. Escherichia coli (Eckert et al., 2011). The M. bovis TraDIS library will be screened in vivo in order to select clones for subsequent in vivo confirmation of in vivo essentiality. A selected number of M. bovis mutants will be constructed through homologous recombination and then validated for their essentiality in cattle in vivo.

This work will allow us to identify the genetic requirements for survival of M. bovis in one of its natural hosts thereby increasing our understanding of the physiological adaptations of M. bovis to the bovine host. Additionally, identification of the genes that are essential for survival in the bovine host will provide an unbiased starting point for the rationale design of new and improved vaccines.

Methodology. The library will be received from colleagues at the RVC and tissues and unused library aliquots will be sent to our colleagues licenced facilities at RVC and LSHTM.

In order to measure gene fitness and to define genes essential for survival in the bovine host, we will challenge cattle with this transposon library by using infection protocols developed and established at the APHA (SOP - BAC0337; all SOP and safety documents referred to in this document are listed at the end of the reference section under their own number). Holstein-Friesian cattle that are 4-6 months old will be infected via the endo-tracheal route; this route results in a lesion distribution that largely reflects the natural infection. The infective dose per animal currently used at APHA in the established protocols is 10,000 CFU, but to allow for screening of as many clones as possible per individual animal, we may use up to 70,000 cfu; the library currently holds 70,000 mutants and therefore by using 70,000
mutants we would be expect that each mutant in the library would be represented in the inoculum; similarly, given that 
each gene is expected to be represented by 16 differently inserted mutants, this would ensure adequate 
representation of each mutated gene in every inoculated cow. It has been shown that infection with 3.2x10^4 CFU 
induces similar levels of pathology to lower infectious doses, with the minimal infective dose (the smallest dose that 
establishes disease reproducibly) being 10 CFU (Dean, 2005).

In phase I, twenty-four animals will be infected with up to 70,000 CFU/animal. Eight weeks after challenge, five 
head/thoracic lymph nodes will be collected at post-mortem examination to recover the surviving clones. Due to size 
constraints, it will not be possible to process whole lungs, therefore, at post-mortem lung pathology will be evaluated 
and samples from lung lesions collected. Lymph nodes and lung samples will be macerated and stored in aliquots for 
shipment to the RVC and/or LSHTM for culturing on modified 7H11 plates for evaluation of clone recovery. All 
cultured clones (CFUs) will be collected and input and output mutant pools will be sequenced by WGS and compared. 
Following the above challenge experiment with an M. bovis transposon library, in Phase II we will validate a set of 
mutants for their essentiality in vivo. We will choose 5-10 genes that would have been predicted to be essential in the 
host from the previous experiment to take forward for validation and infect 6 animals at up to 70,000 CFU/animal with 
a mini-library containing equal amounts of up to 21 strains (2x 10 constructed mutants + M. bovis AF2122/97 
reference strain) - each mutant and the wild type M. bovis AF2122/97 strain will be present at an infectious dose of up 
to 3300 CFU. The challenge and recovery will be performed under the same conditions as described above. 
Both the M. bovis transposon library used in Phase I and the set of M. bovis mutants used in Phase II will be 
generated at the RVC. Also, as culturing of M. bovis from tissue samples will be performed at the RVC and/or 
LSHTM, the GM work carried out at APHA will be restricted to the preparation of inocula in the CL3 laboratories; the 
two animal challenge experiments will be carried out in the animal and post-mortem facilities; the maceration of tissue 
will be carried out in the APHA CL3 laboratories (more details below).

Recipient or parental organism

Construction of the Mycobacterium bovis knockout library will be performed at Royal Veterinary College by our 
colleagues there. No genetic manipulation will take place at APHA. The wild type strain in which the library was 
constructed is Mycobacterium bovis AF2122/97. The knock out library will be used to infect cattle at APHA’s ACDP 3 
and SAPO 3 containment facility, building 268 and tissues will be evaluated in building 270.

Host/vector system

The host for the genetic insertions is Mycobacterium bovis AF2122/97. The library will then be used for infection of 
Cattle - Holstein-Friesian male calves (4-6 months of age). 
Phasmid/phage delivery system:
TraDIS - The delivery of the Himar1 transposon in mycobacteria is mediated by a phasmid system called 
cpMycoMarT7.
Plasmid systems for homologous recombination:
Vectors for use in mycobacteria are based on pAL5000.

Origin & function

TraDIS: 
The <>MycoMarT7 phasmid contains the C9 Himar1 transposase, and the MycoMarT7 transposon on the 
temperature-sensitive phasmid <A>AE87. The MycoMarT7 transposon contains a kanamycin resistance gene and two 
outward facing T7 promoters. The <>MycoMarT7 phasmid was obtained from Dr Graham Stewart from the University 
of Surrey with permission from Dr Eric Rubin from Harvard School of Public Health.
Homologous recombination:
The pAL5000 based plasmid will be obtained from Addgene via Graham Hatful; this plasmid contains the origin for replication in mycobacteria (oriM). We also use shuttle vectors that are able to replicate in both E. coli (contain colEl) and mycobacteria (oriM). We use integrative vectors in mycobacteria that are based on the L5 integration system. This system (originally identified in a mycobacteriophage) allows stable integration of the plasmid at a single specific site in the bacterial genome. This system has been used for over 20 years and allows the stable insertion of genes (for complementation) and reporters (gfp, rfp, lacZ). None of the vectors encode the capacity for conjugation.

Evaluation of foreseeable effects

Evaluations related to potential mutagenesis in this study:
Despite the fact that globally a large number of human TB cases are caused by M. bovis, several lines of evidence suggest that M. bovis and phylogenetically related strains do not exhibit the same virulence and transmissibility for the human host as M. tuberculosis sensu-stricto. A recent report (Gonzalo-Asensio, 2014) showed that three mutations affecting the two-component virulence regulation system PhoPR in M. bovis likely account for this discrepancy. Genetic transfer of these mutations into the human TB agent, Mycobacterium tuberculosis, resulted in down regulation of the PhoP regulon, with loss of biologically active lipids, reduced secretion of the 6-kDa early antigenic target (ESAT-6), and lower virulence. The same authors also observed that insertion of an IS6110 element upstream of the phoPR locus may completely revert the M. bovis phoPR-associated fitness loss, which is the case for an exceptional M. bovis human outbreak strain from Spain. The latter observation was seemingly a rare event but this report suggests that M. bovis, in general, may be less transmissible and/or virulent than M. tuberculosis but that evidently small chromosomal changes (SNP or insertion/deletion) could result in a pathogen with similar phenotypic characteristics as M. tuberculosis. However, the smaller chromosomal size of M. bovis (compared to M. tuberculosis; Garnier, 2003) and rare horizontal gene transfer (Namouchi, 2014) suggest that it is unlikely that M. bovis would have the ability to become more pathogenic than M. tuberculosis. Thus, although rare, it is possible that such a mutant could be generated in any M. bovis transposon library. However, M. tuberculosis, like M. bovis, is an ACDP level 3 pathogens and therefore, in the unlikely event that such a mutant were present in the library, it would not result in development an organism which would be more virulent than M. tuberculosis and the level of containment would still be ACDP containment level 3.

Insertion of a Himar1 transposon into the M. bovis genome will potentially disrupt the function of the gene or operon where it has been inserted. Such disruption is unlikely to generate a pathogenic phenotype, as a deletion is more likely to result in attenuation. Nevertheless, there has been a case where gene deletion has marginally increased the virulence of a laboratory strain, as assessed by the survival of SCID mice (ten Bokum, 2008). However, the virulence increase was only observed in severely immunocompromised mice and is only marginal compared to strains circulating clinically. Similarly, shedding will not be expected to be different than that of the wildtype. Therefore, as mentioned above, the general postulation suggests that mutants generated by TraDIS or constructed by homologous recombination are unlikely to result in a pathogen with greater virulence or shedding potential than M. bovis, which is an ACDP containment level 3 pathogen.

Similarly, targeted deletion of mycobacterial genes is more likely to be detrimental to the environmental survival of M. bovis rather than improve it. Therefore, the risks to the environment caused by gene deletion and complementation are not greater than the wild-type organism. To our knowledge, there have been no reported cases of gene deletion causing an increase in virulence for M. bovis.

It should also be pointed out that all first-line drugs against the disease agents causing TB are targeting genes essential for survival in vivo. Therefore, an insertion of Himar1 transposon in such gene would likely not generate a viable mutant. For that reason, it is highly unlikely that TraDIS would generate a drug resistant mutant that can compromise patient treatment if, despite effectively negligible risk, infection would occur.

Evaluations related to vectors/markers: The Himar1 transposon does not code for any pathogenicity determinants and
so is not expected to increase the pathogenicity of the host organism. Himar1 encodes kanamycin resistance for purposes of selection. Kanamycin is not used clinically, therefore in the extremely unlikely event of accidental infection, treatment regimens will not be complicated.

The plasmid vectors used here for genetic modifications in mycobacteria are non-mobilisable. Therefore the risk of transfer of DNA from mycobacteria into other bacteria - or from HG1 to HG2-3 - is negligible. The kanamycin resistance on these plasmids is not used in therapy and have a history of safe use in the laboratory. One plasmid utilises the phage L5 integrase system and sequences stably integrate into the genome. This does not alter the virulence of the bacteria and integration is stable.

It is expected that the random insertion of the transposon for the manufacture of the mutant library will not generate increased virulence or survival or shedding over and above that of the wild type M. bovis; furthermore the control measures and processes in place at CL3 laboratory and animal facilities (HEPA out, negative air pressure gradient, use of MSCs, PPE, disinfectant, waste treatment and disposal, storage of material) will reduce the risk of exposure or release of the GMM to a minimum.

There is no intention to introduce into the environment.

The risks of infecting cattle with virulent mycobacteria and the post-mortem of cattle infected with virulent mycobacteria have been assessed in documents BAAC 2001/06 and BAAC 2001/01, respectively.

The risk of release during transport is low.

The risk of release of the pathogen during transport from RVC to APHA and of infected tissues from APHA to RVC will not be different to equivalent transport of M. bovis wild-type strain. M. bovis is a Category B pathogen and packaging will be done in accordance with the current ADR (class 6.2 packaging) regulations for the Carriage of Dangerous Goods by Road and in accordance with HSE guidelines (RA.MI008 and SOP BAC0349). The risk of release from laboratory or during transit between CL3 facilities on site will not be different compared to equivalent work using an M. bovis wild-type strain. Infectious material will only leave the CL3 facilities in primary container which is packed in double plastic bags, which themselves will be within a sealed approved container (BioJar). This outer container will be sprayed with 70% ethanol before exiting the CL3 facility, as described in SOP BAC 0349.

Within the scope of work at APHA in this study, no heat-inactivation of M. bovis isolates will be performed. Any sample containing M. bovis pathogens and that will leave the containment facilities at APHA will either be shipped as dangerous goods to our collaborators (the RVC or the LSHTM) or will be destroyed.

The risk of release from the laboratory is low. A potential risk for release of mycobacteria to the environment occurs when inocula are prepared for infection of cattle or when tissues are recovered from animals and macerated for recovery of M. bovis transposon mutant. However, all manipulations of live organisms will be undertaken in ACDP3 facilities inside a class 1 microbiological safety cabinets (MSC). Inocula for infection will be prepared following SOP BAC0340 and tissue homogenization according to SOP BAC0346. Release of pathogens from these dedicated laboratories is prevented through engineering controls (HEPA filtration of exhaust air, negative pressure gradients) as well as procedures applied by fully trained and authorised staff as described in SOP BAC0371.

The risk of release from animal accommodation is considered low. All animal work will take place at APHA's ACDP3 animal facility. The facility is run under negative pressure, the air is extracted through HEPA filters and is connected to a backup generator in case of power failures. Staff working in this facility with infected animals will be wearing PPE and RPE as described in SOPs ASU 295. In addition, disinfection procedures to decontaminate all waste and equipment leaving the facility have been established (SOPs ASU305 and ASU234), please see below, waste disposal section. Access to building 268 is controlled by the building officer and is restricted to authorised staff that have been trained and signed off against ASUF453 (SOP ASU 238; listed below).

The endobronchial infection is described in SOP BAC0337. Following inoculation, the syringe and the cannula will be placed directly into a waste bag; the bag will be sealed and placed with the animal waste for incineration. The
Endoscope will be disinfected prior to removal from the facility using Perastal, an approved disinfectant which does not damage the endoscope. The computer used for visualizing the travel of the endoscope through the animal will be wiped with tissues soaked in Trigene and double bagged, sprayed with 70% ethanol and transported to ACDP3 laboratory where it will be fumigated inside an MSC., following SOP BAC0347. At the end of the cattle study, the animal rooms will be disinfected by formaldehyde fumigation performed by suitably trained staff (SOP ASU 241). Post-mortem examination will take place in building 270, which is under negative pressure relative to the outside environment. The air is extracted through HEPA filters. Building 270 is connected to a backup generator in case of power failures. The areas for post-mortem examination work on a laminar flow principle with air being drawn to the back of the bay to the main air handling unit extracts. The highest bID-risk during post-mortem analysis is at the bench when examining tissues for lesions of BTB, which involves the cutting of tissues. Therefore, staff undertaking PM procedures will wear PPE and RPE are essential as indicated in SOP PTH0356. Samples will be released according to SOP PTH0339 for transport to ACDP3 laboratory facilities for further processing. Following the PM procedure the facility will be disinfected as indicated in SOP ASU 023.

Assessment: Low risk
The likelihood of survival outside of laboratory containment is low. Members of the Mycobacterium tuberculosis complex, including M. bovis, are not free living in the environment. Hence they are only able to grow and multiply in an animal if released in the environment. It is therefore highly improbable that tubercle bacilli could out-compete saprophytic bacteria that are adapted to survival in the environment. If M. bovis were released, it would simply persist in soil or water. M. bovis can survive in soil for up to 6 months and on pasture for at least 49 days (Maddock, 1933). However, it is not known if and how infective these bacilli would be and if they could be presented in the form necessary for infection. Moreover, surface deposited bacilli accessible to UV radiation would be rapidly killed. And given the environment that they would be released into as part of this procedure, they will be most likely accessible to UV light (due to the concrete or bitumen surfaces surrounding these buildings). The consequences of bacilli surviving and being potentially infective will be discussed in the next paragraph.

It is unlikely that a transposon gene-deleted M. bovis would survive outside the laboratory longer than a wild-type M. bovis strain, which contains a full complete genome. The consequences of release form the laboratory are high. Exposure of cattle to M. bovis, a bacterial pathogen already present in UK cattle and wildlife hosts, could lead to infection. Humans are also susceptible to infection, as well as other susceptible domestic and wildlife mammals such as cats, dogs or badgers. However, to cause infection, the bacilli need to be present in the appropriate format and/or dosage. Whilst aerosol infection (most common route associated with tuberculosis) requires a very small infective dose (1 to several CFU), generation of aerosols and their ingestion is unlikely due to the low expected bacillary shedding and loads generated. The oral infection dose is by far higher (10,000+ CFU) and it is unlikely that such high bacillary counts would be released. This would also require the direct ingestion through the oral route of the bacilli, which is unlikely. Further, there are no susceptible free-living experimental animals (e.g. cattle, goats, sheep, pigs) in close proximity of the CL3 laboratories in the Stewart Stockman Building to ingest/inhale tubercle bacilli and thus the risk of infection of such animals is effectively zero. Infection risk to humans outside the containment building is also low as the generation of aerosols is unlikely at any stage and unlikely to be of sufficient density and quantity to infect passing staff. Tuberculosis in humans is treatable.

The transposon and Kanamycin resistance gene inserted into the chromosome of M. bovis pose no additional risk in this respect since the drug resistance marker the bacilli contain have been chosen because they are not used in human medicine.

The risk associated with M. bovis without controls is high but on applying the safety measures detailed in the
associated SOPs, the risk of exposure/release from containment is low.

Special measures.
Recombinant mycobacteria will be handled at CL3 at all times; in the CL3 laboratory suite TB-101 or the SLSD suite of building 7 for preparation of inocula for infection and for maceration of tissues; building 268 for animal infection, and building 270 for post-mortem examination.

These buildings comply with the appropriate control measures that will prevent the release of dangerous or genetically modified microorganisms into the environment. These include filtration of air exhaust through HEPA filters in all the facilities in which the organism will be handled; in the case of the laboratory, the organism will be handled only inside Class 1 microbiological safety cabinets, which will protect personnel in the laboratory and provide double filtration between the organism and the environment. In the case of laboratory waste, both liquid and solid waste material will be inactivated by autoclaving at 1360°C for 1 hr prior to incineration; in the case of the animal accommodation, solid waste and liquid waste that had been adsorbed into solid waste (such as animal urine) will be incinerated, waste that reaches the drain will be heat treated for 2 hrs at 960°C prior to release into the normal effluent; in the case of all the post-mortem facility, solid waste will be incinerated and any liquid waste will be inactivated with a 5% solution of FAM30 for 1 hr, which is the DEFRA approved disinfectant with the approved contact time for inactivation of Mycobacterium bovis.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste from ACDP3 laboratory facility. The vectors used and the knock-out mutants of M. bovis included in these experiments are expected to be equally susceptible to heat and autoclaving as any wild-type strain of M. bovis. Therefore, all waste produced in the laboratory CL3 facilities in this experiment, as well as used PPE, will be autoclaved as per validated protocols (for wild-type M. bovis) prior to disposal. In short, waste will be transported to an autoclave in a closed metal tin. Decontamination will be performed by autoclaving for 1 hour at 136°C after which waste will be put into bags for incineration. Waste disposal generated in the animal facility unit will be undertaken according to ASU234 in 500 litre bunded, lockable metal bins with red lids and biohazard signs attached. Waste will be taken to the incinerator for disposal through burning as described in SOP ASU 234. Waste generated during the post-mortem procedure, including clinical waste and carcass, will be loaded into bins double lined with black bags. The plastic bags will be sealed securely with tape and the outside will be sprayed with 5% FAM30. Disposal will then be through incineration as per PTH 0358.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

02/03/2022
The risk assessment GMRA 2018/03 - Cattle challenge with a transposon mutagenised Mycobacterium library has been reviewed (July 2018) and approved by APHA Biological Safety Committee.

### Project Additional Information

**Purposes of the contained use**

Nipah virus (NiV) poses a significant epidemic threat due to its broad host range and widespread distribution of Pteropus spp. bats which provide a natural reservoir. Human infection can occur following the exposure to infected
pigs, where NiV causes a respiratory and neurological syndrome. Direct pig-to-human transmission was responsible for the first and most devastating NiV outbreaks in Malaysia and Singapore (1998-99), with nearly 300 human cases and over 100 fatalities. Despite the importance of NiV as an emerging disease, no vaccines are currently approved for human or livestock use. We propose that an inexpensive, safe and efficacious vaccine could be developed for use in pigs to protect against NiV infection and transmission, therefore reducing the risk to public health as well as the developing pig industries and small holder farmers in south and southeast Asia.

Previously, a canarypox vaccine vector (ALVAC strain) expressing the NiV glycoprotein (G) or fusion protein (F) (ALVAC-NiV G and ALVAC-NiV F) protected pigs against experimental NiV challenge (Weingartl et al., 2006). High titres of NiV neutralising antibodies were induced with the ALVAC-NiV G vaccine, while despite the low levels of neutralising antibodies induced by the ALVAC-NiV F; all vaccinated pigs were protected against virulent NiV challenge. Despite these encouraging results and the continued threat posed by NiV, no vaccine candidate has progressed towards market. In this project we are systematically analysing the immunogenicity of NiV vaccine candidates including both recombinant protein subunit and viral vectored vaccines. Providing data to support their further evaluation in efficacy studies being conducted by partner institutions. Groups of pigs will be immunised one to two times with the NiV vaccine candidates via the intramuscular route and bled at weekly intervals to determine vaccine-induced immune responses.

This application specifically addresses the use of recombinant bovine herpesvirus type 4 (BoHV-4)-based vectors delivering NiV G and/or NiV F to immunise pigs. Several biological characteristics of BHV-4 makes it an attractive vaccine delivery vector. These include: no pathogenicity, no oncogenicity as the BHV-4 genome is maintained in an episomal state in dividing cells without chromosomal integration, the capability of to accommodate large amounts of foreign genetic material and ability to maintain transgene expression in both undifferentiated and differentiated cells. Multiple recent studies indicate the potential utility for BoHV-4 for development as a vaccine vector platform, with an ability to induce immune responses against heterologous target antigens (Donofrio et al., 2006, Donofrio et al., 2007 and Donofrio et al. 2008).

Recipient or parental organism

Bovine herpes virus 4 (BoHV-4) is a gamma herpesvirus generally associated with subclinical infections in cattle. A BoHV-4 genome was cloned as a bacterial artificial chromosome (BAC) to create a vector platform that is readily engineerable. The BoHV-4 vector has been demonstrated to be suitable to deliver heterologous antigens and induce potent immune responses in a range of species including pigs (Donofrio et al., 2011). The construction of infectious BoHV-4-derived BAC clones in Escherichia coli, followed by progeny virion reconstitution via transfection into permissive eukaryotic cells, has been successfully pursued as a means to rapidly modify the viral genome and adapt it to specific needs. Expression cassettes are inserted into the TK locus of BoHV-4 genome and optimized with different promoters, such as CMV, EF1a and PGK, as well as the woodchuck hepatitis virus post-transcriptional regulatory element to increase transcript half-life. In this specific case, NiV G and NiV F genes were placed under the transcriptional control of a CMV promoter.

Host/vector system

BoHV-4-based vector expressing NiV G and/or NiV F will be used to immunise pigs.

Origin & function

The Pirbright Institute will receive cells infected with recombinant BoHV-4-based vector expressing NiV G or NiV F from The Department of Medical-Veterinary Science of Parma University (Italy). These recombinant viral vector infected cells will be used to immunise pigs at APHA-Weybridge.
Nucleic acid insert contains Nipah Virus Malaysian strain glycoproteins G and F. NiV Malaysian Strain GenBank accession number HMS4S086.

Intended function of the genetic material is to express antigen and induce NiV antigen-specific immune responses in vaccinated pigs. The induction of NiV specific neutralising antibodies and T-cell will be assessed longitudinally in blood samples and in mucosal and associated lymphoid tissues collected post-mortem.

Evaluation of foreseeable effects

The recombinant BoHV-4 vectors will infect cells within the immunised pig which will lead to antigen expression and the induction of NiV specific immune responses. Infection is expected to be restricted to the inoculation site and systemic spread and virus shedding will not occur. There is the possibility that the recombinant NiV G and/or F protein will be embedded in the envelope of the BoHV-4 virion but this is unlikely to alter the cellular tropism, since BoHV-4 entry occurs by fusion of the mature virion envelope with host cell membranes on a wide variety of cell types. There is a low risk of the release of the viral vectors into the environment from the animal accommodation as BoHV-4 vectors will undergo limited replication localised to the inoculation site in immunised pigs. The recombinant viruses will not be shed from vaccinated animals nor will virus be present in blood and tissue samples subsequently collected from immunised animals. There is no evidence of lesions forming at the inoculation site that could provide a source of virus shedding and transmission.

The likelihood of survival of recombinant BoHV-4 vectors outside of laboratory containment is low. As a member of the enveloped Herpesviridae, recombinant BoHV-4 vectors are expected to possess low environmental stability and direct contact between cattle is typically necessary for transmission of BoHV-4. BoHV-4 can be inactivated by lipid solvents such as ether and chloroform, and by physical and chemical agents; it is heat labile (SO°C, 30 min), trypsin sensitive, inactivated at pH 3, and is not stabilized by magnesium chloride. A comprehensive WHO report on herpesvirus survival in the environment concluded that, depending on ambient temperature, pH, and type of animal waste, time in days required for a 90% virus titer reduction varies widely, ranging from less than 1 week for herpesvirus to more than 6 months for rotavirus. Virus inactivation was faster in liquid manure, a mixture of urine and water (pH> 8.0), than in semiliquid wastes that consisted of mixtures of faeces, urine, water, and bedding materials (pH < 8.0) (Sobsey and Meschke, 2003). Bovine herpesvirus was reduced by 1 log10 within 2.5 days (Pesaro et al., 1995). This reduced survival in the environment is not likely to be affected by the expressed NiV genes, therefore the likelihood of the recombinant BoHV-4 vectors surviving in the environment is low.

The risk of infection of humans with recombinant BoHV-4 vectors is effectively zero. There is no reports of BoHV-4 infecting humans naturally. Sera from naive humans, in contrast to sera from other mammalian species, efficiently neutralises BoHV-4 infectivity. The mechanism of this neutralization is complement-dependent and mediated by natural antibodies against the Gala1-3Gal131-4GlcNAc-R epitope acquired on the viral envelope during replication in bovine, swine and ovine cells, which all express Gala1-3Gal131-4GlcNAc-R. Thus human natural antibodies raised against Gala1-3Gal offer an innate immune mechanism that prevents cross-species transmission of gammaherpesviruses to humans (Machiels et al., 2007). In vitro analysis of BoHV-4 replication in human cell lines showed that human lymphoid and myeloid cells are not susceptible to infection, whereas epithelial-derived cells are susceptible to virus entry (range: 72% to 7%), but only poorly permissive for replication (range: 3% to 0.1% based on viral gene expression) (Gillet et al., 2004). Exposure monitoring by e.g. serological testing of animal carers etc. is therefore not necessary. Although BoHV-4 is regarded as safe, immunocompromised individuals shall not handle the vectors or to be potentially exposed to it when immunizing pigs.

Accidental release of the recombinant BoHV-4 vectors could result in infection of animals in the environment. Expression of NiV G or F protein is highly unlikely to alter host range and/or tissue susceptibility of BoHV-4 vectors. However in the unlikely event of this occurring in most animal species e.g. rodents, horses, goats, sheep and pigs, the recombinant vectors are incapable of spreading. The exceptions are the natural host, cattle, and the laboratory host, rabbits, in which the recombinant BoHV-4 vectors could establish a persistent infection and could be transmitted to
animals with close contact. Accidental infection of cattle or rabbits with recombinant BoHV-4 vectors is not expected
to cause disease. The vectors would induce NiV and/or F specific antibody responses that could result in false
positive results in NiV serological diagnostic assays. However NiV outbreaks have never been described outside of
sporadic outbreaks in livestock and humans in south and southeast Asia and the likelihood of ever screening UK
cattle or rabbit populations for seroprevalence is extremely low. In the unlikely event of homologous recombination of
the recombinant BoHV-4 vector (GMM) with a wild-type herpesvirus (e.g. transfer of the NiV gene), the resulting
recombinant virus will not represent any greater hazard or risk than the original GMM vaccine virus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid contaminated materials:
Health and Safety
Executive
Laboratory waste: Place in plastic autoclave bag, double bag in second autoclave bag, spray with 70% ethanol, 10
minutes contact time, then autoclave and incinerate.
Self-life of the 70% ethanol is 1 week.
Autoclave conditions: minimum 15 PSI at 121°C, 30 min.
Animal facilities waste: All solid waste including bedding and PPE must be discarded into a plastic bag which is then
decontaminated with FAM 30 (1 :20) for at least 1 h and removed for incineration. Needles and syringes must be
disposed of into sharps container before bagging and processing as before.
Post-mortems will be performed at days 40-42 of the study. There is no increased risk post-mortem other than those
associated with non-GM post-mortems as no infectious virus will be present in the tissues at this time-point postimmunisation.
Pigs will be transported to the post-mortem room by ASU staff (outlined in ASU SOP 058: Transportation of Animals and General Use of ASU Vehicles. The use of the post mortem room is outlined in SOP
ASU 23 Use and Maintenance - Building 270 and the carcasses will be disposed of by incineration directly from the
post-mortem room (PTH SOP 0358: Waste disposal to cremator from Building 270 containment envelope).

Liquid waste:
Laboratory waste: No cultures performed. Therefore, liquid laboratory waste will be virus-infected SMADSC stocks or
diluted vaccine preparations. Place containers (plastic tubes or cryovials) into plastic bag inside class II MSC, place
bag into second bag, spray outside with 70 % Ethanol (leave for 10 minutes), then remove from cabinet for
autoclaving and incineration.
Autoclave conditions: minimum 15 PSI at 121°C, 30 min. Volumes to be autoclaved will be less than 10 mL.
Animal facilities waste: Liquid waste in animal accommodation occurring during vaccinations will be contained in
syringes and disposed as part of solid contaminated material (see section 5.1). To prevent liquid animal waste,
contaminating the drains, during the first 14 days after inoculation drains will be blocked and liquid discarded by
adsorption into solids (straw or bedding) that will be disposed of as described in section 5.1. At the end of the
experiment, animal accommodation will be cleaned with FAM 30 (1 :20 diluted), contact time 1 h, including drain
covers before drains can be opened again. Water troughs will be drained on straw/bedding and this disposed as solid
waste.
The risk assessment 'Vaccination of pigs with recombinant bovine herpesvirus-4 vectors expressing Nipah virus glycoproteins' was discussed in September 2018 meeting and have been approved by APHA Biological Safety Committee.

### Project Ref 221/19.3

- **Date Ackn'd**: 13/09/2019
- **Date Project Ceased**: 221/19.3
- **CU2 Project Title**: Recombinant prion production and purification to enable development of RT-Quic technology.
- **Class**: Class 2
- **CultureVolumeClass3-4**: ≤ 1 L
- **Non-GMM Consent Granted**: Not Applicable
- **Consent Granted**: Not Applicable
- **Project notified under transitional arrangements**: No
## Project Additional Information

### Purposes of the contained use

Production of non-infectious recombinant prion protein (rPrP) as a reagent for use in Real Time Quaking Induced Conversion (RT-QuIC) assays. These assays detect prion seeding activity for rapid, discriminatory and ante-mortem diagnostic tests of transmissible spongiform encephalopathies (TSEs).

### Recipient or parental organism

Recombinant PrP plasmids donated by Dr. Byron Caughey (Rocky Mountains Laboratory, Colorado, USA) will be propagated and expressed in 2 different commercially available E.coli strains specifically developed for these applications.

1. TOP1 0 E. coli strain (One Shot® TOP1 0 Chemically Competent Cells, Invitrogen) will be used for propagation of rPrP plasmids.
2. Rosetta 2(DE3) E. coli strain (Rosetta™ 2(DE3) Singles™ Chemically Competent Cells, Novagen) will be used for rPrP synthesis.

### Host/vector system

The host is E.coli, gram-negative bacteria. Commercially available strains will be used.

Two types of vector will be used for the expression of the rPrP of interest. They both come from a commercial source (Novagen).

1. The pET24 vector has been used for the insertion of bank vole rPrP DNA sequence (codons 23-230), and sheep VRQ rPrP DNA sequence (codons 25-234). It has been designed for expression from bacterial translation signals carried with in a cloned insert. It therefore lacks the ribosome binding site and ATG start codon present on the pET translation vectors.
2. The pET41 vector has been used for the insertion of sheep ARQ PrP (codons 25-234). The pET41 vector has been designed for cloning and high-level expression of peptide sequences fused with the 220 aa GST-Tag protein.

### Origin & function

   This sequence corresponds to the natural prion protein as encoded by the bank vole genome, devoid of the signal peptide (residues 1-22) and the C-terminal amino acids that are cleaved off in post-translational processing in the natural host. The bank vole natural prion protein is not pathogenic unless made so by in vivo or targeted templating reactions, neither of which are used in the planned activities at APHA. As the sequence encodes a single mammalian protein that does not self-replicate, it is incapable of self-propagation.

   These sequences correspond to two of the allotypes (136/154/171 V/R/Q resp NR/Q) of the natural prion protein as encoded by the sheep genome, devoid of the signal peptide (residues 1-24) and the C-terminal amino acids that are cleaved off in post-translational processing in the natural host. The sheep natural prion protein is not pathogenic unless made so by in vivo or targeted templating reactions, neither of which are used in the planned activities. As the
sequence encodes a single mammalian protein that does not self-replicate, it is incapable of self-propagation. The genetic material is to be used for production of non-pathogenic rPrP with amino acid sequences corresponding to either bank vole or sheep natural prion proteins. The non-pathogenicity of the produced rPrP will be tested by western blot with and without proteinase K. This test will confirm that our protocol lead to the production of the rPrPc and not the rPrPSC. As described in the project summary, the rPrP produced will be used as a core component of the RTQuIC diagnostic test for TSEs, which is to be developed and implemented in a TSE containment facility at APHA Weybridge.

Evaluation of foreseeable effects

Foreseeable effects on lab workers following incidents such as spillage and accidental exposure by inhalation are considered negligible as the components in the proposed procedure are non-colonizing and non-pathogenic. Exposure of the environment to any of the components used in the procedure as a result of spillage, will not to result in harm to organisms in the environment, as none of the components have colonising ability, nor are they pathogenic or mobilisable:

1) TOP10 and Rosetta 2(DE3) E.coli cells are respectively derived from the strains K-12 and BL21, neither of which produce toxins, are pathogenic or have colonising capability.
2) The pET vectors is based on the pBR322 vector and as such are mobilisation defective.
3) The pRARE2 plasmid displaying the chloramphenicol resistance gene, a component of the Rosetta 2(DE3) E.coli cells, is non-mobilisable, there is no risk of transfer of antibiotic resistance to the environment.

No evidence exists that would indicate a risk that these host and vector properties are liable to change or mutation that would alter these properties.

In summary, none of the components form a risk to operators or environment.
As no TSE agent is present and rPrP is non-pathogenic, decontamination measures for TSE agents will not be required. As mentioned previously (section 3.3.3), the non-pathogenicity of the produced rPrP will be check by western blot, with and without proteinase K.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid contaminated waste and glassware to be recycled to the Media department (empty culture bottles) will be surface-decontaminated by repeated spraying with 70 % ethanol to ensure a contact time of 10 min, within the MSC prior to removal (Validation Document VI013 - Validation of 70% Ethanol for the inactivation of HG3 & HG2 Enterobacteriaceae; VTEC Biohazard Unit Working Procedures V11 ; Approval comms for Validation; BTF846). Waste and glassware will then be placed inside autoclave tins which are clamped shut for transport and surface-decontaminated by spraying with 70 % ethanol , 10 min contact time(VI013). Tins must be labelled using autoclave tape with description of waste type and room number, and only then allowed to be transported to the autoclave (using a dedicated trolley for this task) and take through the autoclaving process by support staff (SOP CBU0143 - Collection and disposal of contaminated material).

The autoclave tins with solid waste will be autoclaved using the "Discard Cycle" (holding temperature 134°C for 60 min) which has been validated previously (March 2013) for solid waste followed by incineration on-site (SOP CBU0135 - Autoclave Operation), except for media glassware which will be cleaned and returned to the Media.
Liquid waste including broth cultures and supernatants will be collected into 500 mL red-top pots (GosselinTM Square High Density Polyethylene Bottles (Corning LC500-11)) inside an MSC to which 7.5 g Lab-Sorb will be added to solidify the waste to a gel. The pots will be closed and surface-decontaminated by spraying with 70 % ethanol, 10 min contact time (VI013) within the MSC prior to removal. They will then be placed inside autoclave tins which are clamped shut for transport and surface-decontaminated by spraying with 70 % ethanol, 10 min contact time (VI013). Tins will then be labelled using autoclave tape with description of waste and room number and only then allowed to be transported using a trolley to the autoclave and take through the autoclaving process by support staff (SOP CBU0143 - Collection and disposal of contaminated material). The autoclave tins with solidified liquid waste will then be autoclaved (SOP CBU0135 - Autoclave Operation) using the “Discard Cycle” (holding temperature 134 °C for 60 min). As the previous validation procedure for eradicating bacterial contamination from solidified liquid waste was for volumes up to 100 mL, an additional validation for the 250 mL solidified waste volumes using non-transformed version of the Rosetta 2(OE3) E. coli cells (prior transformation) has been carried out (April 2019). Waste will be subsequently disposed of for incineration on-site (SOP CBU0143 - Collection and disposal of contaminated material).

This risk assessment was presented to and discussed in the APHA Biological Safety Committee meeting in May 2019. The project assessment has been approved by the committee.
**Project Additional Information**

**Purposes of the contained use**

To generate cultures of animal cells that can replicate indefinitely under laboratory conditions. This reduces the need to cull animals to harvest cells, and also standardises the cell culture for better reproducibility of results.

**Recipient or parental organism**

Potentially, tissue derived from any animal.

**Host/vector system**

A pantropic replicant-incompetent retroviral vector based on Moloney murine leukemia virus.

**Origin & function**

SV40 is a large T antigen of simian virus origin, it is widely used in cell immortalisation. It is also available as a combination of large T and small T antigen. hTERT is the catalytic subunit of human telomerase. It is another commonly used immortalisation gene, but it doesn't transform the cells to the same extent as SV40. Both nucleic acid inserts would allow for cell cultures to propagate indefinitely.

**Evaluation of foreseeable effects**

The retroviral vector is replication incompetent. Therefore, once used to transfect the target animal cells, they cannot reproduce themselves or leave the cell to further infect other cells. They are a single use delivery mechanism.
The genes are incorporated randomly into the host genome. This means the experiment will not always be successful. Most cells will die and can be disposed of via standard APHA waste methods. If successful, an immortalised cell line will proliferate, which can then be stored cryogenically for future use.

If staff were accidently injected with the oncogene SV40, there is the potential for this to cause the growth of tumours in the individual, but would not lead to contagious disease (Barbanti-Brodano et al., 2004). This risk is mitigated to LOW by never using sharps during the process, as sharps are not necessary to perform any of the stages. Transfected packaging cells and their supernatant are always handled in a MSC and with the operator using standard PPE (double gloves and disposable arm sleeves). This is to protect the packaging cell line from undesirable bacterial contamination, but also adds an extra layer of biosecurity which helps reduce any accidental release of the viral vector to the environment.

Cells will routinely be produced only from healthy animals. However, as a precautionary step cell lines generated from non-SPF sources may be screened for adventitious agents post-transduction.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste associated with transfection/transduction work is autoclaved at a minimum of 121°C for 30 minutes before incineration on site.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

This risk assessment was presented and discussed at September 2019 meeting. It was agreed that transfection/transduction of the cells should be GM class 2 activity, but handling of resulting immortalised cell lines falls onto GM1 class.

The overall goal of this project is to define the role of the Mycobacterium bovis protein MPB70 in the generation of pathology during infection in cattle. Mycobacterium bovis is an ACDP Hazard Group 3 pathogen. MPB70 is a protein which is constitutively expressed at a high level and secreted by M. bovis. However, in the human pathogen Mycobacterium tuberculosis MPB70 is expressed at lower levels, suggesting a role for MPB70 in host tropism. The NMR structure of MPB70 was determined in 2003 and revealed a FAS1 (Fasciclin-like) domain (Carr et al., 2003). FAS1 domains are present in extracellular proteins and are implicated in cell-to-cell, cell-to-extracellular matrix and extracellular matrix structure adhesion (Park et al., 2009; Seifert, 2018). This suggested a role for MPB70 in cellular aggregation, an initial step in granuloma formation. This hypothesis was explored further to reveal that MPB70 plays a role in driving bovine macrophages to form multinucleated cells, MNC, in vitro (Queval et al., 2021). This work also revealed that M. tuberculosis did not lead to MNC formation from bovine macrophages in vitro, nor did an M. bovis mutant lacking MPB70. Finally, from previous work, it was noted that M. tuberculosis infections of cattle led to much lower numbers of MNCs in granulomas as compared to M. bovis (Villarreal-Ramos et al, 2018; Queval et al, 2021). However, it is not known if this latter observation is due to lower levels of MPB70 production by M. tuberculosis.
M. bovis AF2122/97, which is a GB isolate that was the first M. bovis strain to be genome sequenced (Gamier et al, 2003). It is used worldwide as a well characterised M. bovis strain. No construction of the Mycobacterium bovis knockout strains will be performed at APHA. The M. bovis AF2122/97 wild type, M. bovis AF2122/97 delta mpb70 mutant and M. bovis AF2122/97 delta mpb70(pEW70c2) complemented mutant strains to be used will be supplied by our UCD collaborator at the time of infection in the form of culture stocks ready for dilution and preparation of the inocula. No genetic manipulation of the mutants will be carried out at APHA.

Host/vector system

Mycobacterium bovis AF2122/97; wild type, mutant and complemented mutant will be used to infect cattle (Holstein-Frisian calves 6-8 months of age).

The phAE159 phagemid system was used for homologous recombination. The pEW70c2 plasmid in the M. bovis AF2122/97 delta mpb70(pEW70c2) is derived from pMD31 which contains ColE1 and pAL5000 origins of replication. All vectors are non-mobilizable and non-conjugative.

The DNA insert used to generate the allelic exchange substrate for the M. bovis AF2122/97 mpb70 mutant is the gene encoding hygromycin resistance, originally obtained from Streptomyces hygroscopicus (Garbe et al, 1994). The DNA insert in the pEW70c2 plasmid is the wild type M. bovis AF2122/97 mpb70 gene under the control of its native promoter.

The allelic exchange substrate was used to exchange the chromosomal copy of the wild type mpb70 gene for the disrupted mpb70 gene with a hygromycin selectable marker.

The pEW70c2 plasmid restores the expression of mpb70 in the M. bovis AF2122/97 delta mpb70 mutant back to wild type levels.

Origin & function

Evaluations related to potential mutagenesis in this study:

Recently published data (Queval et al, 2021) indicates that the deletion of mpb70 from M. bovis reduces the ability of the mutant to drive multinucleated cell (MNC) formation from bovine macrophages in vitro. Hence our hypothesis is that this in vitro phenotype of reduced MNC formation will be reproduced during in vivo infection of cattle, representing the reduced virulence of the mutant, and evident after histopathological examination. Furthermore, previous work has suggested a link between BCG vaccine strains that are high producers of MPB70 and osteitis as a complication of BCG vaccination with these strains; conversely, BCG strains that produce low levels of MPB70 have lower rates of osteitis (Wiker, 2008). The complemented mutant containing the mpb70 gene has already been shown to confer wild type expression of mpb70 back to the mutant and to restore the formation of MNC in in vitro. Our expectation is that animals infected with the complemented mpb70 mutant will resemble infection with wild type M. bovis in terms of MNC formation. There is no evidence or expectation that the mutant or complemented mutant have increased virulence as compared to the wild type. Verification of the complemented mutant has maintained the pEW70c2 plasmid will be performed by plating macerated tissue samples on 7H11 agar plates containing Kanamycin. If required, this will also be confirmed by PCR at UCD, using heat killed bacterial pellets shipped from APHA.

In terms of environmental survival of the mutant or complemented mutant, deletion of mycobacterial genes is more likely to be detrimental to the environmental survival of M. bovis rather than improve it. Therefore, the risks to the environment caused by gene deletion and complementation are not greater than the wild-type organism.

Evaluations related to vectors/markers:

The hygromycin marker used for construction of the allelic exchange substrate for inactivation of the mpb70 coding sequence is from Streptomyces hygroscopicus, a soil dwelling actinobacteria. The marker is integrated onto the bacterial chromosomal and as such non-mobilisable.

The pEW70c2 plasmid vector used here for complementation is non-mobilisable. Therefore, the risk of transfer of
DNA from mycobacteria into other bacteria is negligible. Kanamycin and hygromycin are not used in human TB therapy and have a history of safe use in the laboratory. In the extremely unlikely event of accidental infection with the recombinant bacilli, treatment regimens will not be complicated.

Furthermore, the control measures and processes in place at CL3 laboratory and animal facilities (HEPA out, negative air pressure gradient, use of microbiological safety cabinets (MSCs), Personal Protective Equipment (PPE) and Respiratory Protective Equipment (RPE), disinfectant, waste treatment and disposal, storage of material) will reduce the risk of exposure of staff working with the bacteria or release of the genetically modified microorganism to a minimum. As stated in BAAC 2001/06, all staff working with M. bovis must be enrolled with the APHA TB Occupational Health Surveillance Programme. The established Tuberculosis Health Surveillance Protocol must be followed. All staff must have received a BCG vaccination or have evidence of a BCG scar.

**Evaluation of foreseeable effects**

Evaluations related to potential mutagenesis in this study:

Recently published data (Queval et al, 2021) indicates that the deletion of mpb70 from M. bovis reduces the ability of the mutant to drive multinucleated cell (MNC) formation from bovine macrophages in vitro. Hence our hypothesis is that this in vitro phenotype of reduced MNC formation will be reproduced during in vivo infection of cattle, representing the reduced virulence of the mutant, and evident after histopathological examination. Furthermore, previous work has suggested a link between BCG vaccine strains that are high producers of MPB70 and osteitis as a complication of BCG vaccination with these strains; conversely, BCG strains that produce low levels of MPB70 have lower rates of osteitis (Wiker, 2008). The complemented mutant containing the mpb70 gene has already been shown to confer wild type expression of mpb70 back to the mutant and to restore the formation of MNC in in vitro. Our expectation is that animals infected with the complemented mpb70 mutant will resemble infection with wild type M. bovis in terms of MNC formation. There is no evidence or expectation that the mutant or complemented mutant have increased virulence as compared to the wild type. Verification that the complemented mutant has maintained the pEW70c2 plasmid will be performed by plating macerated tissue samples on 7H11 agar plates containing Kanamycin. If required, this will also be confirmed by PCR at UCD, using heat killed bacterial pellets shipped from APHA.

In terms of environmental survival of the mutant or complemented mutant, deletion of mycobacterial genes is more likely to be detrimental to the environmental survival of M. bovis rather than improve it. #### Solid waste:
Waste from CL3 facilities.
The vector used and the knock-out mutant of M. bovis included in these experiments are expected to be equally susceptible to heat and autoclaving as any wild-type strain of M. bovis. Therefore, all solid waste produced in the CL3 facilities in this experiment, as well as used PPE, will be autoclaved as per validated protocols (for wild-type M. bovis) prior to disposal (SOP BAC0358). In short, waste will be transported to an autoclave in a closed metal tin. Decontamination will be performed by autoclaving for 1 hour at 136°C after which waste will be put into bags for incineration.

Waste disposal generated in the animal facility
This will be undertaken according to ASU234 in bunded, lockable metal bins with red lids and biohazard signs attached. Waste will be taken to the incinerator for disposal through burning as described in SOP ASU 234. Disinfection and removal of equipment (endoscope etc.) will follow the procedure described in SOP BAC0337. Waste generated during the post-mortem procedure, including clinical waste and carcass, will be loaded into bins double lined with black bags. The plastic bags will be sealed securely with cable ties and the outside will be sprayed with 5% FAM30. Disposal will then be through incineration as per PTH 0358 in close interaction with the incinerator staff.

#### Liquid waste:
Waste from the CL3 facilities
Liquid waste is treated as per validated protocols (for wild-type M. bovis) prior to disposal (SOP BAC0358). Liquid waste from the laboratory facility is contained first within a robust, leak proof bottle. For removal from the MSC, the bottle is sprayed with 70% ethanol and placed inside a polyethylene bag; this bag is in turn sprayed with 70% ethanol prior to being taken out of the MSC and placed inside an autoclave tin. The tin is closed and autoclaved at 136°C for 1 hr, after which, the contents of the tin are placed in appropriate containers for incineration.

Waste disposal generated in the animal facility
Liquid waste from animal rooms will be processed as described in ASU305; briefly, liquid waste from animal rooms will drain to the effluent treatment plant in which waste will be heated to 96°C for 2 hrs before being released into the public drains. Liquid waste could also be absorbed into solid waste, for instance straw in which case liquid waste will be disposed through incineration, as solid waste.

Liquid waste from the PM room will be disposed in accordance with SOP PTH 0358.

#### General rubbish:
All rubbish will be solid or liquid and hence dealt with as described above.

Date of Significant Change

Project Additional Information
**Purposes of the contained use**

Recombinant expression of mycoplasma protein in E. coli to evaluate specific immunogenic proteins, with the aim of determining the suitability as candidate antigens able to offer improved serological tests for mycoplasma disease in host animals.

**Recipient or parental organism**

*Escherichia coli* B derivative BL21 (DE3) for protein expression

- *Escherichia coli* K-12 derivative (DH5a) for DNA cloning and plasmid manipulation

Both *E. coli* strains are regarded as ACDP HG 1 (Health and Safety Executive, 2007). These *E. coli* strains will be purchased as commercial products from New England BioLabs in a competent form to enable heat-shock transformation.

The *E. coli* hosts for expression studies are disabled strains, unable to survive in the environment and require complex media and growth conditions, and are considered ACDP HG1. These *E. coli* strains will be purchased as commercial products from New England BioLabs in a competent form to enable heat-shock transformation.

Host/vector system

- *Escherichia coli* BL21 (DE3) or DH5a will be the host.

The vector systems are listed below:

- **pGEM vector system** (Promega) for cloning and plasmid manipulations. These plasmids have an origin of replication enabling plasmid replication within *E. coli* cells, there are multiple cloning sites to enable DNA cloning via restriction enzyme digestion and DNA ligation, and they confer ampicillin resistance to transformed *E. coli*.

- **Plasmids of the pET system**, (Merck), pGS system (Genscript), or pGEX system (Genscript) for protein expression work. These plasmids confer either kanamycin or ampicillin resistance to transformed *E. coli*, recombinant protein is expression under control of the T7 promoter (pET, pGS) or tac promoter (pGEX), and lac operator, and they also enable fusion of purification affinity tags, glutathione S tranferase, polyhistidine and S-peptide tag.

**Origin & function**

The gene sequence or gene fragment encoding immunogenic protein(s) will be synthesised commercially to mutate TGA (encoded as tryptophan in mycoplasmas) to TGG to enable protein expression in the GM *E. coli*, from the following *Mycoplasma* species:

- **SAPO2**
  - *M. mycoides* subspecies *capri*
  - *M. capricolum* subspecies *capricolum*
  - *M. capricolum* subspecies *capripneumoniae*
  - *M. agalactiae*
  - *M. putrefaciens* (considered SAPO2 for laboratory work)
SAPO2 & Schedule 5

- M. mycoides subspecies mycoides

No SAPO2 mycoplasmas will be genetically modified under this notification. Mycoplasmas lack typical "virulence" genes such as toxins, cytolysins, and invasins. Instead and candidate genes conferring immunogenic functions appear to be membrane-associated lipoproteins with roles in adhesion and immune evasion. The target DNA cloned in a pET plasmid vector will be introduced into E. coli to carry out protein expression analysis and produce mycoplasma proteins/peptides for use in diagnostic assays.

Cloning of one mycoplasma gene with this type of function is extremely unlikely to generate a virulent E. coli with toxigenic properties, especially as the E. coli recipient strains (BL21 (DE3) or K-12 derivatives (DH5a)) are lab adapted, avirulent, and lack expression of genes mediating long-term colonisation of animal host(s).

We anticipate mycoplasma proteins with immunogenic properties applicable to serological diagnostic assays, will be lipoproteins expressed at the mycoplasma cell-surface with adhesion functionality to cells of the host animal (sheep and goat) cells. It is unlikely that the chosen mycoplasma protein(s) will confer virulence or toxigenic properties in recipient E. coli when produced recombinantly as mycoplasmas do not harbour typical bacterial virulence genes or, with a single exception, toxins. Only the human pathogen Mycoplasma pneumoniae (not used in this project) has been found to produce the community-acquired respiratory distress syndrome toxin (CARDS). Candidate genes encoding a hypothetical protein of unknown function will be assessed in terms of structural homology to known bacterial protein toxins using online search databases (blastP, Uniprot). Any candidate proteins with homology to known toxins will be further investigated and assessment of risks associated with planned protein expression will be undertaken to determine whether protein expression can be safely carried out. Every effort will be made to eliminate selection of mycoplasma genes encoding proteins with any kind of theoretical toxigenic function.

The E. coli hosts for expression studies are disabled strains, unable to survive in the environment and require complex media and growth conditions, and are considered ACDP HG1. DNA within expression vectors will be under the control of vector promoters, and the proposed cloning and protein expression vectors do not carry mobility genes or mating pair formation complex genes enabling conjugation, and thus may be viewed as nonmobilisable. As such, the conference of antimicrobial resistance to ampicillin or kanamycin via transformation with these plasmids will be limited to the recipient E. coli strains DH5a and BL21 (DE3); the chance of horizontal transfer of these antimicrobial resistance genes from recipient E. coli is low.

E. coli expression strains BL21(DE3) have been engineered to contain a genomic insert capable of expressing T7 polymerase. This gene is under the control of a lac promoter and expression is induced on addition of IPTG. In the presence of T7 polymerase, DNA expression is induced from T7 promoter sequences within the constructed vector (pET plasmid). This leads to expression of the inserted mycoplasma DNA. It is unlikely that these fragments will be expressed within these strains outside laboratory conditions. In addition, it is very unlikely that the level of expression observed within the laboratory will be induced from these vectors should they be accidentally transferred to wild type hosts in the environment.

It is extremely unlikely that the expression of one mycoplasma protein within a disabled E. coli host strain would result in a virulent genetically modified organism (GMO), since BL21 strain is ACDP 1 and candidate proteins will not confer E. coli with virulence or toxigenic properties. In addition, signal peptides within recombinant protein(s) will be removed at the gene synthesis stage to prevent transportation to the cell-surface in the GM E. coli, and thus removing the risk of GM E. coli acquiring additional functions such as adhesion. Furthermore, risks associated with recombinant protein function may be reduced by production of truncated proteins/peptides rather than full length proteins. Where appropriate, truncated protein/peptides with superior immunogenic properties will be favoured over native full-length proteins, and as such, may reduce/remove recombinant protein/peptide function through loss of tertiary conformation or regions critical for function. Risks of these GMOs to the operators and environment will be controlled and minimised.

Evaluation of foreseeable effects

We anticipate mycoplasma proteins with immunogenic properties applicable to serological diagnostic assays, will be lipoproteins expressed at the mycoplasma cell-surface with adhesion functionality to cells of the host animal (sheep and goat) cells. It is unlikely that the chosen mycoplasma protein(s) will confer virulence or toxigenic properties in recipient E. coli when produced recombinantly as mycoplasmas do not harbour typical bacterial virulence genes or, with a single exception, toxins. Only the human pathogen Mycoplasma pneumoniae (not used in this project) has been found to produce the community-acquired respiratory distress syndrome toxin (CARDS). Candidate genes encoding a hypothetical protein of unknown function will be assessed in terms of structural homology to known bacterial protein toxins using online search databases (blastP, Uniprot). Any candidate proteins with homology to known toxins will be further investigated and assessment of risks associated with planned protein expression will be undertaken to determine whether protein expression can be safely carried out. Every effort will be made to eliminate selection of mycoplasma genes encoding proteins with any kind of theoretical toxigenic function.

The E. coli hosts for expression studies are disabled strains, unable to survive in the environment and require complex media and growth conditions, and are considered ACDP HG1. DNA within expression vectors will be under the control of vector promoters, and the proposed cloning and protein expression vectors do not carry mobility genes or mating pair formation complex genes enabling conjugation, and thus may be viewed as nonmobilisable. As such, the conference of antimicrobial resistance to ampicillin or kanamycin via transformation with these plasmids will be limited to the recipient E. coli strains DH5a and BL21 (DE3); the chance of horizontal transfer of these antimicrobial resistance genes from recipient E. coli is low.

E. coli expression strains BL21(DE3) have been engineered to contain a genomic insert capable of expressing T7 polymerase. This gene is under the control of a lac promoter and expression is induced on addition of IPTG. In the presence of T7 polymerase, DNA expression is induced from T7 promoter sequences within the constructed vector (pET plasmid). This leads to expression of the inserted mycoplasma DNA. It is unlikely that these fragments will be expressed within these strains outside laboratory conditions. In addition, it is very unlikely that the level of expression observed within the laboratory will be induced from these vectors should they be accidentally transferred to wild type hosts in the environment.

It is extremely unlikely that the expression of one mycoplasma protein within a disabled E. coli host strain would result in a virulent genetically modified organism (GMO), since BL21 strain is ACDP 1 and candidate proteins will not confer E. coli with virulence or toxigenic properties. In addition, signal peptides within recombinant protein(s) will be removed at the gene synthesis stage to prevent transportation to the cell-surface in the GM E. coli, and thus removing the risk of GM E. coli acquiring additional functions such as adhesion. Furthermore, risks associated with recombinant protein function may be reduced by production of truncated proteins/peptides rather than full length proteins. Where appropriate, truncated protein/peptides with superior immunogenic properties will be favoured over native full-length proteins, and as such, may reduce/remove recombinant protein/peptide function through loss of tertiary conformation or regions critical for function. Risks of these GMOs to the operators and environment will be controlled and minimised.
under containment level 2 laboratory conditions, with restricted access to the laboratories where the work is
undertaken, only competent staff will undertake the work, personal protective equipment (including lab coat and
gloves) will be worn at all times, all liquid culturing will be conducted in a class II MSC to reduce inhalation of
aerosolised culture, with opening of centrifugation containers also performed insight a class II MSC. The design of the
DNA cloning and recombinant protein work takes into consideration measures to reduce risk to operators, and this
includes using disabled ACDP HG1 E. coli strains and non-mobilisation plasmids (deficient in conjugation encoding
genes). Live GM E. coli waste generated during this work will never enter the drainage system, it will be inactivated
with heat prior to disposal.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All laboratory waste, which has had contact with the live GM E. coli created in this project will be sealed within sweet
jar containers until point of inactivation (BACO243, BAC5-RA016). All waste containers will be sprayed with 70%
ethanol for a contact time of 10 minutes prior to removal from MSC (validation reference: VI013), and will be
transferred to autoclave tins prior to being autoclaved on a cycle of 134°C for 1 hour sterilisation followed by
incineration (validation reference: VHI005).

Liquid waste generated in this work includes:
• GM E. coli culture (maximum of 2 x 400 mL per experiment)
• Culture supernatant (maximum of 2 x 400 mL per experiment)
• GM E. coli cell pellet lysate

Cultures will be contained in conical flasks or bottles with screw cap lids during shaking incubation. Small volumes of
liquid waste, up to 5 mL, will be placed inside sweet jar containers inside an MSC, and sprayed with 70% ethanol for
10 minutes contact time (validation reference: VI013) prior to removal from the MSC. The sweet jar will be placed
inside an autoclave tin and the contents inactivated on a cycle of 134°C for 1 hour (Validation of discard cycle in
autoclave, room 2, building 4, 2013), followed by incineration. Volumes of waste culture/ supernatant larger 40 mL but
less than 100 mL will be inactivated by autoclaving and then disposed of into the drainage system (autoclave
validation March 2013). Volumes of liquid waste >100 mL but 5250 mL will be transferred into 500 mL red-top pots
(GosselinTM Square High Density Polyethylene Bottles (Corning LC500-11)), and inside an MSC 7.5 g Lab-Sorb (or
appropriate weight to solidify volume of waste <250 mL) will be added to solidify the waste to a gel. The pots will be
closed and surface-decontaminated by spraying with 70 % ethanol, 10 min contact time) prior to removal from the
MSC. The pots will be placed inside autoclave tins prior to being autoclaved on a cycle of 134°C for 1 hour to
inactivate any viable GM E. coli (validation number VHI005 & autoclave validation April 2019), followed by
incineration.

Should a spillage occur inside/outside the MSC, procedures outlined in CBUO105 will be followed.
All general laboratory waste will be generated in a class II MSC and may include include:
• Paper towel
• Plastic packaging
• Paper
• Gloves (non-contaminated)

All general waste will be autoclaved on a cycle of 134°C for 1 hour sterilisation followed by incineration.

Date of Significant Change

Project Additional Information
Purposes of the contained use

GM Ashbya gossypii, either over expressing or not expressing (gene 'knockout' strains) certain Ashbya gossypii genes, will be used to identify potential pesticidal products. The GM Ashbya gossypii will be imported from the USA under a DEFRA licence (currently being applied for). All work will be carried out in the laboratory.

Recipient or parental organism

Ashbya gossypii is a minor plant pathogen of cotton and not pathogenic to humans. It naturally secretes riboflavin and is grown commercially to produce this vitamin. The over expression or deletion of specific genes is not expected to enhance its pathogenicity. It is not present in the UK so will be handled according to DEFRA licence requirements.

Host/vector system

The vector system used in the genetic modification of the Ashbya is a derivative of the pYES2.1-E vector from invitrogen. The genetic modification will be done in Syngenta labs in the USA and the GMMs imported into the UK for research use.

Origin & function

GMMs over expressing Ashbya genes from Ashbya promoters will be generated together with 'knockout' strains that are not expressing certain genes. The individual clones will be characterised in the USA and used in the UK for identification of potential pesticidal compounds.

Evaluation of foreseeable effects

The GM Ashbya will only be grown in contained facilities, in culture. It will not be used to infect plants. Therefore there are expected to be no environmental or health consequences from the proposed work.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be used.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disinfection of work surfaces etc. - Klercide disinfectant will be used to clean work surfaces. It is effective against non-GM Ashbya in culture both on new growth and on established cultures. The genetic modification is not expected to alter this.

Waste management - All waste from work with GM Ashbya will be double bagged within the laboratory for incineration at Jealott's Hill. Any liquid waste will be autoclaved in a facility within the building before being disposed of to foul drain. Information from the Local Rules on autoclaving and incineration on site are attached to this form.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
Please enter comments on the GM safety committee on the risk assessment

The Jealott's Hill GMSC reviewed this programme of work at a meeting on the 12th July. It is recommended that the work proceed after required notification to the HSE.

**Project Additional Information**

**Purposes of the contained use**

To develop a viral vector that can be used to amplify expression of foreign genes in targeted tissues of plants. All proposed work to be done in plant tissue culture.

**Recipient or parental organism**

The plant viral vectors will be used in E. coli, A. tumefaciens, plant cells and plants.
Host/vector system

The GM plant viral vectors will be constructed elsewhere (not in the UK) and used at the notified premises.

Origin & function

A few plant viral sequences from one type of plant viruses will be used and DEFRA licences will be obtained prior to use. Two types of viral vectors will be constructed elsewhere and tested in plant cells/tissues at Jealott's Hill:

1. Gene Replacement Construct: Viral vectors will be used with the essential genes (e.g. coat protein gene) and/or other ORFs replaced by another gene. Initially common reporter genes (eg GUS) will be used with various promoters. If the desired expression levels are achieved then effect genes of interest will replace the reporter genes.

2. Gene Insertion Construct: Viral vectors will be used with reporter genes inserted in any intergenic region of the viral genome. However, the starting vector will have had genes necessary for viral gene expression and regulation, efficient virus replication, host range and symptom development deleted. If the desired expression levels are achieved then effect genes of interest will replace the reporter genes.

Evaluation of foreseeable effects

Human health considerations:
The viruses are plant viruses and do not pose any risk to human health. Any effect genes expressed by the viral sequences will not alter the risk; prior to use, sequences will be screened for homology to known toxins/potential allergens.

Environmental considerations:
The wild type viruses have specific host plants and specific insect vectors of transmission. The insects required for transmission between plants do not occur naturally in the UK and the GM viral sequences will only be used in the contained environment with any DEFRA licence restrictions applied. Thus the liklihood of a specific insect being able to transfer the virus outside of the containment facility is negligible. In addition to this, all the viral vectors have had some or all of the essential viral genes replaced, deleted or interrupted and will not be able to spread from the inoculated site even if the required insect was present. The vector will stay within the plant cells and tissues, replicating and expressing the genes of interest leading to a localised presence of the protein.

Note that there is no intention to use wild type virus or viral particles, only double stranded viral sequences, cloned in the pUC plasmid or Agrobacterium binary vectors will be used as controls.

Conclusion: Given that the planned work is in the contained environment, essential viral sequences for infection and dissemination in the environment are missing and that transmission of the viruses requires specific non-indigenous host insects, the risk to the environment from this work can be considered to be negligible.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Plant cells and tissues will be used in tissue culture and contained growth chambers. Only authorised researchers can access the tissue culture laband the contained growth chamber.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied. DEFRA licence requirements will be met.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste will end up in the site incinerator and all liquid waste will be autoclaved prior to disposal to drain. Solid waste will be collected within the laboratory, double bagged and sealed before transfer to our secure waste compound for incineration. Information on incineration and autoclaving is attached to this form - both are expected to give effectively 100% kill of any GMOs.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
The Jealott's Hill GMSC has reviewed the risk assessment. The committee accepted the original risk assessment with some changes. These changes have been agreed by the GMSC and incorporated into the document submitted to the HSE.

USE OF AGROBACTERIUM RHIZOGENS ON DICOTELYDONs TO GENERATE HAIRy ROOTS

Class 2

Consent Granted

< 1 litre

Class Culture Vol Class 2

Volume Class 3-4

Not applicable

Project notified under transitional arrangements

02/03/2022
Purposes of the contained use

The objective of the work is to develop a rapid assay to test nematocidal genes for efficacy against nematodes in plant roots. Hairy roots will be generated using \textit{Agrobacterium} rhizogenes containing genes coding for potentially nematocidal proteins. The GM hairy roots containing the genes of interest will then be subject to analysis.

Recipient or parental organism

The assay requires the use of \textit{Agrobacterium} rhizogenes. This micro-organism is a plant pathogen and is covered by an existing licence issued by DEFRA (PHL 32F/3787).

Host/vector system

Binary vectory will be constructed in E coli K12 and then transferred to armed \textit{A} rhizogenes for plant transformation. The plant material will be tomato, tobacco, potato and soybean.

Origin & function

Potentially nematocidal proteins have been identified from fungal material (not plant or human pathogenic material). The identification was achieved by challenging nematodes with various extracts from the original organism. The proteins were isolated and identified. The genes encoding these proteins have been cloned and this project is to develop a rapid assay to gauge the effectiveness of these genes in a plant tissue system. Plans will be transformed with \textit{A} rhizogenes to generate hairy roots. Nematode bioassays will then be done on the hairy root material to determine which genes should be developed further. The further development will not involve \textit{A} rhizogenes; plant transformation to generate plantlets will be done using disarmed \textit{A} tumefaciens. In addition to the nematocidal genes, reporter genes will be used, for example GUS and red fluorescent protein (from reef coral, \textit{Discosoma} sp.).

Evaluation of foreseeable effects

Human health considerations.
\textit{A} rhizogenes is a plant pathogen and does not infect humans. Therefore no adverse effects are expected from its use. All sequences of genes to be used and expressed in the hairy root system will be put through a database to identify potential toxins/allergens prior to use. Any genes identified as potentially allergenic/toxic will not be progressed further.

Environmental considerations:
\textit{A} rhizogenes is a gram-negative, soil-borne, motile plant pathogenic bacteria and infection with this bacterium causes hairy root disease. In nature, hairy root disease has been observed on a limited number of plant species (eg apple, cucumber and melon). Therefore the natural host range is restricted, as is the economic and agricultural impact, although outbreaks have occurred in the UK. In contrast, artificial inoculation in the laboratory has been successful on a wide number of plant species and is expected to be successful on essentially all angiosperms and gymnosperms. The wild type bacteria naturally infect plants at wound sites and transfer part of their large plasmid, Ri, to the chromosomal DNA of the plant cell. Reproduction is via cellular division only - the bacteria are non-sporulating. Therefore there is no risk from spore dispersal in air. Infection in nature usually occurs at wounds, for example graft sites, and spreads via contaminated garden/farm tools. Aseptic techniques will be used for all manipulations to prevent cross contamination and spread of \textit{A} rhizogenes.

\textit{A} rhizogenes is susceptible to a wide range of antibiotics and, after transformation, an antibiotic will be used to clear the hairy roots of micro-organisms prior to being used for the nematode bioassay. The genes of interest will be screened on databases and will not be used if homology is found to genes involved in the induction of the hairy root phenotype. Similarly, if nematocidal genes of interest are isolated from species that are pathogenic to plants then DEFRA advice will be sought before their introduction into the hairy root system.

Conclusions:
The planned work does not pose a risk to human health. \textit{A} rhizogenes is a plant pathogen and can infect plant species grown in the UK. It can be spread via contaminated soil, water or media. The proposed work will all be done in vitro using aseptic techniques. In addition, DEFRA licence conditions will be adhered to. Thus the risk to the environment from this work is considered to be negligible.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Plant material, ie hairy roots, will be kept in containment level 2 facilities and the conditions in the DEFRA licence will be adhered to.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied. DEFRA licence requirements will be met.

Project Ref 222/03.1

Date Ackn'd 03/01/2003

CU2 Project Title THE USE OF GENETICALLY MODIFIED PHYTOPHTORA INFESTANS IN IN VITRO

Class 2

CultureVolClass2 < 1 litre

CultureVolumeClass3-4
The overall objective of this work is to investigate the mode of action of novel fungicides by using genetically modified Phytophthora infestans.

The GM P infestans strains fall into 3 groups:

1. P infestans genetically modified to over express specific P infestans genes. These strains will be used to identify potential inhibitors of those genes.
2. P infestans genetically modified such that certain genes are down regulated by a gene silencing mechanism. These strains will be used for helping to determine the mode of action of novel fungicides as well as helping to identify whether a gene is responsible for sensitivity or resistance to a particular fungicide.
3. P. infestans genetically modified to express the B-glucuronidase or fluorescent proteins fused to P. infestans proteins. These strains enable the P infestans protein to be visualised on application of a fungicide. This will help to determine the mode of action of novel fungicides.

P. infestans is an indigenous pathogen of Solanaceous plants, including potato and tomato and is found commonly throughout the UK. The pathogen overwinters as mycelium in infected plant material (eg potato tubers left in the ground after harvesting). On infection of young plants the pathogen spreads to the aerial parts where it produces sporangia on sporangiophores. These sporangia can become airborne or rain dispersed. The sporangia are large and heavy and are only viable for a short period of time (if up to 2 weeks) and in order for the disease to spread they must come into contact with a susceptible host. When the sporangia land on wet potato leaves or stems they then germinate and cause new infections. When sporangia land in water they produce zoospores that only survive for a few hours without a suitable host.

CDNA libraries of P infestans sequences in E. coli will be imported from Syngenta laboratories in the USA. The sequences of genes of interest are known and will be used to screen the libraries. These sequences will then be cloned into the vectors for transformation into P infestans.

P infestans is genetically modified via zoospore or protoplast transformation and the transgenes are stably integrated into the genome. GM strains will be imported from the Netherlands and the USA. In addition, the methodology for transforming P infestans will be implemented on site.

The vectors used will be non-mobilisable E. coli vectors, including pUC18/19, pBlueScript, pGEMT and genetin and hygromycin resistance vectors for co-transformation in P infestans under the control of promoters from Phytophthora species.
1. P infestans genetically modified to over express specific P infestans genes. P infestans genes will be inserted into the above vectors under promoters isolated from Phytopthora species.

2. P infestans genetically modified such that it expresses inverted repeats or antisense copies of certain genes leading to silencing of the native gene(s). Since Phytophthora species are diploid organisms and homologous integration of plasmids has not yet been demonstrated, a gene silencing strategy is the best alternative to inhibit gene expression in this plant pathogenic oomycete. The vectors described above will be used with P infestans sequences inserted in antisense orientation.

3. P infestans genetically modified to express B-glucuronidase and fluorescent proteins fused to P infestans proteins. The genes expressing fluorescent proteins have been isolated from various marine reef anemones and corals and the B-glucuronidase gene has been isolated from E. coli. They are commonly used reporter genes enabling visualisation of proteins. The gene fusion will be inserted into the vectors described above.

Origin & function

1. P infestans genetically modified to over express specific P infestans genes.
Origin of material: P infestans plus commonly used marker genes.
Function: The intention is that the over expression of certain genes will lead to an increased amount of the corresponding protein being present in the cells. The strains will be used to identify potential (chemical) inhibitors of the over expressed genes.

3. P infestans genetically modified to express B-glucuronidase and fluorescent proteins fused to P infestans proteins.
Origin of material: P infestans, various marine reef anemones and corals (eg Zozenthus sp., Anemonia majano and Anemonia sulcata) and E. coli.
Function: The fluorescent proteins and GUS are commonly used reporter genes enabling visualisation of proteins. Fusion with P infestans proteins will enable visualisation of proteins when the GM P infestans is challenged with a potential fungicide.

The sequences of P infestans that will be regulated will be those essential for growth, or whose gene products show high affinity to small molecules (fungicides), or that have been identified by classical mutagenesis as being required for the method of action of the chemical which is being investigated.

2. P infestans genetically modified such that it expresses inverted repeats or antisense copies of certain genes leading to silencing of the native gene(s).
Origin of material: P infestans plus commonly used marker genes.
Function: The intention is that the antisense sequences from P infestans will silence the native genes. These strains will be used for helping to determine the mode of action of novel fungicides as well as helping to identify whether a gene is responsible for sensitivity or resistance to a particular fungicide.

Evaluation of foreseeable effects

Risks to human health:
The comycete P. infestans is an indigenous plant pathogen in this country. The pathogen is unable to colonise or infect even immunocompromised humans. However, all introduced protein sequences will be screened for potential allergenicity/toxicity prior to the strains being grown. Any information that shows a cause for concern will be included in the COSHH assessment and the control measures revised.

Risks to the environment:
There are several scenarios that may affect the pathogenicity of the GM P infestans. For example, if a gene involved in the infection process is turned off then a plant may not recognise that it has been infected; this could lead to an increased host range for the pathogen. Conversely, if a gene required for infection is turned off then the pathogen will be less virulent. There are equally valid scenarios for strains containing genes that have been over expressed. For strains expressing the fluorescent protein it is unlikely that pathogenicity will be increased, as the GMM will be putting extra resource into the production of the extra protein.

The above scenarios rely on the GMMs coming into contact with a suitable host plant. Therefore the implementation of appropriate control measures (containment level 2 plus DEFRA requirements) to reduce the likelihood of this happening (ie the opportunity for infection of potential hosts by the GMMs) means that the overall risk of this work to the environment can be considered to be low.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be autoclaved prior to disposal to drain. Solid material will be bagged up and incinerated on site. These procedures will give essentially 100% kill of viable material.

Decontamination of work surfaces will be done using Klercide 5TM. In a kill test this disinfectant has been shown to be effective against non GM P infestans.

Is an emergency plan required according to regulation 20?

Project Ref 222/03.2

Date Ackn'd 20/11/2003

CU2 Project Title THE USE OF GENETICALLY MODIFIED MYCOSPHAERELLA GRAMINICOLA (M. graminicola) in the control of cereal diseases

Class 2

CultureVolClass2 < 1 litre

CultureVolumeClass3-4

02/03/2022

Page 5341 of 15326
The overall objective of this work is to investigate the mode of action of novel fungicides by using genetically modified M. graminicola. The strains will be generated on site and/or imported from the EU, Switzerland the the USA.

The GM M graminicola that we wish to use falls into 3 types:

1. M graminicola genetically modified to over express M graminicola genes. These strains will be used in the characterization of potential inhibitors of those genes.
2. M graminicola genetically modified such that certain genes are down regulated by disruption, mutation or replacement with a marker gene. These strains will be used to determine the mode of action of novel fungicides as well as helping to identify whether a gene is responsible for sensitivity or resistance to a particular fungicide.
3. M graminicola genetically modified to express the B-glucuronidase or fluorescent proteins or fluorescent proteins fused to M. graminicola proteins. These strains enable the M. graminicola protein to be visualised and on application of a fungicide will support the determination and characterisation of the mode of action of novel fungicides.
M. graminicola genetically modified to over express M. graminicola genes. Initially we wish to insert fusion proteins of a B tubulin from M. graminicola with fluorescent proteins. However, included in the scope of this project are other M. graminicola genes yet to be identified. These genes will be identified in E. coli and prior to transferring to M. graminicola the sequences will be screened for homology to known avirulence or virulence genes. Any positives will not be used, as there is no intention to deliberately generate GM M. graminicola that could be of harm to the environment. These strains will be used in the characterisation of potential inhibitors of those genes.

M. graminicola genetically modified such that certain genes are down regulated by disruption, mutation or replacement with a marker gene. These strains will be used to determine the mode of action of novel fungicides as well as helping to identify whether a gene is responsible for sensitivity or resistance to a particular fungicide.

M. graminicola genetically modified to express the B-glucuronidase or fluorescent proteins or fluorescent proteins fused to M. graminicola proteins. These strains enable the M. graminicola protein to be visualised on application of a fungicide and will support the determination and characterisation of the mode of action of novel fungicides. Initially the a and b tubulin genes will be used. However, as described above, other M. graminicola genes are included in the scope of the project.

Evaluation of foreseeable effects

M. graminicola is not known to cause harm in humans and is not recognised as a human pathogen. Given the planned genetic modifications, it is highly unlikely that the GM M. graminicola that we intend to generate will alter this. Note that all new proteins expressed in M. graminicola will be checked for homology to known toxins and allergens prior to use.

There are two main scenarios by which GM M. graminicola could cause harm to the environment. Both of these scenarios require the GMM to escape from containment. We will be using ACGM Containment Level 2 in addition to DEFRA licence requirements. Yeast like cells or mycelium (which are not airborne) will be used and, assuming that they survived the transfer from containment to outside and found a suitable host plant, they would have to be particularly virulent/pathogenic to survive and establish in the well managed situations at Jealott's Hill (ie within our glasshouses or grounds). We therefore consider the likelihood of escape as very low.

* Transfer of genetic material to WR M. graminicola or other related micro-organisms outside of containment leading to increased pathogenicity/virulence and environmental harm. In order for this to happen the GMM would have to be in the right stage of the growth cycle, meet a compatible micro-organism and locate a suitable host plant. Genetic transfer can only occur between the sexual forms of M. Graminicola and we will be using the yeast like cells and/or mycelium. In addition different mating types would have to meet on a suitable host plant. Therefore together with the very low likelihood of escape and survival we consider the likelihood of the GMM transferring genetic material outside of containment as very low.

* Establishment of GM M graminicola outside of containment, wither in the Jealott's Hill glasshouses or in the surrounding grounds. This requires the escape of a GMM with increased pathogenicity/virulence and for that GMM to reach a suitable host. Given that Jealott's Hill is a highly managed environment and that we employ experienced plant pathologists we believe that the likelihood of the GMM escaping containment and establishing itself in the environs of Jealott's Hill can be considered to be very low. However, in the highly unlikely situation of this happening we will know about it.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be autoclaved prior to disposal to drain. Solid material will be double bagged and incinerated on site. These procedures will give essentially 100% kill of viable material.

Decontamination of work surfaces will be done using Klercide 5TM. In a kill test this disinfectant has been shown to be effective against non GM M. graminicola.
The GMSC considered the risk assessment at a meeting on the 13th November. The project was approved as submitted.

Please enter comments on the GM safety committee on the risk assessment

Purposes of the contained use

Use of genetically modified plant pathogen to help identify novel compounds with fungicidal activity.

Recipient or parental organism

M. graminicola is the causal agent of Septoria Tritici leaf blotch of wheat. It is an indigenous pathogen and is present throughout the UK. The disease is characterised by the development of irregular chlorotic lesions that become necrotic in time. The penetration frequency of germinated conidia on wheat leaves is in general low (Rohel et al., Mol Plant Microbe Interact, 2001, 14:156-163). Inside the necrotic lesions the asexual pycnidia and/or the sexual pseudothecia develop. The teleomorphic pseudothecia can be found throughout the growing season and M. graminicola can complete a sexual cycle in the field within five weeks of infection (Hunter et al., Plant Pathol, 1999, 48:51-57). This implies that spread of the disease does not only depend on splash dispersal of asexual pycnidia spores but is also caused by a constant supply of ascospores (Shaw and Royle, Plant Pathol, 1989, 38:35-43). Recent studies revealed that M. graminicola populations are highly diverse and suggested that sexual reproduction has a major influence on the gene structure of M. graminicola populations (McDonald 1999). The sexual pseudothecia is considered to be largely responsible for the oversummering of the disease in regions where crop rotation is a common agricultural practice.

Origin & function

M graminicola is not known to cause harm in humans and is not recognised as a human pathogen. It is highly unlikely that the GM M. graminicola that we intend to use will alter this status.

There are two main scenarios by which GM M. graminicola could cause harm to the environment. Both of these scenarios require the GMM to escape from containment. We will be using ACGM Containment Level 2 in addition to DEFRA licence requirements. Yeast like cells, asexual conidia or mycelium will be used for experimental purposes. Asexual pycnidia and pycnidiospores may be produced on detached leaf pieces. However pycnidiospores are released in a mucilaginous cirrus and are not air-dispersed. Assuming that they survived the transfer from containment to outside and found a suitable host plant, they would have to be particularly virulent/pathogenic to survive and infect in the absence of an extended dew period and establish in the well managed situations at Jealott's Hill (ie within our glasshouses or grounds). We therefore consider the likelihood of escape as very low.

Evaluation of foreseeable effects

M graminicola is not known to cause harm in humans and is not recognised as a human pathogen. It is highly unlikely that the GM M. graminicola that we intend to use will alter this status.

There are two main scenarios by which GM M. graminicola could cause harm to the environment. Both of these scenarios require the GMM to escape from containment. We will be using ACGM Containment Level 2 in addition to DEFRA licence requirements. Yeast like cells, asexual conidia or mycelium will be used for experimental purposes. Asexual pycnidia and pycnidiospores may be produced on detached leaf pieces. However pycnidiospores are released in a mucilaginous cirrus and are not air-dispersed. Assuming that they survived the transfer from containment to outside and found a suitable host plant, they would have to be particularly virulent/pathogenic to survive and infect in the absence of an extended dew period and establish in the well managed situations at Jealott's Hill (ie within our glasshouses or grounds). We therefore consider the likelihood of escape as very low.

* Transfer of genetic material to WT M. graminicola or other related micro-organisms outside of containment leading to increased pathogenicity/virulence and environmental harm. In order for this to happen the GMM would have to be in the right stage of the growth cycle, meet a compatible micro-organism and locate a suitable host plant. Genetic transfer can only occur between the sexual forms of M. graminicola and we will be using the yeast like cells and/or mycelium. In addition different mating types would have to meet on a suitable host plant. Therefore together with the very low likelihood of escape and survival we consider the likelihood of the GMM transferring genetic material outside of containment as very low.

* Establishment of GM M graminicola outside of containment, either in the Jealott's Hill glasshouses or in the surrounding grounds. This requires the escape of a GMM with increased pathogenicity/virulence and for that GMM to reach a suitable host. Given that Jealott's Hill is a highly managed environment and that we employ experienced plant pathologists we believe that the likelihood of the GMM escaping containment and establishing itself in the environs of Jealott's Hill can be considered to be very low.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full ACGM Containment Level 2 under the 2000 regulations will be applied. Note that waste will be inactivated outside of the building so derogation will be needed under the proposed revised regulations.

Project Ref 222/07.1

Date Ackn'd CU2 Project Title Class CultureVolClass2 CultureVolumeClass3-4

28/11/2007 Development of a protein expression system using genetically modified Class 2 < 1 litre
The objective of this work is to generate genetically modified Mycosphaerella graminicola (lvi graminicola; anamorph Septoria Irifid), which can be used as a protein expression system. Ultimately proteins produced mM graminicola will be used in assays to help investigate the activity and mode of action of novel fungicides. This proposal aims to use the NS1 protein from a variety of influenza A and B virus strains to block the gene silencing machinery of the recipient cells, thus providing an enhancement of heterologous protein expression above current levels.

M. graminicola is the causal agent of Septoria tritici leaf blotch of wheat. It is an indigenous pathogen and is present throughout the UK. The disease is characterized by the development of irregular chlorotic lesions that become necrotic. In time. Under field conditions lv! graminicola over winters as mycelia or pycnidia in infected plants, seeds or field debris. The primary source of inoculate is asexual conidia These are released from the pycnidia by rain, dew or irrigation and splash dispersed to infect leaves. The conidia germinate on the leaf surface, infect the leaves and grow intercellularly within the leaf During this lime necrotic lesions aprar. The fungus produces pycnidia which release conidia and the disease cycle continues (Agrios 1997, Plant Pathology, 4 edition). The penetration frequency of germinated conidia on wheat leaves is in general low (Rohel et al., Mol Plant Microbe Interact, 2001, 14:156-163). During its lifecycle sexual pseudothecia are also produced. These can be found throughout the growing season and M graminicola can complete a sexual cycle in the field within five weeks of infection (Hunter et al., Plant Pathol, 1999, 48:51-57). This implies that spread of the disease is dependant on both the splash dispersal asexual pycnidiaspores and also a constant supply of sexual ascospores (Shaw and Royle, Plant Pathol, 1989, 38:35-43). In laboratory conditions, i.e. in vitro culture, or when infecting plants in the glasshouse or controlled environment conditions, lv! graminicola is not able to undergo sexual reproduction.

Initially, well characterised strains of M graminicola originally imported from the EU will be used. However, ultimately this project may necessitate the use of lab strains imported from Switzerland and the USA. Work with non UK strains will be carried out under an existing Plant Health Licence issued by DEFRA.

M. graminicola will be genetically modified using the Agrobacterium mediated transformation method as reported by Zwiers and De Waard (Cun Genet 2001,39:388-393). Agrobacterium tumefaciens (LBA4404, LBA1 126, GV3 101, LBA1 100, EHA105 and pAG L-l), disarmed by deletion of the phytohormone genes from the Ti plasmid, will be used. A. tumefaciens vectors pGreenFl, pNOV2114, pCGN based and pBINI9 based will be used.
The work will focus on generating 2 groups of M. graminicola, both groups containing sequences derived from influenza NS1 genes with the function of these sequences being assessed by the expression of model proteins, for example, fluorescent proteins or β-galactosidase. NS1 proteins have previously been shown to enhance the expression of GFP in plants by counteracting a host RNA silencing response (Bucher E et al J Gen Virol. 2004 Apr, 85 983-91). The main focus of the work will be the generation of M. graminicola expressing whole NS1 genes from several strains of influenza virus, both human and avian. The NS1 protein has been implicated in counteracting the diverse range of host systems within cells involved with limiting infection by the parent virus. The protein does not function outside the confines of the host cell and is just one of the 11-12 proteins and only one of the 8 RNA components that make up an influenza virus. Therefore the proposed use of NS1 will not allow the reconstitution an influenza virion.

In addition to using whole NS1 genes, M. graminicola will be generated using NS 1 sequences altered to optimise their ability enhance protein expression in the host. For example, using combinations of point mutations, transferring domains between different NS1 proteins or a combination of both techniques.

When generating both sets of GM M. graminicola, genes encoding model proteins will be co-transfected into the cells thus allowing assessment of the effectiveness of the various NS1 containing constructs.

### Evaluation of foreseeable effects

**Environmental considerations:**

It is unlikely that modification of At. ruminwola to express the viral antagonists of gene silencing will alter pathogenicity, host range or tissue tropism. Preliminary work done at Imperial College investigated the effect of a panel of NS1 genes on both homologous and heterologous protein products in transient transformation of mammalian cells. The NS1 was able to up-regulate GFP protein production in mammalian cells, but this did not affect the levels of Vinculin — a typical host protein produced in the cell. This data suggests that NS1 will enhance the expression of heterologous proteins, but not the host’s own proteins in a eukaryotic system. Although this mechanism in mammals is poorly understood, applicable work in plants (Bucher et al. 2004) suggests this enhancement is brought about by the protection of the over expressed coding mRNA for the foreign gene through the NS 1 RNA binding domain, which prevents recmitment to the RNA silencing machinery, which would cause a specific RNA specific silencing action to occur. Therefore the presence of NS1 should not affect native At. ruminicola protein expression and therefore the resulting pathogenicity of the recipient, as these host genes are not nonnally a target for the endogenous RNA silencing apparatus.

In addition, for strains expressing the fluorescent protein it is unlikely that pathogenicity will be increased, as the GM M. graminicola will be putting extra resources into the production of the additional protein. In this work, it is probable that should the NS 1 successfully enhance the production of the chosen marker protein, this will further weaken the M. graminicola.

There is the potential that the NS 1, in antagonizing gene silencing will bring about an alteration in the control of transposons which are controlled by RNAi gene silencing mechanisms in eukaryotic cells. These mechanisms exist to control and limit the rate of gene transfers, It is therefore possible that transposon activity may increase in the presence of NS 1, however this is more likely to have a detrimental affect on the M. graminicola genome as genes are very likely to become disrupted. It would be highly unlikely that a favorable gene constellation will arise from the decrease in RNA silencing abilities.

Genetic transfer to other micro-organisms.

In order for genetic material to be transferred to related micro-organisms the GM At graminicola must be capable of transferring genetic material. In practice this would require At ruminicola to escape from containment into the environment; come into contact with a suitable host, meet a compatible recipient micro-organism and be in the right stage of the growth cycle for the transfer to occur.

Genetic transfer can only occur between the sexual forms of At graminicola. It has a heterothallic, bipolar mating system (Kema et al, Curr Genet, 1996, 30:25 1-258) which means that a sexual cross can only happen if two At graminicola isolates with different mating types meet. Asexual yeast like cells and mycelial forms will be used for this project. At graminicola cannot undergo sexual crosses in the laboratory or when infecting plants grown in the glasshouse or controlled environment conditions.

GM M. graminicola will be grown at ACGM containment level 2 with any extra containment required under the Plant Health Licence covering the host organism. At graminicola will be grown in vitro on agar media in path dishes kept in an airtight plastic container, in liquid media in flasks contained within a growth cabinet or inoculated onto leaf pieces on agar in petri dishes. All plates will be lightly taped shut to prevent loss of the sample should the plate be dropped. All of the work with GM At graminicola will be carried out in a Class 2 microbiological safety cabinet (MSC) that has a HEPA filter on the extract air, in the labs specified on the SOP for the handling of plant pathogens licensed by DEFRA.

From the above it can therefore be assumed that the likelihood of escape of GM At graminicola capable of further infection is very low. However, if it did escape from...
Containment it would have to reach a suitable host in order to establish itself. The closest plants would be either in our own glasshouse or in surrounding fields belonging to Syngenta. Assuming that the yeast-like cells or mycelium survived the transfer outside of containment, the GM At graminicola would have to be particularly virulent/pathogenic in order to establish itself in these well-managed situations.

Therefore, given the control measures and reasons above the likelihood of the GM At graminicola escaping and thus being able to transfer genetic material to related micro-organisms can be considered to be very low. In addition, the likelihood of generating a more pathogenic At graminicola is considered to be low.

Human health considerations: At graminicola is an indigenous plant pathogen in this country. The pathogen is not known to colonise or infect even immuno-compromised humans and therefore poses very little risk to human health. In eukaryotic plant cells, the NS 1 protein acts to sequester double stranded RNA, caused by heterologous gene expression, which would normally be recruited by the IRNA silencing complexes in the cell to generate a specific response to these foreign genes and silence them. (Bucher et al. 2004). It is unlikely that this protein will have an effect on host genes. The protein will not be secreted by the At graminicola and would therefore need to cross the cell wall, effect an entry to the body, and then enter a cell in order for it to act upon exogenous genes. Containment within the At graminicola cell walls and working within microbial safety cabinets when generating aerosols will deny a route of entry to the body.

The NS1 gene has been expressed transiently by several groups in mammalian cell culture, and also been expressed and purified for crystallographic study, with no suggestion or reports of an increased level of toxicity or allergenicity.

The NS1 protein on its own is not infectious and constitutes just one component of the 11-12 necessary components to make an influenza virus. Therefore there is no chance of reconstituting a live virus from this work.

Given the information above and the containment described for environmental protection the risk to human health from carrying out this work is expected to be low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full ACOM Containment Level 2 ll be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste containing experimental material will be double bagged within the laboratory and placed within bins for collection and transfer to the site autoclave facility. Waste will then be autoclaved with the sterilisation phase being at 122°C for 30 minutes and a pressure of 2150mBar. This has been validated locally with a variety of plant pathogens giving 100% kill.

Liquid waste will be collected and autoclaved at 134°C for 20 minutes in an autoclave within the building in which it is generated.

Klercide disinfectant spray will be used for decontamination of work surfaces. It has shown to be effective against actively growing M graminicola.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N
The Use of Genetically modified Phytophthora infestans to visualise the effects of fungicides on target genes

Genes native to Phytophthora infestans will be tagged with a gene for green fluorescent protein and then inserted into Phytophthora infestans. The genes to be tagged will be fungicide targets and this process will enable the visualisation of the effects of the fungicides on the resultant GMM in real time and in vivo. The initial work will involve tagging the genes for tubulin, the products of which form part of the cytoskeleton in oomycetes. If this method of visualisation is successful then the same strategy may be adopted for other fungicide gene targets in Phytophthora infestans. The transformation of Phytophthora infestans will be done at the Scottish Crop Research Institute in Dundee with constructs cloned in E. coli K12 provided by Syngenta. The transformants will then be transferred to Syngenta for the application of fungicides and subsequent visualization of the fluorescent protein. If the project is successful then Syngenta may develop the capability of transformation in house. This Notification only covers work at Syngenta.
**Recipient or parental organism**

P. infestans is an indigenous pathogen of Solanaceous plants, including potato and tomato, and is found commonly throughout the UK. The pathogen overwinters as mycelium in infected plant material (e.g., potato tubers left in the ground after harvesting). On infection of young plants the pathogen spreads to the aerial parts where it produces sporangi on sporangiophores. These sporangia can become airborne or rain dispersed. The sporangia are large and heavy and are only viable for a short period of time (up to 2 weeks) and in order for the disease to spread they must come into contact with a susceptible host. When the sporangia land on wet potato leaves or stems they then germinate and cause new infections. When sporangia land in water they produce zoospores that only survive for a few hours without a suitable host.

**Host/vector system**

Vectors will then be non-mobilisable E. coli vectors (including pTOR containing a kanamycin resistance gene for selection of transformants). The vector containing the gene of interest and the green fluorescent protein will be transformed into Phytophthora infestans using naked DNA and a polyethylene glycol/calcium chloride transformation procedure.

**Origin & function**

**Genes of interest;** these will be P infestans genes thought to be the targets for fungicides. Initial work will be done with tubulin genes. Genes will be screened against databases of known avirulence and virulence genes prior to use.

Green fluorescent protein: from Aequoprea coerulescens, this will be tagged to the gene of interest to enable visualisation of that protein when the GM P infestans is challenged with the fungicide.

Both the gene of interest and AcGFP will have the ham34 promoter and ham34 terminator from Bremia lactucae.

The nptll gene from Streptomyces kanamycticus will be used in the vectors to enable selection of transformants.

**Evaluation of foreseeable effects**

**Risks to human health:**

P. infestans is an indigenous plant pathogen in this country. The pathogen is unable to colonise or infect even immunocompromised humans. However, all introduced protein sequences will be screened for potential allergenicity/toxicity prior to the strains being grown. Any information that shows a cause for concern will be included in the COSHH assessment and the control measures revised.

**Risks to the environment:**

It is unlikely that the pathogenicity of GM P infestans will be greater than the parental organism due to the resource needed to produce the GFP. However, all genes of interest will be screened against databases of known avirulence and virulence genes prior to use. There is no intention to deliberately generating GMMs with increased pathogenicity.

In order for genetic material to be transferred to related mico-organisms the GMM must be capable of transferring genetic material, able to escape from containment, come into contact with a suitable host, meet a compatible recipient micro-organism and be in the right stage of the growth cycle for the transfer to occur.

Genetic transfer can only occur between the sexual forms of P infestans. A sexual cross can only happen if two isolates with different mating types meet. There is largely thought to be only one mating type present in the UK (mating type A1), although there are very rare cases of the A2 mating type occurring. In the unlikely event that the GMM escaped the chances of meeting a suitable mating type with which a sexual cross and genetic transfer could occur is therefore low.

All work will be carried out in a Class 2 Microbiological Safety Cabinet and cultures will be double contained when being transported. In addition a disinfectant which has been validated against P infestans will be used to clean work areaas. Together with the waste procedures below the likelihood of any escapes into the environment is...
considered to be low. Thus the overall risk of the work is considered to be low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be double bagged in autoclave bags and placed in purple wheelie bins specifically for waste which must be inactivated prior to leaving site. This includes all materials licensed by DEFRA and any Class 2 GMM waste. These bins are transferred to the Waste Management Compound and autoclaved at Syngenta. Autoclaved waste is then sent off site for incineration. Liquid waste is autoclaved within the same building in which it is generated prior to disposal to drain.

Decontamination of work surfaces will be done using Klercide 5TM which has been validated against P infestans

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

The GMSC has reviewed the risk assessment and, subject to some changes that have been incorporated into the final document, has approved the programme of work

Project Ref 222/13.1

Date Ackn'd CU2 Project Title Class CultureVolClass2 CultureVolumeClass3-4

02/03/2022
To generate GM plant pathogenic micro-organisms in order to investigate the role of individual genes in the mode of action of novel research compounds with potential fungicidal activity.

A genetic change is often responsible for conferring resistance to a fungicide. In this work we will generate defined genetic change resulting in single amino acid changes in a gene product, or, deletion, disruption, over-expression or silencing of a gene in three plant pathogenic species: Magnaporthe grisea, Fusarium graminearum and Phytophthora capsici. The genetically modified plant pathogens will be assessed for growth in the presence of known fungicidal compounds and novel non-commercially available research compounds. In addition the pathogens will be cultured for extraction of DNA, protein or other extracts for biochemical and molecular biology assays. Information from these tests will help deduce the mode of biological action of such compounds and ultimately contribute to the development of novel fungicidal compounds.

The GM plant pathogens produced will only be used for research purposes in contained laboratory experiments for this project. Transformation of the plant pathogens will take place at Syngenta, Jealotts Hill. However, we will also be importing plant pathogens similarly transformed from Switzerland, EU Member States or the USA. Both sets of GM plant pathogens will be subject to the same growth analytical experiments.

M. grisea causes blast disease of rice and wheat and the wheat blast disease is currently distributed only in tropical potential host plants and none of the proposed strains for use is known to infect wheat. The pathogen is able to overwinter in fields on crop debris. The inoculum is asexual conidia and sexual ascospores.

F. graminearum causes Fusarium ear blight of wheat, barley, maize, rye and oats. This disease is found throughout the UK. In the field the fungus survives over the winter on contaminated host debris and grains. The inoculum is asexual conidia and sexual ascospores which are distributed by wind and rain-splash and infect part of the flowers glumes and ears.

P. capsici causes rot on many tissues of a variety of host plants including tomato, green beans, peppers, pumpkins, melon, cucumber, and is found throughout Europe. The inoculum is sporangia or water-borne motile zoospores. The resting spores are a product of sexual mating.

Vectors for M. grisea and F. graminearum will be non-mobilisable E. coli TOPO-based and pUC-based cloning vectors. These are commonly used and commercially available, usually supplied by Invitrogen. Transformation will be done using a zoospore electroporation method.

Recipient or parental organism

Three plant pathogenic species will be used: Magnaporthe grisea, Fusarium graminearum and Phytophthora capsici. The unmodified strains originate form inside and outside of the UK. Strains originating from outside of the UK will be imported and used under Plant Health Licenses issued by DEFRA.

M. grisea causes blast disease of rice and wheat and the wheat blast disease is currently distributed only in tropical potential host plants and none of the proposed strains for use is known to infect wheat. The pathogen is able to overwinter in fields on crop debris. The inoculum is asexual conidia and sexual ascospores.

F. graminearum causes Fusarium ear blight of wheat, barley, maize, rye and oats. This disease is found throughout the UK. In the field the fungus survives over the winter on contaminated host debris and grains. The inoculum is asexual conidia and sexual ascospores which are distributed by wind and rain-splash and infect part of the flowers glumes and ears.

P. capsici causes rot on many tissues of a variety of host plants including tomato, green beans, peppers, pumpkins, melon, cucumber, and is found throughout Europe. The inoculum is sporangia or water-borne motile zoospores. The resting spores are a product of sexual mating.
The pathogens will be transformed to modify genes identified as potentially conferring resistance to a research compound. Short sections of DNA with sequence similarity to a fungal or oomycete DNA locus of interest can be inserted into cells. The DNA of the chromosome is replaced by the DNA we put into the cell. In this way it is possible to create defined changes such as one or more of the following: replacement of sequences, deletion of sequences, insertion of antibiotic selectable markers or other elements such as promoters.

This method will also include introduction of a gene sequence containing point mutations that later result in amino acid changes when the DNA is translated into a protein. This approach can be used to test the genetic source of resistance to a research compound, either by inserting changes that will induce resistance, or by inserting changes that will remove resistance in an already resistant isolate.

**Evaluation of foreseeable effects**

**Risks to human health:**
The plant pathogens described are not listed in ACDP hazard groups 2, 3, or 4. There is no evidence that they can mate with human or animal pathogens.

*F. graminearum* is found throughout the UK, and although in rare cases some *Fusarium* species been reported to be capable of infecting immunocompromised humans, *F. graminearum* is not known to infect even immunocompromised humans and is therefore not believed to be a risk to human health.

*M. grisea* is not known to infect even immunocompromised humans and therefore is not believed to be of risk to human health.

The proposed genetic modifications are not expected to change any of the above information regarding risks to human health. However, as a precautionary measure introduced gene sequences will be screened for homology to known toxins and allergens. Any information that is a cause for concern will be included in the COSHH assessment and the control measures revised.

**Risks to the environment**

The proposed work does not involve deliberately trying to increase pathogenicity or host range of the plant pathogens. No fungicide targets to date have been associated with increased pathogenicity or host range, but are either core biochemical or essential structural components of the cell. While it is highly unlikely that the genetic modifications might alter the pathogenicity or host range, all modified genes will be screened against the current published data to try and identify any pathogenicity and host range issues. No genetic modification will proceed where there is published reason to believe that this will increase either virulence or host range of the plant pathogen.

In order for genetic material to be transferred to related micro-organisms the GMM must be capable of transferring genetic material, able to escape from containment, come into contact with a suitable host, meet a compatible recipient micro-organism and be in the right stage of the growth cycle for the transfer to occur.

The worst case scenario is that a research compound tested within this work is developed into a commercially available agrochemical and a GM plant pathogen made resistant to that agrochemical or mode of action is released. However, for this scenario to occur, the GM plant pathogen must first escape from the class 2 control measures. The class 2 control measures already in place have a strong history of containing fungal microorganisms, and are considered sufficient for the control of the plant pathogens listed in this risk assessment. Thus GM plant pathogens with resistance to the research compounds are unlikely to be released to the environment.

In the unlikely event that a release were to occur, the GM plant pathogen would have to survive dispersion of the distances necessary to reach a host plant.

- *F. graminearum* is dispersed by air-borne spores and if it escaped it would have to reach cereal-growing areas to come in contact with other *F. graminearum*. The timing of the infectious period is very small and would have to coincide with cereal anthesis, although overwintering on crop debris is also possible (Brown, Urban et al. 2010)
- *M. grisea* is not found in the UK, and therefore if it does escape, mating is highly unlikely. The spores of this plant pathogen would have to reach a cereal that it could infect. This plant pathogen occurs as host-limited forms, meaning some strains can only grow on some of the potential host plant species. The strains used at Jealott's Hill would have to reach rice or barley.
- In the case of *P. capsici*, the spores are water-borne, and therefore very limited in the distance they could travel. The motile zoospores are only mobile for a number of hours before becoming sessile and encysting. The resting spores are viable for a period of months, but have very low mobility (large and sessile).

Furthermore, the strains of the plant pathogens listed here are highly susceptible to and are controlled by currently employed agricultural crop protection chemicals. Even if
the GMMs were to escape control measures, preferential survival of the GMMs in the environment is highly unlikely. Therefore we consider the risk of GM plant pathogens resistant to commercially available fungicides being released into the environment and having an environmental impact to be very low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be double bagged in autoclave bags and placed in purple wheelie bins specifically for waste which must be inactivated prior to leaving site. This includes all materials licensed by DEFRA and any Class 2 GMM waste. These bins are transferred to the Waste Management Compound and autoclaved at Syngenta. Autoclaved waste is then sent off site for incineration. Liquid waste is autoclaved within the same building in which it is generated prior to disposal to drain.

Decontamination of work surfaces will be done using Klercide 5TM which has been validated against the pathogens listed in this notification.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMSC has reviewed the risk assessment and, subject to some changes that have been incorporated into the final document has approved the programme of work.

Project Ref 222/14.1

02/03/2022
The purpose of the proposed work is to establish a generic protein expression system in Botrytis cinerea for proteins of interest to the development of new fungicides. Expression of proteins from plant pathogens such as Botrytis is not reliable in heterologous systems so a system in the native organism using a native promoter will be used. Proteins of interest will be tagged, for example, with a histidine tag at the N or C terminus to allow easier purification of the target protein by exploiting the metal affinity nature of the histidine residues. This expression system will also be used to heterologously express fungal genes in Botrytis, for example, those form obligate pathogens i.e. that require a plant host in order to grow. Expression of tagged genes from other fungi in Botrytis will facilitate protein purification of these otherwise intractible target proteins. The GM Botrytis will be generated in Syngenta labs in Switzerland and imported for use in Syngenta labs in the UK.

Recipient or parental organism
The original strain of Botrytis cinerea is from Germany and so import and use will be done under Plant Health licences issued by DEFRA. Botrytis cinerea is a fungal pathogen of many plant species although the one used for this work (B05.10) is a laboratory strain so is unlikely to be identical to ones in the field.

Host/vector system
Botrytis cinerea will be genetically modified in Syngenta labs in Switzerland and imported to Syngenta labs in the UK for use. It will be transformed with specific PCR products of a construct containing the genes of interest. The constructs will contain a gene encoding the fungal protein of interest and its genomic flanking sequences. The sequence will be modified to include a tag such as 6-12 histidine residues to aid protein purification and a hygromycin resistance cassette to enable selection of the transformants.

Origin & function
Proteins which are potential fungicide targets will be identified and PCR constructs made of the relevant target gene sequences with the addition of a tag (e.g. histidine tag to allow easier purification of target protein by exploiting the metal affinity nature of the histidine residues) and a hygromycin resistance gene to enable selection of transformants on hygromycin. These GM strains will be used at Syngenta, UK to produce the protein of interest. The protein will be used to set up biochemical assays to aid the discovery of new fungicides and to optimise their intrinsic activity.

02/03/2022
**Evaluation of foreseeable effects**

Risks to human health: Botrytis cinera is a plant pathogen and is not known to colonise or infect humans. The genetic modification is not expected to alter this. The genes of interest, histidine tag and hygromycin resistance are not expected to cause harm in humans. Hygromycin is an antibiotic and not used for human treatment so even if there was a potential for spread of the resistance gene it would have a very limited impact in the UK. Thus the risk to human health from the proposed work is expected to be very low.

Risks to the environment: The most significant part of the Botrytis lifecycle for the proposed work is the release of conidia which will be present in the in vitro cultures. All manipulation of Botrytis cultures will be done in Class 2 microbiological safety cabinets and all cultures will be double contained when transported between facilities. Therefore the likelihood of escape from containment of a replicative body is highly unlikely. In the unlikely event of laboratory Botrytis strain is likely to be lower than that of other fungal pathogens in the environment and so it is unlikely to compete successfully and thrive. In addition, wild type Botrytis cinerea is present in the UK environment and is currently controlled by commercially available fungicides. The effectiveness of these fungicides on the GM strains is unlikely to be affected by the proposed modifications as these are in genes unrelated to the mechanism of action of these commercial fungicides. The surrounding land to the laboratories is farmed commercially by Syngenta and any fungal outbreaks are controlled by commercial fungicides. Thus the risks to the environment form the proposed strains of GM Botrytis cinerea are expected to be very low.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None sought

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Waste from the proposed work will be destroyed as per Plant Health Licence requirements issued by DEFRA:

- Solid waste - solid waste will be collected locally and double bagged in autoclave bags. The waste will be placed in wheelie bins specifically for Plant health Licensed and Class 2 GMM waste and transported to our Waste Management facility for autoclaving prior to sending off site for incineration.
- Liquid waste will be collected locally and autoclaved within the building prior to disposal to foul drain.
- Equipment that has come into contact with Botrytis will be washed with 70% ethanol and centrifuge pots soaked in 1% Virkon overnight. Klercide will be used to decontaminate and clean work surfaces. All of these have been validated internally to be effective against Botrytis.

Project Ref 223/01.10

Date Ackn'd 04/06/2001  
CU2 Project Title IDENTIFICATION OF MOLECULAR DETERMINANTS OF VIRULENCE IN FELINE  
Class 2  
Culture Vol Class 2 < 1 litre  
Culture Volume Class 3-4
# Project Additional Information

## Purposes of the contained use

Chimaeric molecular clones of FIV will be generated to enable the molecular determinants of virulence in FIV infection to be defined.

## Recipient or parental organism

FIV is a member of the lentivirus subfamily of the Retroviridae and is a widespread pathogen of the domestic cat. Similar to other lentiviruses, FIV is a host specific, infecting only cats. The virus is transmitted naturally between cats via biting. For further information on the molecular clones, see section 17.

## Host/vector system

**Bacterial hosts** will be derivatives of E coli K-12 (eg XL-1 blue, Top10, Dh5a) and are considered disabled.

The plasmids are derived from pBR328 and are considered non-mobilisable.

## Origin & function

pG8-Mya is a clone of FIV-Glasgow-8 derived from an infected feline T cell genomic library. The FIV-GL8 clone will be genetically modified to introduce mutations representing nucleic acid sequences found in non-virulent isolates in order to identify molecular determinants of virulence that alter in vitro tropism.

## Evaluation of foreseeable effects

The virus is highly labile, does not persist in the environment and is readily inactivated by disinfection. For further information, see section 17.

## Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

## For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Any material coming into contact with GMM material is contained within a sealed container until it is autoclaved in the Department of Veterinary Pathology. Further information, see Section 17.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All materials handled at containment level 2 will be disinfected by steeping in Presept as per manufacturer's instructions.

### Purposes of the contained use

Molecular cloned isolates of feline leukaemia virus are grown to generate viral stocks for use in the diagnostic laboratory and for general laboratory use.

### Recipient or parental organism

Recipients are BHK cells which have been infected with FeLV-A, B and C. Persistently infected cell lines were recovered.

### Host/vector system

Molecular clones of FeLV-A, B and C are integrated in separate BHK-derived cell lines. The cells are persistently infected and produce no visible cytopathogenic effect.

### Origin & function

FeLV-producing cell lines have been used routinely as control cultures for samples requiring subgroup identification.

### Evaluation of foreseeable effects

No risk has been identified. FeLV is not a human pathogen. Thus, there is neither virological nor serological evidence that human beings can be infected with the virus, or that contact with persistently infected cats is a risk factor in human disease (reviewed in Loar AS (1987) The zoonotic potential of feline leukemia virus. Veterinary Clinics of North America, Small Animal Practice. 17:105-115); Butera ST et al. (2000) Survey of veterinary conference attendees for evidence of zoonotic infection by feline retroviruses. Journal of the American Veterinary Medical Association. 217:1475-1479).

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Cultures are inactivated by immersion overnight in Presept solution and/or by placing the plates directly into an autoclave bag and autoclaving.

### Risk assessment passed.

The purpose of this project is to investigate how Campylobacter jejuni induces inflammation and causes diarrhoea.

Background
Campylobacter jejuni is a microaerophilic, Gram negative, flagellate spiral bacterium. It is the leading cause of bacterial food borne diarrhoeal disease throughout the world (1,2). In addition, infection with C. jejuni is frequently associated with a rare but potentially serious form of neuromuscular paralysis known as Guillain-Barre syndrome (3,4). Human infection is usually acquired by the consumption of contaminated food (especially poultry) or water (5,6,7). The clinical spectrum of enteric disease due to C. jejuni and C. coli ranges from severe inflammatory diarrhoea to a generally mild non-inflammatory (watery) diarrhoea (8,9). The former is the most common clinical presentation in patients from industrialised nations, whilst the latter is the usual pattern seen in developing nations (10). The clinical picture may be explained by frequency of exposure to Campylobacter in an individuals immediate environment (10,11). Ketley (12) has speculated that host status modulates disease presentation. Thus primary disease (no immunity) leads to inflammatory diarrhoea by bacterial invasion of the intestinal lamina propria, generation of an inflammatory response and tissue damage due to host mediators and unknown bacterial molecules. Partial immunity would arrest some of the inflammation associated with primary infection resulting in milder disease.

The induction of inflammation by C. jejuni in different host species. It is unknown, taking the two extreme examples, why humans react with a brisk inflammatory response to C. jejuni infection with associated disease symptoms, yet poultry treat the organism as a commensal. We will measure activation of Nf-kB, a central mediator of host inflammation by functional assays, and chemokine and cytokine release from tissue culture cells and primary intestinal tissue from various animal hosts infected in vitro with C. jejuni, to ask fundamental questions as to how tissues from different animal species respond to infection with Campylobacter. Using wild type C. jejuni NCTC 11168 and derivatives with mutations in genes encoding cell surface and secreted proteins, will enable us to define the host inflammatory mediators induces (or not) in intestinal tissue from different animal species. We will use mutants in which genes encoding biosynthesis or modification of surface structures, together with genes encoding putative toxins, are inactivated. Specifically we wish to examine mutants in genes involved in: 1) Capsule biosynthesis (kpsM) 2) LOS biosynthesis genes (waaF, wla deletion) 3) sialylation of LOS by N-acetyl neuraminic acid (neuB1) and sialylation of flagella (neuB2 and 3) 4) Genes for glycosylation of LOS and flagella (wlaC, wlaD,
5) Phospholipase A (pldA) 6) CLDT (cytolethal distending toxin cld) and 7) Putative haemolysin. (hylA). Julian Ketley's group at the University of Leicester and Brendan Wrens group at the London School of Hygiene have constructed a number of mutants in the above cell surface and secreted molecules of C. jejuni that are implicated in host cell interaction and induction of the host inflammatory response. In collaboration with the groups mentioned we will investigate the role of the genes listed above by using these mutants to infect cell lines and primary tissue biopsies from man and various animal species in order to assess their ability to bind to cells and tissues and elicit host inflammatory cytokine and chemokine production. By directly comparing tissue from animal hosts that give different types of clinical response upon infection, we aim to define host molecules up or down regulated by infection, and bacterial factors inducing these host responses. We can only then begin to understand why different host species respond in different ways to these bacteria in terms of initiation of inflammation at the mucosal surface. We intend to characterise wild type C. jejuni mutants in surface structures and secreted proteins to investigate a specific aspect of host/bacteria interaction namely comparative host inflammatory profiles in response to C. jejuni.

PLANTS OF INVESTIGATION
The following experimental procedures will be performed:
(1) Infection of viable primary tissue by C. jejuni.
(2) NF-kB activation - Nuclear extracts and electromobility shift assay.
(3) Secretion of host cells chemokines/cytokines upon infection.
(4) Cell adhesion, invasion and transcytosis assays.
(5) Whole blood assay for determination of cytokine responses.

Conclusions
These experiments should help define the host inflammatory molecules activated upon infection and which bacterial molecules are implicated in tissue inflammation, critical steps in the disease process. We intend to define the basic biology of host/pathogen interaction of C. jejuni with cells from the gastrointestinal tract of different host species by using defined mutants to dissect these processes.

References
Mutants of Campylobacter jejuni have been generated by inverse PCT mutagenesis in the Departments of Genetics, University of Leicester and Department of Infectious and Tropical Diseases, London School of Tropical Medicine and Hygiene. C. jejuni chromosomal DNA is digested with a restriction enzyme and the products allowed to circularise by self ligation. Primers with a unique restriction site amplify the fragments by inverse PCR and the products are cloned and characterised. Cloned products are digested with the unique enzyme, ligated with an antibiotic cassette (kanamycin) and the ligation mix is transformed into C. jejuni by natural transformation or electroporation.

**Host/vector system**

The origin of the genetic material is from a wild type clinical isolate of Campylobacter jejuni. The function of this material is to use it to make defined mutations in genes thought to be involved in virulence and disease causation in man.

**Evaluation of foreseeable effects**

Campylobacter infections are acquired by ingestion and it is assumed that the wild type strain used in these experiments is fully virulent for man. Thus is may cause clinical features if ingested. In our experiments we aim to make mutants of this organism which will be a virulent for man. Thus the foreseeable effects of these mutants are that they will not cause any clinical manifestations in man.

C. jejuni cannot replicate aerobically so there will be no replication of the organism in the environment. Estimation of risk of disease to man or danger to the environment for genetically modified mutants of C. jejuni is very low and for those shown to be attenuated in disease models is effectively zero.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

The risk of laboratory acquired infection will be minimised by the following procedures:-

1) Good laboratory practice (containment level 2)
2) Disinfection
3) Use of safety cabinets for some procedures
4) Autoclaving and incineration

All practices conform to containment level 2 (Collins, C.H. Safety in Clinical and Biomedical Laboratories, Chapman Hall) for work with pathogens in hazard group 2.

To avoid ingestion of Salmonella after working with them hand washing will break the hand to mouth route of transmission. Cultures will be transported in plate racks and leak proof metal boxes.

Chemical disinfectants are used in bench discard and pipette jars, for treating surfaces that become contaminated by spillage and for disinfecting equipment. For standard decontamination of glassware and plastic ware items are immersed in a bleach solution of 412ppm of available chlorine for at least 12 hours (prepared using Presept tablets). All glass and plastic ware is subsequently autoclaved. For killing bacteria in culture suspension, Presept tablets or a clear phenolic are added to give a solution of 2500ppm of available chlorine or 1% phenolic solution and this is left for at least 2 hours before autoclaving. All bacteria grown on solid media are autoclaved before disposal.

For accidents and spillages the affected area should be immediately flooded with a Hibitaine solution (1:1000). The area should be left for 30 minutes and then mopped with disposal towels and these disposed of by autoclaving. Broken glass should be lifted by forceps or pan and brush. If hands become contaminated they should be washed with Hibiscrub.
The decontamination protocols described have been validated in our laboratory using the relevant bacterial strains. Disinfectant effectiveness is tested by the 'in use' test.

Human food borne infection due to Salmonella enteritidis continues to be a serious problem in many countries. The organism is predominantly acquired from ingestion of undercooked poultry and eating food containing raw shell eggs. Salmonella enteritidis infection is endemic in poultry flocks in producing countries but the mechanisms of colonisation and the bacterial factors required for survival within the chicken have not been characterised. Knowledge of these factors might enable prophylactic or novel therapeutic measures to be developed to eradicate this organism from the food chain. The technique of Signature Tagged Transposon Mutagenesis (STM) applied to human and animal bacterial pathogens has identified bacterial genes essential for virulence and survival within the host. We intend to use this powerful genetic technique for the identification of genes required for survival of S. enteritidis within its chicken host, characterise the function of these genes and investigate the potential of utilising these genes and their products to develop live or sub unit vaccines to eradicate this organism from infected birds and flocks. This technique will also enable us to understand the basic biology of bacterial/host interaction, with the ultimate goal of safer food for consumers and less food borne human disease.

Background to the Proposal

Human foodborne salmonella infections continue to be a major international health problem, both in terms of morbidity and economic costs. Over 2000 food poisoning serotypes of Salmonella exist and the prevalence of individual serotypes constantly changes. The main reservoirs for human infections are poultry, cattle, sheep and pigs. The recent patterns of human infections internationally have been dominated by Salmonella enteritidis since the middle 1980s and it is still a significant public health problem. Shell eggs and poultry meat are major sources of S. enteritidis, in particular S. enteritidis phage type (PT) 4. This phage type is capable of invading chicken tissues and persisting in the oviduct, and is therefore more likely than others to contaminate eggs internally while they are being formed. Almost nothing is known about the genetic basis of colonisation and infection of poultry by Salmonella species in general and S. enteritidis in particular. The aim of this project is to address this lack of knowledge using the novel technique of Signature Tagged Mutagenesis (STM). STM is a means of identifying bacterial virulence genes that are essential for infection, survival and proliferation within a specific animal. The great advantage of STM is that by utilising tagged mutants, avirulent strains are detected directly. STM has been used successfully for revealing hereto unknown virulence genes that are important in S. typhimurium infection of mice, and also for virulence gene identification in other human and animal pathogens. STM is most powerful when the genome sequence of the target or closely related organisms are available, which facilitates the identification and further characterisation of the genes inactivated by STM. The genomes of Salmonella enteritidis, S. typhimurium and S. typhi have or are in the process of being sequenced.

Measures to either limit or prevent the infection of chickens with S. enteritidis have clear human public health benefits. In order to safeguard the health of the public and protect consumers, salmonella colonisation has to be controlled in farm livestock. The information obtained from this project could be applied to hasten the elimination of S. enteritidis from the food chain. For example, strains with mutations in the genes identified by STM may have utility as live vaccines or alternatively, the gene products may encode protective immunogens which could be included in subunit vaccines for poultry use. These measures may ultimately lead to a direct decrease in human foodborne salmonellosis.

Aims and Objectives

The objectives of this proposal are to identify the genes that are important for S. enteritidis to survive and causes disease in poultry using STM. Microbial genome databases will be interrogated to determine the identity (if known) and possible function of the genes that are shown to be important in vivo in chickens by STM. The role of the different genes will be analysed in vitro using a variety of assays, (eg is the gene involved in attachment to, invasion of or survival and replication within eucaryotic cells?). We will test the ability of mutants of S. enteritidis generated during this project to immunise chickens against S. enteritidis.

Plan of Investigation
STM is a negative selection method for virulence gene identification. Bacterial genes are mutated by the insertion of transposons carrying a unique DNA sequence tag. Animals are infected with a bank of bacteria containing transposon inserts and after a few days organisms are harvested from the internal organs of the animal. The pool of bacteria recovered from the tissue of the animal is compared with the inoculum by hybridisation, to determine which tags (mutant strains) are absent in the output pool. These bacteria have mutations in genes that contribute to survival in the animal. It is then possible to identify the genes which were absent in the bacteria recovered from the animals because the tag present in the transposon acts as a unique marker for that strain.

Generation of Mutant Bank

Signature tagged mutagenesis (STM) was described by Hensel et al for S. typhimurium and identified new virulence determinants for systemic disease in this organism, some of which are being exploited for live vaccine development. We will follow this powerful proven methodology for generation of our mutant bank in Salmonella enteritidis. A transposon (on plasmid pUTminiTn5Km2) will be used for random insertional mutagenesis of the genome of Salmonella enteritidis. Each transposon contains a different DNA sequence tag which allows mutants to be differentiated from each other. The tags comprise 40bp variable central regions flanked by invariant arms of 20 bp, which allow the amplification and labelling of the central portions by the polymerase chain reaction (PCR). The semi-random format by which tags were designed ensures that the same sequence tag should only occur very rarely and therefore the chance of encountering the same tag twice n a pool of 96 different mutants is effectively nil. PCR amplification of the central regions using radiolabelled 2'deoxyctydine 5'-triphosphate (dCTP) produces probes with ten times more radiolabel in the central regions than in each arm. The incorporation of a unique restriction site at the junction of the central regions and the arms allows the arms to be separated after labelling, generating specific DNA probes comprising the central region. A nucleotide bias used in the central regions also avoids the presence of sites for those restriction enzymes used for ligation before hybridisation analysis and for subsequent cloning of virulence genes. Tags will be ligated into pUTminiTn5Km2 and transformed into E. coli CC118. Transformants are pooled and DNA extracted to transform E. coli S-17lamda-pir. Transformants of E. coli S-17lamda-pir are mated on filters with a nalidixic acid resistant wild type Salmonella enteritidis. After overnight incubation bacteria are recovered from filters by incubation in L-broth containing nalidixic acid and kanamycin and then plated onto L-agar with these antibiotics. Exconjugants are screened on Macnoney agar and LA containing ampicillin. Ampicillin sensitive colonies are assembled into 96 well microtiter dishes, which are used to prepare replica DNA colony blots. We intend to screen the mutant bank in a chicken colonisation model in collaboration with Dr Paul Barrow at Compton and in an egg model to assess genes important for survival in hens eggs. This model will assess the ability of the introduced tagged pool to survive within the chicken alimentary tract the primary site of bird colonisation with these organisms. We may also later screen the bank in a systemic infection model. We also wish to screen our mutant bank for survival in hens eggs and the bacterial factors important in persistance in this environment.

Characterisation of Identified Mutants

Mutants identified will be analysed to determine the DNA sequence of the region immediately flanking the mutation. DNA from prospective mutants is digested with a number of restriction enzymes. The enzymes are chosen because they cut once in the polylinker of pUTmini-Tn5Km2. Digests are run on agarose gels, and transferred to Hybond membranes for Southern hybridisation using the kanamycin resistance gene of the transposon as a probe. Enzymes which give fragments of 3-5kb are used to digest DNA, fragments gel purified and ligated into pUC18. Ligation reactions are used to transform competent E. coli to kanamycin resistance. These inserts are sequenced and should represent part of the sequence of a gene of interest. The observed sequence will be used to probe the salmonella and other bacterial genome databases. This will identify the function of the disrupted gene (if known) which will facilitate further phenotypic analysis of the mutant strains. Identified mutants will then be investigated as to their biological role in the disease process by in vitro and in vivo techniques.

References

The mutants generated by these techniques are all expected to be less virulent or of equal virulence to the parental Salmonella strain. The clinical symptoms of a human swallowing a virulent salmonella include diarrhoea, vomiting, fever and abdominal pain. Illness is generally self limiting in any individual with severe infections requiring antibiotic treatment. In the rare event that a mutant may be more virulent than the wild type parent standard laboratory practice for the containment of class II pathogens are more than adequate to contain the risk (see below). Mating experiments will be performed with laboratory strains of E. coli.

Recipient or parental organism

The origin of the genetic material is from a wild type clinical isolate of Salmonella enteritidis. The function of this material is to use it to make random mutations in chromosomal DNA in order to identify genes thought to be involved in virulence and disease causation in man.

Evaluation of foreseeable effects

Salmonella infections are acquired by ingestion and it is assumed that the wild type strain of Salmonella enteritidis used in these experiments is fully virulent for man. Thus is may cause the clinical features of salmonellosis if ingested. In our experiments we aim to make mutants of this organism which will be avirulent for man and in the model of chicken colonisation. Thus the foreseeable effects of these mutants are that they will not cause any clinical manifestations in man.

Estimation of risk of disease to man or danger to the environment for genetically modified mutants of S. enteritidis is very low and for those shown to be attenuated in disease models is effectively zero.

Project Additional Information

Purposes of the contained use
The use is intended to identify changes in gene expression caused by overexpression of Runx family members and so elucidate the oncogenic mechanism of these genes.

Recipient or parental organism
Moloney murine leukaemia virus is lethal in mice - neonatal infection results in death by thymic lymphoma in 3-4 months. By contrast, the recombinant virus stocks will be replication defective and so a systemic infection is highly unlikely, even if the virus were to escape into the environment and infect susceptible mice. Because the virus is replication defective, the likelihood of spread of the virus to other animals is greatly reduced.

Host/vector system
The constructs will be made in pBabe puro, and packaged in the Phoenix-Eco packaging cell line (Garry Nolan, Stanford University, Stanford CA) so that no replication-competent viruses will be produced. The Phoenix -eco packaging cells are based on 293T cells which have separate gag/pol and env genes so that a combination of unlikely recombination events are required for the production of helper virus (2). The packaging cell lines will be monitored to ensure that no recombinants are produced as the result of infection with other viruses present in the same incubator.

The monitoring will take the form of infection of the packaging cell lines LXSN-EGFP virus, a green fluorescent protein expressing virus which is both defective and based on MoMLV (3). Virus stocks from the packaging cell line infected with LXSN-EGFP virus will be applied to human cells and scanned by fluorescence microscopy to ensure that none of the recombinant viruses have been pseudotyped to form particles which might infect human cells.

Origin & function
Runx2 has been identified as a MYC collaborating oncogene (6) by "retroviral tagging" - the process of cloning proviral integration sites in thymic lymphomas and...
subsequent analysis of these loci for transcribed sequences affected by the insertion of the powerful enhancer elements of the proviral LTR nearby (4). The importance of the deregulated expression of this gene was apparent from the high frequency of integrations at til-1, the integration site near Runx2. Recent work has confirmed the strong collaborative effect between Runx2 and MYC in the development of thymic lymphoma - mice made doubly transgenic for Runx2 and MYC develop tumors much faster and neonatal infection of Runx2 transgenic mice leads to a very high frequency of integrations at c-myc or N-myc (1).

Runx2 is a highly conserved transcription factor (it isa mouse homologue of the Drosophila segmentation gene (runt)) and forms part of a gene family in the mouse along with the Runx1 and Runx3. One of the human homologues of these genes is AML-1, a gene important in acute myeloid leukaemia, as shown by frequent rearrangement of this locus (5). Having produced an animal model for this disease state, we intend to further investigate the molecular mechanisms affected by Runx2 and other family members in primary and immortalised murine cells. Initial results suggest that the normal cell death programs are impaired in the presence of high levels of Runx2. In order to investigate these mechanisms, we propose to make retroviral vectors based on the well known pBabe vectors and use these to make high titre, helper free virus stocks for studies on Runx family members in MEFs and other mouse cells.

Evaluation of foreseeable effects

MoMLV is not included in the ADCP hazard group because it does not infect humans, so delivery of Runx family members to the workers is highly unlikely given that an ectropic packaging cell line will be used. The helper genes in the packaging cell line are separated into two blocks so that recombination to a replication competent virus is highly unlikely. Even in the event of this actually happening and the virus escaping into the environment, the virus tropism will ensure that only mice will be infected. The only possible outcome would be that oncogenesis might be more likely in the infected mice if all the unlikely events took place.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The construction and growth of plasmids containing the Runx family members will be carried out such that no attempt will be made to express the genes in these vectors. The genes will be cloned into a site in the vector (pBabe puro) which contains no promoter elements to drive bacterial expression. The growth of the plasmids in appropriate E.coli K12-derived hosts will only serve to produce enough of the plasmid for later use and so could be carried out at Level 1 containment.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All containment tissue culture flasks and centrifuge tubes will be autoclaved whilst culture medium will be treated with VIRKON to inactivate virus.

Project Additional Information

Purposes of the contained use

The aim of the project is to assess the ability of a number of biological active genes to attenuate atherosclerotic lesion formation in the apoE-/- knockout mouse. ApoE-/- mice develop substantial peripheral lesions. Candidate biologically active genes will be delivered injected systematically through the femoral vein using standard first generation adenoviral vectors or AAV vectors

Recipient or parental organism

All adenovectors to be used in this study are E1-deleted first generation adenoviral vectors based on the pJM17 system (McGrory, W.J., Bautista, D.S. and Graham, F.L.: A simple technique for the rescue of early region I mutations into infectious human adenovirus type 5. Virology 163: 614-617, 1988). In brief, adenoviruses are generated by recombination resulting in the deletion of the E1 region of the viral genome and replacement with the expression cassette. This renders the adenoviruses replication defective. However with these first generation viruses there is still a small risk of recombination with the E1 region in 293 helper cells used to propogate the viruses. All stocks are therefore routinely tested for the presence of replication-competent adenovirus (RCA) and will be negative. All stocks will also be purified on caesium chloride gradients. E1-deleted adenoviruses cannot replicate unless the E1 function is complemented in trans. Therefore the disabled vector is considered a biological agent
unlikely to cause human disease and is assigned to hazard group 1 with containment level 1 as the minimum requirement. However, all the inserted genes are biologically active. None of the transgenes are proto-oncogenes. All transgenes will be under the control of the CMV promoter. There will be a minimal risk of harmful effect of these genes in the organs/tissues. If the replication-defective adenovirus is inadvertently released into the general environment, immune cells will target any infected cells. It is generally accepted that the Ad will be inactivated almost immediately by the immune surveillance cells located in the peripheral system. The recombinant adenovirus will pose less of a threat once in the cell that most expression vectors as they will definitely not replicate or integrate in the host genome. Furthermore, the natural tropism of the adenoviral vectors are not altered from wild type adenoviruses in the viruses proposed for use. AAV vectors have received increasing attention for molecular interventions in vivo and for gene therapy applications due to their low level of immunogenicity in vivo and their ability to integrate into the genome, thus producing sustained expression of transgenes for prolonged periods of time. They also have the ability to infect dividing and non-dividing cells. AAV vectors used in this study are serotype 2 and replication-defective through deletion of the rep and cap genes and insertion of the recombinant gene expression cassette within the AAV inverted terminal repeats (ITRs). The AAV vectors are generated by co-transfection of the AAV vector (carrying the expression cassette) and a helper plasmid carrying the helper functions necessary for AAV packaging in trans. The cells are then infected with a replication-defective herpes simplex virus (HSV) to provide helper function for AAV replication (in place of helper adenovirus). Upon a cytopathic effect in the cells, AAV and HSV particles are harvested. The HSV is removed completely by filter sterilisation to leave recombinant replication-defective AAV particles capable of expressing the transgene. This system is published (Zhang, X, de Alwesh, M., et al. High-tier rAAV production from replicating amplicons and gH-herpes vectors) and has been used for AAV preparation in Glasgow and elsewhere (Institute of Child Health, London). All stocks of AAV vectors will be generated at the Western Infirmary, University of Glasgow. AAV vectors are replication defective. There is some recombination between plasmids that may result in wild type like virus (not fully functional as they contain deletions). However, this is usually minimal (less than 0.01% of stocks). Furthermore, wild type AAV has no known pathogenicity and therefore no harmful consequences of generating even fully wildtype virus is anticipated. None of these sequences are likely to be harmful if expressed. If, by accident, they were introduced in humans via the recombinant vector, they are unlikely to be harmful since they are either reporter genes or a functional gene which would have no effect unless expressed at very high levels. Since we are only using small quantities of replication deficient vector (below 10e9 particles) accidental exposure to the vector is extremely unlikely to result in high levels of protein being produced.

Host/vector system

The adenoviral vectors are generated by homologous recombination between pJM17 and shuttle vectors containing transgene expression cassette and flanking E1 sequences. Following homologous recombination in helper 293 cells which express the helper E1 function in trans, replication-defective first generation adenoviruses are produced. This methodology has been used for many years for the development of recombinant adenoviruses. AAV vectors used in this study are serotype 2 and replication-defective through deletion of the rep and cap genes and insertion of the recombinant gene expression cassette within the AAV inverted terminal repeats (ITRs). The AAV vectors are generated by co-transfection of the AAV vector (carrying the expression cassette) and a helper plasmid carrying the helper functions necessary for AAV packaging in trans. The cells are then infected with a replication-defective herpes simplex virus (HSV) to provide helper function for AAV replication (in place of helper adenovirus). Upon a cytopathic effect in the cells, AAV and HSV particles are harvested. The HSV is removed completely by filter sterilisation to leave recombinant replication-defective AAV particles capable of expressing the transgene. This system is published (Zhang, X, de Alwesh, M., et al. High-tier rAAV production from replicating amplicons and gH-herpes vectors) and has been used for AAV preparation in Glasgow and elsewhere (Institute of Child Health, London). All stocks of AAV vectors will be generated at the Western Infirmary, University of Glasgow. AAV vectors are replication defective.

Origin & function

The adenoviral vector DNAs are standard and originated from the laboratory of Dr. Frank Graham (McGrory, W.J., Bautista, D.S. and Graham, F.L.: A simple technique for the rescue of early region I mutations into infectious human adenovirus type 5. Virology 163: 614-617, 1988). The cytomegalovirus immediate early promoter is a standard viral promoter used for gene expression studies in vitro and in vivo to generate high-level gene expression in all cells transduced by the adenovirus. The AAV system is published (Zhang, X, de Alwesh, M., et al. High-tier rAAV production from replicating amplicons and gH-herpes vectors) and has been used for AAV preparation in Glasgow and elsewhere (Institute of Child Health, London). All transgenes will be constructed from full length cDNAs obtained from other research institutes and verified in our own laboratory prior to subcloning into the relevant vectors.

Evaluation of foreseeable effects

There will be a minimum risk of harmful effect of these genes in organs/tissues. If the replication-defective adenovirus is inadvertently released into the general environment, immune cells will target any infected cells. It is generally accepted that the Ad will be inactivated almost immediately by the immune surveillance cells located in the peripheral system. The recombinant adenovirus will pose less of a threat once in the cell than most expression vectors as they will definately not replicate or
integrate into the host genome. AAV vectors are replication defective. There is some recombination between plasmids that may result in wild-type like virus (not fully functional as they contain deletions). However, this is usually minimal (less than 0.01% of stocks). Furthermore, wild type AAV has no known pathogenicity and therefore no harmful consequences of generating even fully wildtype virus is anticipated. None of these sequences are likely to be harmful if expressed. If, by accident, they were introduced in humans via the recombinant vector, they are likely to be harmful since they are either reporter genes or a functional gene which would have no effect unless expressed at very high levels. Since we are only using small quantities of replication deficient vector (below 10e9 particles) accidental exposure to the vector is extremely unlikely to result in high levels of protein being produced. Consequences of environmental exposure - ‘effectively zero’

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All measures as per HSE containment level 2 for both production of recombinant adenoviruses in the laboratory and animal experimentation

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Laboratory-based experiments: during the production of replication-defective adenoviruses, all solid waste (plastics etc.) are autoclaved prior to disposal. All liquid waste from tissue culture is treated with chlorine-based disinfectants for at least 24 hours prior to disposal. The use of sharps is avoided.

Animal Experiments: All instruments used in the preparation of animals for GM work will be sterilised by autoclaving. Solutions exposed to the viable GMOs will be disinfected with chlorine-based disinfectant. All plastic ware will be autoclaved prior to disposal. Animals receiving the GMO will be housed in separate cages during the procedure-kill time period. All animal carcasses will be disposed of by incineration. Animal bedding will be autoclaved prior to disposal and cages disinfected prior to being re-used.

02/03/2022
The aim of the project is to assess the ability of a number of biological active genes to attenuate the extent of brain damage and to reduce infarct size induced by middle cerebral artery occlusion (MCAO; a model of stroke) in the brains of normotensive (Winstar Kyoto) and stroke sensitive rats (stroke-prone spontaneously hypertensive rats). Candidate biologically active genes will be delivered prior to (up to 1 week prior) MCAO to allow gene expression to occur. The genes will be delivered using standard replication defective first generation adenoviral vectors via a systemic route (infusion of adenovirus through the femoral vein), intracranially (direct stereotactic injection into the brain) or through lateral ventricle infusion into the cerebrospinal fluid.

All adenovectors to be used in this study are E1-deleted first generation adenoviral vectors based on the pJM17 system (McGrory, W.J., Bautista, D.S. and Graham, F.L.: A simple technique for the rescue of early region I mutations into infectious human adenovirus type 5. Virology 163: 614-617, 1988). In brief, adenoviruses are generated by recombination resulting in the deletion of the E1 region of the viral genome and replacement with the expression cassette. This renders the adenoviruses replication defective. However with these first generation viruses there is still a small risk of recombination with the E1 region in 293 helper cells used to propagate the viruses. All stocks are therefore routinely tested for the presence of replication-competant adenovirus (RCA) and will be negative. All stocks will also be purified on caesium chloride gradients. E1-deleted adenoviruses cannot replicate unless the E1 function is complemented in trans. Therefore the disabled vector is considered a biological agent unlikely to cause human disease and is assigned to hazard group 1 with containment level 1 as the minimum requirement. However, all the inserted genes are biologically active. None of the transgenes are proto-oncogenes. All transgenes will be under the control of the CMV promoter. There will be a minimal risk of harmful effect of these genes in the organs/tissues. If the replication-defective adenovirus is inadvertently released into the general environment, immune cells will target any infected cells. It is generally accepted that the Ad will be inactivated almost immediately by the immune surveillance cells located in the peripheral system. The recombinant adenovirus will pose less of a threat once in the cell that most expression vectors as they will definately not replicate or integrate in the host genome. Furthermore, the natural tropism of the adenoviral vectors are not altered from wild type adenoviruses in the viruses proposed for use.
### Host/vector system

The adenoviral vectors are generated by homologous recombination between pjM17 and shuttle vectors containing transgene expression cassette and flanking E1 sequences. Following homologous recombination in helper 293 cells which express the helper E1 function in trans, replication-defective first generation adenoviruses are produced. This methodology has been used for many years for the development of recombinant adenoviruses.

### Origin & function

The adenoviral vector DNAs are standard and originated from the laboratory of Dr. Frank Graham (McGrory, W.J., Bautista, D.S. and Graham, F.L.: A simple technique for the rescue of early region 1 mutations into infectious human adenovirus type 5. Virology 163: 614-617, 1988). The cytomegalovirus immediate early promoter is a standard viral promoter used for gene expression studies in vitro and in vivo to generate high-level gene expression in all cells transduced by the adenovirus. All genes, with the exception of the viral crmA gene (caspase inhibitor), are full-length human cDNA sequences. The adenoviruses have been generated in our own laboratories, provided by international research groups or purchased from the University of Iowa Gene Transfer Core. We are testing these candidate genes, when overexpressed using the adenoviral vector system, to inhibit cell death induced by middle cerebral artery occlusion in rats.

### Evaluation of foreseeable effects

There will be a minimum risk of harmful effect of these genes in organs/tissues. If the replication-defective adenovirus is inadvertently released into the general environment, immune cells will target any infected cells. It is generally accepted that the Ad will be inactivated almost immediately by the immune surveillance cells located in the peripheral system. The recombinant adenovirus will pose less of a threat once in the cell than most expression vectors as they will definitely not replicate or integrate into the host genome.

Consequence of environmental exposure - "effectively zero".

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

## Project Additional Information

### Purposes of the contained use
To determine if overexpression of the cell cycle protein results in a reduction in infact size following stroke and other models of brain injury.

### Recipient or parental organism
Mice and rats.
### Host/vector system

In vitro - introduction into the central nervous system (CNS) of mice and rats. The vector used in this study is an attenuate form of the Herpes Simplex Virus.

### Origin & function

The gene of interest is a cell cycle protein which is activated upon cellular stress such as ischaemia. It has been shown that expression of this protein is upregulated following cerebral ischaemia and it is thought that the role of this protein may be in influencing cell survival. Therefore overexpression of the cell cycle protein may salvage brain tissue following cerebral ischaemia and provide a novel therapeutic target for the treatment of stroke.

### Evaluation of foreseeable effects

When using human herpes viruses as vectors, consideration should be given to the nature and expression level of the novel gene insert. The HSV virus is an attenuated form and is selectively replication competent, only replicating in dividing cells, therefore the virus will be unable to replicate in the adult CNS. We do not expect that insertion of the genes of interest will affect the growth property of HSV.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

HSV vectors will be stored in a double container in a locked freezer. Vectors will be transported between labs in double containment. Lab coats, gloves and glasses will be worn when handling viral vectors. Any contaminated plastic or glassware will be autoclaved, any liquid waste will be placed in Virkon overnight before being disposed of down the sink. A separate Hamilton syringe will be used for injecting vectors, which will be cleaned with 1% Virkon followed by absolute alcohol. All surgical instruments will be cleaned in 1% Virkon followed by absolute alcohol.

Recovery animals will be placed in cages which will be clearly marked to inform biological service staff of the details of the viral vector. A notice will be placed on the animal room to notify staff of the presence of animals treated with viral vectors. Terminal animals will be killed by perfusion fixation with 2% paraformaldehyde in phosphate buffer and the animal carcasses will be incinerated. Animal cages will be autoclaved.

Cage tops will be securely fastened when animals are being transported between Biological Services and WSI labs which are contained within the same building.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All equipment will be sterilised in Virkon followed by 70% Alcohol. This will completely deactivate any virus and is a method, which is commonly practised in virology. All deactivated waste can then be disposed of down the sink with copious amounts of water. Animals, which have been infected with virus, will be perfusion fixed in paraformaldehyde which will deactivate the virus. Animal carcasses will be incinerated.

---

## Project Additional Information

### Purposes of the contained use

JSRV is the cause of ovine pulmonary adenocarcinoma, a naturally occurring lung cancer in sheep. We wish to study this and similar viruses in terms of viral production in cells and their transformation, mutant virus in cell envelope entry, and viral interference mechanisms using transfection assays.

### Recipient or parental organism

All our worked is carried out using standard laboratory disabled strains such as K12 (DH5a) - it is highly unlikely that the pathogenicity will be altered by the manipulations.
described. There will be no attempt to express any of the viruses or viral genes or oncogenes described in this application in bacteria and the vectors do not even carry an appropriate promoter for bacterial expression. Thus no harmful effect to human health is foreseeable.

**Host/vector system**

GMOs described in this application are cloned in commonly used plasmids such as pBlueScript, pCDNA3 etc.

GMOs used:
- JSRV (Jaagsiekte sheep retrovirus)
- EnJSRVs (endogenous retroviruses related to JSRV)
- M-MLV (Moloney - ecotropic-murine leukaemia virus)
- MMTV (Mouse mammary tumour virus)
- Mason-Pfizer monkey virus (MPMV)
- Replication-incompetent retrovirus vectors

**Origin & function**

The procedures concerning the use of GMOs in our laboratory are (a) Virus production; (b) Transformation Assays; © Entry assays; (d) Transfections; (e) General DNA manipulations.

The JSRV DNA constructs used in our laboratory are derived from the plasmid pJSRV21(7), a full-length infectious molecular clone of a JSRV UK isolate. JSRV does not propagate in tissue culture, likely because the viral LTR are expressed specifically in type II pneumocytes (8). Type II pneumocytes are very difficult to isolate in vitro and lose their phenotype in vitro quickly, consequently no in vitro system for the propagation of JSRV has been obtained so far. (a) Viral production is achieved by transient transfection of 293T cells with pCMV2JS21, a derivative of pJSRV21 whose expression is driven by the cytomegalovirus (CMV) immediate early promoter. The CMV promoter, which replaces the proximal U3 region in the JSRV LTR is lost upon transcription. Thus, transfection of pCMV2JS21 in 293T cells induces production of wild type JSRV (eg the CMV promoter is not part of the genome of the produced virions) (7).

293T is a human cell line derived from HEK 293 cells (ATCC cat # CRL 1573). The 293 cell line was derived by transformation of primary cultures of human embryonic kidney (HEK) cells with sheared adenovirus (Ad5) DNA. 293T cells are further 'transformed' by the SV40 T antigen. 293/293T cells are probably the most widely used cell lines in research laboratories as they are easily transfectable by plasmid DNA.

(b) Transformation assays are performed generally on chicken, mouse or rat primary fibroblasts or immortalised cell lines (such as NIH-3T3, RK3E, 208F etc) by transfecting an expression plasmids for the JSRV Env (pCMV3JS21 GP). We also use a variety of derivatives of pCMV3JS21 GP carrying mutations that negatively affect the transformation ability of the JSRV Env or are fused with a tag epitope such as FLAG, HA or Myc. For comparative purposes chimeric envelopes formed by portions of the JSRV Envelope and the ecotropic Moloney murine leukemia virus (M-MLV) or Mouse mammary tumour virus (MMTV) are also employed. These chimeric envelopes have the aim to dissociate the oncogenic potential of the JSRV Env by the use of its natural cellular receptor (Hyaluronidase-2, Hyal-2). To this end the chimeric envelopes are formed by the receptor binding domain (RBD) of murine retroviruses and the remaining portion of the Env protein is derived from JSRV. Further details can be found in the following reference (9).

C) Entry assays. Viral pseudotypes will be used to test the ability of the JSRV Env mutants to mediate cell entry. Cells used for this purpose are in general sheep cell lines such as SCP, sheep choroids plexus, deer lung cells such as OHHI.Lu or mouse cells expressing the Hyal-2 receptor (3T3-Hyal2). Pseudotypes are formed by transfecting Env-expression plasmids (based on pBlueScript) into 293GP-AP or 293GP-Luc (Clontech). 293GP-AP and 293GP-luc express Gag and Pol (eg the core structural proteins) of murine leukemia virus (MLV) and a MLV-based vector expressing alkaline phosphatase (293GP-AP) or luciferase (293GP-Luc) (for control purposes pseudotypes formed with the M-MLV Env or MMTV Env are also used).

The retroviral pseudotypes described above are replication-incompetent and de facto have to be considered emphytropic retroviral vectors considering that the JSRVEnmv can mediate entry into human cells. Viral pseudotypes will be handled in BSL-2 conditions and great care will be taken into reducing the formation of aerosol and avoid the use of glassware/needles.
The generation of replication competent virus in this system is highly unlikely given the fact that the system uses three separate plasmids to express retroviral particles. In addition these assays last only 48-72 hours, further reducing the chances of selection and enrichment of a replication competent recombinant.

(d) Transfections. Studies to investigate interference mechanisms between enJSRVs and JSRV are carried out in 293, 293T and HeLa cells by transient transfection with pCMV2JS21 (and derivatives) and pCMV2enJS56A1 (and derivatives). Western blotting analysis serves to determine viral particle production (in the supernatant) and viral expression (in cell lysates). We also perform confocal microscopy in HeLa cells transiently transfected with the constructs described above. For comparative purposes analogous studies will be performed with (full length) murine retroviruses, such as the ecotropic Moloney murine leukemia virus (M-MLV), mouse mammary tumour virus (MMTV), Mason-Pfizer Monkey virus (MPMV). In all these cases 293T or HeLa cells will be transfected as above and assessed for viral particle production, expression and/or analyzed by confocal microscopy.

In JSRV/enJS56A1 the determinants of viral particle formation and interference map in the amino terminal region of Gag (the main polyprotein forming the retroviral capsid). We have derived a variety of JSRV/enJS56A1 mutants and chimeras to precisely map the defect possessed by enJS56A1 (6). For comparative purposes MPMV and M-MLV mutants and chimeras will be derived to determine whether amino acids substitutions in the amino terminal Gag can induce a defective phenotype similarly to enJS56A1.

(e) General DNA manipulations. All the infectious molecular clones described above are inserted in common commercially-derived vectors such as pBlueScript that do not have appropriate enhancers or promoter elements for bacterial expression. The host microorganisms are the commonly used DH5α, disabled bacteria derived from E. coli K12 strain. No attempt will be made to express full length viruses in bacterial cells.

Evaluation of foreseeable effects

Viruses used in this study: General comments. Oncogenic retroviruses are highly species-specific and interspecies transmission is avoided by a variety of blocks acting at entry (via the interaction with specific receptors) and post-entry levels (10, 11).

A. JSRV (JSRV21, infectious molecular clone). JSRV is the aetiological agent of ovine pulmonary adenocarcinoma (OPA). (OPA is a naturally occurring infectious disease of sheep that is enzootic in the UK. JSRV appears to be strictly species-specific. The disease is not described in other ruminants such as cows and deer. Even in goats (OPA is difficult to reproduce experimentally where it presents a much longer incubation period than sheep and lesions appear localised. (12).

As mentioned above, there is no convenient tissue culture system for the propagation of JSRV. Viral production is achieved by transient transfection of 293T cells with pCMV2JS21, a JSRV infectious molecular clone. 293T cells are human cells and as all human cells lack a functional α-1,3 galactosyltransferase that is instead present in most mammalian cells. Thus, mammalian cells and not human cells express Gal[α 1-3] Gal terminal carbohydrates and it has been shown that animal enveloped viruses (carrying Gal[α 1-3] Gal) can be inactivated by human complement (13, 14). Production of JSRV particles in human cells might bypass this barrier. However, it needs to be noted that a variety of blocks at various levels have evolved to block interspecies transmission of retroviruses. For example, interspecies transmission of JSRV does not occur between sheep and other animal species where the Gal(α1-3) Gal-induced complement inactivation would not occur.

Access: Jaagsiekte sheep retrovirus can theoretically enter human cells as the human Hyaluronidase-2 can function as a receptor for JSRV (15) but there is no indication of whether JSRV could be able to successfully establish infections in these cells. Unfortunately no tissue culture system is available to propagate JSRV in vitro. It is important to underline that a variety of retroviruses (eg amphotropic murine leukaemia virus, Feline leukaemia virus B) can utilise receptors expressed in human cells (16-18) but there is no indication available that they can actually establish infection in humans and certainly no human disease has ever been associated with these viruses.

Expression: No data is available on the possible expression of JSRV in human cells for the lack of a suitable cell culture system for the propagation of this virus. However, reporter assays using the JSRV long terminal repeats (where the viral promoter and enhancer are located) failed to show any significant activity in human lung-cancer derived cell lines (8). Damage. There are no reports in the literature of a higher incidence of lung adenocarcinoma in sheep farmers, veterinarians, sheep handlers etc. Despite OPA being recognised as a disease entity for more than a century (19) By PCR and RT-PCR no evidence of JSRV has been found in human bronchoalveolar carcinomas and adenocarcinomas (20-22). JSRV is thus unlikely to represent any hazard for humans.
The JSRV Env induces transformation of immortalised cells in vitro (4) and can be compared essentially to an oncoprotein. It is necessary a combination of more than one oncogene to transform human primary cells. For example, JSRV has been reported to transform a human-derived bronchial epithelial cell line (BEAS-2B) but this cell line is derived from cells that have been immortalised by the SV40 T antigen (23).

We also have JSRV mutants with critical amino acid substitutions that abrogate their transforming activity in vitro or their capacity to form viral particles. These mutants do not represent for human health a higher risk than wild type JSRV.

B - enJSRVs. The enJSRVs clones used are replication-defective and consequently do not pose any harm for human health. Also enJS66A1 mutants/chimeras where the ability to produce viral particles has been restored are unlikely to pose any risk to humans considering that: a) they possess a frame shift at the end of the pool gene (5); b) the enJSRVs Env does not induce transformation of rodent fibroblasts (3); c) their LTR (Long terminal repeat where viral enhancers and promoters are located) are relatively weak with respect to JSRV (5).

C - MMTV and M-MLV. MMTV and ecotropic M-MLV are mouse retroviruses and do not pose and harm for human health. Also gag mutants/chimeras for both viruses will not change the tropism of these viruses which is determined by the Env gene.

D - MPMV is one of the 5 serotypes of simian type D retroviruses (now classified as Betaretroviruses) (SRVs, simian retroviruses). A study conducted in the 70s show that about 25% of all macaques had antibody reacting to MPMV core antigen in US research primate centres (24). Access: MPMV can infect in vitro human cells. However, extensive serological surveys in the 1970s and 1980s of humans (including primate centres animals handlers) have shown no proof of SRV infection (25). A relatively minor report has showed Abs against betaretroviral Gag in he4althy African from Guinea but no follow up study has been published since then. It is reassuring that MPMV has been extensively studied for 30 years in many laboratories around the world (eg 26-43) and there is no indication of its transmission to humans. Expression and Damage: The pathogenicity in its natural host is not completely clear. Experimental transmission of MPMV in the early 1970s into infant rhesus monkeys induced an immunodeficiency-like disease (26, 27). In nature, saliva is the major source of infection and the most likely route of natural transmission is by percutaneous inoculation by biting and scratching (44, 45).

In conclusion although the potential for disease potential is low we will treat MPMV as a potential infectious agent (see Section 3 'Application of containment procedures').

E. Replication-incompetent retroviral vectors. Both standard ecotropic and more rarely amphotropic replication-incompetent retroviral vectors will be used in this laboratory to verify the efficacy of the envelope/envelope mutants constructed (see 'entry assays' in 'overview of procedures used') or to conveniently introduce genes (including oncogenes) in cell lines. Vectors used are replication defective and are used in a helper-free system. Viral vectors are produced by using either stable 'packaging' cell lines or transient transfection methods but in all cases viruses are produced by expression of viral proteins with three different plasmids and consequently chances of recombination are virtually eliminated. In addition the procedures employed are only for short term experiments (2-3 days) further reducing the chances of recombination. Ecotropic vectors cannot enter human cells while amphotropic vectors have this ability although they cannot spread.

Cells expressing replication competent viruses (that could work as unwanted virus 'helpers' for our vectors) and cells expressing the above mentioned replication incompetent viruses will be grown in separate incubators. In addition, biosafety cabinets, pipette aids, media stocks will be designated for the use of replication competent viruses to prevent cross-contamination. Access: Vectors carrying oncogenes are those that require more attention from a biosafety point of view. Despite being replication incompetent they could be able to enter human cells although spreading will not occur. Effective access to human cells can likely occur with needle-stick injuries. Our procedure minimise this risk as we do not use needles and glassware with material containing live viruses/vectors. In addition we produce only small amount of vector necessary for small scale infection in tissue culture experiments.

Workers will be using waterproof gloves, lab coats and eye protection. Expression and Damage: Amphotropic vectors carrying oncogenes can theoretically be expressed in human cells. In general the combination of more than one 'oncogene' is necessary to induce cell transformation in vivo. Most oncogenes expressed in normal cells lead to a senescence-like phenotype (ie non-proliferative) but could theoretically render cells more susceptible to transformation. All our procedures involving viruses/vectors avoid the use of needles and glass pipettes to minimize the risk of needle stick injuries which are the main source of accidental retrovirus infection. In addition all workers use lab coats and plastic gloves and eye protectors.

Cells expressing replication competent viruses and cells expressing replication incompetent vectors will be grown in separate incubators. In addition, biosafety cabinets will be designated for the use of replication competent viruses and designated pipette aids and designated media stocks will also help to prevent cross-contaminations.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

With the exception of DNA manipulations (performed at Level 1) we will work at Level 2 facilities with all the GMOs in the laboratory. Despite the hazard to human health being low we will treat all the GMOs and viruses in the laboratory as potential infectious agents and we will employ the same procedures for all viruses and vectors used to eliminate any possible confusion.

Handling and disposal of GMOs and contaminated material will be conducted as defined by the containment level(s) specified above, in compliance with the Faculty Safety Policy and the Local Code of Practice for Handling of Genetically Modified Microorganisms waste media. Spillages and contaminated plastic/glass ware will be disinfected with recommended inactivating agent (virkon, 2% solution) and material subsequently autoclaved. All solid waste is autoclaved. Both treatment are proven to completely inactivate retroviruses.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Passed with amendments by local GMSC and amendments added for this submission on 16th September.

Project Ref 223/07.1

Date Ackn’d 03/10/2007
CU2 Project Title Elucidating biological activities of the Herpes simplex virus type 1 ICP27 protein.
Class 2
Culture Class 2 ≤ 1 Litre
**Project Additional Information**

**Purposes of the contained use**
- To grow wild type herpes simplex virus type 1 (HSV-1).
- To grow viruses mutant in the ICP27 gene.
- To grow viruses mutant in the UL13 gene
- To express ICP27 protein in E.coli

**Recipient or parental organism**
- E.coli
- HeLa, Vero, Baby Hamster Kidney cells in cell culture

**Host/vector system**
- E.coli/pGEX
- Mammalian cells in culture/HSV-1 wild type and ICP27 or UL13 mutant virus

**Origin & function**
There are two strains of wild type HSV-1, the KOS virus that was cloned in Chicago and the 17+ virus that was cloned in Glasgow. There are very few genetic differences between these. Both viruses wil be used. The ICP27 gene is a negative regulator of cellular gene expression and a positive regulator of virus gene expression. We possess a bank of viruses with contain deletions or mutation in the ICP27 gene. The mutant viruses are all in the public domain.
- HSV-1 genome with the ICP27 gene deleted
- HSV-1 genome with the ICP27 gene disrupted with a lac-Z gene insertion
- HSV-1 genome with various point mutations and deletions of the ICP27 gene: - deleu, d1-2, d3-4, (all replication deficient 100-fold reduction in progeny) d4-5 (replication defective), d5-6, d6-7 (both replication competent) M11, M15, M16, n263R, and n406R (replication defective)
- HSV-1 genome expressing a EYFP-ICP27 fusion protein

**References**
We also wish to examine the role of the virus protein kinase UL13 in modulating the effects of ICP27 and we possess a virus with the UL13 gene deleted.

The intended functions are to infect cells in culture and to determine differences in efficiency of virus protein expression between the wild type and mutant viruses. For ICP27 this will help map the domain(s) of the ICP27 protein involved in regulating gene expression. The UL13 mutant virus will help discover whether the virus phosphorylates cellular gene expression proteins to modify their functions.

**Evaluation of foreseeable effects**

The risk for human health is small. HSV-1 is present in the environment. Wild type HSV-1 causes cold sores and a high percentage of the human population are chronically infected. Virus contact with broken skin is necessary for infection of naive individuals. Cold sores could develop but these rarely arise in the immunocompetent healthy individual. Apart from d5-6, d6-7, both replication competent, IPC27-mutant viruses are either severely disabled for growth or unable to replicate: 27lacZ (virus null for ICP27; replication incompetent), dleu, d1-2, d3-4, (all replication deficient: 100-fold reduction in progeny) d4-5 (replication incompetent), M11, M15, M16, n263R, and n406R (replication defective). All of these have some defect in replication or gene expression. UL13 mutant viruses are also severely compromised for growth. HSV-1 cannot infect animals other than humans.

E.coli is a bacterium found in the environment and does not cause disease.

ICP27 protein is non-toxic, very labile in the environment and unable to cross cell membranes so has a very low probability of causing deleterious effects upon production in bacterial culture.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

**Virus material**

Cell culture flasks and vials containing virus stocks will be filled with 1% Virkon and immersed overnight. Flasks will be emptied and autoclaved before disposal. Any spills will be flooded with 1% Virkon and mopped up with tissue and tissues will be bagged and autoclaved before disposal. 1% Virkon gives 100% kill.

**Bacterial material**

Culture flasks and vials will be filled with 1% Virkon and immersed overnight. Flasks will be emptied and autoclaved before disposal. Any spills will be flooded with 70% ethanol and mopped up with tissue. Tissues will be bagged and autoclaved before disposal. These procedures give 100% kill.

All workers will wear gloves during all procedures. Gloves will be bagged and autoclaved after use.

Any transportation of virus stocks will be in a sealed plastic box.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
Comments from the GM committee included "please increase background information on herpesvirus infections". This was incorporated into the last risk assessment submitted and the project was approved on the 24 March 2007.

Significant Change ID: 223/13.1a

Date of Significant Change: 19/01/2016

Project Additional Information

Purposes of the contained use:
Primate lentiviruses are a taxonomic group of complex retroviruses that infect more than 40 species of primates
including humans [1, 2]. HIV-1 (Human Immunodeficiency Virus) is a primate lentivirus that emerged in human populations in the early 20th century [3] following multiple transmissions of Simian Immunodeficiency Viruses (SIVs) from chimpanzees [4]. The less successful human pathogen, HIV-2, emerged in humans following multiple transmissions of a lentivirus from Sooty Mangabeys (SIVsmm) [5]. HIV-1 has infected over 50 million people and has caused an AIDS (Acquired Immunodeficiency Syndrome) pandemic that has consumed more than 25 million lives [6, 7]. Interestingly, primate lentiviruses might have ancient origins [8, 9] and many SIVs are not pathogenic in their natural hosts [10]. This is the case for SIVagm which does not seem to cause disease in infected African Green Monkeys [11], although a paucity of data exists considering natural SIV infections of that natural host [12]. The main HIV-1 animal model is SIVmac, a virus transmitted to rhesus macaques from Sooty Mangabeys. Like HIV-1, this virus is highly pathogenic in the normal host, rhesus macaques, possibly due to its recent emergence in rhesus macaques following unintentional experimental transmission from Sooty Mangabeys [13].

Primate lentiviruses are enveloped viruses that have the basic gag (group specific antigen) pol (polymerase) and env (envelope) structure shared by all retroviruses. Primate lentiviruses have a diploid RNA genome whose expression is regulated by tat and rev. Following infection of a target cell, the retroviral genome is reverse transcribed into DNA, translocated to the nucleus and integrated into host DNA [14, 15]. Lentiviruses also encode a number of ‘accessory’ genes that are dispensable for replication in vitro but whose expression is important for pathogenesis in vivo. These genes are mainly involved in downregulating viral receptors following infection in addition to antagonizing innate and intrinsic immune defences. Understanding exactly how different lentiviruses neutralize species-specific blocks to replication is of huge importance in understanding the emergence of new lentiviruses in human populations and how these viruses replicate within the hostile host [16].

This project will investigate the molecular biology and virus-host interactions of primate lentiviruses, focusing on (but not limited to) HIV-1. In addition the related HIV-2, SIVmac, SIVagm, SIVgor and SIVcpz viruses will also be analysed.

1) Primate lentivirus molecular clones, and GM variants will be examined for their ability to replicate/infect/assemble infectious particles in the presence of human and rhesus ISG libraries (and other bovine and avian ISG-libraries currently under construction). Parental clones and GM molecular clones can then be examined in the presence of different ISGs [17, 18].

2) Primate lentivirus molecular clones, and mutants will be examined for their ability to replicate/infect/assemble infectious particles in cell lines/primary cells from different vertebrate hosts in the presence/absence of interferon or in the presence/absence of exogenous antiviral/dependency factors. The specific aims are to characterise the speciesspecific antiviral activities of these cells and also to characterise/overcome other blocks to replication in non-natural species. Parental clones and GM molecular clones can then be examined in cell lines/primary cells from different species in the presence/absence of interferons. The ability of the parental virus and these GM viruses to induce interferons and other inflammatory cytokines will also be considered.

3) Generation of ‘unbiased’ mutagenized libraries to quantify the ‘genetic robustness’ of HIV-1. We have recently completed such an analysis of the CA region of HIV-1 Gag and we will interrogate the robustness of other HIV-1 ORFs in a similar fashion. Mutant libraries will not only be used to investigate the mutant phenotypes but also to investigate the influence of particular viral sequences on permissivity/sensitivity to restriction factors (for example the mutagenized CA library could be used to investigate the dependency of HIV-1 on TNP03 for infection or the ability to evade isoforms of rhesus TRIM5alpha proteins which usually restrict HIV-1 replication. The ability of the parental virus and these GM viruses to induce interferons and other inflammatory cytokines will also be considered.

4) Characterisation of the biological properties of viral ORFs/elements with particular regard to the evasion or antagonism of host antiretroviral defences (including but not limited to APOBECs, TRIMs, Tetherin, SAMHD1 and MX
proteins). Because of the unknown nature of this research (we don't yet know which viral sequences will require modification in 12 months time) the responses in this form are deliberately general to allow us to respond rapidly and appropriately to novel observations. Our work will however always follow the generic workflows highlighted in the attached risk assessments and these are briefly described below.

Class 3 activities:

Workflow A - Reporter modifications. Reporter genes (such as EGFP or luciferase) or epitope tags will be inserted into the proviral molecular clones. These modifications will either be inserted in frame, replace existing ORFs (such as EGFP replacing Nef) or will be combined with elements (such as viral IRESs or the FMDV 2A translational skip) to facilitate expression.

Workflow B - Introducing coding or non-coding mutations via site-directed mutagenesis or by low fidelity PCR

Workflow C - Introducing deletions. These can be either physical deletions of viral sequence or 'functional deletions' where start codons are removed and additional stop codons inserted.

Workflow D - Chimeric viruses. Making targeted viral chimaeras where a single viral ORF/non-coding element is either inserted into the viral genome or used to replace the orthologous/functionally analogous ORF/element.

Workflow E - Examine sequences in isolation. From time to time it will be necessary to exclude most of the viral genome and consider the influence of a single ORF/element on eukaryotic cells. In all cases this work will be limited to single ORFs and short sequence elements. Viral accessory genes will be the most likely desired targets.

Workflow F - Purification to examine biological properties/identify interaction partners. Because of the nature of scientific research it is impossible to provide an exhaustive list of the viral sequences that might be studied in this way. However the most likely scenarios involve over expression of enzymes or structural proteins to purify them and investigate their biological properties. In this workflow, purification from prokaryotic cells or eukaryotic cells might be desired. In all cases this work will be limited to single ORFs or short nucleic acid elements.

9. Barklis E, Mulligan RC, Jaenisch R: Chromosomal position or virus mutation permits retrovirus expression in

Molecular clones to be used will be primate lentiviruses:
- Human Immunodeficiency Virus-1 (HIV-1)
- Human Immunodeficiency Virus-2 (HIV-2)
- Simian Immunodeficiency Virus of Macaques (SIVmac)
- Simian Immunodeficiency Virus of African Green Monkeys (SIVagm)
- Simian Immunodeficiency Virus of Chimpanzees (SIVcpz)
- Simian Immunodeficiency Virus of Gorillas (SIVgor)

Recipient or parental organism

Prokaryotic hosts will be handled at containment level 1 and eukaryotic hosts at containment level 3 (workflows A-D) and containment level 2 (workflows E-F).

Plasmid vectors:
Viral sequences (including full length clones or partial sequences of HIV-1 or other retroviruses) and other genes (cellular, viral or reporter) are available in plasmid-encoded cDNA form. Plasmid vectors are based on bacterial plasmids and contain an origin of replication for prokaryotic cells and selectable antibiotic/drug resistance (pro- or eukaryotic) markers. By themselves these vectors present no risk to human health. Vectors have no selective advantage and would soon be lost from the bacterial population. The bacterial systems are non-mobilisable vectors in a disabled prokaryotic host. Systems for prokaryotic gene expression are under control of an inducible prokaryotic promoter. Systems for eukaryotic RNA or protein expression are under the control of promoters of viral (such as CMV or SV40), eukaryotic (e.g. actin promoter) or prokaryotic (such as T7 or SP6 promoter for in vitro transcription) origin.
Plasmids with eukaryotic promoters such as the CMV promoter can be transcribed in human cells.

Hosts:
Prokaryotic hosts:
Disabled, commercially available K12 derived E. coli strains such as Sure, JM109, XL-strains, DH-strains, Rosetta etc. These strains can only survive in a controlled laboratory environment and will be used for propagation of plasmids. Good microbiological practice and sterilisation of all contaminated waste will prevent release of viable organisms. The risk to the environment is therefore effectively zero.

Eukaryotic hosts:
Vertebrate cell lines of various origins (typically human, non-human primate, mouse, hamster, bovine, bat, chicken etc.) and stably modified derivatives such as TZM-bl indicator cells (derived from HeLa cells).

**Origin & function**

In prokaryotic cells, only selectable (e.g. antibiotic resistance) genes will be translated; prokaryotic cells may also be used for protein expression and subsequent purification.

Virus sequences will be under the control of a promoter that will only generate transcripts in eukaryotic cells or in in vitro transcription reactions.

In eukaryotic cells, the following RNAs will be produced which can be translated into the following gene products:

- **Retroviral RNA and proteins:** By inserting material from other retroviruses into primate lentiviruses we hope to sensitise/desensitise these viruses to inhibition by certain restriction factors or overcome specific replication blocks in certain cell types. For example adding vif from SIVmac desensitises HIV-1 to APOBEC3 inhibition in macaques.
- **Reporter genes:** Reporter genes of prokaryotic or eukaryotic origin (e.g. luciferase, fluorescent proteins etc.). These will be inserted into viruses to facilitate easy monitoring of viral replication (such as replacing nef with EGFP).
- **Host genes/host non-coding sequences:** By inserting this material into primate lentiviruses we hope to sensitise/desensitise these viruses to inhibition by certain restriction factors or overcome specific replication blocks in certain cell types. For example inserting a cellular promoter in the lentiviral LTR could alter dependency on host factors required for tat-dependent transcription.
- **Sequence changes (deletions/insertions/site directed mutagenesis) in viral sequences:** Mutation or deletion will target disruption of protein functions or non-coding viral sequences. This will allow us to make attenuated viruses sensitive to restriction factors (such as HIV-1 lacking Vpu which is more sensitive to tetherin). This will also allow us to study the genetic robustness of lentiviruses and also make modifications to sensitise/desensitise lentiviruses to host restriction or dependency factors. Modifications could also facilitate new interactions (such as modifying HIV-1 Gag to facilitate incorporation of Vpx, expressed in trans, into HIV-1 virions) or introduce epitope tags to monitor viral protein expression.

Techniques used to introduce vectors into cells:

- **Prokaryotic cells:** Introduction of DNA into E. coli will be by heat shock/chemical transformation or by electroporation. These techniques have been extensively described and are widely used; they rely on getting DNA very close to the bacterial membrane and introducing the genetic material through transient pores or membrane fusion.

- **Eukaryotic cells:** Cells will be transfected using transfection reagents such as PEI or by electroporation. Supernatant containing infectious particles can then be used to infect permissive cell lines.

**Evaluation of foreseeable effects**

Foreseeable effects/risk assessment for human health and safety (also see Risk Assessments):

- **Plasmid vectors:** Viral sequences (including full length clones or partial sequences of HIV-1 or other retroviruses) and other genes (cellular, viral or reporter) are available in plasmid-encoded cDNA/proviral form. Plasmid vectors are based on
bacterial plasmids and contain an origin of replication for prokaryotic cells and selectable antibiotic/drug resistance (pro- or eukaryotic) markers. By themselves these vectors present no risk to human health. Vectors have no selective advantage and would soon be lost from the bacterial population. The bacterial systems are non-mobilisable vectors in a disabled prokaryotic host. Transcription of even complete proviral DNA will result in no infectious particles since retroviral gene expression is heavily dependent on splicing and virion assembly cannot proceed in prokaryotic cells. Systems for eukaryotic RNA or protein expression are under the control of promoters of viral (such as CMV or SV40), eukaryotic (e.g. actin promoter, pathway inducible promoter such as STAT, interferon etc.) or prokaryotic (such as T7 or SP6 promoter for in vitro transcription) origin. Plasmids with eukaryotic promoters such as the CMV promoter can be transcribed in human cells. None of the genes used in these studies are known oncogenes. The hazard of expressing ‘foreign’ genes from these eukaryotic promoter plasmids would depend on the expected physiological effects of the foreign gene product and is discussed in more detail below.

HIV-1:
HIV-1 is the aetiological agent of acquired immunodeficiency virus (AIDS) [1-3]. The classification into ACDP hazard group 3 indicates current expert opinion that containment level 3 precautions are considered adequate for controlling the risks associated with working with HIV-1. Changes that will be introduced into the virus sequences will be targeted at disrupting or changing specific functions of viral RNA or viral proteins that will usually attenuate replicative capacity; such changes are highly unlikely to increase virulence (viral load is associated with progression to AIDS) as they modify virus sequences, or change genome length, or lead to expression of additional sequences such as reporter genes which confer no advantage to virus replication (indeed modified viruses are often impaired in vitro and in vivo [1-5]). Despite the low probability that genetic modifications will increase the pathogenesis or risk of infection of a given agent, the ACDP hazard group 3 status of the unmodified primate lentiviruses means modified viruses are still potentially hazardous particularly through sharps injuries/ultracentrifuge accidents [6]. It is also possible that modifications under workflows C or D could potentially influence the cell-tropism of HIV-1 in vivo. For example, insertion of SIVmac vpx into HIV-1 (workflow D) could conceivably better arm this virus to infect macrophages and dendritic cells [7] (although this remains to be demonstrated in vivo). Similarly the rate of viral dissemination to different tissues would likely be reduced from HIV-1 viruses not encoding Vpu [8] (workflow C). It is difficult to predict exactly what changes to cell tropism could occur in vivo but they are unlikely to be substantial. This is because all the primate lentiviruses mentioned in this RA infect very similar cell subsets during a course of infection in vivo (CD4+ve T-cells as the major target for infection with limited tropism for macrophages and dendritic cells. Although infection of many other cell subsets has been documented, such as astrocytes, these do not represent a major target for infection). It is therefore unlikely that an agent more pathogenic than HIV-1 (amongst the most pathogenic primate lentiviruses) could be generated in this way.

HIV-2:
HIV-2 is far less pathogenic than HIV-1 but can cause AIDS-like illnesses in humans. The classification into ACDP hazard group 3 indicates current expert opinion that containment level 3 precautions are considered adequate for controlling the risks associated with working with HIV-2. Changes that will be introduced into the virus sequences will be targeted at disrupting or changing specific functions of viral RNA or viral proteins and can be usually expected to attenuate viral replicative capacity; such changes are highly unlikely to increase virulence as they modify virus sequences, or change genome length, or lead to expression of additional sequences such as reporter genes which confer no advantage to virus replication [9-11]. Despite the low probability genetic modifications will increase the pathogenesis or risk of infection from genetically modified viruses, the ACDP hazard group 3 status of the unmodified virus means modified viruses are still hazardous particularly through sharps injuries/ultracentrifuge accidents. Similarly to HIV-1 it is possible that viruses generated as part of workflows C and D could have altered tropism in vivo. The same reasoning suggests that it is very unlikely that modifying HIV-2 in the manner described in this RA could
make this agent higher risk than HIV-1.

Nonhuman primate (NHP) lentiviruses:
NHP lentiviruses (such as SIVmac, SIVagm SIVcpz and SIVgor). Primate lentiviruses (from NHPs) are only rarely capable of infecting humans and causing disease. Their classification into ACDP hazard group 3 indicates current expert opinion that containment level 3 precautions are considered adequate for controlling the risks associated with working with SIVs. Changes that will be introduced into the virus sequences will be targeted at disrupting or changing specific functions of virus RNA or virus proteins and can usually be expected to reduce replicative capacity; such changes are highly unlikely to increase virulence as they modify viral sequences, or change genome length, or lead to expression of additional sequences such as reporter genes which confer no advantage to virus replication. Although extremely rarely able to productively infect humans, cells of human origin are already permissive for many NHP lentiviruses in vitro. Modifications to investigate cellular tropism are therefore unlikely to increase the risk of human infection [12-16]. However it remains possible that introducing sequences from HIV-1/HIV-2 into NHP lentiviruses could make them more infectious/pathogenic to human hosts and humans have been infected with HIV-1 through sharps injuries/ultracentrifuge accidents [6]. However, even when done deliberately to shift tropism, genetic modification has not yet resulted in the generation of lentiviruses that are pathogenic in their new host [5, 17] an important milestone in developing HIV-1 animal models. Whilst inserting material from human immunodeficiency viruses into NHP lentiviruses could make them more infectious or pathogenic to human hosts, this statement should be considered in light of the fact that NHP lentiviruses rarely infect humans and very rarely cause disease. It is extremely unlikely that NHP lentiviruses could be modified in the manner described in this RA to generate higher risk agents than HIV-1.

Hosts
The host/recipient organism:
Prokaryotic organisms: All strains will be disabled, commercially available E. coli K12 derivatives classified as ‘especially disabled hosts’ by ACDP. These strains cannot colonise humans and are known not to cause harm to humans.
Eukaryotic cells:
Cell lines to be used would not survive inside the immunocompetent human body (immune rejection) and are not known to carry harmful pathogens. Addition of DNA or RNA or infection will confer no growth or survival advantage in or outside the laboratory to these cell lines.
Eukaryotic primary cells would not survive inside the human body (immune rejection) Addition of lentiviral infection will confer no significant growth or survival advantage in or outside the laboratory to these cell lines.
The inserted/donated/mutated genetic material:
Workflow A - Reporter modifications. Reporter genes: Reporter genes of prokaryotic or eukaryotic origin (e.g. luciferase, fluorescent proteins etc.). No harmful properties have been attributed to these proteins. There would be no altered physiology expected if any of these genes were expressed; EGFP for example is a spontaneously fluorescent protein isolated from Aequorea victoria a coelenterate and has no known detrimental effects. Luciferase is another commonly used reporter gene and is derived from the firefly Photinus pyralis or the jellyfish Renilla reniformis. It is an enzyme which catalyses production of light from luciferin and ATP; the light produced is used as a measure of gene activity. The enzyme has no other known biological function. As such these modifications do not themselves present a hazard. However viral clones with reporter modifications are inherently hazardous as virus derived from the parental clones are classified as ACDP hazard group 3 modified viruses present a substantial hazard. Accidental infection of HIV-1 has occurred in laboratory/hospital settings through needle/sharps injury and ultracentrifuge accidents [6] and modified viruses could present a similar hazard.
Workflow B -Introduction of coding/noncoding mutations by site directed mutagenesis or low fidelity PCR: The vast
majority of coding mutations have a substantial negative influence on viral replicative fitness (Rihn et al., 2013) [18-20]. Replicative fitness and viral loads are related viral properties and for HIV-1 high viral loads and viral set points are strongly correlated with a rapid progression to AIDS. However, despite most modifications attenuating viral replication, some will be neutral and considering the classification of parental viruses into ACDP hazard group 3, these viruses could present a similar risk to HIV-1. Accidental infection of HIV-1 has occurred in laboratory/hospital settings through needle/sharp injury and ultracentrifuge accidents [6].

Workflow C - Deletion of accessory genes/noncoding elements. Although viruses lacking accessory genes/noncoding elements are often less infectious/less pathogenic, considering the classification of parental viruses into ACDP hazard group 3, these viruses could present a similar risk to HIV-1. Accidental infection of HIV-1 has occurred in laboratory/hospital settings through needle/sharp injury and ultracentrifuge accidents [6].

Workflow C - Deletion of essential viral genes. Although viruses lacking essential genes are severely attenuated, depending on the type of modification/experiment phenotypic reversion is a possibility. Considering the classification of parental viruses into ACDP hazard group 3, these revertant viruses could present a similar risk to HIV-1. Accidental infection of HIV-1 has occurred in laboratory/hospital settings through needle/sharp injury and ultracentrifuge accidents [6].

Workflow D - Viral gene/noncoding element replacement/insertion. Whilst chimeric viruses will usually be attenuated, it is formally possible that introducing genetic information from human immunodeficiency viruses into NHP lentiviruses could result in a modified NHP lentivirus more competent to infect and cause disease to the human host. In this regard modified NHP lentiviruses are potentially as hazardous as HIV-1 (classified into ACDP hazard group 3). Accidental infection of HIV-1 has occurred in laboratory/hospital settings through needle/sharp injury and ultracentrifuge accidents [6] and it is possible modified chimeric lentiviruses could infect humans.

Workflow D - Chimeric LTRs. Whilst chimeric viruses will usually be attenuated, considering the classification of parental viruses into ACDP hazard group 3, these viruses could present a similar risk to HIV-1. Accidental infection of HIV-1 has occurred in laboratory/hospital settings through needle/sharp injury and ultracentrifuge accidents [6].

Workflows E and F - Extremely low risk. No possibility of generating infectious lentiviruses. Plasmid DNA could contain potential oncogenes. This DNA could lead to transient expression of oncogenes if injected. However transfection in vivo is extremely inefficient so the oncogenic potential of these plasmids in humans would be extremely low. It is unlikely that lab strain prokaryotic cells transformed to contain plasmids encoding single viral ORFs/elements pose a significant hazard to humans. It is possible that certain viral ORFs or elements could provide a growth advantage to cells in culture. However any modest advantage would not overcome immune rejection and these cells would be unable to colonise a human host. It is theoretically possible that endogenous retroviruses could be reactivated through complementation of single ORFs. Most endogenous retroviruses are multiply attenuated and functional endogenous retroviral ORFs are usually present elsewhere in the genome making increased risk from single ORF/element transfection unlikely.

Control measures – assign provisional containment level:

i) consequence/severity of effects: High (possible infection with a virus which is fatal unless treated).

ii) likelihood of effects being realised: Low-Extremely low (infection via occupational exposure to HIV-1 is extremely rare).

iii) overall risk: Low

GM bacteria transformed with plasmids containing viral sequences, reporter genes, other eukaryotic/prokaryotic genes or non-coding sequences for the purpose of preparing DNA (workflows A-F) or purifying protein (workflow F) - Containment Level 1.

Eukaryotic cells containing hazard group 3 modified primate lentiviral sequences (capable of forming infectious virus, or capable of undergoing recombination or minor mutations to form infectious virus - workflows A-D) – Containment
Level 3.

- Containment level 3 and the relevant controls required in the SACGM compendium of guidance together with the additional controls as defined in the attached risk assessment will be used for this work. These controls are detailed in the containment level 3 laboratory Code of Practice and Standard operating procedures. Relevant control measures include, no use of sharps, no use of ultracentrifuges, appropriate personal protective equipment, appropriate use of microbiological safety cabinets and rigorous inactivation/disposal procedures. In addition a specific post exposure prophylaxis (PEP) SOP is in place in case of accidental exposure to HIVs/NHP lentiviruses.

- Eukaryotic cells transfected with plasmids encoding viral ORFs/elements - containment level 2 (workflows E and F).

- Containment level 2 and the relevant controls required in the SACGM compendium of guidance with Good Microbiological Practice and Good Occupational Safety and Hygiene together with the additional controls as defined in the attached risk assessment will be used for this work. Relevant control measures include, appropriate personal protective equipment, appropriate use of microbiological safety cabinets and appropriate inactivation/disposal procedures.

Foreseeable effect/risk assessment for the environment:

HIV-1: Already endemic in the UK and not on any SAPO list. Changes that will be introduced into these virus sequences will be targeted at disrupting or changing specific functions of viral RNA or viral proteins and can be expected to attenuate virus fitness; such changes are highly unlikely to increase virulence as they modify virus sequences, or change genome length, or lead to expression of additional sequences, such as reporter genes, which confer no advantage to virus replication. The modified viruses will not have any inserted foreign genes other than reporter genes (which confer no selective advantage and are not known to be toxic), or sequences from other retroviruses or (usually disruptive) changes in viral genes or non-coding sequences. Changes in viral pathogenesis are therefore unlikely other than as described above under the human health and safety section. In the unlikely event that viral tropism is altered through genetic modification, the decreased fitness of these modified viruses makes them extremely unlikely to pose a risk to the environment. It is difficult to imagine a scenario where modified HIV-1 poses more of a risk to the environment than wild-type endemic HIV-1.

HIV-2: Already present in the UK and not on any SAPO list. Changes that will be introduced into these virus sequences will be targeted at disrupting or changing specific functions of viral RNA or viral proteins and can be expected to attenuate virus fitness; such changes are highly unlikely to increase virulence as they modify virus sequences, or change genome length, or lead to expression of additional sequences, such as reporter genes, which confer no advantage to virus replication. The modified viruses will not have any inserted foreign genes other than reporter genes (which confer no selective advantage and are not known to be toxic), or sequences from other retroviruses or (usually disruptive) changes in viral genes or non-coding sequences. Changes in viral pathogenesis are therefore unlikely other than as described above under the human health and safety section. In the unlikely event that viral tropism is altered through genetic modification, the decreased fitness of these modified viruses makes them extremely unlikely to pose a risk to the environment. It is difficult to imagine a scenario where modified HIV-2 poses a risk to the environment.

NHP lentiviruses: These viruses are not endemic in the UK due to an absence of suitable wild populations of natural hosts (although infections have been documented in captivity), and do not appear on any SAPO lists. These viruses are not transmitted by aerosol and require direct fluid contact with permissive mucosa for transmission to occur underlining the low risk these entities pose to the environment. Changes that will be introduced into these virus sequences will be targeted at disrupting or changing specific functions of viral RNA or viral proteins and can overwhelmingly be expected to attenuate virus fitness; such changes are highly unlikely to increase virulence as they modify virus sequences, or change genome length, or lead to expression of additional sequences, such as reporter genes, which confer no advantage to virus replication. However, although unlikely, some modifications made as part
of workflow D could potentially make NHP lentiviruses more infectious/pathogenic to the human host. If an individual was infected, the virus was able to persist in the human host and was transmissible between humans (3 extremely unlikely properties). These modified viruses could persist in theory persist in the environment.

Hosts:
Prokaryotic organisms: Disabled, commercially available K12 derived E. coli strains. These strains can only survive in a controlled laboratory environment and will be used for propagation of plasmids. Good microbiological practice and sterilisation of all contaminated waste will prevent release of viable organisms. Acquiring antibiotic resistance (from the plasmid vector) or additional sequences (virus or marker gene sequences) will not give these strains any survival advantage in the environment. The risk to the environment is therefore effectively zero.

Eukaryotic cells: Cell lines to be used are not viable outside the laboratory and thus pose no threat to the environment. Addition of plasmid vectors or virus will confer negligible growth or survival advantage in the environment.

In summary
i) consequence/severity of effects: Moderate
ii) likelihood of effects being realised: Extremely Low
iii) overall risk: Low

GM bacteria transformed with plasmids containing viral sequences, reporter genes, other eukaryotic/prokaryotic genes or non-coding sequences for the purpose of preparing DNA (workflows A-F) or purifying protein (workflow F) -
Containment Level 1.

Eukaryotic cells containing hazard group 3 modified primate lentiviral sequences (capable of forming infectious virus, or capable of undergoing recombination or minor mutations to form infectious virus - workflows A-D) – Containment Level 3.
- Containment level 3 and the relevant controls required in the SACGM compendium of guidance together with the additional controls as defined in the attached risk assessment will be used for this work. These controls are detailed in the containment level 3 laboratory Code of Practice and Standard operating procedures. Relevant control measures include appropriate personal protective equipment, appropriate use of microbiological safety cabinets and rigorous inactivation/disposal procedures.

Eukaryotic cells transfected with plasmids encoding viral ORFs/elements - containment level 2 (workflows E and F).
- Containment level 2 and the relevant controls required in the SACGM compendium of guidance with Good Microbiological Practice and Good Occupational Safety and Hygiene together with the additional controls as defined in the attached risk assessment will be used for this work. Relevant control measures include, appropriate personal protective equipment, appropriate use of microbiological safety cabinets and appropriate inactivation/disposal procedures.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Disinfect Lentivirus contaminated material immediately.

Disposable solids (e.g. plasticware such as flasks, tubes, pipette tips etc.)- soak in 1% Virkon (w/v) for a minimum of 12 hours. Transfer solid contents to clear autoclave bags and autoclave at 121°C for a minimum of 20 minutes prior to final disposal by incineration, remaining liquid to be discharged to drain.
Other solids (agar plates, gloves etc.)- placed in a marked box lined with a clear autoclave bag, and disposed of by autoclaving using a make safe cycle of 121°C for at least 20 minutes. Gloves used for lentiviral work should be disinfected with >70% alcohol/ >1% virkon before putting in receptacle for autoclaving. Liquids (e.g. samples, tissue culture media)- add Virkon to final concentration of 1% (w/v) for a minimum of 12 hours followed by autoclaving and then discharge to drains. Liquids (e.g E. coli bacterial growth medium) sterilise with chloros for a minimum of 12 hrs, and then discharge to drains.

Degree of kill:
Chemical Sterilization by Virkon- effectively 100% kill.
Chemical Sterilization with >70% alcohol - effectively 100% kill.
Autoclaving - effectively 100% kill (every run checked and recorded).
Chemical Sterilization by Chloros- effectively 100% kill.

The overall aim of our research is to elucidate the molecular and evolutionary determinants of host range, replication and pathogenicity of influenza viruses. This project involves work on several areas including, epidemiology, mathematical modelling of virus evolution, structural biology, and studies on virus-host interactions and molecular pathogenesis. It is the last aspect i.e. virus-host interactions and molecular pathogenesis with which this application is concerned. Within the CVR, the group of Pablo Murcia will generate the tools to produce recombinant influenza viruses and these viruses will form the basis of the work covered in this application. The work proposed will involve both in vitro, ex vivo infections. Embryonated chicken eggs will also be used as a system for growing some virus stocks.

### Recipient or parental organism

**Parental viruses (non-GMOS from which GMOS would be derived)**

- A/equine/Miami/1963 (H3N8)
- A/equine/Fontainebleau/1979 (H3N8)
- A/equine/Argentina/1995 (H3N8)
- A/equine/Newmarket/1993 (H3N8)
- A/equine/South Africa/2003 (H3N8)
- A/equine/Ohio/2003 (H3N8)
- A/canine/New York/2008 (H3N8)
- A/equine/Mongolia/2009 (H3N8)
- A/wild bird/Mongolia/2009 (H3N8)
- A/wild bird/Mongolia/2010 (H3N8)
- A/wild bird/Mongolia/2011 (H3N8)
- A/swine/England/495/2006 (H1N1)
- A/WSN/33 (H1N1)
- A/Puerto Rico/8/34 (H1N1)
- A/California/04/09 (H1N1)
- A/Brisbane/10/07 (H3N2)

**Recipient organisms:**
Equine influenza virus (EIV) H3N8 (genus Influenzavirus A), and derived recombinant viruses.
Canine influenza virus (CIV) H3N8 (genus Influenzavirus A), and derived recombinant viruses.
Human influenza virus H3N2 and H1N1 (genus Influenzavirus A), and derived recombinant viruses.
Other containment level 2 influenza viruses may be considered as long as they are unrelated to those capable of causing infection of humans.
Reporter systems mimicking Influenza virus replication: Minigenomes of the viruses enumerated above.

**Host/vector system**

**Plasmid vectors:**
Viral sequences (full length clones of Influenza viruses; partial sequences of these and other influenza viruses) and other genes (cellular, viral, reporter) are available in plasmid-encoded cDNA form. RNAs can be transcribed from bacterial promoters (e.g., T7 or SP6 by in vitro transcription or plasmid-expressed RNA polymerase in cells) or eukaryotic promoters (CMV, SV40, cellular promoters, baculovirus promoters etc.). Plasmids for expression of influenza virus sequences (virus rescue or minigenome) typically contain an RNA polymerase I promoter and a hepatitis delta virus ribozyme or a mouse RNA polymerase I terminator. Plasmids contain an origin of replication followed by a prokaryotic selectable marker (usually antibiotic resistance against ampicillin or kanamycin) and sometimes a selectable eukaryotic drug resistance marker such as neomycin or puromycin resistance. The bacterial systems are non-mobilisable vectors in a disabled prokaryotic host.

**Hosts:**

**Prokaryotic hosts:**
Disabled, commercially available E. coli strains such as Sure, JM109, XL-strains, DH-strains, Rosetta etc. These strains can only survive in a controlled laboratory environment and will be used for propagation of plasmids. Good microbiological practice and sterilisation of all contaminated waste should prevent release of viable organisms. The risk to the environment is therefore effectively zero.

**Eukaryotic hosts:**
Vertebrate cell lines of various origins (canine, equine, avian, hamster, bovine, human, etc.), primary cells and explants of various origins (equine and canine).

**Origin & function**

The genetic material to be used in this project will be originated from three sources:
1- Field isolates propagated in embryonated eggs or cell culture.
2- Plasmids containing viral genetic material provided by other researchers.
3- Chemically synthesised plasmids.

The intended functions of the genetic material involved is the production, purification and characterisation of influenza viruses, as well as the production of minigenomes. The viruses produced will be grown in cells and/or embryonated chicken eggs and further used to infect animal and/or human cell lines as well as canine and equine tissue explants and primary cells. To determine the phenotype of infection of a given virus, readouts will include: the capacity for virus replication in tissue culture cells or explants, the ability of the viruses to induce cytopathic effect or histological changes, and the susceptibility of infected cells to apoptosis. If tracheal explants are infected, we will also test for changes in functional attributes such as ciliary beating.

The minigenome systems will be used in vitro. Cells will be transfected with five plasmids encoding the viral polymerase genes and a reporter gene. After transfection cells will be lysed and the activity of the reporter gene (i.e., luciferase activity or fluorescence) will be measured.

**Evaluation of foreseeable effects**

**Foreseeable effects to humans:**

Viruses.
1- Equine and canine influenza viruses have never been associated with human disease in nature. The same applies to the other animal influenza viruses proposed in this
2- Human influenza is typically a mild and self-limiting infection, acquired generally by the respiratory route. Severity depends on the strain of virus and host but in general tends to fall in a spectrum between asymptomatic to ~ 1 week of fever and malaise in otherwise healthy people. Severe illness can occur but is rare, occurring in less than 1% of cases. This level of risk applies to most wild type human H1N1 and H3N2 viruses and to some swine viruses. The laboratory adapted PR8 and WSN strains of H1N1 human influenza are known to be avirulent in man from many volunteer challenge studies as well as a long (> 70 years) history of safe use in the lab. Even seasonal influenza can have potentially serious consequences for anyone who is pregnant, immunosuppressed, asthmatic, or has other respiratory/underlying chronic diseases. Vaccines are available for the circulating human H1N1 and H3N2 strains and the majority of the population has at least some prior immunity to these viruses. The current human influenza vaccine is recommended for all the members of Pablo Murcia’s laboratory handling influenza. Those at risk of severe consequences of influenza (e.g. pregnant women) will be separately notified of the risks of these pathogens immediately after they identify themselves to their PI and occupational health. Individual risk assessments will be carried out governing these specific cases.

3- Reassortant viruses: Reassortants between CIV strains, EIV strains, and between CIV and EIV viruses will not affect their host range. Because CIV is a direct descendant of EIV, the chances that reassortants of these two viruses can infect humans is negligible. Reassortment between either EIV or CIV with human influenza viruses will be done in such a way to avoid the generation of novel antigenic subtypes with the potential to infect humans (such as H1N8, or H3N1 for example).

4- Influenza A virus minigenomes: Minigenomes pose no risk to human health, including those derived from pathogenic influenza A viruses. They cannot propagate on their own. Even if packaged by co-expression of glycoproteins and thus used to infect cells, their own transcriptional activity would be minimal. If packaged into virions, the associated risk is that of the virus itself as reporter genes in minigenomes are not reported to be toxic.

The inserted/donated genetic material.

1- Viral RNA and proteins: Most individually expressed viral proteins are unlikely to have harmful effects in eukaryotic cells, however some could perturb normal cellular metabolism, predispose or protect against cell death or render cells more or less susceptible to other infections if overexpressed or silenced. It is very unlikely that Influenza A virus RNA or proteins would have any harmful toxin-like effect outside cells. Only antigenomic RNA containing an influenza A virus sequence can be translated or give rise to infectious virus (if all necessary genomic information is provided) in eukaryotic cells. Viral non-coding RNA sequences do not encode biologically active molecules that are likely to induce physiological effects in humans on their own. None of the influenza virus gene products are known to be secreted cytotoxins.

2- Reporter genes: no harmful properties have been attributed to reporter genes of prokaryotic or eukaryotic origin (eg luciferase, fluorescent proteins etc.). There would be no altered physiology expected if any of these genes were expressed; eGFP for example is a spontaneously fluorescent protein isolated from Aequorea victoria, a coelenterate and has no known detrimental effects. Luciferase is another commonly used reporter gene and is derived from the firefly Photinus pyralis or the jellyfish Renilla reniformis. It is an enzyme which catalyses production of light from luciferin and ATP; the light produced is used as a measure of gene activity. The enzyme has no other biological function.

3- Sequence changes in viral sequences: Mutation or deletion will target disruption of structural and non-structural protein functions or non-coding viral sequences and are likely to have no deleterious effects on viral replication, thus not increasing risk or hazards to human health associated by viruses genetically modified in such a way.

Foreseeable effects to the environment:

Viruses

1- Equine influenza virus (EIV) has been endemic in the UK for over 40 years and is not on SAPO or ACDP lists. There is a vaccine available for EIV, although most horses have natural immunity due to vaccination or natural infections.

2- Canine influenza virus (CIV) is not thought to be endemic in the UK, and it is not on the SAPO list. In fact, it is not highly transmissible in the only country in which is endemic (USA). Transmission is common only in highly dense dog populations such as those found in animal shelters. Experimental infection results in mild respiratory...
disease. Serological evidence of infection in British foxhounds has been shown, although no outbreaks have been associated with it. Given the low transmissibility and low pathogenicity of CIV, the chance of accidentally infecting dogs initiating a transmission cycle sustained by local dogs is negligible.

3- Human influenza viruses: Currently circulating human influenza A viruses (pdm H1N1, seasonal H1N1, and H3N2) are globally distributed, there are available vaccines, and the majority of the population has at least some prior immunity to these viruses. Antivirals such as oseltamivir and zanamivir are also available. Currently circulating human H1N1 virus can infect swine and is endemic in this species. There are no reports of animal disease caused by human influenza viruses (with the exception of swine).

4- Reassortant viruses: Reassortants between CIV strains, EIV strains, and between CIV and EIV viruses will not affect their host range and thus will have the same risk as the parental viruses if not lower. As described above, reassortment between either EIV or CIV with human influenza viruses will be done in such a way to avoid the generation of novel antigenic subtypes to which human and animal populations have no prior immunity.

5- Minigenomes do not pose any risk to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disposable solids (eg plasticware such as flasks, tubes, pipette tips etc.): soak in 1% Virkon (w/v) for a minimum of 12 hours. Transfer solid contents to clear autoclave bags and autoclave at 121°C for a minimum of 20 minutes prior to final disposal by district council to land fill, remaining liquid to be discharged to drain.

Other solids (agar plates, gloves etc.): placed in a marked box lined with a clear autoclave bag, and disposed of by autoclaving using a make safe cycle of 121°C for at least 20 minutes. Seal contaminated plates (with for example bacterial GMOs) before placing in bag, to avoid lid falling off. Gloves used for influenza virus work should be disinfected with alcohol before putting in containers.

Eggs- after harvesting virus within the safety cabinet, eggs are to be placed in small autoclavable red bags containing paper towel to absorb any fluid coming from the egg. These bags are to be placed in secondary autoclavable bags and autoclaved prior to disposal as regular waste.

Liquids (eg. samples, E. coli culture media, tissue culture media): add Virkon to final concentration of 1% (w/v) for a minimum of 12 hours, then discharge to drains.

Sharps (eg needles, syringes, scalpels): decontaminate in 1% Virkon overnight then place in sharps bin for incineration.

Degree of kill:
Chemical Sterilization by Virkon: effectively 100% kill.
Autoclaving: effectively 100% kill (annual validation).

purposes of the contained use

Arboviruses are transmitted to susceptible vertebrates by arthropod vectors such as mosquitoes. Most arboviruses belong to the Flaviviridae, Bunyaviridae and Togaviridae families of RNA viruses. The interactions between arboviruses and their vectors are highly complex. Arboviruses first come into contact with the mosquito midgut following blood-meal, and must infect arthropod tissues, replicate and spread to the salivary glands from where they can be transmitted to vertebrates via saliva after bite. Through these stages,
arboviruses rely on host factors to support replication but are also confronted to the immune system of the host, summarised in [1-3]. Research on antiviral immune responses in vector arthropods has only in recent times seen some progress yet this area of research is crucial in understanding this virus/host interaction and develop novel antiviral control strategies targeting the vector. It is now clear, mainly from research on arbovirus-infected mosquitoes, that vectors do not passively replicate arboviruses but that immune responses are activated. These can result in activation of immune signalling pathways (STAT, Toll etc.), humoral responses in the arthropod hemocoel and most crucially RNA interference (RNAi) responses. It is not known how immune signalling pathways are activated following infection or how exactly they would mediate antiviral activities, and extracellular responses such as phenoloxidase activities also appear to be involved. The RNAi responses are better understood and form a major antiviral defence. In particular the exogenous RNAi and piRNA pathways are increasingly well studied, and some of the proteins such as Ago, Dicer and Piwi identified. In addition, mostly yet unidentified arthropod host proteins (by extrapolation from work on vertebrates [4]) are likely to contribute to virus entry, replication, exit and potentially spread.

Sequencing of the the genome of several vector species such as Aedes aegypti, Culex quinquefasciatus as well as Anopheles gambiae (https://www.vectorbase.org/) and novel genetic modification techniques (sometimes following adaptation from Drosophila melanogaster) allow the study of gene function in vivo. Among genetic modification techniques, site specific endonucleases such as TALENs, CRISPR-based gene knock out/knock in systems as well generation of mosquito lines with tissue specific transgenic promoters (see [5-8] and references therein) have advanced considerably. These techniques are all based on injection of mosquito embryos with either expression constructs and/or other nucleic acids that mediate recombination, insertion/deletion etc into the host genome. This allows completely new insights into mosquito gene function, in the context of viral infection and beyond. Moreover, transient gene silencing techniques based on RNA interference can be used to study gene function. This approach is based on treating mosquitoes (mainly through injection) with dsRNA against a target gene, inducing a RNAi response and target degradation [9-11].

In this project, we aim to further analyse mosquito gene functions by:

1/ Mosquito transgenics engineeing by targeted deletion or insertion of sequences using molecular biological methods by use of recombination/insertion based methods (PhiC31 integrase, Retrotransposons, TALENs, CRISPR technology etc.).
   * Deletions will be genes or non-coding sequences involved in mosquito immunity or physiology and in virus-host interactions.
   * Insertions will include:
     - Non-coding sequences such as viral sequences or promoter/regulatory regions of genes that are expressed in a tissue specific manner, or non-specifically in several/all tissues.
     - Reporter genes (luciferase, fluorescent proteins etc.) to follow physiological processes and to identify transformants as well as follow genetic inheritance.
     - Genes potentially conferring resistance to arbovirus, interfering with arbovirus replication, or genes linked to mosquito processes that are linked to virus replication (including viral genes) or physiological processes.
     - Inverse repeat constructions (or similarly aimed sequences) of mosquito genes to knock down their expression.

The vectors/nucleic acids used will be modified forms of phiC31 integrase or Cas9 that are supplied in the initial creation of lines by micro-injection of embryos. These exogenous integrase/nucleases are lost during the first generation and so the inserted/modified DNA sequences are effectively immobilised in the subsequently established transgenic lines.

Progeny of adults surviving the injection procedure are screened by fluorescence microscopy to identify stable transgenic lines which are then maintained and assayed for relevant phenotypes. These will include changes in arboviral susceptibility/immunity and mosquito fitness and physiology, as well as expression of reporter genes,

2/ Targeted transient silencing of mosquito genes (immune genes, genes involved in virus-host interaction or general physiology) by dsRNA injection and subsequent RNAi induction. Adults surviving to the injection will be assessed for relevant phenotypes like arboviral resistance/susceptibility, mosquito fitness and physiology.

Mosquito species considered here are:
Ae. aegypti (including laboratory strains such as Liverpool red eye, Higgs white eye etc), or related species such as Ae. albopictus, Ae. vexans from tropical or temperate regions.
An. gambiae (including laboratory strains such as Kisumu etc) and related species such as funestus, arabiensis etc from tropical or temperate regions.

As a general rule, we consider as laboratory strains mosquitoes bred and maintained under standard conditions in a containment level 2 laboratory setting.

Origin & function
In the context of this proposal, the following nucleic acid sequences will be introduced into mosquitoes (embryos, adults).

- Plasmids or cDNA constructs containing sequences for: 1) mosquito proteins involved in immune responses, virus-host interactions, physiological processes; 2) viral proteins; 3) reporter genes or other markers genes (luciferases, fluorescent proteins); 4) enzymes and proteins mediating recombination into and out of the mosquito genome; 5) sequences that can be transcribed into RNA (including hairpins to induce gene silencing).

- Double-stranded RNAs: short siRNAs (approximately 14-30 nucleotides) or longer dsRNAs (approximately 30-600 basepairs) targeting cellular or viral RNA for
degradation, or control dsRNAs/siRNAs.

- ssDNA or ssRNA for example for use with the CRISPR system.

Techniques used to introduce nucleic acids into mosquitoes: microinjection into mosquito body cavity or embryos, or introduction into midgut via feeding.

Evaluation of foreseeable effects

Foreseeable effects/risk assessment for human health and safety:

Plasmid vectors and cDNAs:
Mosquito, or viral sequences, protein or coding or non-coding are available in plasmid-encoded cDNA form. Plasmid vectors are based on bacterial plasmids and contain an origin of replication for prokaryotic cells and selectable antibiotic/drug resistance (pro- or eukaryotic) markers. By themselves these vectors present no risk to human health. Vectors have no selective advantage and would soon be lost from the bacterial population. The bacterial systems are non-mobilisable vectors in a disabled prokaryotic host. Systems for eukaryotic RNA or protein expression are under the control of promoters of eukaryotic (eg actin promoter, tissue specific or pathway inducible) or prokaryotic (such as T7 or SP6 promoter for in vitro transcription) origin. Plasmids with eukaryotic promoters may be transcribed in human cells. None of the genes used in these studies are known oncogenes. The hazard of expressing ‘foreign’ genes from these eukaryotic promoter plasmids would depend on the expected physiological effects of the gene product.

Recipient organisms:

Prokaryotic organisms: All strains will be disabled, commercially available E. coli derivatives classified as ‘especially disabled hosts’ by ACDP. These strains cannot colonise humans and are known not to cause harm to humans.

Mosquitoes (also see paragraph 8, below): Mosquitoes of the species indicated above are obtained from colonies in the UK or abroad. Precautions will be taken to minimise the risk of bites or escapes in strict compliance with standard operating procedures (attached separately). Measures to prevent human bites include storage of arthropods in sealed containers; work in designated rooms with restricted access; wearing of gloves and cooling or CO2 or chemical treatment of arthropods to slow their movement and facilitate handling according to standard operating procedures for CL2 (see attachment). Samples (material from dead arthropods) will be transported to our CL2 laboratory according to standard regulations for transport of samples.

Mosquitoes act as vectors to transmit disease between reservoirs and new hosts. Some GMs will reduce the vectorial capacity of the insect, however some modifications may increase the prevalence and intensity of a virus infection in the mosquito. The risk of a mosquito becoming accidentally infected with an arbovirus following escape is very low. Virus stocks are kept in freezers and infected cells within containers (cell culture flasks etc) and incubators, making it physically impossible for the mosquito to become infected. Arboviruses are enveloped viruses, and if incubated in decontaminating solution such as Virkon these are usually inactivated rapidly; moreover the mosquitoes are unlikely to survive a feed on solutions containing decontaminating agents.

The hazard of short lived escapees being a biting pest is high, but the consequences of the modification alone are negligible and similar to native mosquitoes and other hematophagous insects especially as there are no known mosquito-borne arboviruses present in Scotland. As with non GM uninfected mosquitoes, there is a biting hazard of uninfected GM mosquitoes accidentally released into the insectary. GM modifications are highly unlikely to add to the risk as and mentioned above, the risk of mosquitoes becoming accidentally infected is negligible: the consequence of this biting hazard is effectively zero and is no different to non GM mosquitoes. Precautions will be taken to minimise the risk of bites or escapes with the use of UV light traps traps where adult mosquitoes are manipulated and in strict compliance with Standard Operating Procedures (attached separately). The room housing the GM mosquitoes as well as non GM mosquitoes has a double door/gate system, with a badge access to authorized persons only. Dissection as well as injection of mosquitoes (for germline transformation or transient RNAi), and with nucleic acids will take place in specified rooms in strict compliance with standard operating procedures (attached separately). Decontamination procedures are detailed further in the SOP (attached separately).

This has been detailed further below.
Risk to human health depends on the nature of the genetic material inserted or deleted:

Most individually expressed or silenced viral or cellular proteins (for example immunity proteins, including regulators such as activators or inhibitors) or nucleic acid sequences (for example, silencing inducers targeting virus or host proteins, other small RNAs such as miRNA precursors etc.) in transgenic mosquitoes, or dsRNA injected into mosquitoes to degrade target sequences are unlikely to have direct harmful effects in eukaryotic cells, however some could perturb normal arthropod metabolism. It is very unlikely that any such RNA or proteins would have any harmful toxin-like effect outside cells. Transgenic mosquitoes as such are unlikely to pose any additional risks to human health. This analysis excludes transgenic mosquitoes expressing reporter genes of prokaryotic or eukaryotic origin (eg luciferase, fluorescent proteins etc.). No harmful properties have been attributed to these proteins. There would be no altered physiology expected if any of these genes were expressed; eGFP for example is a spontaneously fluorescent protein isolated from Aequorea victoria a coelenterate and has no known detrimental effects. Luciferase is another commonly used reporter gene and is derived from the firefly Photinus pyralis or the jellyfish Renilla reniformis. It is an enzyme which catalyses production of light from luciferin and ATP; the light produced is used as a measure of gene activity. The enzyme has no other biological function. These genes are improbable in our experience to affect mosquito physiology and virus replication.

Foreseeable effect/risk assessment for the environment:

Hosts:

Prokaryotic organisms: Disabled, commercially available E. coli strains. These strains can only survive in a controlled laboratory environment and will be used for propagation of plasmids. Good microbiological practice and sterilisation of all contaminated waste will prevent release of viable organisms. Acquiring antibiotic resistance (from the plasmid vector) or additional sequences (virus or marker gene sequences) will not give these strains any survival advantage in the environment. The risk to the environment is therefore effectively zero.

Mosquitoes: Some anopheline and aedine mosquitoes are distributed throughout Britain, or parts of Britain. The aedine and anopheline species we intend to use are more suited to tropical and temperate climates however and are not likely to interbreed with any local species. They are not likely to survive or breed outside the laboratory regardless of genetic modification. We estimate that outside the CL2 facility in the surrounding building and facilities, escaped mosquitoes could survive for one to several days but the lack of humidity and water sources is likely to reduce any chances of survival. Outside the building their chances of survival are low, given the relatively cold climate in the surrounding areas throughout the year and we would also not expect mosquitoes to survive for longer than one or several days.

In summary:
* The hazard of short lived escapees being a biting pest is high, but the consequences are negligible and similar to native mosquitoes and other hematophagous insects. GM modification would not increase this potential and would most likely decrease it and thus the risk is effectively zero.
* There are no known sexually compatible species in the UK for anopheline and aedine and so potential for gene spread is virtually non-existant. GM modification would not increase this potential.
* Biologically active products produced by the GM mosquitoes will be in such small amounts that any direct risk is effectively zero.
* GM mosquitoes have been shown to be genetically stable and loss of GM would be extremely unlikely to increase any potential hazards over the reversion to wild type.
* None of the GMs are expected to change the behaviour of the mosquito and make them more aggressive biters.
* Some GM in the mosquito genome may influence ability to transmit and competence for a given arbovirus. However there infectious material is stored in closed containment and thus not accessible for mosquitoes.
* Risk of escape is minimised by manipulating adults in a closed environment (CL2 insectary). Rooms where adult mosquitoes are manipulated also contain UV light traps. Moreover, sinks are either covered up or contain filters to avoid any eggs escaping through the drains.
* GM mosquitoes will have a GFP genetic markers that can be used to distinguish GM strains and others mosquitoes either visually (GFP expression). Strain genetic background can also be checked by PCR in order to control different GM lines. This will be carried out at regular intervals as part of strain housekeeping.
i) consequence/severity of effects; aedine/anopheline GM mosquitoes: low.

ii) likelihood of effects being realised: Low

iii) overall risk: Medium

All with Good Microbiological Practice and Good Occupational Safety and Hygiene as outlined in Standard Operating Procedure.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Maintenance of GM mosquitoes, or injection with dsRNA will take place in a dedicated insectary at Containment Level 2 (CL2). A standard operating procedure (SOP) as described below has also been added separately. RNA and proteins or other cellular material will be isolated from crushed mosquitoes where sample isolation is required. Live mosquitoes may be monitored by microscopy. GM mosquitoes will be maintained and studied inside closed containers. In addition wingless mosquitoes may be used where removal from containment is required.

THIS EXCLUDES MICROINJECTION OF MOSQUITO EMBRYOS WITH NUCLEIC ACIDS OR PROTEINS AS THESE ARE IMMOBILE AND POSE NO RISK.

MOSQUITO CONTROL MEASURES APPLY FOLLOWING INCUBATION OF EMBRYOS FOR HATCHING.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids (pipettes tips, gloves etc.)- place in container (lined with sealed bag), where necessary (see SOP) place in freezer overnight to kill mosquitoes, and dispose of by
autoclaving using a make safe cycle of 121-123°C for 30 minutes.

Arthropod-derived material such as the remains of mosquitoes will be placed in a sealed container (lined with clear bag), where necessary (see SOP) placed in a freezer overnight to kill mosquitoes, and disposed of by autoclaving using a make safe cycle of 121-123°C for 30 minutes.

Liquids (eg. samples) – dispose of by autoclaving using a make safe cycle of either 121-123°C for 30 minutes.

Degree of kill: Autoclaving - effectively 100% kill (annual validation).

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID 223/15.2a
Date of Significant Change 23/06/2020

Project Additional Information

Purposes of the contained use

The measurement of humoral immunity (virus neutralising antibodies, VNA), viral cell tropism (e.g. receptor usage), cellular immunity (e.g. the introduction of viral proteins into target cells for ELISpot) and pathogenicity (e.g. the measurement of restriction factor activity in target cells).

Recipient or parental organism

Multiply disabled E.coli host strains

Host/vector system

Retroviral, rhabdoviral and adenoviral vectors prepared in HEK293/293T cells. The choice of system to be used for the generation of viral pseudotypes for the measurement of virus neutralising antibodies/viral entry is somewhat empirical. Thus, while a retrovirus-based system is preferred for lentiviral Env bearing pseudotypes, a rhabdoviral-based system works better for morbilliviral envelope glycoproteins. It is standard practice to compare different vector systems for the most suitable combination of packaging construct, transfer vector and Env expression vector. Because the biology of envelope incorporation is incompletely understood, our list of vector systems employed includes several variants of pseudotyping systems, thus increasing the likelihood that pseudotyping will be successful.

Origin & function

Evaluation of foreseeable effects

The nature of the envelope glycoprotein expressed on the surface of the pseudoparticles has little effect on the hazard associated with the pseudotypes, the primary difference is in the cell tropism, stability and titre of the pseudotypes produced. Thus murine leukaemia virus (MLV) particles bearing a vesicular stomatitis virus G protein (VSV-G) have a broader tropism (infect cells from many species) and are more stable than MLV particles bearing an ecotropic MLV envelope glycoprotein (will only infect murine cells). Similarly, rhabdovirus pseudotypes appear to be the most stable and efficient means of expressing morbillivirus glycoproteins. They have the highest titre and have the highest likelihood of introducing the foreign gene into recipient cells. As the pseudotypes are designed to express green or red fluorescent proteins (GFP or DSRed), luciferase (luc) or an enzyme such as β-galactosidase (lacZ), the risks to the experimenter and associated laboratory workers are very low. In essence, the aim of pseudotype based projects is to study viral biology and immunology without the requirement for handling replication competent virus. The pseudotyping system is, in essence, a protein-wrapped delivery sytem for a marker gene. While the origin of the vectors alters the efficiency of gene uptake into the target cells, the foreseeable risks are very similar and extremely low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All experiments involving the generation of, or infection with replication defective retroviral, rhabdoviral or adenoviral vectors encoding marker genes such as EGFP, RFP, DSRed or luc will be performed in Class II microbiological safety cabinets in the Retrovirus Research Laboratory. All liquid wastes are discarded into Virkon solution while

02/03/2022
solid wastes (cell culture plasticware etc.) are autoclaved. There is no foreseeable risk of environmental damage involved in these studies.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid and solid wastes will be incubated overnight with Virkon >1000 ppm chlorine prior to disposal. Following overnight incubation in Virkon, all cell culture plasticware will be autoclaved prior to ultimate disposal.

CU2 Project Title Bunyavirus reassortment and tropism

Class 3

CultureVolClass2 < 1 Litre

Consent Granted Yes

Date Project Ceased

CU2 Project Class CultureVol Class3-4

Page 5418 of 15326
The three segmented genome of bunyaviruses (L, M, S) allows these viruses to enhance their genetic potential by reassortment eg a re-shuffling of segments between strains of the same virus species or between closely related species to give raise to new types of bunyaviruses, which can for example influence tropism and virus host interactions by placing M segment encoded glycoproteins into a new genetic background. In this project reassortment between orthobunyaviruses and the consequences thereof, will be investigated. We will also investigate properties of the M segment eg sequence properties and properties of M segment proteins/glycoproteins by swapping sequences and/or domains between orthobunyavirus M segments.

Reassortant orthobunyaviruses, or orthobunyaviruses with mutated M segment sequences (affecting non coding or coding sequences such glycoproteins, non-structural proteins as described below) produced from hazard group 2/ACDP2 bunyaviruses. Use of these viruses and derived reverse genetics systems is notified as described above. This includes the viruses Bunyamwera (BUNV), Schmallenberg (SBV), Akabane (AKAV), Kairi (KRIV), Bwamba (BWV) and Cache Valley (CVV).

Recipient or parental organism

Reassortant orthobunyaviruses, or orthobunyaviruses with mutated M segment sequences (affecting non coding or coding sequences such glycoproteins, non-structural proteins as described below) produced from hazard group 2/ACDP2 bunyaviruses. Use of these viruses and derived reverse genetics systems is notified as described above. This includes the viruses Bunyamwera (BUNV), Schmallenberg (SBV), Akabane (AKAV), Kairi (KRIV), Bwamba (BWV) and Cache Valley (CVV).

Host/vector system

Prokaryotic hosts:
Disabled, commercially available E. coli strains such as Sure, JM109, XL-strains, DH-strains, Rosetta etc. These strains can only survive in a controlled laboratory environment and will be used for propagation of plasmids. Good microbiological practice and sterilisation of all contaminated waste should prevent release of viable organisms. The risk to the environment is therefore effectively zero.

Eukaryotic hosts:
Vertebrate cell lines of various origins (typically human, mouse, hamster, bovine etc.) and invertebrate cell lines of various origins (mosquito, culicoides, tick etc.). The vertebrate BSR-T7/5 cell line (derived from BSR, a clone of BHK) (Buchholz et al., 1999) express T7 RNA polymerase and will be used for virus rescue (infectious virus cDNA clones under control of a T7 promoter), as may similar cell lines expressing T7 RNA polymerase. 

Expression systems/cloning systems:
Plasmid vectors:
Viral sequences (full length cDNA clones of viral genomes or genome segments) are cloned into plasmids for genetic manipulation and propagation. RNAs can be transcribed from plasmids through bacteriophage promoters (ie. T7 or SP6 by in vitro transcription or plasmid-expressed RNA polymerase in cells) or other systems that are not usually transcriptionally functional on their own in eukaryotic cells. Plasmids contain an origin of replication followed by a prokaryotic selectable marker (usually antibiotic resistance against ampicillin or kanamycin). The bacterial systems are non-mobilisable vectors in a disabled prokaryotic host.

Origin & function

Origin of genetic material: hazard group 2 orthobunyaviruses Bunyamwera (BUNV), Schmallenberg (SBV), Akabane (AKAV), Kairi (KRIV), Bwamba (BWV) and Cache Valley (CVV). Reverse genetics systems and cDNA clones for these viruses are available and serve as source.

02/03/2022
Description of activities:
These experiments will only be carried out with the hazard group 2 viruses Bunyamwera (BUNV), Schmallenberg (SBV), Akabane (AKAV), Kairi (KRIV), Bwamba (BWV) and Cache Valley (CVV).

The following experiments will be carried out:
- Reassortment between orthobunyaviruses either by co-infection or by virus rescue techniques.
- Mutations in M segment sequences: shuffling/exchange of M sequences (for example glycoprotein sequences/domains) between orthobunyaviruses.

This includes production of such viruses which also carry attenuating mutations in the L or S segments, such as viruses in which the virulence factors such as NSs have been removed or viruses with tagged L proteins.

We expect such viruses to mirror the pathogenicity of the parent hazard group 2 viruses, but examples such as Ngari virus show that this may not be the case and precautionary principle applies in experiments that potentially alter the tropism and properties of the resulting viruses.

Risk associated with these novel orthobunyaviruses:
Bunyaviruses with potentially altered host or tissue tropism could potentially be infectious through aerosol, in addition to arthropod bite (natural route of transmission) or accidental inoculation. Changes in glycoprotein sequences can potentially affect tissue tropism and this could potentially include immune cells or other cells relevant in fighting orthobunyavirus infections, or tissues that are not usually targets but which usually control these viruses in humans, or tissues not usually affected by orthobunyaviruses. These may for example include epithelial cells in blood vessels, but also developing foetus etc. Thus, there might be an increased risk to human health from viruses described above unless they carry attenuating mutations such as NSs deletion. Moreover it cannot be excluded that aerosol transmission can take place with such altered orthobunyaviruses.

Risks to the environment:
Reassortment and changes in glycoprotein or other M coding sequences (sequence exchanges) can potentially lead to changes in virulence and pathogenicity. Again precautionary principle applies also with regards to risk to the environment, although vector specificity of reassortants or glycoprotein mutants produced as described, is likely to be similar to that of the parent virus. AKV: this virus infects animals and is closely related to SBV and also transmitted by midges and mosquitoes. BWV: again this pathogen, known to cause mild infections in humans in parts of Africa, can be transmitted by a variety of mosquitoes and is known to circulate across parts of Africa (East, West, Central). KRIV: this virus causes infections in animals and is transmitted by mosquitoes. CVV: infects humans and animals and is transmitted by various mosquitoes. In our laboratories, the risk of accidental infection of insects by ingestion of contaminated material is low and the likelihood of virus released from our laboratory infecting local vectors is effectively zero (see disinfection and waste disposal procedures). As for Rift Valley fever virus for example, advice will be given to lab personnel that they should not be in contact with susceptible animals or visit farms/zoos where they could potentially come into contact with susceptible species for a period of 48 hours following work with the viruses above. A form to this effect will be signed by staff working on these viruses. As stated above, in our laboratories, the risk of accidental infection of insects by ingestion of contaminated material is low and the likelihood of virus released from our laboratory infecting local vectors is effectively zero (see disinfection and waste disposal procedures). The risk to the environment is effectively zero.

Changes in host range:
It is possible, going by current understanding of orthobunyaviruses that changes as those described above (reassortant viruses or viruses with swapped M segment sequences or domains obtained from related viruses) show altered host range compared to parent viruses. M segment are likely determinants of host range, though possibly not the only ones. Therefore such a possibility needs to be taken into account.

Changes in tropism:
Again it is possible, going by current understanding of orthobunyaviruses that changes as those described above (reassortant viruses or viruses with swapped M segment sequences or domains obtained from related viruses) are different from parent viruses and show altered tissue tropism. M segment are likely determinants of host range as well as tissue tropism, though again possibly not the only ones. Therefore such a possibility needs to be taken into account.

Alteration of physical and chemical properties of virions:
This is highly unlikely; the M segment proteins of all orthobunyaviruses are likely to behave very similarly with regards to physical and chemical properties, and exchanging
these is unlikely to alter these.

Reversion to wild type:
Reassortant viruses are highly unlikely revert to parent virus, given the number of mutations required to achieve this. The same conclusions is true for mutations in the M segment, as only point mutations are likely to revert. In any case, the parent viruses are classed as hazard group 2 viruses and as such reversion would again attenuate the virus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
The policy of the laboratory is to assume that materials are "infectious" unless they are specifically known to be otherwise.

All liquid and solid waste is to be decontaminated chemically using >1% Virkon solution before sterilisation by autoclaving. Barrycidal is used for routine disinfection as a spray. When handling protein rich liquid, Virkon powder should be added to give a final concentration of not less than 1%.

(a) Wastes from within the Microbiological Safety Cabinets

Paper waste within the hood shall be sprayed with disinfectant and placed in an autoclave bag within a metal bin for autoclaving. Solids which can be submerged will be soaked overnight in disinfectant (Virkon), disposable plastic pipettes will be soaked overnight in pans containing a disinfectant bath (Virkon), and subsequently autoclaved. Fluids containing potentially infectious will be soaked overnight with disinfectant (Virkon) in large sealed plastic bottles (opened during autoclaving) that are sterilised by autoclaving.

Sharps which arise inadvertently or glass slides /coverslips will be placed in metal bins or plastic beakers of disinfectant and labelled clearly and ultimately autoclaved.

(b) Wastes from outside the Microbiological Safety Cabinets

Other waste generated within the room including soiled protective clothing will be sterilised by autoclaving.

Autoclaving conditions:
Dry waste (porous dry load cycle):
This type of waste will be autoclaved with a chamber control temperature of 123°C and a sterilisation temperature of 121°C for 40 minutes. In order to ensure efficient ingress of steam into mixed solid waste materials (e.g. plastics, gowns, gloves, paper*), and to encourage drying of the load, autoclave programming includes vacuum purge cycles.

*Cardboard may release gases during heating that will prevent efficient sterilisation. To ensure efficient sterilisation, cardboard should be autoclaved separately from other dry materials.

Liquid waste:
This type of waste will be autoclaved with a chamber control temperature of 123°C and a sterilisation temperature of 121°C for 40 minutes. Loads containing liquids will be autoclaved separately from solid wastes. The cycle will run in absence of vacuum and has a fixed cooling period at the end of the cycle.
Degree of kill: Chemical Sterilization by Virkon/Barrycidal- effectively 100% kill. Autoclaving - effectively 100% kill (annual validation).

Historical Significant Changes
**Project Additional Information**

**Purposes of the contained use**

The objective of this project is to identify important host and viral determinants of cross-species transmission. We will investigate the ability of interferon stimulated genes (ISGs) of a variety of animal species to restrict replication of a range of important human and animal DNA and RNA viruses of HG 2 and 3. This will allow us to (i) define patterns of antiviral restriction by “homologous” and “heterologous” ISGs; (ii) to assess the risk of future cross-species transmission events and (iii) to identify novel antiviral genes.

**Recipient or parental organism**

DNA and RNA viruses of Hazard Group 2 and 3 will be grown from pre-existing stocks or rescued by reverse genetics that express fluorescent markers like GFP, RFP or luciferase or other markers like HA, V5, iLov. Viruses lacking structural and non-structural proteins will also be grown from pre-existing stocks or rescued by reverse genetics to produce viral like particles, attenuated mutants or replication incompetent viruses. We expect these modifications not to alter the replication, transmission or tropism of the resulting modified viruses. If any the modifications would result in attenuated viruses.

**Host/vector system**

Viruses: DNA and RNA viruses of hazardous groups 2 and 3 modified to express tag markers like GFP and luciferase among others and point mutant and deletion viruses to generate viral like particles, attenuated mutants or replication incompetent viruses.

Prokaryotic hosts:

Disabled, commercially available E. coli strains such as Sure, JM109, XL-strains, DH-strains, Rosetta etc. These strains can only survive in a controlled laboratory environment and will be used for propagation of plasmids.

Eukaryotic hosts:

Vertebrate cell lines of various origins (typically human, mouse, hamster, bovine etc.) and invertebrate cell lines of various origins (mosquito, culicoides, tick etc.).

**Origin & function**

Viruses will either be obtained from original stocks or by reverse genetics techniques using nucleic acids.

**Evaluation of foreseeable effects**

Description of activities:

The project consists of two stages, both involving the use of pathogens of Hazard Group (HG) 2 and 3. Essentially the same experimental protocols will be used but the
containment level used will be defined according to the virus HG.

Stage 1: ISGs will be overexpressed in target cell lines by means os transduction with lentiviruses. 48 hours post transduction the transduced cells will be infected with GFP or luciferase tagged DNA or RNA viruses of HG 2 and HG3. At specific times post infection cells will be fixed and viral replication estimated by quantification of GFP/luciferase signal by FACs.

Stage 2: In stage 1 we will identify ISGs that impaired viral replication. This information will be used in stage 2 to understand the molecular mechanisms of viral restriction for a group of viruses of interest (HG 2 and 3). This will include overexpression of specific wild type and mutant ISGs and assessing replication of wild type and mutant viruses as in stage 1.

Because of the unknown nature of the antiviral candidates, viral sensitivity determinants and possible viral countermeasures (we don't yet know which viruses will need to be tested in 12 months time) this risk assessment is deliberately general to allow us to respond rapidly and appropriately to novel observations.

Risk associated with these novel viruses:
Viruses will be rescued by reverse genetics to express fluorescent markers like GFP, RFP or luciferase or other markers like HA, V5, iLov. Viruses lacking structural and non-structural proteins will also be rescued by reverse genetics to produce viral like particles, attenuated mutants or replication incompetent viruses. We expect these modifications not to alter the replication, transmission or tropism of the resulting modified viruses. If any the modifications would result in attenuated viruses.

Risks to the environment:
Reassortment and changes in glycoprotein or other M coding sequences (sequence exchanges) can potentially lead to changes in virulence and pathogenicity. Again precautionary principle applies also with regards to risk to the environment, although vector specificity of reassortants or glycoprotein mutants produced as described, is likely to be similar to that of the parent virus. For viruses of livestock advice will be given to lab personnel that they should not be in contact with susceptible animals or visit farms/zoos where they could potentially come into contact with susceptible species for a period of 48 hours following work with the viruses above. A form to this effect will be signed by staff working on these viruses. As stated above, in our laboratories, the risk of accidental infection of insects by ingestion of contaminated material is low and the likelihood of virus released from our laboratory infecting local vectors is effectively zero (see disinfection and waste disposal procedures). The risk to the environment is effectively zero.

Changes in host range and tropism:
Due to the size of the foreing markers to be introduced it is unlikely that changes in tropism and host range occur. In any case we expect the modified viruses to have reduced infectivity and narrower host ranges and tropism.

Reversion to wild type:
Reassortant viruses are highly unlikely revert to parent virus, given the number of mutations required to achieve this.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

HG 2 viruses will be handled in CL2 facilities under the following rules:
Disposable solids (e.g., plasticware such as flasks, tubes, pipette tips etc.)- soak in 1% Virkon (w/v) for a minimum of 12 hours. Transfer solid contents to clear autoclave bags and autoclave at 121°C for a minimum of 20 minutes prior to final disposal by district council to landfill, remaining liquid to be discharged to drain.

Other solids (agar plates, gloves etc.)- placed in a marked box lined with a clear autoclave bag, and disposed of by autoclaving using a make safe cycle of 121°C for at least 20 minutes. Seal contaminated plates (with for example bacterial GMOs) before placing in bag, to avoid lid falling off. Gloves used for bunyavirus work should be disinfected with alcohol before putting in containers.

Liquids (e.g., samples, E. coli culture media, tissue culture media)- add Virkon to final concentration of 1% (w/v) for a minimum of 12 hours, then discharge to drains.

HG 3 viruses will be handled in CL3 facilities under the following rules:

The policy of the laboratory is to assume that materials are "infectious" unless they are specifically known to be otherwise.

All liquid and solid waste is to be decontaminated chemically using >1% Virkon solution before sterilisation by autoclaving. Barrycidal is used for routine disinfection as a spray. When handling protein rich liquid, Virkon powder should be added to give a final concentration of not less than 1%.

(a) Wastes from within the Microbiological Safety Cabinets

Paper waste within the hood shall be sprayed with disinfectant and placed in an autoclave bag within a metal bin for autoclaving. Solids which can be submerged will be soaked overnight in disinfectant (Virkon), disposable plastic pipettes will be soaked overnight in pans containing a disinfectant bath (Virkon), and subsequently autoclaved. Fluids containing potentially infectious will be soaked overnight with disinfectant (Virkon) in large sealed plastic bottles (opened during autoclaving) that are sterilised by autoclaving.

Sharps which arise inadvertently or glass slides/coverslips will be placed in metal bins or plastic beakers of disinfectant and labelled clearly and ultimately autoclaved.

(b) Wastes from outside the Microbiological Safety Cabinets

Other waste generated within the room including soiled protective clothing will be sterilised by autoclaving.

Autoclaving conditions:

Dry waste (porous dry load cycle):
This type of waste will be autoclaved with a chamber control temperature of 123°C and a sterilisation temperature of 121°C for 40 minutes. In order to ensure efficient ingress of steam into mixed solid waste materials (e.g. plastics, gowns, gloves, paper*), and to encourage drying of the load, autoclave programming includes vacuum purge cycles.

*Cardboard may release gases during heating that will prevent efficient sterilisation. To ensure efficient sterilisation, cardboard should be autoclaved separately from other dry materials.

Liquid waste:
This type of waste will be autoclaved with a chamber control temperature of 123°C and a sterilisation temperature of 121°C for 40 minutes. Loads containing liquids will be autoclaved separately from solid wastes. The cycle will run in absence of vacuum and has a fixed cooling period at the end of the cycle.

Degree of kill:
Chemical Sterilization by Virkon/Barrycidal- effectively 100% kill.
Autoclaving - effectively 100% kill (annual validation).
The GM committee asked for more detail on the Hazard Group 2 and 3 virus families that would or could potentially be used in the study to allow a more suitable and sufficient risk assessment to be made. This was added to the risk assessment. The aim of Stage 1 of the project was to overexpress ISGs in target cell lines by means of transduction with lentiviruses. There was a connected program of work already notified to HSE (GM223/13.1) which details these lentiviral vector systems, and following comments from the committee this was added to the risk assessment for clarity. More detail was requested on the probability of reversion to the wildtype from tagged versions of the parental viruses and this section of the RA was extended to clarify this.

**Project Ref** 223/19.1

- **Date Ackn'd**: 23/01/2019
- **CU2 Project Title**: Use of virus like particles (VLPs) and replicons to understand fundamental aspects of virus biology
- **Class**: Class 2
- **CultureVolClass2**: < 1 Litre
- **Non-GMM Consent Granted**: Not Applicable

**Date Project Ceased**

- **Withdrawn**: N
- **Tick if notifying a connected programme of work**: N
- **Project notified under transitional arrangements**: N
The objective of this project is to study fundamental aspects of virology and virus-host interactions using VLPs and replicon systems designed to be safely handled at containment level 2. These systems are unable to generate infectious progeny outside of a laboratory as they require one or more essential components to be supplied in trans. We propose to use VLP and replicon systems derived from viruses that normally require containment level 3 or 4 under COSHH Regulations or SAPO.

The research will fall into 3 broad categories:

1. Immunity - We will use VLP and replicon systems to carry out in vitro research to examine how host cells from different species attempt to inhibit and respond to divergent pathogens. Moreover, VLPs provide a valuable way to conduct serology/neutralization studies at containment level 2.

2. Molecular virology - We will use VLP and replicon systems to carry out in vitro research to examine how viral proteins work and what host factors they depend upon to work and whether host or viral components can be chemically inhibited.

3. Structural biology/biochemistry - We will use VLP and replicon systems to determine the structures and biophysical properties of viral proteins and characterise their activities in vitro.

VLP and replicon systems can replicate their genome within an infected/transfected cell and they are (somewhat confusingly) referred to as replication incompetent, replication defective or single cycle because they are unable to sustain more than a single round of infection (without additional component(s) being supplied in trans) because not everything required is encoded by the viral modified/mini genome(s).

The risk assessment is deliberately general to allow us to respond rapidly and appropriately to novel observations/novel available systems. The use of VLP and replicon systems will broaden the study of important pathogens that normally require handling in higher containment (and are therefore oft understudied). However, we will not use a new system without first submitting our intent to the local GM safety committee and considering whether it might constitute a significant change to this risk assessment. In our initial application we have included various iterations of the VLP/replicon approach including some severe human/animal viral pathogens designed to encompass a variety of current approaches and give a flavour for the scope of this work.
VLPs and replicon/minireplicon systems for the viruses requiring containment level 3 or higher under COSHH Regulations or Specified Animal Pathogens Order, including:
- Rabies VLPs
- Vesicular stomatitis virus VLPs
- Marburg VLPs
- Ebola VLPs
- Nipah virus replicons
- Hendra virus replicons
- Tick-borne encephalitis VLPs
- West Nile VLPs
- Dengue VLPs
- Influenza A replicons

In general, replicon/minireplicon systems can be distinguished from VLP systems because replicons lack one or more structural genes and thus do not have a virus like particle component (and are often confined to the transfected/modified cell). In contrast, VLPs must have a cell free stage where the defective/mini genome is packaged into a virus like particle that can then be used to infect new cells (some systems require components to be added in trans to the target cell to detect infection). Crucially, VLP systems cannot be propagated because VLPs do not contain all the genetic material required for sustainable propagation. In each case, the system described is already being handled at containment level 2 in the UK or at the equivalent containment level in the EU/USA.

Host/vector system

The plasmid components come in a range of plasmid DNA vectors. The details of the plasmid vector should not increase the inherent risk of any VLP/replicon systems. Viral components might also be delivered in trans using retroviral or lentiviral systems (such as engineered cell lines expressing Rabies glycoproteins). This will not alter the risks associated with the VLP/replicon systems. Eukaryotic cells will also be modified to express genes not of viral origin (such as interferon stimulated genes or restriction factors). This will usually be achieved using standard plasmid transfection or retroviral/lentiviral vectors. Similarly, eukaryotic cells might be depleted of host genes by knockout or knockdown (plasmid/retro or lentiviral based systems). This will not influence the risk of the VLP/replicon systems.

Origin & function

VLPs and replicons will be generated by transfection/infection of cell lines of various origins with cDNA clones and vectors expressing modified viral proteins and genomes or through infection of cells with VLPs. Due to the lack of expression of viral structural and/or replication genes in the modified genomes contained in the VLPs, VLPs are unable to generate infectious progeny upon infection of unmodified target cells. The proposed modifications in the components of existing VLP and replicon systems (point mutations, deletions, insertions of tags) are unlikely to increase the chance of recombination that could lead to viable progeny. Mutant VLPs will include point mutants, frame deletions, analogous or orthologous gene swaps within members of the same viral family, addition/replacement of reporter genes (Le. luciferase, GFP, CAT, RFP etc.) and tags (Le. GFP, RFP, HA, V5, etc).

Evaluation of foreseeable effects

The proposed modifications (point mutants, frame deletions, analogous or orthologous gene swaps within members of the same viral family, addition/replacement of reporter genes and tags) should not increase the inherent risk of the
VLPs/replicons.

Risks to human health:
In the unlikely event of human exposure, the VLP and replicon systems will be unable to produce infectious progeny to sustain a full cycle of replication and thus the likelihood of harm is minimal/negligible.

Prokaryotic organisms: All strains will be disabled, commercially available E. coli K12 derivatives classified as 'especially disabled hosts' by ACDP. These strains cannot colonise humans and are known not to cause harm to humans.

Eukaryotic cells:
Cell lines to be used would not survive inside the immunocompetent human body (immune rejection) and are not known to carry intact harmful pathogens. Addition of DNA or RNA or infection will confer no growth or survival advantage in or outside the laboratory to these cell lines.

Eukaryotic primary cells would not survive inside the human body (immune rejection).

Risks of reversion to wild-type/propagation competence:
The VLP/replicon systems are only able to undergo a single round of infection and as such are no longer viruses or pathogens. The foreseeable effects therefore surround the possibility of unintentional generation of viruses derived from the VLP/replicon system (reversion). The major ways this could occur include 1) Recombination occurring in vitro, and 2) Unintentional exposure of a virus-infected cell (either in vitro or in vivo) to a VLP/replicon system. Foreseeable effects for both will be consecutively discussed.

1) Recombination in vitro. The systems have been designed to minimise the risk of recombination. Homologous sequences between the minigenomes and the transcomplementing ORFs have been removed. In many cases, the compartmentalised nature of minigenome replication minimises the risk of recombination as VLP/minigenome RNAs are spatially separated from cellular RNAs. In many systems, unintentional reversion in culture has been specifically investigated and not observed.

2) Unintentional transfection or infection of virus-infected cells in vitro is unlikely to result in reversion. We do not possess the viral counterparts for most of the VLP/replicon systems at our centre (if we do they are stored and used in separate containment facilities) so homologous sequences are therefore unlikely to be present. In the case of Influenza A Virus replicons, reassortance is unlikely as full genome segments will not be used. Thus, there would be minimal consequences arising from unintentional coinfection in vitro.

Unintentional exposure of a virus-infected cell (either in vitro or in vivo) to a VLP/replicon system. Unintentional exposure of humans (already infected with a virus and working at our centre) would not be predicted to result in reversion. Similarly, virus-infected animals in the environment exposed to VLPs would be unlikely to cause reversion. Most similar viruses are not endemic within the UK, homologous sequences are unlikely to be present and because the VLPs can only undergo a single round of infection, it is unlikely that a single cell will be exposed to VLP and endemic virus. In the case of Influenza A Virus replicons, reassortance is unlikely as full genome segments will not be used. Thus, these systems will have minimal consequences following accidental exposure/release to the environment.

Risks to the environment
In our laboratories, the risk of accidental infection of insects by ingestion of contaminated material is low and the likelihood of virus released from our laboratory infecting local vectors or animals in the local environment is effectively zero (see decontamination and waste disposal procedures below). Even in the complete absence of disinfection the replication defective nature of these systems means the risk to the environment is extremely low.

Changes in the viral glycoproteins, including point mutations, deletions, insertions or the use of glycoproteins from related viruses could potentially change the host range of these VLPs. However, given that we will never restore viral genes usually supplied in trans into the viral genomes, the risk to the natural hosts and the level of containment required to handle them remains the same as the parental VLPs as they are unable to sustain more than a single round of infection.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All the systems used in this study are missing at least one essential component that must be supplied in trans to generate infectious progeny. Outside of the laboratory, they are unable to sustain an infection. They are therefore unable to cause severe human disease or be a serious hazard to employees; they cannot be considered as disease-producing organisms and are unlikely to spread from the laboratory and/or to the community. Hence, we seek permission to handle all VLP and replicon systems described in this proposal at containment level 2.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disposable solids (e.g. plasticware such as flasks, tubes, pipette tips etc.) - soak in at least 1 % w/v Virkon solution (final concentration) overnight. Transfer solid contents to clear autoclave bags and autoclave at 135°C for 5 minutes. Other solids (agar plates, gloves etc.) - placed in a marked box lined with a clear autoclave bag, and autoclaved at 135°C for 5 minutes. Liquids (eg. samples, tissue culture media) - add Virkon to final concentration of at least 1 % (w/v) overnight.

Degree of kill:
Chemical Sterilization by Virkon - effectively 100% kill.
Autoclaving - effectively 100% kill (annual validation).

Following overnight decontamination in Virkon all liquid waste is to be disposed to drains. Autoclaved solid waste is to be disposed by district council to landfill.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GM Safety Committee asked for more information regarding the risks associated with the presence of replicationcompetent endogenous retroviruses when transducing cells of mammalian origin. The risk assessment was amended to clarify this point. The GMSC was satisfied that containment and control measures were suitable for this project and that class 2 classification was appropriate.

Project Additional Information

Purposes of the contained use

The project aims to identify genes and investigate processes involved in the molecular genetics and biochemistry of parasitic protozoa (Trypanosoma and Leishmania spp.) and their interaction with their hosts. Key areas of interest are identifying genes and investigating the mechanisms involved in important phenotypes such as sequestration, drug resistance, virulence, pathogenesis and infectivity. The main approach will be to examine the differences between parasite strains to determine genes involved in these phenotypes.

Recipient or parental organism

Organisms to be used in this study
(a) Trypanosoma spp are capable of infecting a range of mammals, including man, cattle and rodents. The predominant Trypanosoma species used in this study will be Trypanosoma brucei brucei and Trypanosoma brucei gambiense. We will occasionally use other subspecies including (but not limited to) Trypanosoma brucei rhodesiense and Trypanosoma congolense.
(b) Leishmania spp. are capable of infecting a range of mammals including man, dogs and rodents. The predominant Leishmania species used in this study is Leishmania tarentolae, isolated from the Moorish Gecko Tarentola maurianica. This is non-pathogenic to mammals. We may occasionally use Leishmania mexicana, L. infantum, and L. major.
Examined by RNA interference (RNAi). Currently, this is only possible in T. brucei, where several vectors have been designed for expression of double stranded RNA to result in the generation of a strain that is more virulent, has a wider host range or additional tissue tropism than the donor strain. Functions of specific genes will be examined by RNA interference (RNAi). Several vectors have been designed for expression of double stranded RNA corresponding to the target gene using tetracycline induction of the bacterial T7 phage RNA polymerase. Plasmids of choice include the p2Ti (LaCount, D.J., Bruse, S., Hill, K.L., and Donelson, J.E. (2000). Mol. Biochem. Parasitol. 111, 67-76.) and pZJP (Wang, Z., Morris, J.C., Drew, M.E., and Englund, P.T. (2000). J. Biol. Chem. 275, 40174-40179.) series and the T. brucei, pH vectors (Bieber, S., Wirtz, E., Lorenz, P., and Clayton, C.E. (1997). Mol. Biochem. Parasitol. 85, 99-112). These vectors have low to medium levels of trans gene expression.

1. Gene disruption. Generation of mutant parasites by insertional mutagenesis (Insertion of selectable markers by homologous recombination). The types of positive selectable markers that will be used include drug resistance genes of prokaryotic origin, such as neo, hyg, pur, ble, bia or sat. These drug resistance genes do not confer resistance to drugs commonly used to treat trypanosomosis or Leishmania infections in man or animals.

2. Homologous gene expression. The expression of homologous genes in trypanosomes or Leishmania will be achieved from episomal expression vectors or via integration into the genome. These vectors provide low to medium levels of gene expression.

3. Heterologous gene expression. The expression of heterologous genes in trypanosomes or Leishmania will be achieved from episomal expression vectors or via integration into the genome. The commercially available eukaryotic Lexsy gene expression system produces large amounts of correctly post-translationally modified proteins. We may occasionally conduct these experiments to test for cross species complementation. In particular, we wish to test if genes from trypanosomes are able to fulfill the same function in Leishmania (and vice versa). This is of some importance in drug design, as we wish to be able to design inhibitors against drug targets that might have therapeutic value in both related organisms. Thus, genes that are essential in both organisms and that are able to function in each species are good targets for the development of a generic anti-trypanosomatid drug.

5. Inducible expression of endogenous or foreign genes. Again, this relies upon tetracycline induction of the target gene via the bacterial T7 phage RNA polymerase. In T. brucei, the pHD vectors (Bieber, S., Wirtz, E., Lorenz, P., and Clayton, C.E. (1997). Mol. Biochem. Parasitol. 85, 99-112) are examples for inducible expression in both bloodstream and procyclic stage cells. These vectors have medium to high levels of trans gene expression.

6. Gene product localisation will be examined by creating translational fusions of the genes and epitopes to which antisera are commercially available (for example HA, BB2, MYC, TAP, FLAG), or that provide autofluorescence (any of the colour variants of aequorin; GFP, EFP, YFP etc.). These vectors have low to medium levels of expression.

7. Non-trypanosomatid genes for example, encoding reporter genes (e.g. GFP and luciferase) will be expressed from various chromosomal loci to provide measures of expression. These vectors have low to medium levels of trans gene expression.

Host/vector system

Prokaryotic hosts include disabled, commercially available E. coli strains such as E.coli K12 or BL21 derivatives.

Plasmids containing DNA derived from the host; coding and non-coding nucleic acid sequences; promoters and enhancers. These also contain a ‘selectable marker’, usually a drug resistance marker e.g. puromycin, hygromycin and neomycin resistance. Plasmids may also contain material of prokaryotic or bacteriophage origin engineered to deliver e.g. dsRNA (e.g. tet-repressor and T7 polymerase). Reporter genes such as GFP, mCherry and luciferase. Plasmids also contain an origin of replication followed by a prokaryotic selectable marker (usually antibiotic resistance against ampicillin or kanamycin).

Mice, both wild type and genetically modified (e.g. genes involved in immune response, etc.) infected with wild-type and GM Trypanosoma or Leishmania.

Tsetse flies (wild-type only) will be infected with wild-type or GM trypanosomes.

We will also perform transmigration assays using endothelial cells of mammalian origin, including genetically modified endothelial cells.

Origin & function

Trypanosoma and Leishmania spp.; lab strains bred and maintained in our facilities (or obtained from collaborators/companies); GM strains already produced in the University of Glasgow (approved class 3 activity GM37/99.1).

The following types of genetic modification for Trypanosoma and Leishmania spp are envisaged:

1. Gene disruption. Generation of mutant parasites by insertional mutagenesis (Insertion of selectable markers by homologous recombination). The types of positive selectable markers that will be used include drug resistance genes of prokaryotic origin, such as neo, hyg, pur, ble, bia or sat. These drug resistance genes do not confer resistance to drugs commonly used to treat trypanosomosis or Leishmania infections in man or animals.

2. Homologous gene expression. The expression of homologous genes in trypanosomes or Leishmania will be achieved from episomal expression vectors or via integration into the genome. These vectors provide low to medium levels of gene expression.

3. Heterologous gene expression. The expression of heterologous genes in trypanosomes or Leishmania will be achieved from episomal expression vectors or via integration into the genome. The commercially available eukaryotic Lexsy gene expression system produces large amounts of correctly post-translationally modified proteins. We may occasionally conduct these experiments to test for cross species complementation. In particular, we wish to test if genes from trypanosomes are able to fulfill the same function in Leishmania (and vice versa). This is of some importance in drug design, as we wish to be able to design inhibitors against drug targets that might have therapeutic value in both related organisms. Thus, genes that are essential in both organisms and that are able to function in each species are good targets for the development of a generic anti-trypanosomatid drug.

5. Inducible expression of endogenous or foreign genes. Again, this relies upon tetracycline induction of the target gene via the bacterial T7 phage RNA polymerase. In T. brucei, the pHD vectors (Bieber, S., Wirtz, E., Lorenz, P., and Clayton, C.E. (1997). Mol. Biochem. Parasitol. 85, 99-112) are examples for inducible expression in both bloodstream and procyclic stage cells. These vectors have medium to high levels of trans gene expression.

6. Gene product localisation will be examined by creating translational fusions of the genes and epitopes to which antisera are commercially available (for example HA, BB2, MYC, TAP, FLAG), or that provide autofluorescence (any of the colour variants of aequorin; GFP, EFP, YFP etc.). These vectors have low to medium levels of expression.

7. Non-trypanosomatid genes for example, encoding reporter genes (e.g. GFP and luciferase) will be expressed from various chromosomal loci to provide measures of expression. These vectors have low to medium levels of trans gene expression.

Reporter genes, such as GFP, antibiotic resistance genes and luciferase. Parasite candidate genes for desired phenotypes will be replaced by antibiotic resistance markers. Candidate genes may be taken from naturally occurring virulent strains and inserted into less virulent naturally occurring strains to examine traits such as infectivity, drug resistance and virulence, e.g. genes for cysteine peptidases, genes for trypanosome cell surface proteins and transporters.

It is envisaged that genes modified in this project will lead to either no change in virulence or a loss of virulence. None of the genes to be modified in this project are thought to result in the generation of a strain that is more virulent, has a wider host range or additional tissue tropism than the donor strain. Functions of specific genes will be examined by RNA interference (RNAi). Currently, this is only possible in T. brucei, where several vectors have been designed for expression of double stranded RNA.

Evaluation of foreseeable effects

It is considered likely that gene disruptions will be detrimental to parasite survival or will have no phenotypic difference from wild type cells. The transformed trypanosomatids expressing foreign genes, or with trypanosomatid genes modified to be linked to epitope tags, are highly unlikely to have phenotypic differences from wild type cells, or from trypanosomatids with gene knockouts. Add-back experiments where genes of interest are knocked out and subsequently replaced will be unlikely to have a higher pathogenic phenotype than naturally occurring virulent parasite strains.

Hazards arising from the alteration of any existing pathogenic traits:
It is possible that disruption of Trypanosoma or Leishmania genes will alter the pathogenicity of the parasites. It is envisaged however that genes modified in this project will lead to either no change in virulence or a loss of virulence (hence the desire to create gene-specific deletion mutants for use as e.g. attenuated live vaccines). None of the experiments are envisaged to increase the hazard beyond the inherent hazard in working with naturally occurring parasites. Genetically modified parasites will be tested in vivo models (mice, tsetse flies). Procedures for maintenance of animals infected with genetically modified trypanosomatids are covered by the Home Office inspectorate; Animals (Scientific Procedures) Act 1986.

Potential hazards of sequences within the GMM being transferred to related micro-organisms:
The potential for GM parasites to transfer the genetically altered material to related organisms is extremely low as for both trypanosomes and leishmania genetic exchange only occurs in the insect vector between compatible strains.

Risk to human health:

Procyclic form trypanosomes are considered non-infective to mammals. The standard operating procedures and containment processes will be followed to ensure that the likelihood of a health hazard is negligible.

Bloodstream form trypanosomes are, however, potentially harmful. An important feature of safe handling of bloodstream stage trypanosomes is that there is no record of transmission of these parasites by the aerosol route; neither can these organisms penetrate unbroken skin or mucous membranes. The only possible route of infection is through direct inoculation, a hazard which is negligible due to strict standard operating procedures involving the use of either blunt needles and/or the use of needle proof gloves.

For promastigote Leishmania, there is no record of transmission of these parasites by the aerosol route; neither can these organisms penetrate unbroken skin or mucous membranes. However, it is possible that Leishmania It is considered likely that gene disruptions will be detrimental to parasite survival or will have no phenotypic difference from wild type cells.

The transformed trypanosomatids expressing foreign genes, or with trypanosomatid genes modified to be linked to epitope tags, are highly unlikely to have phenotypic differences from wild type cells, or from trypanosomatids with gene knockouts. Add-back experiments where genes of interest are knocked out and subsequently replaced will be unlikely to have a higher pathogenic phenotype than naturally occurring virulent parasite strains.

Hazards arising from the alteration of any existing pathogenic traits:
It is possible that disruption of Trypanosoma or Leishmania genes will alter the pathogenicity of the parasites. It is envisaged however that genes modified in this project will lead to either no change in virulence or a loss of virulence (hence the desire to create gene-specific deletion mutants for use as e.g. attenuated live vaccines). None of the experiments are envisaged to increase the hazard beyond the inherent hazard in working with naturally occurring parasites. Genetically modified parasites will be tested in vivo models (mice, tsetse flies). Procedures for maintenance of animals infected with genetically modified trypanosomatids are covered by the Home Office inspectorate; Animals (Scientific Procedures) Act 1986.

Potential hazards of sequences within the GMM being transferred to related micro-organisms:
The potential for GM parasites to transfer the genetically altered material to related organisms is extremely low as for both trypanosomes and leishmania genetic exchange only occurs in the insect vector between compatible strains.

Procyclic form trypanosomes are considered non-infective to mammals. The standard operating procedures and containment processes will be followed to ensure that the likelihood of a health hazard is negligible.

Bloodstream form trypanosomes are, however, potentially harmful. An important feature of safe handling of bloodstream stage trypanosomes is that there is no record of transmission of these parasites by the aerosol route; neither can these organisms penetrate unbroken skin or mucous membranes. The only possible route of infection is through direct inoculation, a hazard which is negligible due to strict standard operating procedures involving the use of either blunt needles and/or the use of needle proof gloves.

For promastigote Leishmania, there is no record of transmission of these parasites by the aerosol route; neither can these organisms penetrate unbroken skin or mucous membranes. However, it is possible that Leishmania It is considered likely that gene disruptions will be detrimental to parasite survival or will have no phenotypic difference from wild type cells.
through direct inoculation, a hazard which is negligible due to strict standard operating procedures involving the use of either blunt needles and/or the use of needle proof gloves.

For promastigote Leishmania, there is no record of transmission of these parasites by the aerosol route; neither can these organisms penetrate unbroken skin or mucous membranes. However, it is possible that Leishmania amastigotes can be transmitted via aerosols and so any work with amastigotes will be handled in a class II microbiological safety cabinet. All work handling Leishmania will be carried out in containment level 2 facilities.

Environmental risks:
Capacity of the GMM to survive, establish, disseminate with and/or displace other organisms:
The chance of escape into the environment is negligible as the genetically modified parasites will be contained within either CL2 or CL3 (T. b. rhodesiense) facilities and handled under COSHH Standard Operating Procedures.
The parasites are unable to survive outside the mammalian body or vector and so do not pose an environmental risk.
Infected mice will be housed in containment facilities in dedicated SAPO rooms. As this is a vector borne infection and the vectors are not native in the UK the possibility of the establishment in the environment is negligible/effectively zero.
Thus, the possibility of escaped infected tsetse vectors establishing in the UK is not possible, as the flies cannot survive for prolonged time periods in our climate.

Ability to cause harm to animals:
The host preferences of each trypanosome species may differ, but Trypanosoma congolense, T. vivax and T. brucei have a wide host range among mammals. Leishmania spp can infect canids, especially dogs. The chance of escape into the environment is however negligible as the genetically modified parasites will be contained within either CL2 or CL3 (T. b. rhodesiense) facilities and handled under COSHH Standard Operating Procedures. The parasites are unable to survive outside the mammalian body or vector and so do not pose an environmental risk. Infected mice will be housed in containment facilities in dedicated SAPO rooms. As these are vector borne infections and the vectors are not native this country the possibility of passing this infection to the vector and then to another animal is negligible.

Infected mice will be housed in containment facilities in dedicated rooms. As this is a vector borne infection and the vectors are not native this country the possibility of passing this infection to the vector and then to another animal is negligible.
Tsetse flies will be housed in dedicated containment facilities (in a separate building from mice) and caged before infection. The possibility of escaped infected tsetse vectors establishing in the UK is not possible as the flies cannot survive in our climate and so do not pose a risk to establishing within the UK.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Infected mice will be housed in containment facilities in dedicated rooms. As this is a vector borne infection and the vectors are not native this country the possibility of passing this infection to the vector and then to another animal is negligible.
Tsetse flies will be housed in dedicated containment facilities (in a separate building from mice) and caged before infection. The possibility of escaped infected tsetse vectors establishing in the UK is not possible as the flies cannot survive in our climate and so do not pose a risk to establishing within the UK.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Work with T. b. rhodesiense will be conducted at containment level 3 with less than the minimum containment conditions (see below) normally required for that containment level under the COSHH Regulations following HSE guidance in the ACDP Approved List of Biological Agents (Pages 8-9 and 30-31).
• There is no requirement for the laboratory to be sealed and fumigated.
• There is no requirement for negative pressure or HEPA filtering of exhaust air before discharge (no risk of infectious aerosols being generated).
• Within the restricted access laboratories, the workplace and equipment may be shared with research activities performed with HG2 Trypanosoma spp. In this case, all work with T. b. rhodesiense will be clearly labelled and separated either physically or temporally from other work in the laboratory wherever possible.
• While observation windows are present within the double inner containment rooms of the tsetse suite, there is no window in the outer “airlock” access doors. A procedure of agreed check-ins will be used to monitor staff while using the tsetse suite.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All liquid and solid waste is to be decontaminated chemically before sterilisation by autoclaving* 3% Chemgene (Trigene/Distel), 3% chloros, 5% Bleach or 1% Virkon will be used for disinfection.
Leishmania and Trypanosoma cultures and infected blood are disposed of into containers containing 3% Chemgene (Trigene/Distel), 3% chloros, 5% Bleach or 1% Virkon, which instantly kills these parasites (bloodstream forms of T. brucei are killed at a concentration of 0.1% within 20s)
• The surfaces of the microbiological safety cabinet and laboratory benches will be disinfected after any activity.
• Contaminated glassware, general apparatus and safety clothing should be decontaminated by immersion in chloros, Chemgene (Trigene/Distel) Bleach or Virkon.
Potentially contaminated lab coats must be autoclaved.

- Specialised equipment should be decontaminated by wiping with tissues soaked in chloros, Chemgene (Trigene/Distel) Bleach or Virkon.
- All potentially contaminated waste materials must be made safe before disposal by immersion in chloros, Chemgene (Trigene/Distel) Bleach or Virkon.
- If a spillage of viable organisms occurs, the contaminated areas must immediately be swabbed with industrial methylated spirit (IMS), chloros, Chemgene (Trigene/Distel) Bleach or Virkon. All accidents or potentially dangerous occurrences must be reported immediately to the Head of Laboratory or local safety Officer.
- Disinfected waste should be drained and transferred to the designated autoclave bags which are sealed when full and autoclaved.

**Autoclaving**

- All infected waste will be autoclaved before disposal. All frozen waste must be brought up to ambient temperature prior to autoclaving.
- On removal from the autoclave, the bags are placed in the clinical waste container which, when full, is sent for incineration by the designated company.
- Uninfected tsetse flies should be killed by freezing prior to disposal by autoclaving. Infected flies should be kept frozen overnight, brought back to room temperature and handled as animal by-product (ABP) waste, and sent for incineration as described.
- All waste bedding and waste material (gloves etc.) and carcasses will be autoclaved and disposed of by incineration undertaken by a commercial waste specialist company. If the autoclave does not meet the required specification at any time, bedding will be stored at –20°C for >48hrs and then disposed of by the same company as hazardous waste and incinerated.

Contaminated syringes and needles should be disposed of in the dedicated sharps bin which, when full, should be sent for incineration by the designated company. Autoclave conditions: Inactivated by autoclaving under conditions that maintain 121°C for at least 30 min with full steam penetration.

All autoclaved waste is to be incinerated

---

The GM Safety Committee recommended that minimum containment level required for each parasite (under COSHH Regulations or SAPO) should be clearly stated in the risk assessment.

Leishmania amastigotes present a risk of infection through aerosols; the GMSC asked for the risk assessment to clearly state that all work involving these forms must be carried out in a class II microbiological safety cabinet.

Additional information was requested with regards to the nature of work conducted on animal models and the question of genetic exchanges between parasite strains in animals was raised.

All these points were addressed in the final version of the risk assessment; the GMSC considered that appropriate containment and control measures had been assigned and approved the document for work to be carried out at CL2, except for T. b. rhodesiense which will be handled at CL3 with less than the minimum containment conditions.

Page 5435 of 15326
African trypanosomiasis is a disease caused by the parasites of the genus Trypanosoma. These parasites affect both humans and animals with significant social and economic impact. Although the disease has been recognised for centuries, many aspects regarding the pathogenesis of the disease, and the complex host-pathogen interactions dictating disease outcome, remain unknown. We will use a wide range of immortalised and primary cell lines of human and animal origin: i) to dissect the pathways involved in the crosstalk between African trypanosomes and their vertebrate host, and ii) to explore the pathological basis of infection by African trypanosomes, including neuroinflammation, skin inflammation, and kidney disease, amongst others. These studies will include, but not limited to one or more of the following procedures:

1. Culture of primary cells of human or other animal origin for in vitro studies
2. Culture of immortalised cell lines of human or other animal origin for in vitro studies
3. Genetic manipulation (knockout, knockdown, in situ genome tagging, overexpression) of primary and immortalised cell lines of human and animal origin to study to function of genes of interest in the context of pathogenicity, immune response, and host-pathogen interactions
4. Co-culture of cell lines of human or other animal origin with African trypanosomes. This work will be carried out under the approved class 3 activity GM223/19.2.
5. Generation of 3D culture systems (e.g., spheroids, assembloids) derived from primary and/or immortalised cell lines of human and/or other animal origin
**Recipient or parental organism**

| Cell lines of human or other mammalian origin |

**Origin & function**

Genetically modified human and mammalian cells will be produced in this project. These cells (e.g. HEK293, hCMEC/D3 just to mention a few examples) will be purchased from commercial suppliers. The cell lines might be considered “wild type”, if they do not have any genetic modifications beyond immortalisation, or “modified” if they harbour genetic modifications beyond immortalisation with SV40 (e.g. constitutive expression of fluorescent proteins). The wild type cell lines will be used to introduce genetic modifications when required. They cannot survive outside of culture media and have a history of safe use. We will also use primary cell lines. These cells will be engineered to create gene deletions, in situ genome tagging, gene knockdown library, overexpression.

Parent lines will be purchased from commercial sources (both immortalised or primary cell lines) which are screened for bloodborne viruses (e.g. HIV, HBC) and/or mycoplasma. Mammalian (non-human) primary cell lines (e.g. from mice) will be derived from animals housed in animal facilities, which are routinely screened for viruses and/or other pathogens.

The intended purpose is to test the function of selected genes in mammalian systems in vitro. The genes to be selected for modification will be dictated by transcriptomic analysis, whole-genome association studies, or related. Genes will be amplified in house or purchased commercially. We will introduce genetic modifications in a homotypic manner (e.g. human genes in human cell lines, for example).

**Evaluation of foreseeable effects**

The genetically modified mammalian cell lines cannot survive outside of culture media and have a history of safe use.

Hazard associated with the vector systems

Plasmids to be used shall be from commercial sources. They will be maintained in the host cell by antibiotic pressure, in the absence of which the plasmid is lost. None of these sequences present any hazard to humans or the environment. The final genetically modified cells will contain stably integrated DNA copies of the lentiviral vectors encoding the transgene expression cassettes. The cells will be free of lentivirus. As a result, they will pose no hazard to human health or the environment, since they are unable to colonise humans or survive outside the laboratory culture. In addition, they are replication-defective which means that the vector cannot multiply on its own unless supplied with certain proteins in trans. CRISPR-Cas9 system does not encode any protein that could promote replication.

Nevertheless, it will be important to prevent human exposure or environmental release of the replication defective lentiviruses which are used to transiently effect gene transfer. The worse-case scenario in case of infection is integration at a site that disrupts expression of a gene necessary for tumour suppression. Risk against this will be reduced through the use of appropriate physical containment and inactivation processes.

The plasmid vector contains antibiotic resistance genes, which if transferred to a micro-organism in the environment might confer resistance on a species able to infect humans or animals. However, these antibiotic resistance genes are already widespread in the environment and so this is not considered to be a significant hazard. This risk is addressed by rigorous waste disposal procedures.

Hazard arising from inserted gene products

We anticipate that most of the genes to be modified will be related to immune response, host-pathogen interactions, and any other that might be of relevance based on genetic screenings, transcriptomics analysis or genome-wide association studies. The resulting GMMs themselves would not be predicted to be any more harmful to human health than the parental wild-type strains, as there are no genes to be expressed that constitute toxins or pathogenic determinants. The risk of the modified cell lines
To humans is negligible. The transfer of genetic material (including antibiotic resistance genes) into related species in the environment is unlikely due to use of non-mobilizable plasmids. None of the genetic modification is likely to confer a survival advantage in the environment. The GMM cannot survive outside laboratory conditions and so hazard to the environment is minimal.

The proposed use of CRISPR/Cas9 is intended to study the effects of knocking out the host genes in response to infection with African trypanosomes, so would be very unlikely to increase the level of harm, compared to the unmodified strain.

There is no potential for harm to human or animal health or the environment using non-viral vectors.

The mammalian cells would not survive in genetically non-identical humans, causing rapid rejection and will not be expressing toxic or harmful products. All primary cells for these experiments will be obtained from laboratory animals or commercially from serologically tested donors (e.g., HUVECS) and will present no significant risk to human health.

The lentiviral vectors used are multi-attenuated meaning they are devoid of all potentially pathogenic virus encoded functions. In addition, they are replication-defective, which means that the vector cannot multiply on its own unless supplied with certain proteins in trans. CRISPR-Cas9 system does not encode any protein that could promote replication outside of transfected cells and under regulated conditions (e.g., antibiotic selection, induction with tetracycline, etc.)

Due to the restricted host range of the constructs, their lack of ability to survive outside laboratory conditions, restrictions on access to the facility and the risk control and disinfection/disposal measures described in this assessment, we conclude that the risk to human health or the environment by the proposed program is effectively zero.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste inactivation:
All GMM liquid waste will be inactivated using a validated disinfection method (eg 1% virkon, 5% chemgene or similar).
All solid waste, including waste destined for incineration, will be inactivated by autoclaving prior to disposal (100% kill).
Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile.
Waste disposal:
After disinfection all liquid waste will be flushed down the sink with a large amount of water.
Solid waste which was in contact with trypanosomes will be incinerated after autoclaving. Solid waste which was not in contact with trypanosomes will be disposed of by district council to landfill.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N
The GM Safety Committee asked for more detailed information on waste inactivation and disposal. The risk assessment was amended accordingly. The containment level required for this work was discussed, including for the experiments involving trypanosomes; conclusion was reached that CL2 was appropriate for the generation and maintenance of GM mammalian cells as described in the risk assessment and the RA was amended to clarify this point. The GMSC was satisfied that containment and control measures were suitable for this project and that class 2 designation was appropriate.

**Purposes of the contained use**

The entry of all enveloped viruses requires the action of virally-encoded membrane fusion proteins that are presented on the surface of virus particles. These proteins are critical determinants of viral transmission, cellular/species tropism and, consequently, pathogenesis. Understanding the molecular mechanisms of viral attachment, receptor
engagement and membrane fusion requires a structure-to-function investigation of viral fusion proteins. The membrane fusion machinery is also a key target of antibody-mediated immunity and a full understanding of virus entry also requires consideration of immune interactions.

We aim to investigate the mechanisms of viral membrane fusion/immune interactions using wild type and mutant viral proteins presented in the context of three non-replicating/surrogate systems: i) retroviral pseudoviruses, bearing the protein(s) of interest and encoding a reporter gene ii) exogenously expressed viral proteins in the context of eukaryotic cells iii) soluble proteins purified to high concentrations. In each case, the viral protein is presented in a context that does not permit viral replication and poses little/no risk to human health or the environment.

In the first instance we will use these systems to investigate the following groups of viruses: coronaviruses, hepaciviruses, pegiviruses, pestiviruses, hepadnaviruses, rhabdoviruses, retroviruses and influenza. Other viral species/genus may also be considered for investigation upon assessment by the local GM safety committee. Nonetheless, we will ensure that the proteins of interest have no known intrinsic pathogenic/oncogenic potential and the principal biological risks will be those associated with the general use of retroviral vectors.

**Recipient or parental organism**

We are investigating the entry mechanisms of enveloped viruses including human pathogens (e.g. hepatitis C, coronaviruses). However, we have selected surrogate experimental systems that do not support the generation of any replication competent viruses and allow us to investigate viral proteins in isolation. We will also investigate the host factors that facilitate virus entry and, therefore, will manipulate human/animal proteins using similar systems. Importantly, we will not generate GMOs carrying proteins of known intrinsic pathogenic/oncogenic potential.

**Host/vector system**

We will use three surrogate experiment systems incorporating different host/vector combinations.

i) Retroviral pseudovirus.

This is a very commonly used approach in which the viral fusion protein(s) of interest are presented on the surface of pseudovirus particles comprised of replication incompetent retroviral packaging components based on either HIV (e.g. 8.91 or NL4.3LUC) or MLV (e.g. pCIG), and a reporter gene encoded by a self inactivating transfer plasmid (Sanders 2002; Temperton et al. 2005; Kim et al. 2001; Hsu et al. 2003). The resultant pseudovirus particles follow the authentic entry pathway of the protein(s) under investigation and can be easily assayed through detection of the reporter gene product, but are incapable of replication. Being highly tractable and safe, this approach is the industry standard for the study of membrane fusion proteins from pathogenic viruses without substantive risk to human health or the environment.

ii) Exogenous protein expression in eukaryotic cells.

When over expressed in cells viral fusion proteins typically accumulate within intracellular compartments or at the cell surface, where they are amenable to functional and immunological characterisation. For example, in vitro fusion assays rely on cell surface expressed viral proteins that are activated to allow membrane fusion between adjacent cells. Alternatively, we will use the cells as a simple source of protein for antigenic evaluation by approaches such as ELISA or immunofluorescence. We will also introduce exogenous host proteins that act as receptors and entry factors for the viruses under investigation. In all cases genes encoding the proteins of interest are introduced by transfection with expression plasmids or through transduction with self-inactivating lentiviral vectors.

iii) Expression and purification of soluble proteins.

Viral membrane fusion proteins are anchored to the virus particle/host cell through transmembrane domains. However, if engineered to remove these regions and to direct efficient secretion, the proteins of interest will accumulate in extracellular medium of transfected cells, where they are available for affinity purification. Alternatively, soluble proteins can be expressed in prokaryotic systems and liberated by cellular disruption. The resultant high purity proteins are then suitable for various assays such as cellular binding activity, biophysical analysis or structural characterisation. Our investigations may also require the same strategy to produce high purity recombinant antibodies that target proteins of interest or soluble versions of host receptor proteins. In all cases genes encoding the proteins of interest are introduced by transfection/ transformation with expression plasmids or through transduction with self-inactivating lentiviral vectors.

Generation of pseudovirus and expression of exogenous proteins will occur in standard eukaryotic cell lines, such as those available through ATCC or similar archives, for examples HEK 293T, CHO or HeLa. Soluble proteins may also be expressed in standard disabled bacterial strains.

For all of the above systems the components originate from DNA plasmids that are generated and propagated in standard disabled bacterial strains (e.g. D5a). The following types of plasmids will be used:

- Retroviral packaging plasmids (e.g. HIV, 8.91 or MLV, pCIG (Naldini et al. 1996; Bock et al. 2000)).
- Transfer plasmids encoding reporter genes (e.g. GFP, CSGW or Luciferase, CSFLW (Demaison et al. 2002)).
- Viral membrane fusion protein expression plasmids. The protein(s) of interest will be encoded in standard expression plasmids (e.g. pCDNA3 or pD607) or
self-inactivating lentiviral transfer plasmids (e.g. pDUAL (Escors et al. 2008; Zufferey et al. 1998)) for introduction in to eukaryotic cells. Similarly, for prokaryotic expression, we will use standard bacterial expression plasmids (e.g. pNIC28-Bsa4).

- Antibody expression plasmids. Recombinant antibodies relevant to our investigation will be encoded on CMV expression plasmids (e.g. Oxgene OGS527) for introduction in to mammalian cells.

- Host receptor protein expression plasmids. Recombinant host-encoded receptor proteins relevant to our investigation will be encoded in standard CMV expression plasmids (e.g. pCDNA3 or pD607) or lentiviral transfer plasmids (e.g. pDUAL) for introduction in to eukaryotic cells, and for prokaryotic expression we will use standard bacterial expression plasmids (e.g. pNIC28-Bsa4).

Genetic manipulation of viral membrane fusion proteins, antibodies and host receptor proteins will be used to test hypotheses using the above experimental systems. These manipulations will be limited to those necessary to investigate the function and immune interactions of the viral membrane fusion proteins. We will make no substantive modifications to the background plasmids or viral vector systems.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GMM waste will be treated in line with local institutional practices:

- Liquids (e.g. culture media), viral cultures and cells are inactivated in 1% w/v (final concentration) Virkon solution overnight, then discharged to drain.
- Disposable solids that have been in contact with GM material (e.g. flasks, tubes, pipette tips, etc.) are soaked in 1% w/v (final concentration) Virkon solution overnight, then solid contents are transferred to clear autoclave bags for autoclaving (134°C for 5min) while remaining liquid is discharged to drain.
- Other solids (e.g. agar plates, gloves, etc.) are autoclaved at 134°C for 5min.
- Autoclaved waste is disposed by district council to land fill.

Degree of kill:
- Chemical inactivation by Virkon – effectively 100% kill
- Autoclaving – effectively 100% kill (annual validation)

### Historical Significant Changes

- Date of Additional Info
- Significant Change ID
- Date of Significant Change
**Project Additional Information**

**Purposes of the contained use**

The aim of the activities is to utilise SFV for expressing a variety of foreign proteins that could be of either viral or cellular origin. The foreign proteins could be derived from viruses that are human pathogens such as hepatitis C virus (HCV) or respiratory syncitial virus (RSV). The purpose is to use SFV to express high levels of the proteins in mammalian cells. This permits the study of the properties and functions of individual components of a particular virus in the absence of all other viral components.

**Recipient or parental organism**

The vectors used for introduction of foreign sequences into SFV are derived from the SFV viral genome. SFV is a well studied virus which does have a wide natural host range (including birds, rodents and anthropod vectors) but this does not include man.

It is intended eventually to use Sindbis virus also.

**Host/vector system**

Host system(s):
- Bacterial: Disabled E. coli K12-derived strains such as DH5.
- Mammalian: a range of tissue culture cell lines of mammalian origin.

Vector system(s):
- Mobilisation-defective plasmids pGEM1, pSFV1 and its derivatives. SFV-based expression in animal cells requires in vitro synthesis of recombinant RNA from pSFV1-derived and pSFV3 plasmids.

**Origin & function**

Hepatitis C virus (HCV), GBV-B and respiratory syncytial virus (RSV)

The system will be used for studying proteins encoded by these viruses.

**Evaluation of foreseeable effects**

Semliki Forest Virus is being used to study proteins from other viruses in this programme and evaluation of effects has to take into account both it and the other virus species involved. HCV is a natural human pathogen that causes chronic infection. The only documented route of infection is by contact with infected blood. The natural host for GBV-B is unknown, although there are literature reports that it is infectious in tamarins. It is not known whether humans are susceptible to infection. From studies elsewhere on infection of chimpanzees by HCV and GBV-B, infection is only successful using the entire genome. Generation of full-length genomic RNA of HCV in the SFV system is not possible. Furthermore, in the SFV system, there will be no combination of vectors introduced into cells that permits generation of full-length HCV and GBV-B genomes by any recombination mechanism. Hence, infectious HCV cannot be produced. It is not expected that HCV and GBV-B proteins will be toxic to man. Although wild-type SFV can infect animals, the system produces disabled virus that will give only a single round of infection. The most significant consequence of infection by direct inoculation may be an immune response to SFV proteins and those inserted into the vector. There is a possible risk of infection by either aerosols or direct inoculation. Therefore, any SFV particles produced by the vector system will be handled in a safety cabinet and no sharps will be used.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
DISINFECTION POLICY
The three methods for disinfection are as follows:
1. Chloros - 1% v/v
2. Virkon - 1% w/v
3. Autoclaving

All of the above methods can be used for herpes, adeno, vaccinia, bunya, respiratory syncitial, measles, chandipura and baculo viruses. Material derived from other viruses must be disinfected by autoclaving and possibly incineration as described in the relevant risk assessment form.

The methods are also suitable for E.coli.

Chloros (outwith the laboratory)
For bulk overnight steeping of glassware
Laboratories will be supplied daily with a trolley on which are large round vats for heavy glassware and smaller rectangular vats for light glassware. The appropriate volumes of stock Chloros is pre-dispersed in accompanying plastic bottles.
N.B. With the exception of empty pipette cans and chloros containers, no other items are permitted on this trolley.

Virkon (within the laboratory)
For bulk liquids (e.g. discarded tissue culture media)
Virkon powder* should be added to give a 1% w/v final concentration and the container mixed thoroughly.

For large containers (e.g. burrers, large and medium tissue culture flasks)
Treat with 1% w/v Virkon, either by adding powder and filling with water as above, or by dilution of a fresh concentrate. Stock solutions of Virkon must be dated: they retain efficacy for 1 week. Care should be taken to resuspend any pelleted or clumped material and to completely fill the container, swabbing the threads and then inverting closed flasks and burrers to ensure the neck is treated.

With both of the above methods the treated containers must be soaked for a minimum of 1 hour before disposing liquid down the sink, glassware to normal wash-up and plasticware to normal solid waste (black bags). It is recommended that materials being disinfected are clearly marked. For large glass conical flasks (greater than 1 litre capacity) These should be filled with 1% w/v Virkon and placed on the designated trolleys located on the first and second floors. The washroom staff will empty these trolleys first thing in the morning. These trolleys are for the disposal of large flasks only - other material must not be left on them. For surfaces, equipment and instruments Surfaces should be swabbed with 1% w/v Virkon (less than one week old). Equipment and instruments can be similarly disinfected but extreme caution should be exercised with electrical equipment. If in doubt see the Technical Services Manager.

*While Virkon is regarded as an extremely safe compound, care should be taken when dispensing dry powder in bulk. A protective face mask could be used to prevent inhalation.

Autoclaving  For small vessels (e.g. petri dishes and small tissue culture flasks) These should be placed in the biological waste discard boxes (lined with clear bags) in each lab. For higher risk organisms (e.g. clinical isolates, hepatitis, HIV) These should be placed in the biological waste discard boxes (lined with biohazard bags) which will be autoclaved prior to incineration of the contents.

For contaminated material (e.g. burrers with fungi or bacteria) These should not be opened but transported and loaded, at the allotted time, into the "dirty" autoclave in the washroom for inclusion in the liquid discard cycle. All lids must be loosened at the autoclave when the material is loaded. In the event that the "dirty" autoclave is still running the previous cycle, being serviced or out of order, all discarded boxes or other contaminated materials must be returned to their lab of origin. They MUST NOT be left at the autoclave or given to the washroom staff. For other methods - Any other method or disinfecting agent (e.g. sensitivity reactions) must be treated as a separate experimental procedure with it's own evaluation of efficacy and risk assessment form. General Aerosols Benchworkers should be wary of all techniques and manipulations which give rise to aerosols when using hazardous materials e.g. filling used burrers contaminated with viruses. Where practicable these procedures should be performed in an appropriate safety cabinet. Biological materials  It is recommended that all vessels used with biological materials be disinfected e.g. burrers used for non infected cell growth be treated with Virkon before discarding to normal waste. WASTE DISPOSAL The disposal of waste chemicals and solvent can often cost more than the original material. It is important, therefore, when orders are placed for chemicals that only sufficient is ordered for your immediate use. Waste disposal must be considered as integral to all laboratory procedures. These note summarise the principles of waste disposal organisation and describe the approved System of Work for discarding labware. The guidance principle is that scrupulous care must be taken to protect the interest of cleaners, other staff, the public and the environment.

Waste-bag colour code and disposal routes  BLACK = Non-hazardous; cleaners may remove  RED = These are for material requiring the attention of specialist waste disposal operators. Cleaner's can request assistance from specialist staff when the bag becomes full. It is the individual users' responsibility to ensure that the contents of the bag are disposed of as envisaged. The bags must be sealed securely to prevent escape of noxious substances, including aerosols.
disposal companies and are for compounds (e.g. ethidium bromide) identified in risk assessment forms. See "Waste Chemicals" below. YELLOW = These will not be available to laboratory workers. They are for incineration of autoclaved clinical waste. TRANSPARENT/BIOHAZARD = Microbiological waste for autoclaving. These must be transported in the metal disposal boxes and placed in the "dirty" autoclave in the washroom at the appropriate times. General Waste General waste in the laboratory may be put into the normal disposal containers. However, it is important that broken glass and other hazardous waste is kept separate. Waste solvents Solvent waste is collected in metal drums at the back of the spirit store. Potential hazards exist in mixing different solvents and there are separate drums for each of 3 categories of waste: 1) Flammable, e.g. ether, methanol, acetone. 2) Non-flammable, e.g. DMSO, phenol, chloroform. 3) Oils, e.g. waste from centrifuges, pumps, etc.

The material and amount disposed of in each category must be entered into the appropriate log book provided stating your name and date. Consult The Technical Services Manager if you are in any doubt as to which category your waste belongs. Make sure that there is adequate room left in the drum before starting. There should always be an empty drum below the one in use. If you finish a drum, inform The Technical Services Manager. Absorption granules for soaking up any solvent spillage are available in the solvent store.

From Divisional Safety Committee minute of 22/09/2000

5 Genetic modification proposal: Analysis of GBV-B structural proteins
In discussion there emerged more concern with the introduction of a new virus to the institute than with the proposed GM aspects. It was not known whether the virus is human or tamarin originally. The chief interest was as a model for HCV infection and, in this case, its structural proteins.

5.1 RME noted that there was one report in the literature of VSV glycoproteins being expressed in Semliki Forest Virus.

5.2 There was some concern with the statement "not envisage..... will produce infectious virus" However, part 10 did address concerns.

5.3 It was important to check with the ACDP on the classification GBV. (see 4.2 above)

5.4 The question has to be answered whether it extended previously agreed work, and hence whether a new notification to the HSE was needed.

5.5 It was recommended that the reference to "Experience of expression with HCV....." be moved from part 10 to part 7. Subject to these constraints the proposal was accepted. From the Virology Safety Committee minutes of 07/02/2001

24 Use of Semliki Forest Virus to study RSV proteins

It was noted that the original use of Semliki Forest virus has not constituted genetic modification. A further proposal was now considered to introduce GM of this virus and Notification of a new Activity was indicated. The present proposal represented an additional GM use of SFV.

24.1 The autoclaving of all waste was queried: the normal regime should be adequate (AW to check). Also, the ACGM Guidance Notes provided a model for the environmental risks. (RT to discuss with RS).

24.2 Subject to these changes the proposal was accepted at class 2.

**Date Ackn’ed** 26/08/2021  
**CU2 Project Title** GENETIC MODIFICATION OF CALICIVIRUSES

**Class** Class 2  
**CultureVolClass2** < 1 Litre

**Non-GMM Consent Granted** Consent Granted

**Project notified under transitional arrangements** N

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

Study of the structure and function of Norwalk-like viruses, and related viruses of public health significance.

**Recipient or parental organism**

Human small round structured virus (SRSV)  
Feline calicivirus (FCV)

**Host/vector system**

**Hos system(s)**

1. **Prokaryotic**
   
   Plasmid propagation - E.coli TG2, JM101, DH5a, MC1061  
   Expression in E.coli - E. coli BL21, BL21 (DE3)

2. **Eukaryotic**
Yeast protein expression system - Pichia pastoris
Insect cell lines - Spodoptera frugiperda
Mammalian cell lines - MRC5, HeLa, Ohio HeLa, 293, BSC-1, VERO, RD, CHO, BHK

Vector system(s)
1. Prokaryotic
   - Plasmid propagation - pBR322, pUC, PGEM, pJM1, pEMBL, PACYC184, pBLUESCRIPT
   - Protein expression - pGEMEX, pET, pUC119

3. Eukaryotic
   - Protein expression in yeast - pPIC9, pPIC3
   - Protein expression in insect cells - Autographa californica baculovirus
   - Protein expression in mammalian cells - pcDNA3, pREP, pTM1 & pTM3 (vaccinia expression), vTF7-3 (vaccinia T7 system), MVA-T7, fowlpox T7, non-cytopathic Sindbis virus replicons Virus expression in eukaryotic cells

Origin & function
FCV full genome and cloned segments of SRSV will be used to study the structure and function of individual proteins and the replication of the virus.

Evaluation of foreseeable effects
The predicted characteristics of the proteins indicate that there will be no toxic effect on humans or the environment. (Those produced in other laboratories have been used to raise antibodies and had no toxic effect).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
none

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

DISINFECTION POLICY
The three methods for disinfection are as follows:-

1. Chloros - 1% v/v
2. Virkon - 1% w/v
3. Autoclaving

All of the above methods can be used for herpes, adeno, vaccinia, bunya, respiratory syncitial, measles, c handipura and baculo viruses. Material derived from other viruses must be disinfected by autoclaving and possibly incineration as described in the relevant risk assessment form.

The methods are also suitable for E.coli

02/03/2022
Chloros (outwith the laboratory)

For bulk overnight steeping of glassware

Laboratories will be supplied daily with a trolley on which are large round vats for heavy glassware and smaller rectangular vats for light glassware. The appropriate volumes of stock Chloros is pre-dispensed in accompanying plastic bottles.

NB  With the exception of empty pipette cans and chloros containers, no other items are permitted on this trolley.

Virkon (within the laboratory)

For bulk liquids (eg. discharded tissue culture media)

Virkon powder *should be added to give a 1% w/v final concentration and the container mixed thoroughly.

For large containers (eg. burrers, large and medium tissue culture flasks)

Treat with 1% w/v Virkon, either by adding powder and filling with water as above, or by dilution of a fresh concentrate. Stock solutions of Virkon must be dated: they retain efficacy for 1 week. Care should be taken to resuspend any pelleted or clumped material and to completely fill the container, swabbing the threads and then inverting closed flasks and burrers to ensure the neck is treated.

With both of the above methods the treated containers must be soaked for a minimum of 1 hour before disposing liquid down the sink, glassware to normal wash-up and plasticware to normal solid waste (black bags) - laboratory personnel must remove any large bulk waste to cleansing department bins. It is recommended that materials being disinfected are clearly marked.

For large glass conical flasks (greater than 1 litre capacity)

These should be filled with 1% w/v Virkon and placed on the designated trolleys located on the first and second floors. The washroom staff will empty these trolleys first thing in the morning. These trolleys are for the disposal of large flasks only - other material must not be left on them.

For surfaces, equipment and instruments

Surfaces should be swabbed with 1% Virkon (less than one week old). Equipment and instruments can be similarly disinfected but extreme caution should be exercised with electrical equipment. If in doubt see the Technical Services Manager.

*While Virkon is regarded as an extremely safe compound, care should be taken when dispensing dry powder in bulk. A protective face mask could be used to prevent inhalation.

Autoclaving

For small vessels (eg petri dishes and small tissue culture flasks)
These should be placed in the biological waste discard boxes (lined with clear bags) in each lab.

For higher risk organisms (e.g., clinical isolates, hepatitis, HIV)

These should be placed in the biological waste discard boxes (lined with biohazard bags) which will be autoclaved prior to incineration of the contents.

For contaminated material (e.g., burrers with fungi or bacteria)

These should not be opened but transported and loaded, at the allotted time, into the "dirty" autoclave in the washroom for inclusion in liquid discard cycle. All lids must be loosened at the autoclave when the material is loaded.

In the event that the "dirty" autoclave is still running the previous cycle, being serviced or out of order, all discard boxes or other contaminated materials must be returned to their lab of origin. They MUST NOT be left at the autoclave or given to the washroom staff.

Other methods

Any other methods or disinfecting agent (e.g., stericol, gluteraldehyde, SDS) required for scientific or personal reasons (e.g., sensitivity reactions) must be treated as a separate experimental procedure with its own evaluation of efficacy and risk assessment form.

General

Aerosols

Benchworkers should be wary of all techniques and manipulations which give rise to aerosols when using hazardous materials eg. filling used burrers contaminated with viruses. Where practicable these procedures should be performed in an appropriate safety cabinet.

Biological materials

It is recommended that all vessels used with biological materials be disinfected eg. burrers used for non infected cell growth be treated with Virkon before discarding to normal waste.

WASTE DISPOSAL

The disposal of waste chemicals and solvent can often cost more than the original material. It is important, therefore, when orders are placed for chemicals that only sufficient is ordered for your immediate use. Waste disposal must be considered as integral to all laboratory procedures. These notes summarise the principles of waste disposal organization and describe the approved System of Work for discarding labware.

The guiding principle is that scrupulous care must be taken to protect the interests of cleaners, other staff, the public and the environment.

Waste-bag colour code and disposal routes

BLACK = Non-hazardous; cleaners may remove
RED = These are for material requiring the attention of specialist waste disposal companies and are for compounds (e.g., ethidium bromide) identified in risk assessment
forms. See "Waste Chemicals" below.

YELLOW = These will not be available to laboratory workers. They are for incineration of autoclaved clinical waste.

TRANSPARENT/BIOHAZARD = Microbiological waste for autoclaving. These must be transported in the metal disposal boxes and placed in the "dirty" autoclave in the washroom at the appropriate times.

General waste

General waste in the laboratory may be put into the normal disposal containers. However, it is important that broken glass and other hazardous waste is kept separate.

Waste solvents

Solvent waste is collected in metal drums at the back of the spirit store. Potential hazards exist in mixing different solvents and there are separate drums for each of three categories of waste:

1. Flammable, eg ether, methanol, acetone.
2. Non-flammable, eg DMSO, phenol, chloroform.
3. Oils, eg waste from centrifuges, pumps, etc.

The material and amount disposed of in each category must be entered into the appropriate log book provided stating your name and date. Consult The Technical Service Manager if you are in any doubt as to which category your waste belongs. Make sure that there is adequate room left in the drum before starting. There should always be an empty drum below the one in use. If you finish a drum, inform The Technical Services Manager. Absorption granules for soaking up any solvent spillage are available in the solvent store.

Please enter comments on the GM safety committee on the risk assessment
From the Divisional Safety Committee minute of 03/05/2000

   RME spoke to the proposal which, if accepted, would represent a new programme of work requiring notification to the HSE.

9.1 Caliciviruses caused human gastrointestinal disease typified by an acute but usually shortlived episode of severe diarrhoea and vomiting. Currently they were classified at ACDP level 2.

9.2 Growth in tissue culture could not yet be achieved and there was no testing of Virkon effectiveness. It was noted that were a tissue culture system to become available this would materially alter the safety implications (though not a genetic modification issue in itself).

9.3 The project would involve recovery of unmodified virus from cDNA clones. For future modification of clones a further proposal would be brought to the Committee.

9.4 The Committee accepted the proposal. A submission to the ACGM would follow.

Project Additional Information

Purposes of the contained use

To study respiratory syncytial virus and related viruses of public health significance.

Recipient or parental organism

Respiratory Syncytial Virus (RSV)

Host/vector system

**Host Systems**

1) Propagation of viral cDNA. Standard laboratory hosts.
   - JM109
   - DH5
   - Late6 (a derivative of SURE, developed for maintenance of large, unstable plasmids such as the RSV antigenome).

2) Expression in mammalian cell-lines i.e. production of infectious virus particles. Established cell lines.
   - HepC
   - BHK
   - Cos-7

**Vector systems**

i) Propagation of viral cDNA
   - pGEM - (Promega)
   - pCITE - (Novagen)

Origin & function

Isolates of RSV
RSV is relatively common in the human population. The experiments are designed to study the functions and interactions of the proteins encoded by the RSV genome. It is expected that engineered virus will be no more hazardous than the wild type. Eventually it is hoped to identify viral proteins which are potential targets for antiviral drugs.

Evaluation of foreseeable effects

RSV is relatively common in the human population. The experiments are designed to study the functions and interactions of the proteins encoded by the RSV genome. It is expected that engineered virus will be no more hazardous than the wild type. Eventually it is hoped to identify viral proteins which are potential targets for antiviral drugs.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

DISINFECTION POLICY

The three methods for disinfection are as follows:

1. Chloros - 1% v/v
2. Virkon - 1% w/v
3. Autoclaving

All of the above methods can be used for herpes, adeno, vaccinia, bunya, respiratory syncitial, measles, chandipura and baculo viruses. Material derived from other viruses must be disinfected by autoclaving and possibly incineration as described in the relevant risk assessment form.

The methods are also suitable for E. coli.

Chloros (outwith the laboratory)

For bulk overnight steeping of glassware

Laboratories will be supplied daily with a trolley on which are large round vats for heavy glassware and smaller rectangular vats for light glassware. The appropriate volumes of stock Chloros is pre-dispersed in accompanying plastic bottles.

NB With the exception of empty pipette cans and chloros containers, no other items are permitted on this trolley.

Virkon (within the laboratory)

For bulk liquids (eg discarded tissue culture media)

Virkon powder *should be added to give a 1% w/v final concentration and the container mixed thoroughly.

For large containers (eg burrlers, large and medium tissue culture glasks)

Treat with 1% w/v Virkon, either by adding powder and filling with water as above, or by dilution of a fresh concentrate. Stock solutions of Virkon must be dated: they retain efficacy for 1 week. Care should be taken to resuspend any pelleted or clumped material and to completely fill the container, swabbing the threads and then inverting closed flasks and burrlers to ensure the neck is treated.
With both of the above methods the treated containers must be soaked for a minimum of 1 hour before disposing liquid down the sink, glassware to normal wash-up and plasticware to normal solid waste (black bags) - laboratory personnel must remove any large bulk waste to cleansing department bins. It is recommended that materials being disinfected are clearly marked.

For large glass conical flasks (greater than 1 litre capacity)

These should be filled with 1% w/v Virkon and placed on the designated trolleys located on the first and second floors. The washroom staff will empty these trolleys first thing in the morning. These trolleys are for the disposal of large flasks only - other material must not be left on them.

For surfaces, equipment and instruments.

Surfaces should be swabbed with 1% w/v Virkon (less than one week old). Equipment and instruments can be similarly disinfected but extreme caution should be exercised with electrical equipment. If in doubt see the Technical Services Manager.

* While Virkon is regarded as an extremely safe compound, care should be taken when dispensing dry powder in bulk. A protective face mask could be used to prevent inhalation.

Autoclaving

For small vessels (eg petri dishes and small tissue culture flasks)

These should be placed in the biological waste discard boxes (lined with clear bags) in each lab.

These should be placed in the biological waste discard boxes (lined with biohazard bags) which will be autoclaved prior to incineration of the contents.

For contaminated material (eg burrers with fungi or bacteria).

These should not be opened but transported and loaded, at the allotted time, into the "dirty" autoclave in the washroom for inclusion in liquid discharge cycle. All lids must be loosened at the autoclave when the material is loaded.

In the event that the "dirty" autoclave is still running the previous cycle, being services or out of order, all discarded boxes or other contaminated materials must be returned to their lab of origin. They MUST NOT be left at the autoclave or given to the washroom staff.

Other methods

Any other method or disinfecting agent (eg stericol, gluteraldehyde, SDS) required for scientific or personal reasons (eg sensitivity reactions) must be treated as a separate experimental procedure with its own evaluation of efficacy and risk assessment form.

GENERAL

Aerosols
Benchworkers should be wary of all techniques and manipulations which give risk to aerosols when using hazardous materials eg. filling used burrers contaminated with viruses. Where practicable these procedures should be performed in an appropriate safety cabinet.

Biological materials

It is recommended that all vessels used with biological materials be disinfected eg. burrers used for non infected cell growth be treated with Virkon before discarding to normal waste.

WASTE DISPOSAL

The disposal of waste chemicals and solvent can often cost more than the original material. It is important, therefore, when orders are placed for chemicals that only sufficient is ordered for your immediate use. Waste disposal must be considered as integral to all laboratory procedure.s These notes summarise the principles of waste disposal organisation and describe the approved System of Work for discarding labware.

The guiding principle is that scrupulous care must be taken to protect the interests of cleaners, other staff, the public and the environment.

Waste-bag colour code and disposal routes

BLACK = Non-hazardous; cleaners may remove
RED = These are for material requiring the attention of specialist waste disposal companies and are for compounds (eg ethidium bromide) identified in risk assessment forms. See "Waste Chemicals" below.
YELLOW = These will not be available to laboratory workers. They are for incineration of autoclaved clinical waste.
TRANSPARENT/BIOHAZARD = Microbiological waste for autoclaving. These must be transported in the metal disposal boxes and placed in the "dirty" autoclave in the washroom at the appropriate times.

General waste

General waste in the laboratory may be put into the normal containers. However, it is important that broken glass and other hazardous waste is kept separate.

Waste solvents

Solvent waste is collected in metal drums at the back of the spirit store. Potential hazards exist in mixing different solvents and there are separate drums for each of three categories of waste:

1. Flammable, eg ether, methanol, acetone
2. Non-flammable, eg DMSO, phenol, chloroform.
3. Oils, eg waste from centrifuges, pumps, etc.

The material and amount disposed of in each category must be entered into the appropriate log book provided stating your name and date. Consult The Technical Services Manager if you are in any doubt as to which category your waste belongs. Make sure that there is adequate room left in the drum before starting. There should always be an empty drum below the one in use. If you finish a drum, inform The Technical Services Manager. Absorption granules for soaking up any solvent spillage are available in the solvent store.
From Divisional Safety Committee minutes 13/09/2000

10. Genetic modification proposal: Genetic manipulation of respiratory syncytial virus

It was intended to use a commercially available system (from Aviron) which did not need M2. Although the proposer would start using vaccinia strain T7 he would move away from this to a fowlpox or sindbis virus system.

10.01 Fundamentally it would be an RSV rescue system and as such represented a new programme of work. On this basis it was agreed by the Committee at level 1 or (vaccinia) level 2.

10.02 This would be submitted to the HSE as a paramyxovirus programme.

## Project Additional Information

### Purposes of the contained use
To study the proteins of hepatitis C virus.

### Recipient or parental organism
BVDV

### Host/vector system

**Host system(s):**
- Bacterial: Disabled E. coli K12-derived strains such as DH5
- Mammalian: Human hepatocyte derived cell lines (eg Huh-7, HepG2 etc), BHK, MDBK

**Vector system(s):**
- Mobilisation defective plasmids.

### Origin & function
HCV genomic cDNA sequences expressing viral proteins will be used for structure and function analysis.
If successful, the system will generate chimeric pseudotype BVDV particles carrying HCV structural proteins which may change its host and tissue tropism. Furthermore, the pseudotype particles are likely to encapsidate replication competent chimeric cDNA genome carrying HCV structural genes. Therefore, these particles could infect cells and replicate if injected into humans. It is virtually impossible to predict the outcome of accidental infection of humans with the chimeric particles and hence the categorization of the proposed work as class 3 activities.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

DISINFECTION POLICY
The three methods for disinfection are as follows:

1. Chloros - 1% v/v
2. Virkon - 1% w/v
3. Autoclaving.

All of the above methods can be used for herpes, adeno, vaccinia, bunya, respiratory syncitial, measles, chandipura and baculo viruses. Materials derived from other viruses must be disinfected by autoclaving and possibly incineration as described in the relevant risk assessment form.

The methods are also suitable for E. coli.

Chloros (outwith the laboratory)

For bulk overnight steeping of glassware.

Laboratories will be supplied daily with a trolley on which are large round vats for heavy glassware and smaller rectangular vats for light glassware. The appropriate volumes of stock Chloros is pre-dispensed in accompanying plastic bottles.

NB With the exception of empty pipette cans and chloros containers, no other items are permitted on this trolley.

Virkon (within the laboratory)

For bulk liquids (eg discarded tissue culture media)

Virkon powder * should be added to give a 1% w/v final concentration and the container mixed thoroughly.

For large containers (eg burrlers, large and medium tissue culture flasks)

Treat with 1% w/v Virkon, either by adding powder and filing with water as above, or by dilution of a fresh concentrate. Stock solutions of Virkon must be dated: they retain efficacy for 1 week. Care should be taken to resuspend any pelleted or clumped material and to completely fill the container, swapping the threads and then inverting.
closed flasks and burrfers to ensure the neck is treated.

With both of the above methods the treated containers must be soaked for a minimum of 1 hour before disposing liquid down the sink, glassware to normal wash-up and plasticware to normal solid waste (black bags) - laboratory personnel must remove any large bulk waste to cleansing department bins. It is recommended that materials being disinfected are clearly marked.

For large glass conical flasks (greater than 1 litre capacity)

These should be filled with 1% w/v Virkon and placed on the designated trolleys located on the first and second floors. The washroom staff will empty these trolleys first thing in the morning. These trolleys are for the disposal of large flasks only - other material must not be left on them.

For surfaces, equipment and instruments.

Surfaces should be swabbed with 1 w/v Virkon (less than one week old). Equipment and instruments can be similarly disinfected but extreme caution should be exercised with electrical equipment. If in doubt see the Technical Services Manager.

* While Virkon is regarded as an extremely safe compound, care should be taken when dispensing dry powder in bulk. A protective face mask could be used to prevent inhalation.

Autoclaving

For small vessels (eg petri dishes and small tissue culture flasks)

These should be placed in the biological waste discard boxes (lined with clear bags) in each lab.

For higher risk organisms (eg clinical isolates, hepatitis, HIV)

These should be placed in the biological waste discard boxes (lined with biohazard bags) which will be autoclaved prior to incineration of the contents.

For contaminated material (eg burrs with fungi or bacteria)

These should not be opened but transported and loaded, at the allotted time, into the "dirty" autoclave in the washroom for inclusion in liquid discard cycle. All lids must be loosened at the autoclave when the material is loaded.

In the event that the "dirty" autoclave is still running the previous cycle, being serviced or out of order, all discard boxes or other contaminated materials must be returned to their lab of origin. They MUST NOT be left at the autoclave or given to the washroom staff.

Other methods.

Any other method or disinfecting agent (eg stericol, gluteraldehyde, SDS) required for scientific or personal reasons (eg sensitivity reactions) must be treated as a separate experimental procedure with its own evaluation of efficacy and risk assessment form.

General
Aerosols
Benchworkers should be wary of all techniques and manipulations which give rise to aerosols when using hazardous materials eg filling used burrers contaminated with viruses. Where practicable these procedures should be performed in an appropriate safety cabinet.

Biological materials
It is recommended that all vessels used with biological materials be disinfected eg burrers used for non infected cell growth be treated with Virkon before discarding to normal waste.

WASTE DISPOSAL

The disposal of waste chemicals and solvent can often cost more than the original material. It is important, therefore, when orders are placed for chemicals that only sufficient is ordered for your immediate use. Waste disposal must be considered as integral to all laboratory procedures. These notes summarise the principles of waste disposal organisation and describe the approved System of Work for discarding labware.

The guiding principle is that scrupulous care must be taken to protect the interests of cleaners, other staff, the public and the environment.

Waste-bag colour code and disposal routes.

BLACK - Non-hazardous; cleaners may remove

RED - These are for material requiring the attention of specialist waste disposal companies and are for compounds (eg ethidium bromide) identified in risk assessment forms. See "Waste Chemicals" below.

YELLOW - These will not be available to laboratory workers. They are for incineration of autoclaved clinical waste.

TRANSPARENT/BIOHAZARD - Microbiological waste for autoclaving. These must be transported in the metal disposal boxes and placed in the "dirty" autoclave in the washroom at the appropriate times.

General waste
General waste in the laboratory may be put into the normal disposal containers. However, it is important that broken glass and other hazardous waste is kept separate.

Waste solvents
Solvent waste is collected in metal drums at the back of the spirit store. Potential hazards exist in mixing different solvents and there are separate drums for each of three categories of waste:

1. Flammable, eg ether, methanol, acetone.
2. Non-flammable, eg DMSO, phenol, chloroform.
3. Oils, eg waste from centrifuges, pumps, etc.

The material and amount disposed of in each category must be entered into the appropriate log book provided stating your name and date. Consult the Technical Services Manager if you are in any doubt as to which category your waste belongs. Make sure that there is adequate room left in the drum before starting. There should always be an empty drum below the one in use. If you finish a drum, inform the Technical Services Manager. Absorption granules for soaking up any solvent spillage are available in the solvent store.
From the local Committee minute of 01/05/2002:

It was noted that all relevant staff were CL3 trained.

6.1 In discussion no major problems were identified but it was noted that, with BVDV being modified, HSE approval of a new GM Activity would be required.

6.2 It was noted that RME and others had used a similar HCV protease-dependent system.

6.3 Some textual revisions were required, to strengthen the proposal. The introduction should state that BVDV is not a Specified Animal Pathogen. Also, a few more papers on existing recombinants should be cited since there are more recent papers on recombination in vitro (RME to advise). Section 6 should mention that some recombinants will have both BVDV glycoproteins and HCV proteins.

6.4 Subject to these changes, the proposal was agreed for presentation to the HSE as a new class 3 notification.

This project covers the broad area of the use of disabled adenovirus vectors for the expression of cloned genes of interest in mammalian cells. Several such vector systems are now available, some commercially, and while they vary in detail, they have in common the lack of the essential E1A gene, and therefore they can be propagated only in complementing cell lines. This genetic modification proposal is intended to register the use of adenovirus vectors for gene expression in the Division of Virology. The risk assessment for each such project will be considered on an individual basis as such proposals are made, with specific reference to the vector system and cloned inserts being used. These future proposals will be considered as an amendment to this parent proposal.

Recipient or parental organism

Complementing cell lines 293 and 911, which express the adenovirus E1A protein, will be used to propagate stocks of the recombinant adenoviruses.

Host/vector system

The viruses will be used for experimentation in standard mammalian cultured cell lines such as Hep2, human foetal fibroblasts and Vero cells. The virus vectors are those commercially supplied by BD Biosciences (for full information see http://wwwbdbiosciences.com/clontech/techinfo/manuals/index.shtml). These are rountinely used in many laboratories around the world and are accepted as Category 2 pathogens.

The adenovirus vectors to be used are of two types. Firstly those in which constitutive expression of the cloned genes is under the control of the human cytomegalovirus immediate-early promoter region. Secondly, a tri-partite inducible expression system, in which expression of the cloned genes is controlled by an inducible tetracycline responsive promoter, and the tetR-VP16 fusion activator protein provided in trans by a second adenovirus vector (Ad.CMV-rtTA). Thus the recombinant proteins will be expressed only in cells treated with tetracycline derivatives and co-infected with both adenoviruses.

Origin & function

The initial list of the viruses to be utilised is:-
Ad.CMV-null: Adenovirus vector with HCMV IE promoter and no insert.
Ad.TRE-null: Adenovirus vector with Tet-responsive promoter and no insert.
Ad.CMV-GFP: Adenovirus vector with HCMV promoter and EGFP insert.
Ad.TRE-GFP: Adenovirus vector with Tet-responsive promoter and EGFP insert.
Ad.CMV-PMLwt: Adenovirus vector with HCMV promoter and wt PML insert.
Ad.CMV-rtTA: Adenovirus vector expressing the doxycycline-inducible transactivator of the TRE promoter.
Ad.TRE-PMLwt: Adenovirus vector with Tet-responsive promoter and wt PML insert.
Ad.TRE-ICPO: Adenovirus vector with Tet-responsive promoter and ICPO insert.
Ad.TRE-n212: Adenovirus vector with Tet-responsive promoter and ICPO insert truncated at residues 212.

Abbreviations:
HCMV  Human cytomegalovirus.
TRE  Tetracycline responsive element.
GFT  enhanced green fluorescent protein
PML  Promyelotic leukaemia protein.
ICPO  Infected cell protein O of HSV-1
HSV-1  herpes simplex virus type 1

Evaluation of foreseeable effects

The adenoviruses to be used are defective for the essential E1A gene products and they are also deleted for the E3 region, so they are unable to replicate and spread in normal human cells. However, the inserted genes are designed to be expressed in mammalian cells, and therefore the project is designated as Level 2. Increased expression of the PML proteins is very unlikely to be harmful since PML is expressed in a wide range of cell types, and high level expression of PML is a normal consequence of interferon treatment of cells. ICPO is very unlikely to be more harmful to man when expressed in the tet inducible vector virus pair than when expressed during the course of a normal HSV-1 infection. Detailed safety guidance concerning these adenovirus vectors, and the protocols approved for their use in the National Institutes of Health, Bethesda USA, is available at: http://www.bdbiosciences.com/clontech/techinfo/manuals/index.shtml

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Extract from the Divisional Safety Handbook.

DISINFECTION POLICY

The three methods for disinfection are as follows:
1. Chloros - 1% v/v
2. Virkon - 1% w/v
3. Autoclaving

All of the above methods can be used for herpes, adeno, vaccinia, bunya, respiratory syncitial, measles, chandipura and bacula viruses. Material derived from other viruses must be disinfected by autoclaving and possibly inceration as described in the relevant risk assessment form.

The methods are also suitable for E. coli.

Chloros (outwith the laboratory)
For bulk overnight steeping of glassware
Laboratories will be supplied daily with a trolley on which are large round vats for heavy glassware and smaller rectangular vats for light glassware. The appropriate volumes of stock Chloros is pre-dispensed in accompanying plastic bottles.

NB With the exception of empty pipette cans and chloros containers, no other items are permitted on this trolley.

Virkon (within the laboratory)

For bulk liquids (eg discarded tissue culture media)
Virkon powder *should be added to give a 1% w/v final concentration and the container mixed thoroughly.

For large containers (eg burriers, large and medium tissue culture flasks)
Treat with 1% w/v Virkon, either by adding powder and filling with water as above, or by dilution of a fresh concentrate. Stock solutions of Virkon must be dated: they retain efficacy for 1 week. Care should be taken to resuspend and pellet or clumped material and to completely fill the container, swabbing the threads and then inverting closed flasks and burriers to ensure the neck is treated.

With both of the above methods the treated containers must be soaked for a minimum of 1 hour before disposing liquid down the sink, glassware to normal wash-up and plasticware to normal solid waste (black bags) - laboratory personnel must remove any large bulk waste to cleansing department bins. It is recommended that materials being disinfected are clearly marked.

For large glass conical flasks (greater than 1 litre capacity)
These should be filled with 1% w/v Virkon and placed on the designated trolleys located on the first and second floors. The washroom staff will empty these trolleys first thing in the morning. These trolleys are for the disposal of large flasks only - other material must not be left on them.

For surfaces, equipment and instruments
Surfaces should be swabbed with 1% w/v Virkon (less than one week old). Equipment and instruments can be similarly disinfected but extreme caution should be exercised with electrical equipment. If in doubt see the Technical Services Manager.

* While Virkon is regarded as an extremely safe compound, care should be taken when dispensing dry powder in bulk. A protective face mask could be used to prevent inhalation.

Autoclaving
For small vessels (eg petri dishes and small tissue culture flasks)
These should be placed in the biological waste discard boxes (lined with clear bags) in each lab.

For higher risk organisms (eg clinical isolates, hepatitis, HIV)
These should be placed in the biological waste discard boxes (lined with biohazard bags) which will be autoclaved prior to incineration of the contents.

For contaminated material (eg burriers with fungi or bacteria)
These should not be opened but transported and loaded, at the allotted time, into the 'dirty' autoclave in the washroom for inclusion in liquid discard cycle. All lids must be loosened at the autoclave when the material is loaded.

In the event that the 'dirty' autoclave is still running the previous cycle, being services or out of order, all discard boxes or other contaminated materials must be returned to
their lab of origin. They must not be left at the autoclave or given to the washroom staff.

Other methods
Any other method or disinfecting agent (eg stericol, gluteraldehyde, SDS) required for scientific or personal reasons (eg sensitivity reactions) must be treated as a separate experimental procedure with its own evaluation of efficacy and risk assessment form.

General

Aerosols
Benchworkers should be wary of all techniques and manipulations which give rise to aerosols when using hazardous materials eg filling used burriers contaminated with viruses. Where practicable these procedures should be performed in an appropriate safety cabinet.

Biological materials.
It is recommended that all vessels used with biological materials be disinfected eg burriers used for non infected cell growth be treated with Virkon before discarding to normal waste.

WASTE DISPOSAL
The disposal of waste chemicals and solvent can often cost more than the original material. It is important, therefore, when orders are placed for chemicals that only sufficient is ordered for your immediate use. Waste disposal must be considered as integral to all laboratory procedures. These notes summarise the principles of waste disposal organisation and describe the approved System of Work for discarding labware.

The guiding principle is that scrupulous care must be taken to protect the interests of cleaners, other staff, the public and the environment.

Waste-bag colour code and disposal routes.

BLACK = Non-hazardous; cleaners may remove.
RED = These are for material requiring the attention of specialist waste disposal companies and are for compounds (eg ethidium bromide) identified in risk assessment forms. See "Waste Chemicals" below.
YELLOW = These will not be available to laboratory workers. They are for incineration of autoclaved clinical waste.
TRANSPARENT/BIOHAZARD = Microbiological waste for autoclaving. These must be transported in the metal disposal boxes and placed in the "dirty" autoclave in the washroom at the appropriate times.

General waste
General waste in the laboratory must be put into the normal disposal containers. However, it is important that broken glass and other hazardous waste is kept separate.

Waste solvents
Solvent waste is collected in metal drums at the back of the spirit store. Potential hazards exist in mixing different solvents and there are separate drums for each of three categories of waste.

1. Flammable, eg ether, methanol, acetone.

Project Ref 26/11.1
Arboviruses are transmitted to susceptible vertebrates by arthropod vectors such as mosquitoes or ticks. Most arboviruses belong to the Flaviviridae, Bunyaviridae and Togaviridae families of RNA viruses. While arboviruses can cause disease in vertebrates ranging from febrile illness to more severe complications, depending on virus and/or host- as well as cell death in infected cultured cells, this appears not to be the case in the arthropods that transmit them. In fact, arbovirus-infected arthropods display few or no signs of disease (Fragkoudis et al., 2009), and this effect can be mimicked in arthropod cell culture.

Infection of mosquito or tick cells usually begins with an acute phase with high titre virus production followed by a persistent infection which, once established can last the life time of the arthropod cell culture. The biological reasons behind persistence are poorly understood and are believed to be linked to innate immune responses of the arthropod host. Research on antiviral immune responses in vector arthropods has only in recent times seen some progress yet this area of research is crucial in understanding this virus/host interaction and develop novel antiviral control strategies targeting the vector. It is now clear, mainly from research on arbovirus-infected mosquitoes, that vectors do not passively replicate arboviruses but that immune responses are activated. These can result in activation of immune signalling pathways (STAT, Toll etc.), humoral responses in the arthropod hemocoel and most crucially RNA interference (RNAi) responses. It is not known how immune signalling pathways are activated following infection or how exactly they would mediate antiviral activities, and extracellular responses such as phenoloxidase activities also appear to be involved. The RNAi responses are better understood and form a major antiviral defence. Viral replication induces production of double stranded RNA which serves as a substrate for dicer-type nuclease activities to produce virus-induced small interfering RNAs (also called viRNAs in the context of viral infection) which are integrated into the RNA-induced silencing complex (RISC). The RISC presumably mediates antiviral activities by finding viral RNAs through complementarity with viRNAs and then mediating nucleolytic cleavage of those viral RNAs. Although some steps in this antiviral pathway are known, mechanisms, triggers etc. are poorly understood. In addition, arthropod cells might differentially regulate subsets of their own small RNA repertoire following infection by arboviruses.

In this project, we aim to further analyze:

- The induction, regulation and mechanisms of antiviral signalling pathways such as STAT, TOLL, IMD etc. in arthropod cells such as mosquito and tick cells, as well as mosquitoes and tick organ cultures. This project will look at protein functions and signalling regulation within these pathways.
- The induction, regulation and mechanisms of humoral, extracellular antiviral responses. We will analyse viral triggers and key components that lead to activation of extracellular responses. This project will be carried out in arthropod cells such as those derived from mosquitoes and ticks, but also live mosquitoes, and tick organ culture.
To study virus replication in arthropod cells, we will use a cDNA copy of the LGTV genome (a positive-stranded RNA of approx. 11 kb encoding a polyprotein with structural sequences followed by non-structural sequences) available, allowing manipulation of the genome (Rumantsyev et al., 2006). This plasmid has been engineered or will be engineered to delete sequences (for example for replicon production), mutate specific sequences or insert genes such as reporter genes (for example fluorescent molecules such as YFP, eGFP or various types of luciferase), insect immune response inhibitors or drug resistance genes (to facilitate selection of cells harbouring replicons). Genetic changes that will be introduced into the virus sequences (point mutations, deletions, insertions) will be targeted at disrupting specific functions of virus RNA or virus proteins and can be expected to attenuate virus fitness; such changes are highly unlikely to increase virulence. The viral envelope glycoprotein and capsid protein sequences which are the major determinants of host range and cell tropism will not be changed beyond the addition of marker genes such as GFP (as fusion or cleavable inserts into this coding region); host range and cell tropism are therefore unlikely to be altered. Changes to viral sequences will target disruption of viral protein functions or sequences.

LGTV can be directly used to infect cells. cDNA plasmids with LGTV sequences will be amplified using standard disabled laboratory strains of bacteria (usually strain BD1528 which is routinely used for flavivirus cDNAs). Plasmids or transcribed RNA will be transfected into eukaryotic cells. Depending upon the construct, in eukaryotic cells this may result in replication of virus RNA and production of new virions. Virus or virus replicon particles generated from these plasmids will be used to infect eukaryotic cell and tissue cultures, to investigate virus replication in arthropod cells such as tick cells or tick organ cultures (derived from ticks). The use of LGTV expressing a reporter gene such as GFP or luciferase will allow accurate, rapid, efficient, localised and repetitive monitoring of infection of cells and tissues which is important for immunity studies.

In addition to the use of LGTV, we plan to carry out comparative studies between LGTV replicons and replicons of other arthropod-borne flaviviruses such as tick-borne encephalitis or dengue virus; those replicons are not covered by Schedule 5 and no sequences for complete schedule 5 virus genomes (e sequences encoding missing structural genes that are required to complement the full set of viral proteins to produce infectious virion) are stored in-house. Those replicon RNAs will not be packaged; only RNA will be introduced into cells to study replication; replicons will not be mixed in the same cells (either by co-transfection/infection or potential superinfection by spreading virus) with sequences of related viruses from within the same genus to avoid recombination events during co-infection (recombination can only occur when viruses replicate in the same cell). Like LGTV-derived replicons, other flavivirus replicons pose no risk to safety to human and animal health as they cannot spread and transfected cells will be eliminated by cell death or the immune system. Experiments with these replicons will be carried out to study host innate immune responses (RNAi, immune signalling) and/or virus-host cell interactions (protein interactions, replication complex localization in cells etc.). These experiments will complement studies carried out in other laboratories.
2. As a model for Togaviridae (genus Alphavirus) infection of arthropod cells, we will study infections by Semliki Forest virus (SFV). SFV is naturally found in central and Southern Africa and is transmitted between animals and birds by mosquitoes (mainly Ae. aegypti and africanus). SFV can infect man and is classified as a hazard group 2 pathogen by the ACDP. The alphavirus genome consists of a single strand of positive sense RNA of around 12 kb. This RNA codes for two open reading frames. The first codes for the non-structural viral replicase proteins (nsP1, 2, 3 & 4), the second for the viral structural proteins (C, E1, E2 & E3). Expression of the replicase proteins is under the control of a promoter (P) in the 5’ non-coding region of the virus. Expression of the structural proteins is under the control of a subgenomic promoter (SP) which is activated later in infection and leads to a high level of expression from this second open reading frame.

There are several strains of SFV which have been derived from natural isolates, these include prototype SFV4, L10, A7 and A7(74). Each of these strains has been cloned and sequenced and is available as a series of plasmids which can be amplified in standard bacterial systems. In vitro transcription of the plasmid cDNA can give rise to an RNA which when transfected into cells can give rise to infectious virus; alternatively RNA is transcribed from transfected plasmid under control of eukaryotic promoters such as the CMV promoter. The SFV cDNAs can be engineered to give rise to virus mutants or engineered viruses. The prototype strain SFV4 forms the basis of the SFV vector system which is widely used for eukaryotic gene expression (Smerdou and Liljestrom, 1999). SFV natural isolates, cDNA derived viruses and mutant viruses derived from these cDNA clones have been used extensively by us and others. In mice, different strains show different pathogenicity and these are likely to be due to sequence differences. We will produce and use genetically engineered SFV viruses mutated in viral proteins or sequences expressing additional genes (reporter genes such as luciferase or fluorescent proteins, insect immune response antagonists etc.) as part of the non-structural open reading frame, the structural or from duplicated subgenomic promoters (Siu et al., 2011; Attarzadeh-Yazdi et al., 2009). If the coding sequence for a protein such as a reporter gene would be inserted into the viral structural polyprotein-coding sequence, in the resultant hybrid polyprotein the added protein would be separated from the structural proteins by protease cleavage sites. No changes to the sequence of the structural proteins would ensue so that there would be no changes to virus tropism resulting from changes to the structural proteins. Introduction of additional sequences into SFV is likely to provide no change or to decrease virulence. Changes to viral sequences will target disruption of viral protein functions or sequences.

In addition to infection with SFV, it is possible to use virus-derived replicons. In replicons, the structural genes are replaced by a polylinker which allows insertion of foreign sequences. The system exploits the wide cell tropism of SFV, but has no potential for virulence since genes for the viral structural proteins are deleted. A helper system is also available whereby recombinant RNA can be packaged into infectious virus-replicon particles (VRP); this system is deemed extremely safe (Smerdou and Liljestrom, 1999). Packaging of genomic RNA into new virions is absolutely dependent on a packaging sequence in the replicase gene. Packaged VRPs are made by using cells which also express the viral structural genes (usually by cotransfection of structural gene-encoding mRNA transcripts). In the absence of genes encoding the viral structural proteins in replicons, new infectious virus particles capable of initiating a propagating infection cannot be regenerated in VRP-infected cells; VRPs are thus also referred to as ‘suicide particles’. Replicons can be used to express reporter genes or other genes of interest such as insect RNAi inhibitors.

SFV and engineered variants will be used to infect eukaryotic cell and tissue cultures, as well as arthropods such as mosquitoes. The use of genetically modified marker viruses will allow monitoring of infected cells and tissues, determination of the spread of infection and dissection of specific tissues / areas or even specific cells for further analysis. Again these properties are very useful to study immune responses in arthropod cells and tissues.

In addition to the use of SFV we plan to carry out comparative studies with other arthropod-borne alphavirus replicons such as those derived from chikungunya virus; those replicons are not covered by schedule 5 and no sequences for the complete genome (ie sequences encoding structural genes required to complement the viral protein set to give infectious virions) will be stored in house. Those replicons will not be packaged into VRPs, only RNA will be introduced into cells to study replication; replicons will not be mixed with related viruses from within the same genus in the same cell (either by co-infection/transfection, or potential superinfection by spreading virus) to avoid recombination events during co-infection. Like SFV-derived replicons, other alphavirus-derived replicons pose no risk to safety or human health as they cannot spread and transfected cells will be eliminated by cell death or the immune system. Experiments with these replicons will be carried out to study host innate immune responses (RNAi, immune signalling) and/or virus-host cell interactions (protein interactions, replication complex localization in cells etc.). These experiments will complement studies carried out with LGTV and allow us to verify how broadly relevant some findings (those that do not rely on formation of infectious virus or/and virus spread) obtained with a model virus are to other members of the family.
out with SFV and allow us to verify how broadly relevant some findings (those that do not rely on formation of infectious virus or/and virus spread) obtained with a model virus are to other members of the family.

References:

Recipient or parental organism

Arboviruses and derived replicons used will be of the Flaviviridae and Togaviridae (genus Alphavirus) virus families.

Togaviridae:
Semliki Forest virus prototype (SFV4), and strains such A7 and A7(74).
Semliki Forest virus-derived replicons and virus-replicon particles.
Other arthropod-borne alphavirus replicons (for example derived chikungunya virus).

Flaviviridae:
Langat virus (strain TP21, the most commonly used lab strain, or others).
Langat virus-derived replicons.
Other arthropod-borne flavivirus replicons (for example derived from tick-borne encephalitis virus and dengue virus).

Host/vector system

All organisms will be used at containment level 2, which is routine practice.
Plasmid vectors:
Viral sequences (including full length clones or partial sequences of SFV or LGTV) and other genes (cellular, viral or reporter) are available in plasmid-encoded cDNA form. RNAs can be transcribed through bacterial promoters (ie. T7 or SP6) or eukaryotic promoters (CMV, SV40 etc.) Plasmids contain an origin of replication followed by a prokaryotic selectable marker (usually antibiotic resistance against ampicillin or kanamycin) and sometimes a selectable eukaryotic drug resistance marker such as neomycin or puromycin resistance. The bacterial systems are non-mobilisable vectors in a disabled prokaryotic host.

Hosts:

Prokaryotic hosts:
Disabled, commercially available E. coli strains such as Sure, JM109, XL-strains, DH-strains, Rosetta etc. These strains can only survive in a controlled laboratory environment and will be used for propagation of plasmids. Good microbiological practice and sterilisation of all contaminated waste should prevent release of viable organisms. The risk to the environment is therefore effectively zero.

Eukaryotic hosts:
Vertebrate cell lines of various origins (typically mouse, hamster, etc.) and invertebrate cell lines of various origins (mosquito, tick etc.). Mosquitoes, mainly strains of Ae. aegypti (such as the laboratory strain Liverpool red eye). Tick organ cultures from dissected ticks.

Origin & function

In prokaryotic cells, only selectable (eg antibiotic resistance) genes will be translated.

Virus sequences will be under the control of a promoter that will only generate transcripts in eukaryotic cells or in vitro transcription reactions.

In eukaryotic cells, RNA will be translated into the following gene products:

- Arboviral proteins and RNAs (SFV and LGTV, or replicons of related arboviruses): Proteins involved in replication and transcription of viral genetic material and virus structural proteins. Some of these virus proteins will interact with host-cell components and may affect host cell responses to infection; these interactions are not currently known. If all virus sequences are translated new virions may be generated; replicons are non-propagative viral RNAs (capable of replication). Partial RNAs do not give rise to propagating infectious material but can display biological activities (ie. RNAi inhibitory, expression of some viral proteins for example for packaging of replicons).

- Non-arboviral genes: Genes of prokaryotic (eg CAT) or eukaryotic (eg. reporter genes such as luciferases or fluorescent proteins such as GFP; inhibitors of insect immunity ie. RNAi inhibitors, signalling inhibitors, melanization inhibitors etc.) origin. No proteins known to interfere with vertebrate immune responses will be cloned into full length SFV or LGTV. The recombinant foreign proteins to be expressed provide no significant increase in the hazard to human health; none are toxic or likely to produce disease in the quantities that could be produced by accidental exposure to these systems. Non translated RNA sequences have no known toxic effects and pose no risk to human health.

Techniques used to introduce insert or vectors into cells:

Prokaryotic cells: Introduction of DNA into E. coli will be by heat shock/chemical transformation. These techniques have been extensively described and are widely used; they rely on getting DNA very close to the bacterial membrane and introducing the genetic material through pores or membrane fusion.

Eukaryotic cells: Mammalian cells will be transfected using reagents such a lipofectamine or by electroporation. Virus genomes will be introduced into cultured cells or tick organ cultures by infection with virus or virus replicon particles (VRP), using transfection reagents or by electroporation.
Note: location and nature of where experiments are to be carried out:

GM 26 (CVR Church Street):
- Preparation, characterisation and genetic manipulation of viruses and replicons.
- Infection of cell lines and organ cultures, preparation of lysates, extracts and fixed tissues for downstream analysis.

GM223 (CVR Garscube Estate):
- Infection of Ae. aegypti mosquitoes with Semliki Forest virus (SFV) (wild type or genetically modified) or VRPs by bloodmeal.
- Isolation of SFV, or nucleic acids or proteins from Ae. aegypti mosquitoes for downstream analysis (for example real time PCR for quantification of gene expression, reporter gene assays etc.).
- Fixation of mosquito tissues for downstream analysis (immunofluorescence, fluorescent reporter gene expression).

Evaluation of foreseeable effects

Foreseeable effects/risk assessment for human health and safety (also see Risk Assessments):

Plasmid vectors:
Viral sequences (including full length clones or partial sequences of SFV or LGTV) and other genes (cellular, viral or reporter) are available in plasmid-encoded cDNA form. Plasmid vectors are based on bacterial plasmids and contain an origin of replication for prokaryotic cells and selectable antibiotic/drug resistance (pro- or eukaryotic) markers. By themselves these vectors present no risk to human health. Vectors have no selective advantage and would soon be lost from the bacterial population. The bacterial systems are non-mobilisable vectors in a disabled prokaryotic host. Transcription of even complete viral cDNA (SFV or LGTV) will result in no infectious RNA since the promoters are not active in prokaryotic hosts. Systems for prokaryotic gene expression are under control of an inducible prokaryotic promoter. Systems for eukaryotic RNA or protein expression are under the control of promoters of viral (such as CMV or SV40), eukaryotic (eg actin promoter, pathway inducible promoter such as STAT) or prokaryotic (such as T7 or SP6 promoter for in vitro transcription) origin. Plasmids with eukaryotic promoters such as the CMV promoter can be transcribed in human cells. None of the genes used in these studies are oncogenes. The hazard of expressing ‘foreign’ genes from these eukaryotic promoter plasmids would depend on the expected physiological effects of the foreign gene product and is discussed in more detail below.

SFV:
In Africa, natural infections have been associated with mild febrile illness (Mathiot et al., 1990). Various laboratory strains of SFV including prototype-SFV4, L10, A7 and A7(74) have been used extensively in many laboratories and even (in the past) for student practical classes. There is one report of laboratory based human disease. Death of a laboratory worker in Germany was associated with infection by the Osterrieth strain of SFV (Willems et al., 1979). This (Osterrieth) strain of SFV is no longer used experimentally. Whilst the above case report is noted, it dates back over 30 years and is difficult to reconcile with the extensive use of other strains of SFV with no reported adverse effects over a 50 year period. This case report makes the unpublished observation that antibodies against SFV can be demonstrated in the serum of many laboratory personnel working with it. It is generally considered that the individual who died was probably immunosuppressed and therefore highly susceptible to infection. Anecdotal reports and reported laboratory incidents indicate no human clinical signs after accidental inoculation with various laboratory strains of SFV. The classification into ACDP hazard group 2 indicates current expert opinion that containment level 2 precautions are considered adequate for controlling the risks associated with working with SFV. The viral envelope glycoproteins and capsid protein sequences are the major determinants of host range and cell tropism and will not be changed beyond the addition of marker genes such as GFP (as fusion or cleavable inserts into this coding region) into the structural open reading frame; host range and cell tropism are therefore unlikely to be altered. SFV is classified as ACDP hazard group 2. Personnel working with this virus are expected to inform occupational health should they become pregnant or immunosuppressed.

LGTV:
Under normal conditions, LGTV is only very rarely pathogenic to humans; live virus has been used in vaccine trials in humans (Dubov et al., 1962). Development of this vaccine was stopped in the 1980s because of rare (1 in 20,000) occurrences of post-vaccinal neurological disease (Rumyantsev et al., 2006). Genetic changes that will be introduced into the virus sequences will be targeted at disrupting specific functions of virus RNA or virus proteins and can be expected to attenuate virus fitness; such changes are highly unlikely to increase virus virulence as they modify virus sequences, or change genome length, or lead to expression of additional sequences such as
reporter genes which confer no advantage to virus replication. As for SFV, the viral envelope glycoproteins and capsid protein sequences which are the major determinants of host range and cell tropism will not be changed beyond the addition of marker genes as fusion or cleavable inserts into the region coding the structural proteins; host range and cell tropism are therefore unlikely to be altered. LGTV is not listed on the ACDP list but should be classified as hazard group 2 (current use in the UK and internationally, see http://www.healthsafe.uab.edu/pages/biosafety/biosafetymanual.pdf). Personnel virus working with this virus are expected to inform occupational health should they become pregnant or immunosuppressed.

The host/recipient organism:
Prokaryotic organisms: All strains will be disabled, commercially available E. coli derivatives classified as 'especially disabled hosts' by ACDP. These strains cannot colonise humans and are known not to cause harm to humans.

Eukaryotic cells and tick organ cultures:
Cell lines to be used would not survive inside the human body (immune rejection) and are not known to carry harmful pathogens. Addition of DNA or RNA will confer no growth or survival advantage in or outside the laboratory to cell lines of vertebrate or arthropod origin. The tick organ cultures are derived from dissected ticks and are immobile culture systems. As with the cell lines they could not survive in humans. Organ cultures are generally derived from ticks sourced from 'pathogen-free' colonies; ticks from other sources (for example 'field ticks') could carry other pathogens and will not be used in these studies.

Mosquitoes (also see paragraph 8, below): These will be sourced only from 'pathogen-free' laboratory colonies (provided by Prof. Eileen Devaney, University of Glasgow). Precautions will be taken to minimise the risk of bites or escapes in strict compliance with standard operating procedures (attached separately). Work with virus replicons and VRPs will be done under the same procedures and containment as work with infectious virus (wild type or genetically modified). Measures to prevent human infection include storage of infected arthropods in sealed containers; work in designated rooms with restricted access; wearing of gloves and cooling of arthropods to slow their movement and facilitate handling. Samples (dead arthropods or material from these) will be transported to our CL2 laboratory according to standard regulations.

The inserted/donated genetic material:
Viral RNA and proteins, cellular proteins: Most individually expressed viral or cellular proteins (for example arthropod immune response inhibitors) are unlikely to have harmful effects in eukaryotic cells, however some could perturb normal arthropod cellular metabolism, predispose or protect against cell death or render cells more or less susceptible to other infections. It is very unlikely that SFV or LGTV (and other alphavirus, flavivirus or insect virus) RNA or proteins would have any harmful toxin-like effect outside cells. RNA containing the complete SFV or LGTV sequence can give rise to infectious virus in eukaryotic cells; alphavirus and flavivirus replicon RNAs are non-propagative and pose no harm (individual infected cells are likely to die or be eliminated by the immune system). Viral non-coding RNA sequences are likely to have minimal effects on virus replication, especially outside arthropod cell systems, and do not encode biologically active molecules that are likely to induce physiological effects in humans. As described under (9), no proteins or sequence which could interfere with immune responses in vertebrates will be cloned into viral genomes. Reporter genes: Reporter genes of prokaryotic or eukaryotic origin (eg luciferase, fluorescent proteins etc.). No harmful properties have been attributed to these proteins. There would be no altered physiology expected if any of these genes were expressed; eGFP for example is a spontaneously fluorescent protein isolated from Aequorea victoria a coelenterate and has no known detrimental effects. Luciferase is another commonly used reporter gene and is derived from the firefly Photinus pyralis or the jellyfish Renilla reniformis. It is an enzyme which catalyses production of light from luciferin and ATP; the light produced is used as a measure of gene activity. The enzyme has no other biological function. Other non coding RNA sequences: Any effects these elements have on gene expression are likely to be minimal. They may affect gene function or virus replication in individual cells but are unlikely to lead to whole body physiological effects as they do not code for the production of secreted bioactive molecules, and are unlikely to have any biological effects outside arthropod cell systems.

Sequence changes in viral sequences:
Mutation or deletion will target disruption of non-structural protein functions or non-coding viral sequences and are likely to have no or deleterious effects on viral replication, thus not increasing risk or hazards to human health associated by viruses genetically modified in such a way.

Control measures – assign provisional containment level:
GM bacteria transfected with plasmids containing viral sequences - Containment Level 1.
Eukaryotic cells (including tick organ cultures) containing alphavirus or flavivirus sequences unable to form complete infectious virus – Containment Level 1.
Eukaryotic cells (including tick organ cultures) containing full length SFV/LGTV sequences (capable of forming infectious virus, or capable of undergoing recombination or minor mutations to form infectious virus) – Containment Level 2.
Arthropods containing viral sequences unable to form complete infectious virus – Arthropod Containment Level 2.
Arthropods containing full length viral sequences (capable of forming infectious virus, or capable of undergoing recombination or minor mutations to form infectious virus) – Arthropod Containment Level 2.
All with Good Microbiological Practice and Good Occupational Safety and Hygiene. Wear laboratory coat and gloves. For work with mosquitoes, wear a white laboratory overall with elastic cuffs, gloves and a mosquito net that covers the head. A microbiological safety cabinet will be used where appropriate.

Foreseeable effect/risk assessment for the environment:

SFV: This virus is not endemic in the UK. It is not on the SAPO list. It is not clear whether suitable vertebrate hosts and insect vectors are present to establish an infection in this country. SFV can infect vertebrates (such as rodents) and certain biting insects. It is unclear whether suitable hosts are present. Transmission to vertebrates is by inoculation and to insect is by feeding on blood of an infected vertebrate. SFV is naturally transmitted by mosquitoes such as Aedes aegypti and Aedes africanus. Given the absence of these specific mosquitoes in Scotland and low pathogenicity of strains, the chance of infected laboratory mosquitoes (unlikely to survive for any extended length of time in the local environment) initiating a transmission cycle sustained by local insects is negligible. The modified viruses or replicons or replicons of other arthropod-borne alphaviruses will not have any inserted foreign genes other than non-harmful genes or sequences, or disruptive changes in non-structural genes or non-coding sequences; changes in virus pathogenesis are therefore unlikely other than as described above under the human health and safety section. In the absence of a suitable host or vector these viruses would not survive in the environment and the risk is effectively zero.

LGTV: This virus is not endemic to the UK. It is not on the SAPO list. LGTV is naturally transmitted by ticks; it was originally isolated from Ixodes granulatus ticks in SE Asia. The competence of UK ticks for this virus is unknown. A related virus, Louping-III virus, is found in ticks throughout the British Isles. Given the location of our laboratories, tick populations are likely to be very low in the immediate vicinity. Ticks generally acquire infection from a blood meal on vertebrates and as ticks are excluded from our laboratories, and viruses stored in closed containers the chance of accidental tick infection is negligible. Modified viruses or replicons or replicons of other arthropod-borne flaviruses do not contain anything other than non-harmful genes or sequences, or disruptive changes in non-structural genes or non-coding sequences; changes in virus pathogenesis are therefore unlikely other than as described above under the human health and safety section. The likelihood of virus released from our laboratory infecting a local tick is effectively zero (see disinfection and waste disposal procedures).

Hosts:

Prokaryotic organisms: Disabled, commercially available E. coli strains. These strains can only survive in a controlled laboratory environment and will be used for propagation of plasmids. Good microbiological practice and sterilisation of all contaminated waste will prevent release of viable organisms. Acquiring antibiotic resistance (from the plasmid vector) or additional sequences (virus or marker gene sequences) will not give these strains any survival advantage in the environment. The risk to the environment is therefore effectively zero.

Eukaryotic cells: Cell lines (and tick organ cultures) to be used are not viable outside the laboratory and thus pose no threat to the environment. Addition of plasmid vectors or virus will confer no growth or survival advantage in the environment.

Mosquitoes: Arthropods will be contained as described above under ‘risk to human health’ (and as detailed below, section 8). If arthropods carrying infectious material were to escape from our facilities they would have no survival advantage in the environment but could transmit the infection by bite. Whether this would initiate a natural sustainable cycle of SFV infection in Scotland is unlikely given the generally low mosquito activity. Given that escaped uninfected arthropods and natural arthropods will be
rare and that virus samples are in sealed containers and generally used in microbiological safety cabinets, the chances of arthropods becoming infected in the laboratory outside containment are virtually zero.

In summary

i) consequence/severity of effects: Low

ii) likelihood of effects being realised: Negligible

iii) overall risk: Effectively zero

Final classification: GM bacteria transfected with plasmids containing viral or other eukaryotic sequences (unable to cause disease, minimal hazard to health and environment) - Containment Level 1. Eukaryotic cells (including tick organ cultures) containing viral sequences unable to form complete infectious virus – Containment Level 1. Eukaryotic cells (including tick organ cultures) containing full length SFV or LGTV sequences (capable of forming infectious virus, or capable undergoing recombination or mutation to form infectious virus) – Containment Level 2. Arthropods containing viral sequences (full length, partial) – Arthropod Containment Level 2.

All with Good Microbiological Practice and Good Occupational Safety and Hygiene. Wear laboratory coat and gloves. For work with mosquitoes, wear a white laboratory overall with elastic cuffs, gloves and a mosquito net that covers the head. As a routine measure all work will be carried out Containment level 2. A microbiological safety cabinet will be used where appropriate.

References:

Infection of mosquitoes will take place in a dedicated insectary at arthropod containment level 2 (AcCL2). A standard operating procedure (SOP) has been added separately.

Whole mosquitoes will be injected or fed (membrane feeding or capillary tube) with liquid (including blood) containing virus derived material, infectious virus, or a mixture of these. Viruses, RNA and proteins will be isolated from crushed mosquitoes. Virus infected live mosquitoes may be monitored by microscopy. Arthropods will be studied inside closed containers. In addition wingless mosquitoes may be used (wings will be removed from cold immobilised mosquitoes inside containment – glove box; see below.

ArCL2 is suitable for arthropods infected with hazard group 2 pathogens (human or animal) or Class 2 GMOs eg Semliki Forest virus, Langat virus etc.

Containment:

• The ArCL2 room will be arthropod-proof. Entrance door into insectary separated from surrounding facilities by additional door.
• door to facility will have clear signage indicating ‘arthropod containment level 2, no unauthorized entry’;
• any ventilation inlets and outlets of room and incubators will be screened with gauze or similar of pore size small enough to trap the smallest arthropod life cycle stage;
• windows (if present) and doors will be sealed;
• sinks (if present) will have an adequate arthropod-proof trap or be sealed;
• measures will be taken to enable escapees to be easily detected and recaptured or destroyed (white/clear walls);
• solid and liquid waste will be autoclaved (some invertebrates are not killed by chemical disinfectants or fumigants);
• an insecticidal spray will be available for use in an emergency (ONLY) (use of insecticides may render the room unfit for invertebrates for a long period, if not permanently; non-residual type insecticides should be chosen; insecticides do not have an immediate “knock-down” effect on ticks, but could cause long-term damage);
• infected flying insects will be kept in primary and secondary containment (glove box, incubator);
• primary containers for mosquitoes will be either (i) solid material sealed with a tight-fitting (tape secured with an elastic band) net lid or, (ii) a sleeved netting cage;
• secondary containment for mosquitoes will be either: (i) ‘arthropod-proof’ incubator, transparent or with transparent inner door, (ii) large and robust transparent sealed plastic bag with pin-prick air holes, (iii) transparent glove box, (iv) transparent Perspex box sealed (tape or elastic band) with a net cover;
• experimental containers (both primary and secondary) will be labelled to indicate the date, workers initials, arthropod species, number of arthropods and the nature of any infectious agent; the number of arthropods in each standard primary container will be kept to a minimum and for flying arthropods will not exceed numbers that can be easily counted (ie. 20)
• numbers will be adjusted as arthropods are removed (or to record escapees); each arthropod will be accounted for as the work proceeds through to final fixation or disposal;
• all experiments will also be recorded in a log book (species, worker initial, date, number of arthropods, nature of infectious agent);
• flying or crawling arthropods will be handled on white trays to detect escapees;
• infected arthropods will be killed before they are taken out of the containment facility;
• operating protocols designed to minimise escape and bites will be adhered to.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GM26 (CVR Church Street)

Solids from cell culture (eg plasticware such as flasks, tubes, pipettes tips etc.) - soak in 1% Virkon (w/v) for a minimum of 12 hours. Dispose of as normal solid waste (black bag).

Other solids (agar plates, gloves etc.) placed in a metal disposal box (lined with clear bag) and disposed of by autoclaving using a make safe cycle of 121oC for 30 minutes.

Arthropod-derived material such as the remains of mosquitoes or tick organ cultures will be placed in a metal disposal box (lined with clear bag) and disposed of by autoclaving using a make safe cycle of 121oC for 30 minutes.

Liquids (eg samples, culture supernatants, tissue culture media) – add Virkon to final concentration of 1% (w/v) for a minimum of 12 hours, then discharge to drains.

Liquids (E. coli culture medium)- add Virkon to final concentration of 1% (w/v) for a minimum of 12 h, then discharge to drains.

Sharps (in sharps bin, eg needles, syringes, scalpels) - autoclave by using a make safe cycle of 121oC for minutes.

Degree of kill:
Chemical Sterilization by Virkon- effectively 100% kill.
Autoclaving - effectively 100% kill (annual validation).

GM223 (CVR Garscube Estate):

Solids (pipettes tips, gloves etc.)- place in container (lined with sealed bag) and dispose of by autoclaving using a make safe cycle of 121-123oC for 30 minutes.

Arthropod-derived material such as the remains of mosquitoes will be placed in a sealed container (lined with clear bag) and disposed of by autoclaving using a make safe cycle of 121-123oC for 30 minutes.

Liquids (eg. samples) – dispose of by autoclaving using a make safe cycle of either 121-123oC for 30 minutes.

Degree of kill:
Autoclaving - effectively 100% kill (annual validation).

**Please enter comments on the GM safety committee on the risk assessment**
1. GM 26 committee comments (approval date 25/08/11; see below):

The CVR Church Street GM subcommittee met on 22/08/11 to consider the proposal:
"Arthropod host cell/arbovirus interactions and immune responses induced by virus replication."

Subcommittee members:
R E
J M
A P
F R

The subcommittee members agreed recommendations for modifications to the following topics:

- In Section 12 (Describe the waste management measures etc) of the HSE Notification and Section 16 (Proposed experiments etc, sub-heading Waste Disposal) of the Risk Assessment:
  - Some of the autoclaving cycles specified were not available on the autoclave at the CVR Church Street site.
  - Procedures appropriate for clinical waste, incineration and microwaving were either not in use at the CVR Church Street site or would be expensive to implement. They were considered to be unnecessary for this proposal.
  - The procedure specified placing arthropod derived material into a sealed container for autoclaving. However, autoclaving requires containers be open to allow entry of steam.
  - No procedures for disinfection of contaminated material were described. All material is to be rendered safe by autoclaving, which would entail contaminated material being stored and transported to the autoclaves. This was considered an unacceptable risk, especially for liquid waste, and requires an effective disinfection procedure to be put in place.
  - The subcommittee decided that the relevant entries under section 12 in the HSE Notification and section 16 of the Risk Assessment should be replaced with the existing waste disposal and disinfection policies employed at the CVR Church Street site. These are available on the local intranet. Before this can be approved, validation must be obtained regarding the effectiveness of Virkon for inactivating LGTV and SFV.

- In Section 6 (Purpose of the contained use), reference is made to subgenomic replicons of other arboviruses (eg chikungunya and dengue) that are not otherwise included in this proposal. A full description of the work to be carried out with these agents, the nature of the hazards and the precautions required should be included in both the HSE Notification and Risk Assessment.

Clarification is required for section 8 (Containment and control measures for GMOs that are not micro-organisms; page 11) of the HSE Notification and for section 11, sub-heading Hosts (page 8) of the Risk Assessment concerning the transport of arthropods. The latter states that; "Samples (dead or non-mobile arthropods (our italics) or material from these) will be transported to our CL2 laboratory according to standard regulations." The subcommittee agreed that no living infected arthropods would be allowed in the CVR Church Street site and that they should only be handled in an insectary.
The reference to; “the city centre location of our laboratories” on page 10 of the Risk Assessment is not appropriate for the CVR Garscude site and should be removed.

Under section 7, sub-heading Control measures (page 8) of the HSE Notification, the use of appropriate PPE (not just gloves) should be specified.

An estimate of virus quantities (eg pfu/ml) should be provided in addition to the culture volumes in the HSE Notification, section 9 (Maximum culture volumes per experiment; page 11) and the RA section 16 (Culture volumes; page 14).

The requested changes were made and on 25/08/11 the revised documents were circulated to and approved by the subcommittee members.

2. GM223 committee comments (approval date 20.10.2011, see below):

"The risk assessment was clear but clarification on local mosquito activity was required; more detail on any full length viruses being held, and careful consideration of any possible recombination events was deemed essential. Risks to immune-suppressed personnel needed to be mentioned.

These points have been addressed in form CU2 and Risk Assessment, and on the 20.10.2011 the revised documents were approved.

Dr. G on behalf of the committee."

02/03/2022
The Bunyaviridae is one of the largest taxonomic arbovirus groups (over 300 named isolates). Viruses within the Bunyaviridae are classified into five genera: Orthobunyavirus, Hantavirus, Nairovirus, Phlebovirus and Tospovirus following molecular organization and serotyping [1]. Within a genus, viruses show similar patterns in the sizes of their genome segments and structural proteins, and whether or not non structural proteins are encoded. Bunyaviruses are important examples of emerging viruses, including pathogens of humans and/or animals [2,3]. The bunyavirus genome is a tri-segmented single-stranded RNA genome of negative (or ambisense) polarity that encodes four structural proteins. The genome segments are called L (large), M (medium) and S (small). The L RNA encodes the L protein, the M RNA segment Gn and Gc, and the S RNA the N protein. In addition, some viruses encode non-structural proteins called NSm (M segment) and NSs (S segment). The segments are encapsidated by the nucleocapsid (N) protein and interact with the viral RNA dependent RNA polymerase, the L protein, to form ribonucleoprotein complexes (RNP) known as nucleocapsids. During replication, a positive-stranded antigenome is produced which serves as the template for de novo production of negative-stranded genomes. The polymerase L also transcribes shorter mRNAs which direct synthesis of bunyavirus proteins; interestingly, caps are “snatched” from cellular mRNAs. The bunyavirus terminal 3’ and 5’ sequences are largely complementary and interact to give the genome a characteristic pan-handle structure; these terminal sequences (and other sequence elements adjacent to the protein-coding regions) contain elements regulating transcription and replication of the bunyavirus genome. The RNPs are contained within a lipid envelope into which the two viral glycoproteins Gn and Gc are inserted. Replication occurs in the cytoplasm of infected cells, and viruses mature by budding at Golgi membranes (reviewed in [4]).

Most bunyaviruses are transmitted by arthropod vectors such as mosquitoes or ticks. Infection of arthropod cells is usually not cytopathic while vertebrate cells die following infection. Understanding the molecular basis for the different outcomes of infection in these cells of different origin is of fundamental importance, and may help in the development of new control measures for arboviral diseases. This is likely to imply immune responses (which differ in both hosts) and virus host interactions [5,6]. Research on antiviral immune responses in arthropod vectors has focused on positive-strand RNA viruses. Arthropod vectors activate immune responses upon infection, i.e. immune signalling pathways, humoral responses and most crucially RNA interference (RNAi) responses. Viral replication induces production of double stranded RNA, the RNAi-inducing substrate cleaved by dicer-type nuclease activities to produce virus-induced small interfering RNAs (also called viRNAs in the context of viral infection) which are integrated into the RNA-induced silencing complex (RISC). The RISC mediates nucleolytic cleavage of complementary viral RNAs. In addition, arthropod cells might differentially regulate subsets of their own small RNA repertoire following infection by arboviruses. In vertebrates, it is clear the interferon response is a key factor in limiting bunyavirus replication and this process, as well as bunyavirus antagonism of the interferon (as well as other host antiviral responses such as PKR) is an area which has seen important progress although important questions remain [6].

This project will investigate bunyavirus molecular biology and virus/host interactions, including structure-function analyses of viral proteins and the role of signals within viral RNAs, the interactions of bunyaviruses with host cell components, as well as the role of immune responses in controlling bunyavirus replication.
Two orthobunyaviruses will be at the core of this project. Bunyamwera virus (BUNV) is the prototype virus of the family [7]. Originally isolated in Uganda from infected mosquitoes, most of our understanding of bunyavirus biology is due to studies on this model bunyavirus. We will also study Schmallenberg virus (SBV), which was recently isolated from cattle in Germany and leads to disease (fever, diarrhoea, malformations, abortion) in cattle and sheep [8,9]. Non-hazardous minigenome systems (see below) of bunyaviruses of higher containment levels such as Rift Valley fever virus (RVFV) [10] may also be studied.

A reverse genetics systems that allows manipulation of the BUNV genome is available [11,12]. Cultured cells constitutively expressing bacteriophage T7 RNA polymerase are transfected with a mixture of 3 plasmids, each containing a full-length cDNA copy of one of the bunyavirus genome segments under control of T7 promoter and terminator sequences, and a hepatitis delta ribozyme sequence. Intracellular transcription produces exact copy RNA transcripts that act as viral mRNAs and templates for viral RNA synthesis that result in production of infectious virus. The system was initially established with BUNV and was subsequently adopted by other bunyaviruses such as the orthobunyavirus LaCrosse [13,14]. A reverse genetics system allows us to introduce mutations into the orthobunyavirus genome, as well as to introduce new sequences (such as reporter genes) or change or delete sequences [15,16,17]. Similarly, minigenome systems can be constructed in which only the coding sequences between the terminal orthobunyavirus sequences (either genomic or antigenomic) are replaced with a reporter gene such as Renilla luciferase (RLuc) or eGFP. A minigenome will be transcribed if N and L proteins are co-expressed from expression plasmids, which is useful to study the role of sequences and proteins in replication and in packaging as minigenome RNPs can be introduced into virions following superinfection with BUNV for example [18,19] and potentially also virus replicon particles (VRPs) by co-expression of glycoproteins. Minigenomes are on their own non-propagating and are used to mimik virus replication, and thus are a safe alternative to study for example replication of high-containment bunyaviruses.

In this project, we aim to work on the following topics as listed below. Eukaryotic host systems will be cells of vertebrate or invertebrate origin.

1) Development and use of reverse genetics systems for BUNV and SBV. Such a system is already in use for BUNV, and the SBV system will be designed along the same principles as the BUNV system. Similar systems for other bunyaviruses of the same hazard group may be considered for comparative studies.

Reverse genetics systems will be used to:
- Introduce mutations into the bunyavirus sequences. These can target coding or non-coding sequences although amino acid sequences of the glycoproteins will not be changed, to avoid alterations of host cell tropism.
- Introduce deletions and insertions into bunyavirus sequences, targeting coding or non-coding sequences. Deletions can for example target parts of non-coding regions, insertions can be reporter genes, bunyavirus genes may be completely replaced with other sequences.
- Exchange sequences between bunyavirus segments and within segments. Sequences from within bunyavirus segments will be transferred to other segments or transferred to other regions of the same segment.

Recombinant and wild type bunyaviruses will be used to:
- Study viral growth, gene expression, replication and packaging mechanisms in host cells.
- Study interactions with the host cell (replication, interaction with host cell factors, immunity).

2) Development and use of bunyavirus minigenome systems
- A BUNV minigenome is already in use and similar system will be developed for SBV. Minigenome systems will be used (as read-outs) in studies on protein functions (cellular, viral), sequence function, segment packaging (packaging by glycoproteins co-expression, or following co-infection) and complementation studies (ie. BUNV N in SBV minigenome).
- Minigenome systems of others bunyaviruses will be developed or obtained for studies on replication and packaging (Rift Valley fever virus etc).

3) Functional studies and expression of bunyavirus proteins.
- Manipulation of protein sequences by introduction of point mutations, deletions, insertions, fusion to other sequences such as reporter genes, tags etc.
- Expression of bunyavirus protein to study interactions with host cell components and cellular localisation.
- Expression of bunyavirus proteins by prokaryotic expression systems, for example for protein purification.
- Expression of bunyavirus proteins by eukaryotic expression systems (plasmid, retroviral expression), for example to produce packaging cell lines, cell lines expressing virus-like particles, or cell lines to study protein function.
- Expression of bunyavirus proteins by eukaryotic expression systems (plasmid, retroviral expression), to produce packaging cell lines for bunyavirus sequences (segments or minigenomes; production of single round infectious particles) and cell lines expressing virus-like particles.
- Silencing of bunyavirus gene expression or host genes involved in bunyavirus replication by RNA interference.

4) Studies on host immunity.
- Interactions of bunyaviruses (wild type, recombinant, minigenome) with vertebrate host responses, and counteraction of host responses (for example by NSs proteins) will be investigated. Immune signalling/antiviral responses (including activation mechanisms), and viral interference therewith, will be analysed. This will involve studies of extra- and intra-cellular host molecules. Role of immunity in host cell tropism (infections of cells from different species) will also be investigated. These studies will also use reporter genes inducible upon activation of a given pathway. Vertebrate-origin cell culture models are available.
- Interactions of bunyaviruses (wild type, recombinant, minigenome) with arthropod host responses, and counteraction of host responses will be analysed. Studies of the RNA interference response (host proteins regulating this mechanisms, identification and role of cellular and viral small RNAs, role of bunyavirus sequences in countering host responses) as well the role of immune signalling pathways and antiviral responses (including activation mechanisms) will be investigated. This will involve extra- and intra-cellular pathways (for example extracellular melanisation pathways). These studies will also use reporter genes inducible upon activation of a given pathway. Arthropod-origin cell culture models are available.
- The roles of bunyavirus RNAs in activating or inhibiting vertebrate or arthropod immune responses will be investigated (expressed in viral systems such as Semliki Forest virus or plasmid-based expression).

References:
Viruses and derived replicons to be used will be of the Bunyaviridae family:
- Schmallenberg virus (SBV) (Orthobunyavirus).
- Bunyamwera virus (BUNV) (Orthobunyavirus).
- Recombinant viruses derived from BUNV and SBV.
- Minigenome systems derived from BUNV, SBV, and other bunyaviruses (Rift Valley fever virus etc.).

Other containment level 2 bunyaviruses (Guaroa virus, Maguari virus, Toscana and Sandfly fever phleboviruses etc.) may be considered as required.

No infectious containment level 3 or 4 viruses will be used.

Host/vector system

All organisms will be used at containment level 2, which is routine practice.

Plasmid vectors:
Viral sequences (full length clones of BUNV or SBV; partial sequences of these and other bunyaviruses) and other genes (cellular, viral, reporter) are available in plasmid-encoded cDNA form. RNAs can be transcribed from bacterial promoters (ie. T7 or SP6 by in vitro transcription or plasmid-expressed RNA polymerase in cells) or eukaryotic promoters (CMV, SV40, cellular promoter, baculovirus promoters etc.). Plasmids for expression of bunyavirus sequences (virus rescue or minigenome) contain a T7 RNA polymerase promoter, T7 terminator and a hepatitis delta-derived ribozyme sequence. Plasmids contain an origin of replication followed by a prokaryotic selectable marker (usually antibiotic resistance against ampicillin or kanamycin) and sometimes a selectable eukaryotic drug resistance marker such as neomycin or puromycin resistance. The bacterial systems are non-mobilisable vectors in a disabled prokaryotic host.

Lentiviral expression vectors: only at GM Centre 26; use is covered in CVR GM form 41 and amendments.

Hosts:

Prokaryotic hosts:
Disabled, commercially available E. coli strains such as Sure, JM109, XL-strains, DH-strains, Rosetta etc. These strains can only survive in a controlled laboratory environment and will be used for propagation of plasmids. Good microbiological practice and sterilisation of all contaminated waste should prevent release of viable organisms. The risk to the environment is therefore effectively zero.
Eukaryotic hosts:
Vertebrate cell lines of various origins (typically human, mouse, hamster, bovine etc.) and invertebrate cell lines of various origins (mosquito, culicoides, tick etc.). The
vertebrate BSR-T7/5 cell line (derived from BSR, a clone of BHK) (Buchholz et al., 1999) expresses T7 RNA polymerase and will be used for minigenome assays and virus
rescue, as may similar cell line expressing T7 RNA polymerase.

In prokaryotic cells, only selectable (eg antibiotic resistance) genes will be translated; prokaryotic cells may also be used for protein expression and subsequent purification.

Virus sequences will be under the control of a promoter that will only generate transcripts in eukaryotic cells or in vitro transcription reactions.

In eukaryotic cells, the following RNAs will be produced which may be translated into the following gene products:

- Bunyavirus proteins and RNAs (BUNV and SBV, or minigenomes): Proteins involved in replication and transcription of viral genetic material and virus structural
proteins. Some of these virus proteins will interact with host-cell components and may affect host cell responses to infection; few of these interactions are currently known.
If all virus sequences are translated new virions may be generated; minigenomes are non-propagative viral RNAs (capable of replication). Partial RNAs do not give rise to
propagating infectious material but may display biological activities (ie. RNAi inhibitory).

- Non-bunyavirus genes or sequences: Genes of prokaryotic (bacteriophage polymerases) or eukaryotic (eg. reporter genes such as luciferases or fluorescent proteins
such as GFP; inhibitors of arthropod innate immunity, vertebrate or arthropod host genes etc.) origin. Reporter gene sequences will also be present in bunyavirus
minigenome RNA. The recombinant foreign proteins to be expressed provide no significant increase in the hazard to human health; none are toxic or likely to produce
disease in the quantities that could be produced by accidental exposure to these systems. Non translated RNA sequences (including T7 terminator and hepatitis delta
ribozyme in plasmids used for virus rescue or minigenomes) have no known toxic effects and pose no risk to human health.

Techniques used to introduce insert or vectors into cells:

Prokaryotic cells: Introduction of DNA into E. coli will be by heat shock/chemical transformation. These techniques have been extensively described and are widely used;
they rely on getting DNA very close to the bacterial membrane and introducing the genetic material through pores or membrane fusion.
Eukaryotic cells: Cells will be transfected using transfection reagents such a lipofectamine or by electroporation. Virus genomes or sequences will be introduced into
cultured cells by infection with virus or virus replicon particles (VRP). Lentiviruses will be packaged and used to infect target cells.

Note- Nature of experiments are to be carried out at Church Street and Garscube Estate:

GM 26 (CVR Church Street):
- Preparation, characterisation and genetic manipulation of bunyaviruses and bunyavirus minigenomes.
- Protein expression and purification (prokaryotic cells), protein expression and purification (eukaryotic cells including lentiviral expression), protein interaction and
modification studies.
- Infection/transfection of cell lines, preparation of lysates for downstream applications (including sequencing).
- Reporter gene assays, immunofluorescence studies.

GM223 (CVR Garscube Estate):
- As above; exception: separate GM notification for lentiviral/retroviral expression required.
Foreseeable effects/risk assessment for human health and safety (also see Risk Assessments):

Plasmid vectors:
Viral sequences (including full length clones or partial sequences of SBV or BUNV or other bunyaviruses) and other genes (cellular, viral or reporter) are available in plasmid-encoded cDNA form. Plasmid vectors are based on bacterial plasmids and contain an origin of replication for prokaryotic cells and selectable antibiotic/drug resistance (pro- or eukaryotic) markers. By themselves these vectors present no risk to human health. Vectors have no selective advantage and would soon be lost from the bacterial population. The bacterial systems are non-mobilisable vectors in a disabled prokaryotic host. Transcription of even complete viral cDNA (SBV or BUNV) will result in no infectious RNA since the promoters are not active in prokaryotic hosts. Systems for prokaryotic gene expression are under control of an inducible prokaryotic promoter. Systems for eukaryotic RNA or protein expression are under the control of promoters of viral (such as CMV or SV40), eukaryotic (eg actin promoter, pathway inducible promoter such as STAT, interferon etc.) or prokaryotic (such as T7 or SP6 promoter for in vitro transcription) origin. Plasmids with eukaryotic promoters such as the CMV promoter can be transcribed in human cells. None of the genes used in these studies are oncogenes. The hazard of expressing ‘foreign’ genes from these eukaryotic promoter plasmids would depend on the expected physiological effects of the foreign gene product and is discussed in more detail below.

BUNV:
Infection with this virus can cause a febrile illness with headache, arthralgias, rash and infrequent central nervous system involvement (Gonzalez and Georges, 1988). The classification into ACDP hazard group 2 indicates current expert opinion that containment level 2 precautions are considered adequate for controlling the risks associated with working with BUNV. The viral glycoprotein amino acid sequences are the major determinants of host range and cell tropism and will not be changed beyond the addition of marker genes as fusion or cleavable markers into the structural open reading frame. Genetic changes that will be introduced into the virus sequences will be targeted at disrupting or changing specific functions of virus RNA or virus proteins and can be expected to attenuate virus fitness; such changes are highly unlikely to increase virulence as they modify virus sequences, or change genome length, or lead to expression of additional sequences such as reporter genes which confer no advantage to virus replication.

SBV:
This an animal pathogen, and not likely to be a risk to human health by current guidelines (http://ecdc.europa.eu/en/publications/Publications/Forms/ECDC_DispForm.aspx?ID=795). Genetic changes that will be introduced into the virus sequences will be targeted at disrupting or changing specific functions of virus RNA or virus proteins and can be expected to attenuate virus fitness; such changes are highly unlikely to increase virus virulence as they modify virus sequences, or change genome length, or lead to expression of additional sequences such as reporter genes which confer no advantage to virus replication. As for BUNV, the viral glycoprotein amino acid sequences which are the major determinants of host range and cell tropism will not be changed beyond the addition of marker genes as fusion or cleavable markers. SBV is not listed on the ACDP or SAPO list but is recommended to be classified as hazard group animal pathogen 2 (see attached recommendation). We propose to treat SBV like BUNV in terms of risk for human infections and health unless other regulation is in place for a particular pathogen. In addition, personnel working with SBV should not be in contact with susceptible animals or visit farms/zoos where they could potentially come into contact with susceptible species for a period of 48 hours. A form outlining that they have understood their responsibility with regards to minimising the risks to the environment associated with this virus will be signed by personnel working on SBV.

Personnel working with these viruses are expected to inform occupational health should they become pregnant or immunosuppressed, and if planning pregnancy inform the PI so that precautionary measures can be introduced following advice from occupational health.

Bunyavirus minigenomes:
Minigenomes pose no risk to human health, including those derived from pathogenic bunyaviruses such as Rift Valley fever virus. They cannot propagate on their own, replication requires co-expression of L and N proteins. Even if packaged by co-expression of glycoproteins and thus used to infect cells, their own transcriptional activity would be minimal. If packaged into virions, the associated risk is that of the virus itself as reporter genes in minigenomes are not reported to be toxic.

Note 1: Should material such as minigenomes or other sequences be obtained for bunyaviruses listed under schedule 5 regulations, no additional sequences that could potentially be used to assemble the full length genome of a schedule 5 pathogen will be stored in locations that do not have required licenses.
Note 2: No reassortment experiments between BUNV, SBV or closely related orthobunyaviruses will be carried out as class 2 activity, to eliminate the possibility of creating viruses with enhanced pathogenicity such as Ngari (Gerrard et al., 2004). No work with two or more viruses of different bunyavirus species will be carried out in parallel in the same microbiological safety cabinet. Microbiological safety cabinets are decontaminated between experiments (UV and/or alcohol). The risk of accidental co-infection is effectively zero.

The host/recipient organism:
Prokaryotic organisms: All strains will be disabled, commercially available E. coli derivatives classified as ‘especially disabled hosts’ by ACDP. These strains cannot colonise humans and are known not to cause harm to humans.

Eukaryotic cells:
Cell lines to be used would not survive inside the human body (immune rejection) and are not known to carry harmful pathogens. Addition of DNA or RNA or infection will confer no growth or survival advantage in or outside the laboratory to cell lines of vertebrate or arthropod origin.

The inserted/donated genetic material:
Viral RNA and proteins, cellular proteins: Most such bunyavirus-expressed viral (such as inhibitors of insect immunity; where tested in vivo this has led to more rapid death of arthropod vectors) or cellular proteins are unlikely to have harmful effects in eukaryotic cells, however some could perturb normal cellular metabolism, predispose or protect against cell death or render cells more or less susceptible to other infections if overexpressed or silenced. It is very unlikely that BUNV or SBV (and hazard group 2 bunyaviruses) RNA or proteins would have any harmful toxin-like effect outside cells. Only antigenomic RNA containing a bunyavirus sequence can be translated or give rise to infectious virus (if all necessary genomic information is provided) in eukaryotic cells; minigenome RNAs are non propagative and pose no harm (individual cells replicating minigenome are likely to die or be eliminated by the immune system). Viral non-coding RNA sequences are important in bunyavirus replication but do not encode biologically active molecules that are likely to induce physiological effects in humans on their own.

No proteins that are known to interfere with immune or host responses in vertebrates will be cloned into bunyavirus genomes for the purpose of virus rescue under containment level 2 conditions, to avoid producing potentially highly pathogenic bunyaviruses by adding a more potent host response antagonist that those already present in bunyavirus genomes.

Reporters: Reporter genes of prokaryotic or eukaryotic origin (eg luciferase, fluorescent proteins etc.). No harmful properties have been attributed to these proteins. There would be no altered physiology expected if any of these genes were expressed; eGFP for example is a spontaneously fluorescent protein isolated from Aequorea victoria a coelenterate and has no known detrimental effects. Luciferase is another commonly used reporter gene and is derived from the firefly Photinus pyralis or the jellyfish Renilla reniformis. It is an enzyme which catalyses production of light from luciferin and ATP; the light produced is used as a measure of gene activity. The enzyme has no other biological function. Introduction of these reporter genes is unlikely to increase the risk associated with these viruses.

Other non-coding RNA sequences (siRNAs, dsRNAs, other RNAs): Any effects these elements have on overall gene expression are likely to be minimal. They may affect gene function or virus replication in individual cells but are unlikely to lead to whole body physiological effects as they do not code for the production of secreted bioactive molecules.

Other sequence changes in viral sequences:
Mutation or deletion will target disruption of non-structural protein functions or non-coding viral sequences and are likely to have no or deleterious effects on viral replication, thus not increasing risk of hazards to human health associated by viruses genetically modified in such a way. No changes will be introduced that will change the amino acid sequence of the glycoproteins Gn and Gc (with the exception of in-frame fusion to reporter genes) so viral tropism is not affected.
Summary:
Genetic changes that will be introduced into the BUNV or SBV sequences as described above can be expected to attenuate virus fitness (with the exception of insect immunity inhibitors, but this does not concern human health); such changes are highly unlikely to increase virus virulence as they modify virus sequences (which are optimized for replication), or change genome length, or lead to expression of additional sequences such as reporter genes which confer no advantage to virus replication or have no effects outside the infected cell. Therefore we do not expect increased risk or hazards associated with viruses modified in such a way.

Control measures – assign provisional containment level:
GM bacteria transformed with plasmids containing viral sequences, reporter genes, other eukaryotic/prokaryotic genes or non-coding sequences  - Containment Level 1. Eukaryotic cells containing bunyaviral sequences unable to form complete infectious virus, or plasmids expressing reporter genes, other eukaryotic/prokaryotic genes or non-coding sequences – Containment Level 1. Eukaryotic cells containing hazard group 2 bunyavirus sequences (capable of forming infectious virus, or capable of undergoing recombination or minor mutations to form infectious virus) – Containment Level 2.

All with Good Microbiological Practice and Good Occupational Safety and Hygiene. Wear laboratory coat and gloves. A microbiological safety cabinet will be used where appropriate (see below). Work with infectious bunyaviruses should take place in a microbiological safety cabinet. Spray gloves with alcohol when working outside the hood or before disposing.

Foreseeable effect/risk assessment for the environment:
BUNV: This virus is not endemic in the UK, and it is not on the SAPO list. It is not clear whether suitable vertebrate hosts and insect vectors are present to establish an infection in this country. BUNV can infect vertebrates (such as rodents) and certain biting insects. Transmission to vertebrates is by inoculation and to insect is by feeding on blood of an infected vertebrate. BUNV was isolated from mosquitoes in Uganda. Given the absence of these specific mosquitoes in Scotland and low pathogenicity of virus strains, the chance of accidentally infected arthropods initiating a transmission cycle sustained by local insects is negligible. The modified viruses will not have any inserted foreign genes other than non-harmful genes or sequences (with exception of inserted insect immunity inhibitors, which may lead to rapid death of infected arthropods), or (usually disruptive) changes in viral genes (with the exception of glycoproteins, whose amino acid sequences will not be changed) or non-coding sequences; changes in virus pathogenesis are therefore unlikely other than as described above under the human health and safety section. In the absence of a suitable host or vector these viruses would not survive in the environment and the risk is effectively zero. Arthropods are kept out of labs and the risk of accidental infection of insects by ingestion of contaminated material is also effectively zero for BUNV.

SBV: This virus has now been detected in the UK, and infections are most likely the result of midges carried from mainland Europe to the UK (Veterinary Record, News & Reports- see reference below). However other blood-feeding arthropods cannot be ruled out and vector competence studies are required. It is not yet on SAPO or ACDP lists and the recommendation (including for infection of insects) from Scottish Government (Rural and Environmental directorate) is to handle this pathogen as a category 2 animal pathogen (see attached recommendation). We propose, until further notification, to work with SBV at containment level 2 similarly to BUNV. The modified viruses do not contain anything other than non-harmful genes or sequences (with the exception of inserted insect immunity inhibitors, which may lead to rapid death of infected arthropods), or disruptive changes in genes (with the exception of glycoproteins, whose amino acid sequences will not be changed) or non-coding sequences; changes in virus pathogenesis are therefore unlikely other than as described above under the human health and safety section. If SBV was to escape the lab and infect local midges (or possibly other arthropods), there is a significant risk it could initiate a transmission cycle although this virus might arrive here by natural means (competence of local midges for SBV is not known but there is a significant risk they may be able to act as vectors). However arthropods are kept out of labs and the risk of infection of arthropods by ingestion of contaminated material is low and the likelihood of virus released from our laboratory infecting local vectors is effectively zero (see disinfection and waste disposal procedures). In addition, advice will be given to lab personnel that they should not be in contact with susceptible animals or visit farms/zoo where they could potentially come into contact with susceptible species for a period of 48 hours following work with SBV. A form outlining that they have understood their responsibility with regards to minimising the risks to the environment associated with this virus will be signed by personnel working on SBV.
Note: No proteins which could interfere with immune or host responses in vertebrates will be cloned into bunyavirus genomes for the purpose of virus rescue under containment level 2 conditions, to avoid producing potentially highly pathogenic bunyaviruses by adding a more potent host response antagonist that those already present in bunyavirus genomes.

We propose to use containment group 2 bunyaviruses (see point 7) similar to BUNV unless other regulations are in place for a particular pathogen.

Minigenomes: These systems derived from BUNV, SBV or other bunyaviruses are non-propagative and even if packaged, pose no or no additional hazard.

Hosts:

Prokaryotic organisms: Disabled, commercially available E. coli strains. These strains can only survive in a controlled laboratory environment and will be used for propagation of plasmids. Good microbiological practice and sterilisation of all contaminated waste will prevent release of viable organisms. Acquiring antibiotic resistance (from the plasmid vector) or additional sequences (virus or marker gene sequences) will not give these strains any survival advantage in the environment. The risk to the environment is therefore effectively zero.

Eukaryotic cells: Cell lines to be used are not viable outside the laboratory and thus pose no threat to the environment. Addition of plasmid vectors or virus or minigenomes will confer no growth or survival advantage in the environment.

In summary

i) consequence/severity of effects: Severe

ii) likelihood of effects being realised: Low

iii) overall risk: Low

Final classification: GM bacteria transformed with plasmids containing viral sequences, reporter genes, other eukaryotic/prokaryotic genes or non-coding sequences (unable to cause disease, minimal hazard to health and environment) - Containment Level 1.

Eukaryotic cells containing bunyaviral sequences unable to form complete infectious virus, or plasmids expressing reporter genes, other eukaryotic/prokaryotic genes or non-coding sequences – Containment Level 1.

Eukaryotic cells containing bunyavirus sequences capable of forming infectious virus, or capable undergoing recombination or mutation to form infectious virus – Containment Level 2.

All with Good Microbiological Practice and Good Occupational Safety and Hygiene. Wear laboratory coat and gloves. As a routine measure all work will be carried out at Containment level 2. A microbiological safety cabinet will be used where appropriate. Work with infectious bunyaviruses should take place in a microbiological safety cabinet. This additional layer of security also is to prevent accidental contamination of any arthropods (thus reducing risk to the environment). Spray gloves with alcohol when working outside the hood or before disposing. Traps to catch arthropods will be present in labs were work with live infectious bunyaviruses is carried out.

References:
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disinfect bunyavirus-contaminated material immediately.

GM26 (CVR Church Street)

Solids from cell culture (e.g. plasticware such as flasks, tubes, pipette tips etc.) - soak in 1% Virkon (w/v) for a minimum of 12 hours. Dispose of as normal solid waste (black bag).

Other solids (agar plates, gloves etc) - placed in a metal disposal box (lined with clear bag) and disposed of by autoclaving using a make safe cycle of 121°C for 30 minutes. Gloves used for bunyavirus work should be disinfected with alcohol before putting in containers.

Liquids (e.g. samples, culture supernatants, tissue culture media) – add Virkon to final concentration of 1% (w/v) for a minimum of 12 hours, then discharge to drains.

Liquids (E. coli culture medium) - add Virkon to final concentration of 1% (w/v) for a minimum of 12 hours, then discharge to drains.

Sharps (in sharps bin, e.g. needles, syringes, scalpels) - autoclave by using a make safe cycle of 121°C for 30 minutes.

Degree of kill:
Chemical Sterilization by Virkon - effectively 100% kill.
Autoclaving - effectively 100% kill (annual validation).

GM223 (CVR Garscube Estate):

Disposable solids (e.g. plasticware such as flasks, tubes, pipette tips etc.) - soak in 1% Virkon (w/v) for a minimum of 12 hours. Transfer solid contents to clear autoclave bags and autoclave at 121°C for a minimum of 20 minutes prior to final disposal by district council to landfill, remaining liquid to be discharged to drain.

Other solids (agar plates, gloves etc.) - placed in a marked box lined with a clear autoclave bag, and disposed of by autoclaving using a make safe cycle of 121°C for at least 20 minutes. Seal contaminated plates (with for example bacterial GMOs) before placing in bag, to avoid lid falling off. Gloves used for bunyavirus work should be disinfected with alcohol before putting in containers.

Liquids (e.g. samples, bacterial culture media, tissue culture media) - add Virkon to final concentration of 1% (w/v) for a minimum of 12 hours, then discharge to drains.

Sharps (in sharps bin, e.g. needles, syringes, scalpels) - autoclave by using a make safe cycle of 121°C for at least 20 minutes, then incinerated.

Degree of kill:
Chemical Sterilization by Virkon - effectively 100% kill.
Autoclaving - effectively 100% kill (annual validation).
1. GM 26 committee comments:

The CVR Church Street GM subcommittee met on 22/08/11 to consider the proposal: "Bunyavirus molecular biology and virus/host interactions."

Present:
*********** personal details removed

The following topics were discussed:

The committee members had no concerns regarding the overall aims of the proposed experiments. Overall the work with Bunyamwera virus (BUNV) was approved for handling under normal class 2 conditions. Questions were raised over some aspects of the work with Schmallenberg virus (SBV). Additional questions on risk to the environment and containment were also discussed.

This points have been addressed in form CU2 and the Risk assessment, and on the 15.03.2012 the documents were approved.

On behalf of the CVR Church Street subcommittee, Dr. P

2. GM223 committee comments:

"The risk assessment was clear and comprehensive but a number of clarifications in particular on risk to the environment by SBV (vectors, accidental contamination of local arthropods) were required.

These points have been addressed in form CU2 and Risk Assessment, and on the 15.03.2012 the revised documents were approved.

Dr. G on behalf of the committee."

Establishment of a reverse genetics system for drosophila C virus

Drosophila C virus (DCV) belongs to the genus Cripavirus now classed within the Dicistroviridae family (previously Picornaviridae) within the order Picornavirales. It is a single stranded, positive-stranded RNA virus with a genome length of approximately 9300 bases. Unlike picornaviruses, the genome encodes two open reading frames (ORF) which encode (towards the 5’ end) an open ORF coding for non-structural proteins and (towards the 3’ end) an ORF coding structural proteins. The non-structural ORF encodes proteins involved in virus replication (including the RNA interference inhibitor 1A), while the structural ORF encodes viral envelope proteins. Both open reading frames are translated via separate internal ribosome entry sites in the genome. A Vpg protein is attached to the 5’ end the 3’ end contains a poly A sequence. These viruses are non-enveloped (1).

DCV has a worldwide distribution (including UK) and is also found in laboratory strains of Drosophila melanogaster and cultured cells (D. Obbard, University of Edinburgh, personal communication); it can also infect a variety of drosophila species (6). Infection leads to more rapid development, females are heavier and lay more eggs. Infection occurs by ingestion and infection is not pathogenic, although this may vary between flies. Interestingly, infection by injection leads to rapid death of flies (4). DCV is not a SAPO or ACDP pathogen; it does not infect vertebrate cells.

The genetic and molecular tools available for D. melanogaster make it a very useful model to study virus-host interactions and virus pathogenesis in an easily grown and genetically manipulated host. DCV has been particularly used in studies on antiviral immune signalling and RNA interference responses in drosophila (7); this research has led the insect virology field for many years. The DCV 1A protein acts as a viral suppressor of RNA interference (10), yet the virology of these virus/drosophila interactions is overall poorly understood in contrast to the extensive knowledge we have of drosophila genes and physiology. DCV is also inhibited by endosymbiotic Wolbachia bacteria in drosophila (9). This is similar other RNA viruses such as arboviruses in mosquitoes (which may be a useful control measure in public health strategies) yet it is not known...
how inhibition by the endosymbiont is mediated and powerful drosophila genetics may be required to solve this question and improve the uses of Wolbachia endosymbions (5).

Despite the strength of D. melanogaster genetics, a major drawback of drosophila immunity research is that no reverse genetics system is available to manipulate and study the genome of DCV. This project aims to develop an infectious DCV clone to apply reverse genetics technology to this virus. A dicistrovirus infectious clone has so far only been described for Rhopalosiphum padi dicistrovirus (RhPV) (2, 8). This clone is not very efficient and one of the major drawbacks is that the length of the 3’ poly A tail is not known for these viruses; it is likely to be similar to picornaviruses and of 20-60 nucleotides in length. However the RhPV infectious clone has no such sequence, bar a very short internal poly A stretch. This may be one of the reasons why the RhPV infectious clone is relatively weak, and possibly efforts to make a DCV infectious clone so far may have failed due to missing 3’ poly A tails.

The prototype DCV strain is isolate EB, but sequences of other isolates are available.

We propose to:
- Propagate the cloned DCV sequence. The DCV genome will be cloned into a plasmid backbone such as pUC-type or other vector. Transcription of the viral cDNA into RNA will be under control of a bacteriophage RNA polymerase promoter (T7, SP6 or similar) or eukaryotic promoter, and RNA introduced into insect cells or infectious clone cDNA transfected into insect cells for virus rescue. Where required, ribozyme-encoding sequences (hammerhead ribozyme, hepatitis delta ribozyme or similar) will be added to the genome ends (5’ and/or 3’ ends) to generate correct termini in the transcribed RNA as has been described previously (3).

- Manipulate the cloned DCV genome by molecular biological methods. This will be achieved by insertion of sequences (reporter genes such as luciferase or fluorescent proteins, drug resistance genes, other eukaryotic genes, non-coding sequences), deletion of sequences (point deletions, deletion of larger sequences) or point mutations within the DCV sequence. No changes will be made to sequences encoding the structural proteins, to avoid changes in viral tropism. Alterations to viral sequences such as those described above usually result in a fitness decrease. Modifications of the viral genome sequence will also include adding of poly A tails either by in vitro poly-adenylation or adding a cloned poly A sequence to the viral cDNA. Chimeras between strains of DCV (exchange of protein-coding sequences or non-coding sequences) will be created to study the role of strain-specific differences on replication, immunity and pathogenesis.

- If infectious DCV can be successfully rescued, we will delete the structural open reading frame 2 (or parts of it) to create non-propagating replicons and a packaging system (co-expression of DCV structural proteins in replicon-transfected cells) to obtain virus replicon particles.

- Individual DCV sequences (coding or non-coding) will be cloned into eukaryotic or prokaryotic vectors (plasmid or Semliki Forest virus or derived replicon) for molecular biological manipulation and/or expression purposes. Manipulated sequences may be re-introduced into the DCV infectious clone.

Studies to be undertaken with a DCV infectious clone and/or derived replicons:
- Immune responses of insect cells against DCV infection. We will study RNA interference and other mechanisms (immune signalling) that control DCV replication and viral interference therewith.
- Replication and polyprotein processing in insect cells. We will analyse sequences and mechanisms involved in these processes, as well as cellular factors involved in promoting or inhibiting DCV replication and spread.
- Virus entry, replication compartment formation and exit from insect cells. The tools for DCV manipulation (in particular viruses encoding reporter genes and replicons/virus replicon particles) developed in this project will allow to track these processes more efficiently (timing of events, determination of virus production etc.).
- Above studies will also be carried out in Wolbachia-infected insect cells to further study the mechanisms by which this micro-organism inhibits RNA virus replication.
- No experiments in vertebrate cells are planned.
Recipient or parental organism

Drosophila C virus. The infectious clone will be based on the sequence of strain EB; other strains or sequences from other strains may also be cloned.

Host/vector system

All organisms will be used at containment level 2, which is routine practice throughout the Church Street CVR site.

Plasmid vectors:
Viral sequences (including full length clones or partial sequences of DCV) and other genes (cellular, viral or reporter) are available in plasmid-encoded cDNA form. RNAs can be transcribed through bacterial promoters (ie. T7 or SP6) or eukaryotic promoters. Plasmids contain an origin of replication followed by a prokaryotic selectable marker (usually antibiotic resistance against ampicillin or kanamycin) and sometimes a selectable eukaryotic drug resistance marker such as neomycin or puromycin resistance. The bacterial systems are non-mobilisable vectors in a disabled prokaryotic host.

Hosts:

Prokaryotic hosts:
Disabled, commercially available E. coli strains such as Sure, JM109, XL-strains, DH-strains, Rosetta etc. These strains can only survive in a controlled laboratory environment and will be used for propagation of plasmids. Good microbiological practice and sterilisation of all contaminated waste should prevent release of viable organisms. The risk to the environment is therefore effectively zero.

Eukaryotic hosts: Invertebrate cell lines of various origins (drosophila, mosquito, tick etc.). These will be used to grow virus or express/silence individual proteins or sequences. Cells grown in standard media such as L-15 or Schneiders and are maintained in cooled cell culture incubators.

Origin & function

In prokaryotic cells, only selectable (eg antibiotic resistance) genes will be translated.

Virus sequences will be under the control of a promoter that will only generate transcripts in eukaryotic cells or in vitro transcription reactions.

In eukaryotic cells, RNA will be translated into the following gene products:

• Viral proteins and RNAs: Proteins involved in replication and transcription of viral genetic material and virus structural proteins. Some of these virus proteins will interact with host-cell components and may affect host cell responses to infection (for example 1A RNAi suppressor). If all virus sequences are translated new virions may be generated; replicons are non-propagative viral RNAs (capable of replication). Partial RNAs do not give rise to propagating infectious material but can display biological activities (ie. RNAi inhibitory, expression of some viral proteins for example for packaging of replicons).

• Non-viral genes: Genes of prokaryotic (eg CAT) or eukaryotic (eg. reporter genes such as luciferases or fluorescent proteins such as GFP; inhibitors of insect immunity ie. RNAi inhibitors, signalling inhibitors, melanization inhibitors etc.) origin. The recombinant foreign proteins to be expressed provide no significant increase in the hazard to human health; none are toxic or likely to produce disease in the quantities that could be produced by accidental exposure to these systems. Non-translated RNA sequences have no known toxic effects and pose no risk to human health.

Techniques used to introduce insert or vectors into cells:

Prokaryotic cells: Introduction of DNA into E. coli will be by heat shock/chemical transformation. These techniques have been extensively described and are widely used; they rely on getting DNA very close to the bacterial membrane and introducing the genetic material through pores or membrane fusion.

Eukaryotic cells: Cells will be transfected using reagents such a lipofectamine or by electroporation. Virus genomes will be introduced into cultured cells by infection with
virus or virus replicon particles (VRP), using transfection reagents or by electroporation.

**Evaluation of foreseeable effects**

Foreseeable effects/risk assessment for human health and safety (also see Risk Assessments):

Plasmid vectors:
Viral sequences (including full length clones or partial sequences of DCV) and other genes (cellular, viral or reporter) are available in plasmid-encoded cDNA form. Plasmid vectors are based on bacterial plasmids and contain an origin of replication for prokaryotic cells and selectable antibiotic/drug resistance (pro- or eukaryotic) markers. By themselves these vectors present no risk to human health. Vectors have no selective advantage and would soon be lost from the bacterial population. The bacterial systems are non-mobilisable vectors in a disabled prokaryotic host. Transcription of even complete viral cDNA will result in no infectious RNA since viral elements are not active in prokaryotic hosts. Systems for prokaryotic gene expression are under control of an inducible prokaryotic promoter. Systems for eukaryotic RNA or protein expression are under the control of promoters of viral (such as CMV, baculovirus-derived IE promoter), eukaryotic (eg actin promoter, pathway inducible promoter such as STAT) or prokaryotic (such as T7 or SP6 promoter for in vitro transcription) origin. Plasmids with eukaryotic promoters such as the CMV promoter can be transcribed in human cells. None of the genes used in these studies are oncogenes. The hazard of expressing ‘foreign’ genes from these eukaryotic promoter plasmids would depend on the expected physiological effects of the foreign gene product and is discussed in more detail below.

DCV:
This virus is not known to infect or replicate in human cells or other cells of vertebrate origin. It is not a ACDP pathogen. Work with this virus or recombinant DCV does not pose a risk to human health. Replicons are non-propagating even within virus-replicon particles and pose no risk.

The host/recipient organism:
Prokaryotic organisms: All strains will be disabled, commercially available E. coli derivatives classified as ‘especially disabled hosts’ by ACDP. These strains cannot colonise humans and are known not to cause harm to humans.

Eukaryotic cells:
Insect cell lines to be used would not survive inside the human body (immune rejection) and are not known to carry harmful pathogens. Addition of DNA or RNA will confer no growth or survival advantage in or outside the laboratory to these cell lines.

The inserted/donated genetic material:
Viral RNA and proteins, cellular proteins: Most individually expressed viral or cellular proteins (for example arthropod immune response inhibitors) are unlikely to have harmful effects in eukaryotic cells, however some could perturb normal arthropod cellular metabolism, predispose or protect against cell death or render cells more or less susceptible to other infections. It is very unlikely that DCV RNA or proteins would have any harmful toxin-like effect outside cells. RNA containing the complete DCV sequence can give rise to infectious virus in insect cells; replicon RNAs are non-propagating and pose no risk. Viral non-coding RNA sequences are likely to have minimal effects outside arthropod cell systems, and do not encode biologically active molecules that are likely to induce physiological effects in humans.

Reporter genes: Reporter genes of prokaryotic or eukaryotic origin (eg luciferase, fluorescent proteins etc.). No harmful properties have been attributed to these proteins. There would be no altered physiology expected if any of these genes were expressed; eGFP for example is a spontaneously fluorescent protein isolated from Aequorea victoria a coelenterate and has no known detrimental effects. Luciferase is another commonly used reporter gene and is derived from the firefly Phontinus pyralis or the jellyfish Renilla reniformis. It is an enzyme which catalyses production of light from luciferin and ATP; the light produced is used as a measure of gene activity. The enzyme has no other biological function.

Other non coding RNA sequences: Any effects these elements have on gene expression are likely to be minimal. They may affect gene function or virus replication in individual cells but are unlikely to lead to whole body physiological effects as they do not code for the production of secreted bioactive molecules, and are unlikely to have any biological effects outside arthropod cell systems.

Sequence changes in viral sequences:
Mutation or deletion will target disruption of non-structural protein functions or non-coding viral sequences and are likely to have no or deleterious effects on viral replication, thus not increasing risk or hazards to human health associated by viruses genetically modified in such a way. Deletions in the structural genes to produce replicons will result in non-propagating virus-derived RNAs that pose no risk, even if packaged into virus replicon particles. Expression of sequences by Semliki Forest virus and derived replicons is covered under GM26/CVR_AK_1.

Control measures – assign provisional containment level:
GM bacteria transfected with plasmids containing viral or other eukaryotic sequences - Containment Level 1.
Eukaryotic cells containing DCV sequences unable to form complete infectious virus – Containment Level 1.
Eukaryotic cells containing full length DCV sequences (capable of forming infectious virus, or capable of undergoing recombination or minor mutations to form infectious virus) – Containment Level 2.

All with Good Microbiological Practice and Good Occupational Safety and Hygiene. Wear laboratory coat and gloves. A microbiological safety cabinet will be used where appropriate.

Foreseeable effect/risk assessment for the environment:

DCV: This virus is not on the SAPO/ACDP lists. It can infect drosophila by ingestion; recombinant virus is likely to be less fit than wild type but may may be able to infect drosophilid species and other insects. Virus is kept within containment and no accidental infections of arthropods can take place. Replicons are non-propagating even within virus replicon particles and pose no risk. Arthropods and food are kept away from the laboratories and waste sterilized before disposal (see below) and it is therefore unlikely that any lab-acquired infection and/or escape can take place.

Hosts:
Prokaryotic organisms: Disabled, commercially available E. coli strains. These strains can only survive in a controlled laboratory environment and will be used for propagation of plasmids. Good microbiological practice and sterilisation of all contaminated waste will prevent release of viable organisms. Acquiring antibiotic resistance (from the plasmid vector) or additional sequences (virus or marker gene sequences) will not give these strains any survival advantage in the environment. The risk to the environment is therefore effectively zero.

Eukaryotic cells: Cell lines to be used are not viable outside the laboratory and thus pose no threat to the environment. Addition of plasmid vectors or virus will confer no growth or survival advantage in the environment.

In summary

i) consequence/severity of effects: Low

ii) likelihood of effects being realised: Low

iii) overall risk: Low
Final classification: GM bacteria transfected with plasmids containing viral or other eukaryotic sequences (unable to cause disease, minimal hazard to health and environment) - Containment Level 1.
Eukaryotic cells containing DCV sequences unable to form complete infectious virus – Containment Level 1.
Eukaryotic cells containing DCV sequences (capable of forming infectious virus, or capable undergoing recombination or mutation to form infectious virus) – Containment Level 2.

All with Good Microbiological Practice and Good Occupational Safety and Hygiene. Wear laboratory coat and gloves. As a routine measure all work will be carried out Containment level 2. A microbiological safety cabinet will be used where appropriate.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| Solids from cell culture (eg plasticware such as flasks, tubes, pipettes tips etc.) - soak in 1% Virkon (w/v) for a minimum of 12 hours. Dispose of as normal solid waste (black bag).
| Other solids (agar plates, gloves etc. ) placed in a metal disposal box (lined with clear bag) and disposed of by autoclaving using a make safe cycle of 121oC for 30 minutes.
| Liquids (eg samples, culture supernatants, tissue culture media) – add Virkon to final concentration of 1% (w/v) for a minimum of 12 hours, then discharge to drains.
| Liquids (E. coli culture medium)- add Virkon to final concentration of 1% (w/v) for a minimum of 12 h, then discharge to drains.
| Sharps (in sharps bin, eg needles, syringes, scalpels) - autoclave by using a make safe cycle of 121oC for minutes.

Degree of kill:
Chemical Sterilization by Virkon- effectively 100% kill.
Autoclaving - effectively 100% kill (annual validation).

**Is an emergency plan required according to regulation 20?** N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
1. GM 26 committee comments (approval date 22/02/12; see below):

The CVR Church Street GM subcommittee met on 31/01/12 to consider the proposal:
"Establishment of a reverse genetics system for drosophila C virus"

Subcommittee members:
R E
J M
J M
A P
F R (convener)

As Drosophila C virus only infects arthropods, it is not considered hazardous. Therefore, no objections were raised against the proposed work. However, clarification was requested for the following points:

How will the virus be propagated? The culture conditions should be described.

The Risk Assessment contains the statement "DCV: This virus is not a ACDP pathogen. It is not known to infect or replicate in human cells, and there is no risk associated with using this virus." (page 7, Vectors and GMOs). In the GM application the same section (page 5, point 7) states "DCV: This virus is not able to infect or replicate in human cells or other cells of vertebrate origin." These statements should be made to be consistent and accurate.

More clarity is required over the potential for infection of, and expression in, mammalian cells. This is particularly relevant in light of the subsequent discussion over the need for Notification (see below), which would only be required if there is a threat to human health or the environment. For example, it is proposed to clone genes under the CMV (and possibly other mammalian) promoter. Is this promoter active in insect cells and if not, why is it being used?

Also, SFV can infect mammalian cells so its use as a vector is potentially harmful. In the Notification (page 3) it is stated that "Individual DCV sequences (coding or non-coding) will be cloned into eukaryotic or prokaryotic vectors (plasmid or Semliki Forest virus or derived replicon) for molecular biological manipulation and/or expression purposes." In the Risk Assessment the sentence reads: (plasmid or Semliki Forest virus replicon or derived replicon). These statements should be made to be consistent and accurate.

Although only experiments in insect cells are listed under "Detailed descriptions and description/use of genetic modification:" (page 2-4 of Notification) a positive statement that no experiments in mammalian cells are planned should be inserted.

On page 2 of the Notification it is proposed to clone the DCV genome into a plasmid backbone. However, the section on Host/vector system (page 4) contains the statement that "Viral sequences (including full length clones or partial sequences of DCV) and other genes (cellular, viral or reporter) are available in plasmid-encoded
The discussion on this proposal raised the question of whether a Notification is required in this case. DCV is an insect pathogen that appears to pose no risk to human health and would have low or negligible environmental consequences if it escaped from the laboratory. It therefore resembles baculovirus, which is classified at containment level 1 except when specifically intended as a vector for gene expression in mammalian cells or when encoding viral functions that could themselves transmit to mammalian cells. Page 9-10 of the Risk Assessment Form includes the statement: “If the answer to questions 11 and 12 is negligible, you may believe that you have sufficient information at this stage to classify the project to class 1, as defined in the Contained Use Regulations 2000. In order to do this you should be confident that in the event of a total breach of containment the GMO would be of no or negligible risk to human health or the environment.” The committee therefore requested that the reason for suggesting that work involving DCV is classified as containment level 2 should be further evaluated and the results of such an evaluation be conveyed back to the subcommittee. If a Notification is deemed unnecessary a Risk Assessment would still be required for GM work.

As part of the same discussion it was suggested that to save effort and expense, planned future work on Arboviruses should be assessed in terms of the likely need for further applications for Notification. If more potential applications are identified consideration should be given to the possibility of combining the proposals into a single Notification covering as many viruses as possible.

Response from A K to GM Committee comments (06.02.2012):

Project notified under transitional arrangements N
The Orthomyxoviridae is defined by viruses that have a negative-sense, single stranded and segmented RNA genome. Viruses within the Orthomyxoviridae are classified into five genera: Influenza viruses A, B, C, Thogotovirus and Isavirus. Within a genus, viruses show similar patterns in the sizes of their genome segments as well as structural and non-structural proteins. Influenza A viruses are typical examples of emerging viruses, including pathogens of humans and/or animals (5). Influenza B virus appears predominantly restricted to humans but it has also been isolated from seals; and influenza C virus infects humans and pigs. Types A and B are the cause of seasonal annual epidemics of acute respiratory disease among humans, and type A viruses have caused occasional pandemics – worldwide epidemics caused by a virus having new antigenic surface proteins among an antigenically naive population. Influenza A virus infections can cause a severe and debilitating febrile illness that can lead to fatal pneumonia and increase the risks associated with secondary bacterial chest infections, particularly in the very young, chronically ill, immunocompromised or elderly.

The influenza A virus genome is composed of eight segments of single-stranded RNA of negative polarity that encodes for up to 14 proteins. The genome segments are called PB2 (polymerase basic), PB1, PA (polymerase acidic), HA (haemagglutinin), NP (nucleoprotein), NA (neuraminidase), M (matrix) and NS (non-structural). Influenza A viruses are sub-classified according to the antigenic characteristics of the surface glycoproteins, the haemagglutinin (H) and neuraminidase (N). There are 17 H and 10 N subtypes known to date. The four major pandemics of the last hundred years were caused by H1N1 (1918 [Spanish flu], and 2009 [swine flu]), H2N2 (1957, Asian flu) and H3N2 (1968, Hong Kong flu) viruses. Currently, influenza A virus subtypes H1N1 and H3N2, and influenza B virus, are co-circulating in the human population. Avian viruses (such as H5N1, H7N7, and H7N9 viruses) have also caused human infections, and epizootics of highly pathogenic H5N1 and H7N9 avian viruses in several Asian countries since 1997 have raised the spectre of a new pandemic.

During replication, a positive-stranded antigenome is produced which serves as the template for de novo production of negative-stranded genomes. The influenza A virus terminal 3’ and 5’ sequences are highly conserved and largely complementary, and interact to give the genome a characteristic pan-handle structure. The RNPs are contained within a lipid envelope into which the viral glycoproteins (HA, NA and M2) are inserted. Replication occurs in the nucleus of infected cells.

Most influenza viruses are transmitted by direct and indirect contact. Some influenza viruses are transmitted through aerosol droplets. Cytopathic effect (CPE) depends on both viruses and host cells. For example, pandemic H1N1 virus causes CPE in Madin-Darby canine cells whereas most equine influenza viruses do not. At the same time, some equine influenza viruses cause CPE in dog tracheal explants whereas others do not. Understanding the molecular basis for the different outcomes of infection in these cells and tissues of different origin is of fundamental importance, and may help in the development of new control measures for influenza emergence. This is likely to imply immune responses (which differ in both hosts) and virus-host interactions.

Although much is known about the function(s) of individual influenza virus proteins, much more remains to be learned about the factors involved in host–pathogen interactions that affect host range and disease outcome. The overall aim of our research is to elucidate the molecular and evolutionary determinants of host range, replication and pathogenicity of influenza viruses.

The work to be undertaken forms part of a comprehensive programme of viral emergence and molecular pathogenesis, involving researchers from different groups within the Centre for Virus Research (CVR). It involves work on several areas including, epidemiology, mathematical modelling of virus evolution, structural biology, and studies...
on virus-host interactions and molecular pathogenesis. It is the last aspect i.e. virus-host interactions and molecular pathogenesis with which this GM risk assessment is concerned. Within the CVR, the groups of Pablo Murcia and Benjamin Hale will generate the tools to produce recombinant influenza viruses and these viruses will form the basis of the work covered in this risk assessment. The work proposed will involve both in vitro, ex vivo, and in vivo infections. Embryonated chicken eggs will also be used as a system for growing some virus stocks.

Many Hazard Group 2 (HG2) influenza viruses will be at the centre of this project: equine influenza virus (EIV), canine influenza virus (CIV), low pathogenic avian influenza viruses (AIV), and human influenza viruses (H1N1, H3N2). Other viruses which will be used include laboratory-adapted and mouse-adapted strains, as well as currently circulating influenza viruses and influenza viruses that infect other animal species (e.g. swine). We will also generate viruses that contain segments from highly-pathogenic avian influenza A viruses in the background of an attenuated laboratory strain. These viruses will lack a major virulence determinant from highly-pathogenic viruses and will also be engineered such that they do not possess the antigenic novelty associated with pandemic-potential of these strains. Non-hazardous minigenome systems (see below) of influenza viruses will also be studied.

Reverse genetics systems that allow manipulation of the influenza virus genome are readily available (2). Cultured cells are transfected with a mixture of 8 to 12 plasmids, each containing a full-length cDNA copy of one of the influenza virus genome segments under control of a Pol I promoter and terminator sequences, and a hepatitis delta ribozyme sequence. Intracellular transcription produces exact copy RNA transcripts that act as viral mRNAs and templates for viral RNA synthesis that result in production of infectious virus. Similarly, minigenome systems can be constructed in which only the coding sequences between the terminal influenza A virus sequences (either genomic or antigenomic) are replaced with a reporter gene such as Renilla luciferase (RLuc) or eGFP. A minigenome will be transcribed if the polymerase and nucleoprotein genes are co-expressed from expression plasmids, which is useful to study the role of sequences and proteins in replication and also in packaging as minigenome. Minigenomes are on their own non-propagating and are used to mimic virus replication.

1- In vitro and ex vivo infections to study influenza virus replication, host range and pathogenesis.
We will establish and characterise influenza virus infection in cell lines of various origins (human, canine, equine, etc), primary cultures derived mainly from humans, horses and dogs, as well as canine and equine tracheal explants. Primary cell cultures and explants from other animal species might also be employed.

For the canine/equine project, we will mainly be using H3N8 viruses derived from canine and equine strains (for example A/canine/New York/2008 and A/equine/Ohio/2003). Other equine and canine viruses of the same lineage will also be cloned and rescued by reverse genetics. All equine and canine influenza viruses belong to the ACDP hazard group 2. It should be noted that no equine or canine influenza virus has been associated with human disease.

We will also generate by reverse genetics the following human influenza viruses: mouse-adapted A/WSN/33 (H1N1), A/PR/8/34 (H1N1) and the non-mouse adapted 2009 H1N1 pandemic strains (e.g. A/England/195/2009, or A/California/04/2009) as well as other human seasonal strains (e.g. A/New York/312/2001 (H1N1) and A/Victoria/3/75 (H3N2)) as appropriate. All human influenza viruses used will belong to ACDP hazard group 2 and will be predicted to be antigenically similar to components of the seasonal trivalent or quadrivalent vaccine. The viruses will therefore be used at CL2.

Reverse genetics will also be used to construct recombinant viruses with mixed gene segments enabling identification of virulence determinants or identification of host factors that impact specific strains. The ability to perform site directed mutagenesis to produce viruses containing targeted mutations in specific genes will allow further characterization of the role of specific proteins. Readouts will include the capacity for virus replication in tissue culture cells, or explants, as well as ability of the viruses to induce histological changes and the susceptibility of infected cells to apoptosis. In addition, we will examine a number of changes in functional attributes following virus infection, such as ciliary beating if appropriate.

2- Viral genetics of host restriction, adaptation, and interactions with host-cell functions. The contribution that individual virus genes (focusing on the ‘internal’ or non-glycoprotein genes) make to defining host range and pathogenicity will be probed by creating reassortants between the strains of influenza described above in section (1). For the highly-pathogenic avian influenza A viruses, we will not generate nor seek to possess complete sets of reverse genetics clones, and will only use a selection of individual internal segments to generate viruses in the background of attenuated laboratory-adapted influenza viruses (such as WSN or PR8 strains). In this regard, it is
co-transfected into a sub-confluent monolayer of co-cultivated HEK293T and MDCK (Madin-Darby canine kidney) cells. Subsequent amplifications of the virus will be

We will ensure that reassortants between CIV strains, EIV strains, and between CIV and EIV viruses will not affect any immunological protection as they are all phylogenetically very similar (CIV is a direct descendant of EIV). Reassortants between the H3N8 avian-like strains and PR8 is unlikely to result in any increased risk as use of PR8 internal genes together with novel surface glycoproteins is standardised in traditional influenza virus vaccine production worldwide (even with highly virulent influenza viruses such as H5N1), and has been approved by the World Health Organization (6).

Virus reassortments will be generated by reverse genetics that contain select internal segments from highly pathogenic viruses with the surface glycoproteins (HA and NA) from lab-adapted strains (e.g. PR8 or WSN). This will ensure that the viruses are likely to be antigenically similar to the currently used human vaccine, and sensitive to clinically approved NA inhibitors such as oseltamivir. Reassortants will be limited to the ‘internal’ genes of the highly pathogenic virus and are therefore expected to retain the basic tropism of the parental strain, as well as any immunological protection. In the case of using the PR8 and WSN backgrounds, this also means that attenuated characteristics are likely to be maintained. The HA gene of H5N1 viruses is a primary pathogenicity determinant and deletion of its polybasic cleavage site severely attenuates the virus in mammalian and avian models of infection. In addition, the classification of HPAI influenza involves the nature of the haemagglutinin – H5 or H7 subtypes with a polybasic cleavage site expected to produce systemic spread in infected poultry. Current ACDP guidelines state that H5 or H7 viruses modified such that they do not possess a polybasic cleavage site in HA can be handled under CL2 conditions. By only working with the ‘internal’ genes of these strains, we will further reduce any risk as not only will the polybasic cleavage site be removed, but there will be no novel HA (such as H5 or H7) to which humans have never been exposed to previously. The reassortants are unlikely to fall under SAPO regulations as no H5 or H7 HA with a polybasic cleavage site will be used. This will be clarified, and appropriate SAPO licences sought, prior to any work commencing. Use of lab-adapted HA and NA genes (from WSN and PR8) will accentuate any attenuation in humans (e.g. Clements et al., J Clin Micro, 1992, 30 655-62, and Clements et al., J Clin Micro, 1989, 27, 219-22) and is likely to provide cross-protection from H1N1-containing vaccines such as the current seasonal vaccine (the 2009 H1N1 pandemic vaccine (still used in current trivalent vaccines) provides protection against “old” H1N1 viruses between the years 1918 and 1947 (Medina et al., Nature Communications, 2010, Manicassamy et al., PLoSPathogens 2010). PR8 was isolated in 1934, whilst WSN was isolated in 1933.

We will use viruses generated by ourselves and also plan to use recombinant viruses based on A/equine/Ohio/2003, A/canine/New York/2008 (both H3N8), A/WSN/33 or A/PR/8/34 (both H1N1) and A/California/04/2009. In some cases we will add fluorescent tags for labelling and live tracking of viral particles. One possible approach will be to use a FlAsH currently being developed at Institut Pasteur. The FlAsH tag (Invitrogen) is a short (6 residues) peptide tag that has been fused to influenza gene NP and used in a reverse genetics plasmid-based system to produce infectious viral particles carrying the tagged NP protein. Cell-permeable FlAsH reagent, binding with high affinity to the FlAsH tag, is used to stain the cells, and can be excited at 508 nm wavelength. Emission at 528 nm can be detected using standard fluorescence microscopy settings, allowing identification of infected cells. Alternatively, we will use the similar technology SNAP tag, or the autofluorescent GFP/RFP protein domains. Luciferase genes may also be incorporated into recombinant viruses.

In order to compare host range determinants of equine and canine viruses, we will use reverse genetics to construct mutant versions of A/canine/New York/2008 and A/equine/Ohio/2003. The dose of the inoculum will vary, although for most of our experiments we infect explants with a very small dose (200 pfu).

As a reverse genetics system is not currently available for some canine and equine viruses, such a system will be constructed. We will clone various CIV and EIV sequences into an 8-plasmid system widely used for influenza reverse genetics. Genomic segments corresponding to genes coding for proteins HA, NA, M, NS, PB1, PB2, PA and NP including the 3’ and 5’ non-coding regions will be PCR-amplified and cloned into pHW2000 vector in which the cloning site is flanked by the Poll promoter and hepatitis delta ribosome sequences. If necessary, sequences corresponding to PB1, PB2, PA and NP genomic segments will be cloned into pHMG, where protein expression will be under the control of a mouse hydroxymethylglutaryl-coenzyme A reductase (HMG) promoter.

The method to be used for the production of recombinant EIV and CIV by reverse genetics is adapted from previously described procedures (3). The 8-12 plasmids will be co-transfected into a sub-confluent monolayer of co-cultivated HEK293T and MDCK (Madin-Darby canine kidney) cells. Subsequent amplifications of the virus will be
performed on MDCK cells or embryonated chicken eggs.

Reassortant and wild type influenza viruses will be used to:
- Study viral growth, gene expression, replication and pathogenesis in host cells and tissues.
- Study interactions with the host cell (replication, interaction with host cell factors, immunity).

3- Viral genetics using influenza virus minigenome systems
- Minigenome systems for a broad range of influenza A viruses are already in use (1, 4). We will use minigenome systems that have been generated by others. If required, we will derive existing minigenome systems by cloning the segments of interest of the viruses under study (e.g. EIV, CIV, etc). Minigenome systems will be used (as read-outs) in studies on protein functions (cellular, viral), sequence function, segment packaging (packaging by glycoproteins co-expression, or following co-infection) and complementation studies (i.e. CIV PB2 in EIV viral polymerase complex).

4- Functional studies and expression of influenza virus proteins.
- Manipulation of protein sequences by introduction of point mutations, deletions, insertions, fusion to others sequences such as reporter genes, tags etc.
- Expression of influenza virus proteins to study interactions with host cell components and cellular localisation.
- Expression of influenza virus proteins by prokaryotic expression systems, for example for protein purification.
- Expression of influenza virus proteins by eukaryotic expression systems (plasmid, retroviral expression), for example to produce packaging cell lines, cell lines expressing virus-like particles, or cell lines to study protein function.
- Expression of influenza virus proteins by eukaryotic expression systems (plasmid, retroviral expression), to produce packaging cell lines for influenza virus sequences (segments or minigenomes; production of single round infectious particles) and cell lines expressing virus-like particles.

5- Studies on host immunity.
- Interactions of influenza viruses (wild type, reassortants, minigenome) with host responses, and counteraction of host responses will be investigated. Immune signalling/antiviral responses (including activation mechanisms), and viral interference therewith, will be analysed. This will involve transcriptomic studies as well as studies of extra- and intra-cellular host molecules (e.g. proteins). Role of immunity in host cell tropism (infections of cells from different species) will also be investigated. These studies will also use reporter genes inducible upon activation of a given pathway. Cell culture models are available.

B/Yamagata/88

Note: that all of the above viruses are HG2, and will therefore be handled under CL2 conditions.

A/Vietnam/1203/2004 (HPAI H5N1), or related [only the internal segments of this virus will be used]
A/Shanghai/1/2013 (H7N9), or related [only the internal segments of this virus will be used]

The above 2 virus types are HG3, but we will only use genetically modified versions (as detailed below in section 11) which are modified to remove major pathogenicity determinants and the antigenic novelty associated with strains of pandemic-potential. The justifications are reasoned in section 11, and such modified viruses have been assessed locally to be HG2 pathogens, which will be handled under CL2 conditions.

Recipient organisms:

Equine influenza virus H3N8 (genus Influenzavirus A), and derived recombinant viruses.
Canine influenza virus H3N8 (genus Influenzavirus A), and derived recombinant viruses.
Human influenza virus H3N2 and H1N1 (genus Influenzavirus A), and derived recombinant viruses (e.g. see above).

Other containment level 2 influenza viruses (e.g. avian viruses previously characterised as exhibiting low pathogenicity, or swine viruses, etc.) may be considered as long as they are unrelated to those capable of causing infection of humans.
At no point will viruses be produced that have surface antigens with a multibasic cleavage site in H5 or other livestock influenza virus HA proteins. It should also be noted that the equine/canine project and the human/avian projects will be performed by different investigators at different sites. We will therefore physically separate work to minimise the likelihood of reassortment between different viruses. We do not exclude possible future work on viruses expressing H5N1 antigens at CL2 as per current ACDP guidelines (e.g. low-pathogenic H5N1 viruses engineered to lack the polybasic cleavage site: “HALo”). However, such work will only be done after a separate notification to the local safety committee and relevant addendum to our local Risk Assessment.

Human influenza B virus (e.g. B/Yamagata/16/88), and derived recombinant viruses.

Reporter systems mimicking Influenza virus replication:
Minigenomes of CIV, EIV, and other influenza A and B viruses (for example swine influenza virus).

Host/vector system

Plasmid vectors:
Viral sequences (full length clones of Influenza viruses; partial sequences of these and other influenza viruses) and other genes (cellular, viral, reporter) are available in plasmid-encoded cDNA form. RNAs can be transcribed from bacterial promoters (e.g. T7 or SP6 by in vitro transcription or plasmid-expressed RNA polymerase in cells) or eukaryotic promoters (CMV, SV40, cellular promoters, baculovirus promoters etc.). Plasmids for expression of influenza virus sequences (virus rescue or minigenome) typically contain an RNA polymerase I promoter and a hepatitis delta virus ribozyme or a mouse RNA polymerase I terminator. Plasmids contain an origin of replication followed by a prokaryotic selectable marker (usually antibiotic resistance against ampicillin or kanamycin) and sometimes a selectable eukaryotic drug resistance marker such as neomycin or puromycin resistance. The bacterial systems are non-mobilisable vectors in a disabled prokaryotic host.

Hosts:
Prokaryotic hosts:
Disabled, commercially available E. coli strains such as Sure, JM109, XL-strains, DH-strains, Rosetta etc. These strains can only survive in a controlled laboratory environment and will be used for propagation of plasmids. Good microbiological practice and sterilisation of all contaminated waste should prevent release of viable organisms. The risk to the environment is therefore effectively zero.

Eukaryotic hosts:
Vertebrate cell lines of various origins (typically human, mouse, avian, hamster, bovine, canine, equine, etc.), primary cells and explants of various origins (typically human, swine, equine and canine).

In prokaryotic cells, only selectable (eg antibiotic resistance) genes will be translated; prokaryotic cells may also be used for protein expression and subsequent purification.

Virus sequences will be under the control of a promoter that will only generate transcripts in eukaryotic cells or in vitro transcription reactions.

In eukaryotic cells, the following RNAs will be produced which may be translated into the following gene products:

1-Influenza viruses and RNAs (or minigenomes): Proteins involved in replication and transcription of viral genetic material and virus structural proteins. Some of these virus proteins will interact with host-cell components and may affect host cell responses to infection; few of these interactions are currently known. If all virus sequences are translated new virions may be generated; minigenomes are non-propagative viral RNAs (capable of replication). Partial RNAs do not give rise to propagating infectious material.

2-Non-influenza virus genes or sequences: Genes of prokaryotic (bacteriophage polymerases) or eukaryotic (eg. reporter genes such as luciferases or fluorescent proteins such as GFP; plant or arthropod immunity modulators) origin. Reporter gene sequences will also be present in influenza minigenome RNA. The recombinant foreign proteins to be expressed provide no significant increase in the hazard to human health; none are toxic or likely to produce disease in the quantities that could be produced by accidental exposure to these systems. Non translated RNA sequences (including T7 terminator and hepatitis delta ribozyme in plasmids used for virus rescue or rescue of other RNA viruses).
minigenomes) have no known toxic effects and pose no risk to human health.

Techniques used to introduce insert or vectors into cells:

1- Prokaryotic cells: Introduction of DNA into E. coli will be by heat shock/chemical transformation/electroporation. These techniques have been extensively described and are widely used; they rely on getting DNA very close to the bacterial wall and introducing the genetic material through pores or membrane fusion.

2- Eukaryotic cells: Cells will be transfected using transfection reagents such as lipofectamine or by electroporation. Virus genomes or sequences will be introduced into cultured cells by infection with virus or virus replicon particles (VRP).

**Origin & function**

The genetic material will originate from the parental organisms:

- A/California/04/09 (pdmH1N1)
- A/Netherlands/602/09 (pdmH1N1)
- A/Mexico/4108/09 (pdmH1N1)
- A/Brisbane/59/07 (H1N1)
- A/Brisbane/10/07 (H3N2)
- A/Wyoming/3/03 (H3N2)
- A/Moscow/10/99 (H3N2)
- A/Panama/2007/99 (H3N2)
- A/Texas/36/91 (H1N1)
- A/Puerto Rico/8/34 (H1N1) [PR8]
- A/WSN/33 (H1N1) [WSN]
- A/equine/Miami/1963 (H3N8)
- A/equine/Fontainebleau/1979 (H3N8)
- A/equine/Argentina/1995 (H3N8)
- A/equine/Newmarket/1993 (H3N8)
- A/equine/South Africa/2003 (H3N8)
- A/equine/Ohio/2003 (H3N8)
- A/canine/New York/2008 (H3N8)
- A/equine/Mongolia/2009 (H3N8)
- A/wild bird/Mongolia/2009 (H3N8)
- A/wild bird/Mongolia/2010 (H3N8)
- A/wild bird/Mongolia/2011 (H3N8)
- A/swine/England/495/2006 (H1N1)
- B/Yamagata/88

- A/Vietnam/1203/2004 (HPAI H5N1), or related [we will only use the internal segments from these viruses]
- A/Shanghai/1/2013 (H7N9), or related [we will only use the internal segments from these viruses]

Alternatively, viral sequences of these and related viruses (similar strains and same ACDP classification) can be synthesised. We do not exclude possible future work on viruses expressing H5N1 surface antigens at CL2 as per current ACDP guidelines (e.g. low-pathogenic H5N1 viruses engineered to lack the polybasic cleavage site: "HALo"). However, such work will only be done after a separate notification to the local safety committee and relevant addendum to our local Risk Assessment.
The intended functions of the genetic material involved is the production, purification and characterisation of influenza viruses, as well as the production and use of minigenomes. In turn, the viruses produced will be used to infect human or animal cell tissues and cells to determine the cellular processes involved in pathogenesis and replication through virological and molecular biological methods.

Evaluation of foreseeable effects

Plasmid vectors: Viral sequences (including full length clones or partial sequences of influenza A virus or other influenza viruses) and other genes (cellular, viral or reporter) are available in plasmid-encoded cDNA form. Plasmid vectors are based on bacterial plasmids and contain an origin of replication for prokaryotic cells and selectable antibiotic/drug resistance (pro- or eukaryotic) markers. By themselves these vectors present no risk to human health. Vectors have no selective advantage and would soon be lost from the bacterial population. The bacterial systems are non-mobilisable vectors in a disabled prokaryotic host. Systems for prokaryotic gene expression are under control of an inducible prokaryotic promoter. Systems for eukaryotic RNA or protein expression are under the control of promoters of viral (such as CMV or SV40), eukaryotic (eg actin promoter, pathway inducible promoter such as STAT, interferon etc.) or prokaryotic (such as T7 or SP6 promoter for in vitro transcription) origin. Plasmids with eukaryotic promoters such as the CMV promoter can be transcribed in human cells. None of the genes used in these studies are oncogenes. The hazard of expressing ‘foreign’ genes from these eukaryotic promoter plasmids would depend on the expected physiological effects of the foreign gene product and is discussed in more detail below.

Viruses: Influenza is typically a mild and self-limiting infection, acquired generally by the respiratory route. Severity depends on the strain of virus and host but in general tends to fall in a spectrum between asymptomatic to ~ 1 week of fever and malaise in otherwise healthy people. Severe illness can occur but is rare, occurring in less than 1% of cases (see below). This level of risk applies to most wild type human H1N1 and H3N2 viruses and the porcine viruses. Equine H7N7, H3N8 and canine H3N8 viruses have not been associated with significant illness in humans. In addition, the laboratory adapted PR8 and WSN strains of H1N1 human influenza are known to be avirulent in man from many volunteer challenge studies as well as a long (> 70 years) history of safe use in the lab. The GM viruses containing internal segments from H5N1 or H7N9, but with the surface glycoproteins from WSN or PR8 would retain antigenic properties of the lab-adapted PR8/WSN viruses, which are likely covered by the current human influenza vaccine, and which have not been associated with disease despite their wide use worldwide for decades.

Even seasonal influenza can have potentially serious consequences for anyone who is pregnant, immunosuppressed, asthmatic, or has other respiratory/underlying chronic diseases. Vaccines are available for the circulating human H1N1 and H3N2 strains and the majority of the population has at least some prior immunity to these viruses. All laboratory workers and staff within the department are recommended to receive the annual human influenza vaccine, and all workers using shared resources (even if not directly involved in the work) are made aware of the risk assessment for influenza virus work. Those at risk of severe consequences of influenza (e.g. pregnant women) will be separately notified of the risks of these pathogens immediately after they identify themselves to their PI and occupational health. Individual risk assessments will be carried out governing these specific cases.

The antivirals oseltamivir, zanamivir and amantidine are also available for treatment or prophylaxis if needed. We have procedures for staff to seek medical advice and prophylactic treatment following any possible significant accidental exposure events. Note, we will not handle any known antiviral-resistant strains of influenza virus in the same location as other viruses with different antigenic profiles in order to limit the possibility of accidental reassortment generating an anti-viral resistant virus with new antigenic properties.

Vaccines are also available for horses/dogs against EIV and CIV. Workers with these viruses will be advised to not have contact with either horses or dogs for 48h after last handling the viruses.

Personnel working with these viruses are expected to inform occupational health should they become pregnant or immunosuppressed, and inform the PI so that precautionary measures can be introduced following advice from occupational health. We also have a policy whereby those with flu-like symptoms do not come to work, do not handle influenza viruses experimentally, and inform their PI immediately. This policy will further limit any possible accidental reassortment between laboratory viruses and circulating human viruses, should a worker accidentally expose themselves to a laboratory virus whilst simultaneously infected with a circulating virus. The local PI (Pablo Murcia or Benjamin Hale) will take responsibility for enforcing this, and will similarly assume responsibility for the safety and compliance of any visiting workers.

Influenza A virus minigenomes:

Minigenomes pose no risk to human health, including those derived from pathogenic influenza A viruses. They cannot propagate on their own. Even if packaged by
co-expression of glycoproteins and thus used to infect cells, their own transcriptional activity would be minimal. If packaged into virions, the associated risk is that of the virus itself as reporter genes in minigenomes are not reported to be toxic.

Note: No reassortment experiments involving the glycoproteins of human and animal influenza A viruses (for example an influenza A virus carrying a human H1 and an equine N8) will be performed, to eliminate the possibility of creating viruses for which humans or animals have no prior immunity. Furthermore, we aim to physically separate work on different influenza viruses such that accidental reassortment to generate a more pathogenic strain, or an antigenically novel strain with new properties, cannot occur from our work (see details in Risk Assessment).

Hosts

The host/recipient organism: Prokaryotic organisms: All strains will be disabled, commercially available E. coli derivatives classified as ‘especially disabled hosts’ by ACDP. These strains cannot colonise humans and are known not to cause harm to humans.

Eukaryotic cells: Cell lines and tissues to be used would not survive inside the human body (immune rejection) and are not known to carry harmful pathogens. Addition of DNA or RNA or infection will confer no growth or survival advantage in or outside the laboratory to cell lines and tissues.

What hazards do the inserted genetic material or other genetic modification pose?

The inserted/donated genetic material:

Viral RNA and proteins, cellular proteins: Most individually expressed viral or cellular proteins are unlikely to have harmful effects in eukaryotic cells, however some could perturb normal cellular metabolism, predispose or protect against cell death or render cells more or less susceptible to other infections if overexpressed or silenced. It is very unlikely that Influenza A virus RNA or proteins would have any harmful toxin-like effect outside cells. Only antigenomic RNA containing an influenza A virus sequence can be translated or give rise to infectious virus (if all necessary genomic information is provided) in eukaryotic cells; minigenome RNAs are non propagative and pose no harm (individual cells replicating minigenome are likely to die or be eliminated by the immune system). Viral non-coding RNA sequences are important in influenza virus replication but do not encode biologically active molecules that are likely to induce physiological effects in humans on their own. None of the influenza virus gene products are known to be secreted cytotoxins.

Reporter genes: Reporter genes of prokaryotic or eukaryotic origin (eg luciferase, fluorescent proteins etc.). No harmful properties have been attributed to these proteins. There would be no altered physiology expected if any of these genes were expressed; eGFP for example is a spontaneously fluorescent protein isolated from Aequorea victoria a coelenterate and has no known detrimental effects. Luciferase is another commonly used reporter gene and is derived from the firefly Photinus pyralis or the jellyfish Renilla reniformis. It is an enzyme which catalyses production of light from luciferin and ATP; the light produced is used as a measure of gene activity. The enzyme has no other biological function.

Sequence changes in viral sequences:

Mutation or deletion will target disruption of structural and non-structural protein functions or non-coding viral sequences and are likely to have no or deleterious effects on viral replication, thus not increasing risk or hazards to human health associated by viruses genetically modified in such a way.

Foreseeable effects to the environment:

Canine influenza virus: This virus is not thought to be endemic in the UK, and it is not on the SAPO list. In fact, it is not highly transmissible in the only country in which is endemic (USA). Transmission is common only in highly dense dog populations such as those found in animal shelters. CIV was first isolated from greyhounds in USA. Experimental infection results in mild respiratory disease. Serological evidence of infection in foxhounds in the UK has been shown, although no outbreaks have been associated with it. Given the low transmissibility and low pathogenicity of CIV, the chance of accidentally infecting dogs initiating a transmission cycle sustained by local
dogs is negligible. Reassortants carrying gene segments from EIV will likely display lower fitness and will pose minimal risks to dogs, if any. The modified viruses will not have any inserted foreign genes other than non-harmful genes or sequences, or (usually disruptive) changes in viral genes or non-coding sequences; changes in virus pathogenesis are therefore unlikely other than as described above under the human health and safety section. In the absence of a suitable host these viruses would not survive in the environment and the risk is effectively zero. Dogs are kept out of labs and the risk of accidental infection of dogs by contact of contaminated material is minimal for CIV. However, as some members of staff bring their dogs to work there is a potential risk of infection of those animals if they access the laboratories.

Equine influenza virus: This virus has been endemic in the UK for over 40 years and infections are most likely the result of horse movement and inadequate vaccination schedules. EIV is not on SAPO or ACDP lists. There is a vaccine available for EIV, although most horses have natural immunity due to vaccination or natural infections. The modified viruses do not contain anything other than non-harmful genes or sequences, or disruptive changes in viral genes or non-coding sequences; changes in virus pathogenesis are therefore unlikely other than as described above under the human health and safety section. If EIV was to escape the lab and infect local horses, there is minimal risk it could initiate a transmission cycle. Horses are kept out of labs and the risk of accidental infection of horses by contact of contaminated material is minimal. The closest horses to the lab are kept at the Weipers Centre and up to date vaccination against EIV is a requirement for admission.

Avian-like equine influenza virus (H3N8): This virus is highly pathogenic in horses (20% mortality) and there is no cross reactivity between classical EIV and avian-like EIV. Reassortants of this virus will be done using PR8 as a backbone (HA and NA of avian like EIV + the six internal genes of PR8), so the resultant viruses will be highly attenuated. No other reassortant viruses including the surface glycoproteins (HA and NA) of avian like EIV will be generated. Reassortants carrying the internal genes of avian-like EIV and the external genes of classical EIV will have a minimum risk to initiate a transmission cycle as most horses in the UK have immunity against the surface glycoproteins of classical EIV. It is important to note that PR8 has been used as a backbone to generate vaccines against highly pathogenic H5N1 viruses and thus is very safe to use. If these reassortants were to escape they would have very low fitness due to the attenuation conferred by the PR8 genetic background.

Human influenza viruses: Currently circulating human influenza A viruses (pdm H1N1, seasonal H1N1, and H3N2) are globally distributed, there are available vaccines, and the majority of the population has at least some prior immunity to these viruses. The antivirals oseltamivir and zanamivir are also available for treatment or prophylaxis if needed.

Viruses constructed will be based on the widely used laboratory strains A/WSN/33 (H1N1), A/PR/8/34 (H1N1) (all mouse adapted and known [WSN, PR8] to be attenuated in man) or more recent low pathogenicity human strains to which most people will have substantial amounts of pre-existing immunological protection: A/Udorn/72 or A/Victoria/3/75 (H3N2) viruses, the current human influenza strains A/England/195/2009, A/California/04/2009 (both 2009 H1N1 pandemic viruses) and the A/New York/312/2001 strain (‘seasonal’ H1N1). Such antigenic and attenuated properties will be maintained in viruses bearing the surface glycoproteins of WSN/PR8 and the internal segments of H5N1 or H7N9 viruses.

The experiments proposed involve gene deletion, mutation or replacement of specific genes with the corresponding gene from one of the other strains listed. For reassortants between the human-derived or laboratory adapted viruses, this is not predicted to create viruses with novel tropism or pathogenicity as they either already share similar characteristics (the recent human isolates) or are highly attenuated in humans (PR8, WSN). In the case of reassortants incorporating genes from animal strains of influenza, we also do not expect any change in tropism because the human or laboratory adapted HA and NA genes will be retained. In the case of reassortants incorporating genes of the avian-like equine influenza virus, the six internal genes will be derived from PR8, thus attenuating the virus significantly.

We propose to use containment level 2 for all other HG2 influenza A viruses (as specified on page 2) similar to CIV and EIV unless other regulations are in place for a particular pathogen.

Minigenomes: These systems derived from other influenza A viruses are non-propagative and even if packaged, pose no or no additional hazard.
Prokaryotic organisms: Disabled, commercially available E. coli strains. These strains can only survive in a controlled laboratory environment and will be used for propagation of plasmids. Good microbiological practice and sterilisation of all contaminated waste will prevent release of viable organisms. Acquiring antibiotic resistance (from the plasmid vector) or additional sequences (virus or marker gene sequences) will not give these strains any survival advantage in the environment. The risk to the environment is therefore effectively zero.

Eukaryotic cells: Cell lines to be used are not viable outside the laboratory and thus pose no threat to the environment. Addition of plasmid vectors or virus or minigenomes will confer no growth or survival advantage in the environment.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

| N/A |

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We propose to generate influenza viruses bearing the 6 internal gene segments from H5N1 or H7N9, with the 2 surface glycoproteins of laboratory-adapted H1N1 viruses WSN or PR8. Currently, both H5N1 and H7N9 viruses should be handled at CL3 according to ACDP guidelines.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

**Disinfect influenza virus-contaminated material immediately.**

**GM26 (CVR Church Street)**

- Solids from cell culture (eg plasticware such as flasks, tubes, pipette tips etc.) - submerged soak in a minimum of 1% Virkon (w/v) for at least 12 hours. Rinse solids then go to landfill. Virkon is added to the plasticware prior to removal from the MSCII.

- Other solids (agar plates, gloves etc.) placed in a sealed container (lined with clear bag) and disposed of by autoclaving using a make safe cycle of 121°C for 30 minutes. Gloves used for influenza virus work should be disinfected with alcohol before putting in containers prior to autoclaving.

- Liquids (eg. samples, culture supernatants, tissue culture media) – add Virkon to final minimum concentration of 1% (w/v) for at least 12 hours, then discharge to drains. Virkon is added to the liquid waste prior to removal from the MSCII.

- Liquids (E. coli culture medium) - add Virkon to final minimum concentration of 1% (w/v) for at least 12 hours, then discharge to drains.

- Sharps (e.g. needles/syringes, scalpels) - decontaminate in 1% Virkon overnight, then place in sharps bin for incineration.

- Spills of infectious liquid - immediately inactivated with powdered Virkon (rather than liquid spray, to minimise aerosol generation - large spill), or absorbed into paper towels soaked in Virkon (minimum 1% - small spill). Soaked paper towels then autoclaved. Surface wiped down with Virkon soaked paper towels and then disinfected with alcohol prior to drying.

**Degree of kill:**

- Chemical Sterilization by Virkon- effectively 100% kill.
- Autoclaving - effectively 100% kill (annual validation).

**GM223 (CVR Garscube Estate):**

- Disposable solids (eg plasticware such as flasks, tubes, pipette tips etc.) - soak in 1% Virkon (w/v) for a minimum of 12 hours. Transfer solid contents to clear autoclave.
bags and autoclave at 121°C for a minimum of 20 minutes prior to final disposal by district council to landfill, remaining liquid to be discharged to drain.

Other solids (agar plates, gloves etc.)- placed in a marked box lined with a clear autoclave bag, and disposed of by autoclaving using a make safe cycle of 121°C for at least 20 minutes. Seal contaminated plates (with for example bacterial GMOs) before placing in bag, to avoid lid falling off. Gloves used for influenza virus work should be disinfected with alcohol before putting in containers.

Liquids (eg. samples, E. coli culture media, tissue culture media)- add Virkon to final concentration of 1% (w/v) for a minimum of 12 hours, then discharge to drains.

Sharps (eg needles, syringes, scalpels) - decontaminate in 1% Virkon overnight then place in sharps bin for incineration.

Degree of kill:
Chemical Sterilization by Virkon- effectively 100% kill.
Autoclaving - effectively 100% kill (annual validation).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
1. GM 26 committee comments:

The CVR Church Street GM subcommittee met on 29/04/2013 to consider the proposal:
“Influenza virus pathogenesis, host range and virus/host interactions”

Present:
Roger Everett
John McLauchlan
Joyce Mitchell
Arvind Patel
Emma Thomsen
Frazer Rixon (convener)

The subcommittee agreed the following recommendations.

Vaccination
The existing recommendation is that anyone working with influenza in Church Street should be vaccinated. This requirement for vaccination is not clearly stated in the RA. For example, on pages 16, 20 and 22 of the RA it is stated that vaccines are available against the human influenza but there is no mention that vaccination is advised. In addition, the potential seriousness of infection is downplayed. Thus, on pages 11, 13, 17 and 22 infection is described as mild, or typically mild and self-limiting. This takes no account of the potentially serious consequences for anyone who is pregnant, immunosuppressed, asthmatic, or has other respiratory diseases. We suggest that text is inserted into the forms at appropriate places stating that people working with influenza should be vaccinated and that anyone with a flu-like illness should not report to work or go to A&E, but should inform Occupational Health. In addition, vulnerable groups should be identified in the documents and warned of the potential risk.

Risk
The subcommittee considered that the greatest risk of generating unforeseen viruses through reassortment was posed by workers who were already infected with a circulating strain. Therefore, it is particularly important that the guidelines should make it clear that people suspected to be infected should not work on this project and these guidelines must be enforced. As the proposed work covers two separate sites (Church Street and Garscube), a local PI must assume responsibility for the safety and compliance of any visiting workers at Church Street and this must be clearly stated.

Scope
Although the proposal states (p11 of RA) that “equine, canine, and low pathogenicity avian viruses are unlikely to be used at this (Church Street) site”, the subcommittee did not wish to rule out such use in future. Therefore, the above statement should be removed and the text modified so as not to preclude use of these viruses at Church Street.

Disinfection
Under Waste Disposal (RA page 20) it should be made clear that Virkon is added to infectious liquid waste before it is removed from the safety cabinet.

Text
A number of matters were identified relating to the layout and wording of the RA:
The Church Street site (GM26) is designated as both a primary location (RA page 9) and a secondary location (page 11) for proposed laboratory work. This is ambiguous
and needs to be clarified.
Change BSL 2 laboratory to containment level 2 laboratory (RA page 9).
Church Street policy at present is that oseltamivir-resistant flu can only be handled in room 310. This should be specified.
References to Virkon treatment should make it clear that the final concentration must be ≥1%.
Spills of infectious or contaminated liquids should be inactivated with Virkon before being cleaned up (RA page 15).
Remove the reference to visual inspection of the safety cabinet by the PI (RA page 17).
List COSHH 237 under point 15 (RA page 19).

Following discussion between the co-applicant Ben Hale and Frazer Rixon, a second meeting of the CVR Church Street GM subcommittee was called for 27/05/2013, to discuss further the handling of reassortants containing genome segments from high pathogenicity avian influenza strains.

Present:
John McLauchlan
Joyce Mitchell
Arvind Patel
Emma Thomsen
Frazer Rixon convener.

Invited: Ben Hale

Apologies: Roger Everet

The subcommittee agreed the following additional recommendations:

Background information on the polybasic site and its importance for pathogenicity should be included in the proposal and it should contain a clear statement that viruses containing a polybasic site would not be generated or used.

The proposal could include mention of low-pathogenic H5N1 viruses engineered to lack the polybasic cleavage site: "HALo" but should contain a clear statement that work with such viruses would require prior consideration and approval by the local safety committee.

Methods to prevent accidental reassortment of genome segments resulting in viruses with potentially novel antigenic properties should be specified.
The requested changes were made and on 23/06/13 the revised documents were circulated to and approved by the subcommittee members on 25/06/13.

2. GM223 committee comments 13/05/13

The comments of GM 223 were that this was a detailed risk assessment with a lot of evidence, justification of arguments and references. The recommendations were primarily in agreement with those of GM 26 as detailed above and the PIs were notified accordingly. Clarification on any SAPO licence requirements was requested. Careful consideration should be given to the potential for reassortment of genome segments and this should be reflected in the laboratory practices. All workers using the designated facilities should be made aware of all pathogens and GMOs being handled in the areas. All solid waste generated from this project will be autoclaved and it is recommended that Virkon treated liquid waste also be autoclaved. Where this is not possible then references/documentation should be provided to support Virkon disinfection as a validated means alone for inactivation of the liquid waste generated.

GM 223 approved the revised documents on 24/06/13

The objective of this project is to investigate the interaction of hepatitis B virus (HBV) and hepatitis D virus (HDV) with host cells with a view to understanding the roles of viral and host factors in virus infection and replication, and their contribution to virus-associated pathogenesis. We will first establish in vitro cell culture systems to generate infectious virus using well-characterized prototype and patient-derived replication-competent viral genomic DNA. Viruses generated thus will be then used to infect different target cell lines to study, at the mechanistic level, the functions of the relevant viral and host components (e.g. proteins and/or nucleic acids) and the impact of their interactions on virus pathogenesis. It is hoped that the results obtained will inform development of novel anti-viral therapeutic avenues and may lead to bats as a new animal model for HDV.

Description of activities:

HBV is the prototypic member of the family Hepadnaviridae, which includes avian, primate and rodent hepatitis viruses. All hepadnaviruses share the property of restricted host range, a strong, but not exclusive, tropism for hepatocytes, and the ability to cause liver damage. HBV is a major human pathogen causing a chronic inflammatory liver disease often leading to the development of hepatocellular carcinoma (HCC). The clinical significance of HBV is easily demonstrated by the fact that more than 250 million people worldwide are chronically infected. HBV has a relaxed circular partially double-stranded DNA genome of approximately 3.2 kb. Following infection, the HBV genome is transported to the nucleus and converted to covalently closed circular (ccc) DNA which serves as a template for transcription of viral RNAs. Following transport of the pre-genomic RNA and translation in the cytoplasm, selective encapsidation of the RNA into the nucleocapsid ensues, along with encapsidation of RNA polymerase. In the immature capsid, the 3.5 kb mRNA is reverse-transcribed, to yield minus strand DNA. The RNA is degraded and the DNA strand is replicated, producing the second, shorter DNA strand. Nucleocapsids containing DNA genomes then acquire their outer envelope, probably by budding into the endoplasmic reticulum (ER) in areas where viral surface antigens (HBsAg) are inserted. The resulting particles are then transported from the cell by normal pathways of vesicular transport. There are 3 forms of HBsAg (called large, medium and small or L-HBsAg, M-HBsAg and S-HBsAg, respectively) which all share the same C-terminal (i.e. S-HBsAg), with the M-HBsAg being extended at its N-terminus by 55 amino acid (aa) preS2 segment and L-HBsAg additionally containing an N-terminal 108 to 119 aa preS1 domain.

HDV belongs to the genus Deltavirus causes chronic hepatitis D. The virion carries a circular single-stranded negative-sense RNA genome of ~1.7 kb in length. The viral replicative intermediate of positive-sense polarity encodes the delta antigen (HDAg) that is not packaged into the virion. HDV requires HBV as a helper virus in the form of its envelope proteins (i.e. HBsAg) to form infectious virus particles. Co-infection with HDV is associated with more severe pathological complications (e.g. increased risk of liver failure in acute infections and development of liver cancer in chronic infections) compared to HBV alone. HDV RNA replication occurs in the nucleus and the viral ribonucleoprotein is transported to the Golgi where it is enveloped by HBsAg. The secretion of the assembled virion is thought to occur via Golgi. Co-expression of HDV genome with HBsAg results in secretion of HDV particles into cell medium. This medium can be used as a source of HDV to infect susceptible naïve cells in which the virus initiates a single-cycle infection; i.e the virus delivers its replication-competent genome, but is unable to produce progeny virions as the cells lack HBsAg. While HDV has historically been considered a virus of humans, recent metagenomic sequence data obtained here at the MRC – University of Glasgow Centre for Virus Research (CVR) has discovered RNA which appears to represent an analogous virus (HDVb) circulating among wild bats (Desmodus rotundus) in South America (Bergner et al., unpublished data). Little is known of HDVb, but genomic similarities to HDV suggest it is likely to have a similar biology (i.e., narrow host range and requirement for a helper virus such as bat hepadnavirus). Ongoing sequencing studies here at the CVR aim to identify the analogous bat-associated HDVb genome using metagenomic sequencing and PCR. On account of the presence of HBsAg on HBV and HDV virions, both viruses share the same cell entry pathway although their genomes replicate differently. Cell entry is mediated by initial attachment of the virus to the cell surface heparin sulfate proteoglycans (HSPGs) followed by a specific interaction with the hepatocyte-specific sodium taurocholate co-transporting polypeptide (NTCP) (Yan et al., 2012 eLife1,e00049). The virus interaction with HSPG is mediated by the N-terminal preS1 domain of L-HBsAg and the antigenic loop of the S-HBsAg, while the interaction with NTCP is solely mediated by preS1. It is likely that additional as yet unidentified host factors are also required for virus entry into target cells.

The proposed project consists of 6 major components:

1. Generation of infectious viruses: We will use the well-characterized tetracycline-inducible HBV expressing cell line, Hep38.7-Tet (Ogura et al., Biochemical and Biophysical Research Communications 452 (2014), 315–321), to generate HBV for use in work described here. Additionally, we will also transfect mammalian cells (including hepatocytes) with replication-competent HBV DNA derived from well-characterised isolates or patients infected with different viral genotypes and isolates. This is expected to initiate a fully productive virus life cycle in transfected cells. Evidence of virus infection and replication will be monitored by the detection of viral RNA (by...
In vitro evolution of HBV and HDV: To reveal viral determinants of sensitivity/resistance to antiviral factors and reveal potential resistance pathways to antiviral molecules replication in cultured hepatocytes or other permissive target cells (vertebrate origin).

We will be co-transfected together with replication-competent HBV DNA and the yield of HBV will be quantified. In all instances, the methods described in step 1 above will be

Transduction with lentiviral vectors encoding each ISG prior to infection with HBV representing different genotypes and isolates. Alternatively, ISG-encoding vectors

Screen the ability of hundreds of individual ISGs to inhibit viral replication can be considered. Briefly, hepatocytes, including Hep38.7-Tet (or other permissive target cells)

Organoids derived from the human hepatocyte cell lines that stably express the virus entry receptor NTCP. The specificity and the mechanisms of viral entry will be explored further using a panel of in-house generated antibodies to preS1, the N-terminal domain of the L-HBsAg that plays a role in viral entry via its interaction with NTCP. Together, these experiments will allow us to measure and study the mechanics of virus entry and resistance to drugs, and to evaluate vaccine escape.

Infection of cells with clinical HBV isolates: Sera collected from HBV-infected individuals will be used as an inoculum for infection of appropriate cell lines. Initially all patients will be recruited in UK and only samples tested negative for cytomegalovirus and HIV will be used. Samples from overseas and/or from patients screened positive for HIV might be used at a later stage of the project. In this case, samples will be screened for the infectious agents most likely to be present in the sera (depending on their origin). Samples containing adventitious agents will be excluded and any import into the CVR will be subject to the local Safety group approval. Evidence of infection will be monitored as described in step 1 above.

Investigating the effects of interferon-stimulated genes (ISGs) in HBV and HDV infection: Type I interferons (IFNs) suppress the replication of HBV in vitro and in vivo. However, the success of IFN therapy is variable and influenced by the HBV genotype. Despite this, relatively little is known about which host ISGs inhibit HBV and why some genotypes respond better to IFN therapy. We have developed libraries of ISGs from humans, rhesus macaques and cows as well as diverse ISGs from diverse vertebrate species (Schoggins et al., 2011, Nature 472(7344):481-485; Kane et al., 2016 Cell Host Microbe 20(3):392-405). These libraries are arrayed so that in a single screen the ability of hundreds of individual ISGs to inhibit viral replication can be considered. Briefly, hepatocytes, including Hep38.7-Tet (or other permissive target cells) will be transduced with lentiviral vectors encoding each ISG prior to infection with HBV representing different genotypes and isolates. Alternatively, ISG-encoding vectors will be co-transfected together with replication-competent HBV DNA and the yield of HBV will be quantified. In all instances, the methods described in step 1 above will be used to quantify the level of virus infection/gene expression and/or replication in order to identify inhibitory ISGs. Similarly we are interested in which ISGs inhibit the replication of HDV and whether such inhibition is direct or a consequence of HBV inhibition (indirect). Thus, we will examine the ability of different ISGs to inhibit HDV replication in cultured hepatocytes or other permissive target cells (vertebrate origin).

In vitro evolution of HBV and HDV: To reveal viral determinants of sensitivity/resistance to antiviral factors and reveal potential resistance pathways to antiviral molecules or antiviral candidates we will propagate HBV (and HBV and HDV) in the presence of antiviral factors (genes from various species), candidate antiviral molecules, approved antivirals, antiviral cytokines or experimental drugs. The methods described in step 1 and sequencing approaches will be used to monitor changes in the viral genome(s) selected during the passage experiments.
We will use a genetically engineered stable cell line, Hep38.7-Tet, conditionally replicating and secreting HBV particles as source of virus in our studies. Additionally, we will generate HBV and HDV by reverse genetics following transfection with patient-derived infectious genomic DNA into hepatocyte cell lines. Where necessary, appropriate genetic modifications will be introduced into the relevant part of the viral genomic cDNA to generate genetically modified (GM) viruses of interest. These modifications may include specific mutation of amino acids that are functionally and structurally important in virus infection/replication, for reactivity to antibodies of interest, and for conferring antiviral resistance (the latter will be based on those observed in circulating strains, or those identified in our studies on ‘in vitro evolution of HBV and HDV’ as described in point 6, of Section 6). Additionally, we will also attempt to generate viruses expressing reporter genes or epitope tags (including but not limited to GFP, RFP and Luciferase). The modifications are not expected to alter host tropism.

Host/vector system

Viruses: Different WT and GM derivatives of HBV and HDV, including a bat-associated subtype of HDV (HDVb).

Bacterial: Disabled E. col K12-derived strains such as DH5α. These strains can only survive in a controlled laboratory environment and will be used for propagation of plasmids.

Mammalian: Various vertebrate hepatocyte and non-hepatocyte stable cell lines.

Vector systems: Non-mobilisable pUC-derived plasmids, pBluescript, pCDNA and lentiviral vectors

Origin & function

Virus will mainly be obtained from a HBV producer cell line, Hep38.7-Tet, which will be obtained from collaborators in Japan. This cell line is well-characterised by them (Ogura et al., Biochemical and Biophysical Research Communications 452 (2014), 315-321) and is widely used by different groups. It will be imported from Japan as ‘UN2814 Category A infectious Substance affecting humans’ and will be handled in our Containment Level 3 (CL3) facilities. Additionally, we will produce both HBV and HDV by reverse genetics using patient-derived viral genomic nucleic acids for HBV and HDV and bat-derived viral genomic nucleic acids for HDVb. We also plan to attempt to directly propagate viruses derived from clinical samples (serum/plasma) following inoculation into cultured cells.

GM cell lines that ectopically express host proteins of interest (e.g. the virus receptor NTCP, viral dependency or restriction factors) will be generated. In some cases cell lines lacking host factor(s) identified as of interest in the study will be generated either through transient knock-down or permanent gene knock-out technologies. These GM cell lines will allow assessment of the functions of the relevant viral and/or host factors on virus infection, replication and pathogenesis.

Evaluation of foreseeable effects

Risk associated with HBV and HDV generated in this project: Viruses will be rescued by reverse genetics. There are no plans to carry out extensive mutational analyses of the viral genomes - mutations introduced will be mainly based on sequences circulating in patients including those conferring resistance to drugs. Additionally, in order to understand and delineate at molecular level aspects of viral life cycle (e.g. entry, replication, assembly) we may create specific amino acid changes in viral or host proteins of interest, or insert reporter genes or epitope tags (including but not limited to GFP, RFP and Luciferase). However, we expect these modifications to not adversely alter the replication, transmission or tropism of the viruses. If anything, the modifications would result in attenuated viruses.

Risks associated with GM cell lines: As mentioned above, the HBV producer cell line, Hep38.7-Tet, will be used as one source of virus. This cell line will always be handled under our CL3 facilities: the Richard M. Elliott Biosafety Laboratories (REBL) and/or MacRobert Blood-Borne Virus (BBV) laboratory (see section 11 below). All work will be strictly performed as per the criteria laid out in the REBL and BBV CL3 laboratories Codes of Practice and Risk Assessment associated with this Notification (see disinfection and waste disposal procedures). Risk of accidental infection to personnel working in the CL3 laboratory is very low, and the likelihood of virus being released from the laboratory is effectively nil.

Risks to the environment: Both HBV and HDV are Hazard Group 3 pathogens. In accordance with this classification all work involving the generation and handling of these viruses proposed will be performed in our REBL or MacRobert BBV CL3 facilities as described above (see section 11 below). HDVb is currently unclassified with respect to ADCP Hazard Group, and has never been found or suspected to infect humans or species other than bats. Nevertheless, as a precaution, potentially infectious HDVb will be handled only in our CL3 facilities. All work is strictly performed as per the criteria laid out in the REBL and BBV CL3 laboratories Codes of Practice and Risk Assessment associated with this Notification (see disinfection and waste disposal procedures). Risk of accidental infection to personnel working in the CL3 laboratory is very low, and the likelihood of virus being released from the laboratory is effectively nil. Therefore, the risk to the environment is effectively zero.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We have recently been granted derogation under Regulation 19 of the Genetically Modified (Contained Use) Regulations 2014 to dispense with sealability for the MacRobert BBV CL3 laboratory in relation to work with wild-type and genetically modified Hepatitis C virus (HCV) and Human Immunodeficiency virus (HIV) - notified activities GM26/99.3a and GM223/13.1b, respectively.

Similarly to HCV and HIV, HBV and HDV are blood-borne viruses, they are not infectious through the aerosolised/airborne route. Although aerosolised infection by highly concentrated HBV or HDV stocks remains a theoretical transmissible route, no case has been documented. Moreover, both viruses are sensitive to common chemical disinfectants such as 70% Industrial Methylated Spirit (IMS), Virkon and Distel. Little is known oh HDVb, but genomic similarities to HDV suggest it is likely to have a similar biology (i.e., narrow host range and a requirement for a helper virus such as bat hepadnavirus). Considering the transmission routes of HBV and HDV and the scope of work we intend to do (as detailed in this form and the attached risk assessment), we consider that the risk of using highly toxic fumigants (such as formaldehyde or hydrogen peroxide) surpasses the risk of contamination by or release of the viruses and we propose to dispense with fumigation for room disinfection. Instead, we propose to use chemical surface disinfectants for regular and emergency disinfection procedures, as detailed in the attached risk assessment.

Hence, we are seeking derogation from full containment level 3 measures and propose to handle HBV and HDV/HDVb in the MacRobert BBV derogated CL3 laboratory in the same way as already consented by HSE for HCV and HIV: uncontained infectious material will only be handled in microbiological safety cabinets (MSC); no concentration of virus by ultracentrifugation will be permitted and propagation of virus will be limited to no more than 10 to the 6 genome copies/ml. No laboratory-acquired infection of HBV or HDV via aerosols have ever been reported in this concentration range. Any work requiring higher titres of HBV or HDV will necessitate concentration of the virus by ultracentrifugation or other means and will be carried out in the REBL CL3 Suite, which operates under more stringent safety procedures and is suitable for room fumigation for regular and emergency disinfection. See associated risk assessment for fully detailed containment measures, inactivation and waste disposal procedures.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment Level 2 areas:

Liquid waste: add Virkon to final concentration of 1% (w/v) overnight, then discharge to drains.

Disposable solids (eg plasticware such as flasks, tubes, pipette tips etc.): soak in 1% Virkon (w/v) overnight. Transfer solid contents to autoclave bags and autoclave at 121°C for a minimum of 15 minutes prior to final disposal by district council to landfill, remaining liquid to be discharged to drain.

Other solids (agar plates, gloves etc.): place in a marked box lined with a clear autoclave bag, and autoclave at 121°C for at least 15 minutes. Seal contaminated plates before placing in bag, to avoid lid falling off. Gloves should be disinfected with alcohol before putting in containers.

Degree of kill:

Chemical sterilisation by Virkon - effectively 100% kill

Autoclaving - effectively 100% kill (annual validation)

MacRobert BBV derogated CL3 laboratory:

Liquid waste: decontaminate in Virkon 1% w/v (final concentration) overnight. When handling protein rich liquid, Virkon powder should be added to give a final concentration of no less than 1% w/v. After inactivation, discharge liquids to drain.

Solid waste from within the MSC: discard paper waste within the MSC into a metal bin lined with autoclave bag for autoclaving. Cell culture plastics which can be submerged must be soaked overnight in 1% w/v Virkon prior to autoclaving. Flasks, once liquid has been removed, can be rinsed with 1% w/v Virkon, capped, surface-decontaminated with 70% IMS and disposed of into the metal bin outside the MSC for autoclaving. Disposable plastic pipettes must be submerged overnight in 1% w/v Virkon prior to autoclaving. Gloves must be sprayed with 70% IMS prior to being discarded into an autoclave bin.

Sharps which arise inadvertently or glass slides/cover slips must be placed into clearly labelled sharps bins containing enough 1% w/v Virkon solution to cover all material and autoclaved.

Solid waste from outside the MSC: other waste generated within the laboratory, including soiled lab coats/gowns must be placed directly into disposable bags for autoclaving.

All solid waste is to be autoclaved at 121°C for 15 minutes prior to being sent for incineration.
Degree of kill:
Chemical sterilisation by Virkon - effectively 100% kill
Chemical sterilisation by 70% IMS - effectively 100% kill
Autoclaving - effectively 100% kill (annual validation)

The Richard M. Elliott Biosafety Laboratories (REBL) CL3 Suite:
Liquid waste: decontaminate in Virkon 1% w/v (final concentration) overnight. When handling protein rich liquid, Virkon powder should be added to give a final concentration of no less than 1% w/v. After chemical inactivation, liquid waste must be either autoclaved at 121°C for 15 min or disposed through ACTINI effluent treatment plant (135°C for 2 minutes).
Solid waste from within the MSC: spray paper waste with 1% w/v Virkon within the MSC, then with 70% IMS outside the MSC prior to autoclaving. Solid which can be submerged must be soaked overnight in 1% Virkon w/v (final concentration) prior to autoclaving. Solids which cannot be submerged must be filled with or soaked in Virkon 1% w/v (final concentration) for 10 minutes, wiped down with 1% w/v Virkon within the MSC then with 70% IMS outside the MSC prior to autoclaving. Sharps which arise inadvertently or glass slides/cover-slips must be placed into clearly labelled sharps bins containing enough Virkon solution to cover all material and autoclaved.
Solid waste from outside the MSC: other waste generated within the laboratory, including soiled protective clothing, must be sterilised by autoclaving. Solid waste is to be autoclaved at 134°C for 5 minutes, fabrics are to be autoclaved at 134°C for 3.5 minutes.
Following ACTINI treatment or autoclaving, liquid waste is disposed to drain. After autoclaving solid waste is sent for incineration.
Degree of kill:
Chemical sterilisation by Virkon - effectively 100% kill
Autoclaving - effectively 100% (annual validation)

The local GM Committee asked for more detail on the origin of the human clinical samples and the nature of biological agents likely to be present in the sera. This section of the risk assessment was extended to clarify this point. Assurance was sought that in vitro propagation of viruses in the presence of antiviral factors would not give rise to 'super-resistant' viruses and the risk assessment was amended to consider this eventuality. More information was requested on the oncogenic properties of HDV; the risk assessment was extended to clarify this point.

The GM Committee was satisfied that containment and control measures were suitable for this project. The Committee was equally satisfied by the justification for derogation from full containment level 3 and by the boundaries set up for the work to be carried out in the derogated CL3 facility.

Purposes of the contained use

The purpose of this project is to understand the molecular biology of bunyavirus replication, including structure-function analysis of viral proteins, the role of cis-acting signals within vRNA and the interactions of bunyaviruses with host cells.

Recipient or parental organism

E. coli K-12 derivatives (e.g. DH5a), E. coli B strains (e.g. BI-21), S. cerevisiae strains AH109 and Y187 (from Clontech) Mammalian cell lines (e.g. vero, BHK, Hep2, mRC-5, 293, HeLa), insect cell lines (e.g. Aedes albopictus C6/36, S. frugiperda).

Host/vector system

pUC series, pBluescript, pET series vectors for E. coli. pGBK7 and pGADTT7 for yeast cells. pcDNA and non-cytopathic Sinbis virus replicons pSinRep for mammalian cells. pIB/v5-His for insect cell lines. pBac vectors for generating recombinant baculovirus systems. Autographa californica nuclear polyhedrosis (AcNPV) derivatives such as AcPAK6 for insect cell lines. Expression in Vaccinia virus vectors pTF7-5 and pSC11 for constructing recombinant vaccinia viruses. Vaccinia virus vTF-7 and MVA-T7. Lentivirus vector pLenti-IRES-puro.

Origin & function

Bunyaviral genes:- N-nucleocapsid (binds viral RNA), L-viral RNA dependent RNA polymerase, Gn-viral glycoprotein (receptor binding, cell fusion), Gc- viral glycoprotein (Receptor binding, cell fusion), NSs - non-structural protein (interferon antagonist; blocks RNA polymerase II transcription), NSm - non-structural protein (Localises to Golgi- unknown function).

Cellular genes encoding proteins that interact with bunyavirus proteins:- HeLa genome library for screening by yeast-2-hybrid assay. Specific genes:- Med8 (a component of the Mediator complex involved in the regulation of RNA polymerase II mediated transcription), ARC-32 (mosquitto cell homologue of Med8), other individual genes that encode proteins which interact with bunyavirus proteins once they have been indentified by the yeast-2-hybrid screening.

Evaluation of foreseeable effects

E. coli

The K-12 cell lines are known to be non-pathogenic (see ACGM Compendium of Guidance (ISBN: 0-7176-1763-7). The E. coli cell lines have been less well characterised than the K-12 strains. BL-21 cells are less well characterised than K-12 strains but have a long history of safe use. A recent publication has shown that BL-21 cells is non-pathogenic ans unlikely to survive in certain host animal systems (Chart, H. et al J. Applied Microbiology Vol 89, pages 1048-1058 (2000)). It is thus considered that BL-21 cell are non-pathogenic, though care will be taken when handling this cell line.

Baculovirus System:

The Baculoviruses system have a long history of safe use. The system has been used extensively to infect insect cells with foreign genes and there has been no published evidence that viable recombinant virus has been produced in these cells.

Yeast Cells

Yeast cells are considered to be especially disabled host cells and it is not considered that any of the hybrid proteins expressed will alter the biological properties of the host.

Vaccinia vectors:

Vaccinia virus can infect humans and is classified as an ACDP category 2 pathogen. None of the inserted genes to be expressed is likely to significantly alter the pathogenicity of the vaccinia vector. Recombinant genes have been targeted in the viral thymidine kinase gene and such recombinants are considered to be attenuated relative to the parent. Therefore containment level 2 which is used to contain the parent virus is appropriate for handling the recombinant virus. The avoidance of sharps will reduce the major route of infection which is subcutaneous inoculation.
Disabled Lentivirus
Disabled lentivirus vectors are widely used for expressing foreign genes under level 2 containment. Inoculation of the virus into man could result in integration of the viral genome and expression of the foreign gene. Avoidance of sharps will minimise this route of infection.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
All work with the GMOs will be performed in Category 2 containment facilities as defined in the ACGM Compendium of Guidance (ISBN: 0-7176-1763-7). Appropriate operating procedures will be implemented to ensure only authorised, appropriately trained, personnel can carry out this work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All plastic waste from experiments will be autoclaved at 120°C for 30 minutes at 15 p.s.i.
All media and liquids will be treated with Virkon solution before disposal as per the manufacturer's instructions.
Spillages will be dealt with by soaking the area in neat Virkon.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The genetic modification project notification has been studied by the Chemical and Biological Hazards Sub-Committee and has been provisionally ratified the project as a category 2 project as defined by the GMO (Contained Use) Regulations 2000.

Culture volume: 50 mls maximum.

Deactivation:

a) liquid (spent broth):
   i) volumes of up to 5 mls: treatment with Precept tablets or hycolin for a minimum of 24 h or alternatively by autoclaving.
   ii) volumes of > 5 mls - 50 mls: sterilisation by autoclaving or via incineration.

b) solid (Petridishes, Eppendorf tubes etc.)
   i) transfer into bags or boxes followed by incineration, or by
   ii) autoclaving and transfer into boxes.

Monitoring and deactivation:
Complete inactivation of live cells undertaken within the Department is regularly checked by withdrawing aliquots from disinfected or autoclaved material and plating out on LB agar plates to analyse for microbial growth. No microbial growth has been detected.

Project Additional Information

Purposes of the contained use
To understand the fundamental determinants of virulence and the determination of bacterial physiology and regulatory behaviours relevant to the ways in which bacteria establish and coordinate benign and pathogenic interactions with each other and their hosts, as a framework for the development of novel diagnostic and therapeutic interventions, including vaccine development.

Recipient or parental organism
The species and strains used will be naturally occurring strains of N. meningitidis, N. gonorrhoeae, E. coli, H. influenzae, and H. pylori. Wherever possible / normally these will be fully sequenced strains, where the manipulations are performed in highly determined genetic backgrounds. In addition, where the use of such strains does not compromise the experimental goals, parent strains of N. meningitidis will be partially attenuated ‘capsule null’ strains. Other studies will be performed in laboratory (Class 1) strains of E. coli, where possible derived from sequenced strain K12.

Host/vector system
For the naturally transformable species (N. meningitidis, N. gonorrhoeae, H. influenzae, and H. pylori), DNA transformation / chromosomal insertion/deletion mutants will be generated by natural transformation. For E. coli, plasmid constructs will be used for extra-chromosomal modification, and suicide vectors for targeted chromosomal insertion / deletions.

Origin & function
The origins of the material used will be primarily from other naturally occurring strains, the only other genes will be widely used selectable markers and reporter genes. No marker or reporter will be used that is not widely used and known not to influence virulence. No selectable agent used for routine clinical treatment or prophylaxis will be used. The purpose of the experiments is primarily to explore the contributions of naturally occurring genes and gene combinations to virulence, in terms of gene complement and expression. Thus, the studied functions and genes are endogenous, and are primarily studied in a way that addresses naturally occurring functions, interactions, and evolutionary processes. The functions include core metabolic functions that affect niche adaptation, and virulence factors that directly influence the interaction of bacteria with each other, with the host, and within the host-associated microenvironmental conditions.

Evaluation of foreseeable effects
a) Risk assessment for human health and safety
The unmodified pathogenic species included within this proposal are ACDP hazard group 2 microorganisms. In each instance the donor and recipient species are the same except during gene construction / manipulations in disabled E. coli. Therefore, no new or additional potential risks will be created through the movement of any candidate virulence gene to a new potentially pathogenic species background.
N. meningitidis is the principal cause of bacterial meningitis and is a cause of serious septicaemia. It is normally a harmless human commensal. N. gonorrhoeae is the cause of gonorrhoeae, and more rarely conjunctivitis, pharyngitis, rectal infection and rarely disseminated infection.

H. pylori is a cause of infective gastritis and peptic ulcer disease, that if left untreated can pr-dispose to gastric cancer and, very rarely, lymphoma.

E. coli is a cause of urinary tract infections and occasionally infectious diarrhoea, although it normally exists as a harmless human commensal organism.

Haemophilus influenzae is a cause of respiratory infections, meningitis, and otitis media. The strain used is predominantly Rd, which is a capsule-deficient attenuated strain. The experiments using this species are limited to reporter gene systems that report phase variation, and these do not enhance or alter any virulence property.

The mutations that are to be introduced are each likely to result in a reduction rather than an increase in fitness and / or virulence. The majority of mutations will either fix a gene ON that is normally present within the species and where the removed variability of the gene confers fitness, or will ablate expression of genes resulting in the loss of a normal function. Antibiotic markers will be used that are not normally the primary therapeutic agents. The reporter genes and counter-selectable markers will be either neutral or lead to a reduction in bacterial fitness. Gene transfer in these species does not necessitate the use of vectors that will increase the subsequent movement of altered genes, and the populations are broadly panmictic, and thus combinations of genes created in the laboratory experiment will be occurring naturally, and when not selected / naturally present will be predominately selected against due to reduced fitness. There will be no introduction of virulence genes from one pathogenic species to another. For these reasons none of these manipulations will effect the host range, enhance or broaden tissue tropism, or decrease susceptibility to host defence mechanisms.

It is a characteristic of our work that we study the phenotypic and physiological consequences of naturally occurring behavioural determinants. We do this primarily in panmictic populations in which these elements are free-moving within and between the bacterial populations, and thus the phenotypes generated will be naturally occurring. Thus, in our experiments we will not create phenotypes or strains that are more virulent than those that can and do arise naturally.

After consideration of all factors, the assessment of risk to human health indicates no greater hazard than are likely with the ‘wild-type’ unmodified strains. Therefore all work with these microorganisms will be undertaken at the ACGM Containment Level 2 with the use of safety cabinets as appropriate.

Assignment of provisional containment level: Containment level 2 with the use of a microbiological safety cabinet for the manipulation of N. meningitidis in suspension / whenever aerosols could be created, or within a Category 3 facility. All procedures will be conducted with good microbiological practice and good occupational safety and hygiene.

Additional precautions for working with N. meningitidis:
N. meningitidis represents a greater hazard than the other pathogens included within this programme of research, particularly when in suspension and there is a potential for the generation of aerosols. As a result a microbiological safety cabinet will be used for all manipulations involving suspensions of the organism. Meningococcal work in the laboratory focuses upon serogroup B strains. Wherever possible a strain that has been attenuated by inactivating the siaD gene will be used. This gene is required for the formation of the capsule, which is largely responsible for the organisms’ capacity to evade the immune response and cause invasive disease such as septicaemia and meningitis. Vaccines are not available to the serogroup B meningococci, but vaccines will be offered, where appropriate, depending on the availability of vaccines for the strains that are being handled.

b) Nature of the work to be undertaken:
 Constructs for altering the expression and phenotypes of the pathogens will be prepared in disabled E. coli strains. These will then be transformed into the experimental
pathogen strains. The phenotypes of the altered strains will be determined using standard methods including direct studies of the cells by gel electrophoresis, and investigation of their altered behaviours under different environmental conditions, in cell-culture model systems and animal models as appropriate.

The experiments proposed use small-scale cultures. Up to 200ml maximum culture volumes will normally be used for disabled E. coli. Up to 1L will be used for protein preparation / purification. Work on the hazard group 2 organisms will be predominantly conducted on solid media. Liquid culture volumes will not exceed 200 ml.

No non-standard laboratory operations will be used. Animal containment Level 2 will be used for in vivo work with the use of a microbiological safety cabinet where appropriate.

c) Risk assessment for environmental harm

For the reasons described in the above section on risks to human health and safety, and in the ‘Overview of the project’ the modified strains are likely to be generally reduced in fitness compared to the wild-type organisms. Therefore, in each instance, the risks to the environment of the genetically modified organisms and their capacity to survive, establish and disseminate is likely to be equivalent to, or usually lower than that of the ‘wild-type’ strain. Mutants will be phenotypically and genetically stable and the potential for transfer of genetic material between GMOs and other organisms is negligible. The risk of transfer to humans is medium but the likelihood of a hazard being manifested is negligible because of the containment measures that will be employed and because the resistance markers that will be used are not primary therapeutic agents used against these organisms. E. coli has a broad host range while H. pylori, whilst there are some animal hosts, is primarily a human adapted species. In the cases of the pathogenic Neisseria species, these have no environmental or secondary host reservoirs so their route of dissemination is limited by their species specificity for man. Therefore, for each of these species, the overall risk is effectively zero and no additional containment or control measures are considered necessary to protect the environment other than those described to protect human health.

Containment level 2 will be applied for all laboratory work and animal containment Level 2 for in vivo work. A microbiological safety cabinet will be used for the manipulation of N. meningitidis in suspension / whenever aerosols could be created. All procedures will be conducted with Good Microbiological Practice and Good Occupational Safety and Hygiene. The containment and control measures that will be applied for handling the recombinant bacteria are indicated on the attached tables.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

**Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.**

**Liquids (eg samples, culture supernatants, tissue culture media) – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge to drains.**

**Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.**

**Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.**
Degree of kill

Autoclaving: effectively 100% kill (annual validation).
Incineration: effectively 100% kill (annual validation).

#### Purposes of the contained use

<table>
<thead>
<tr>
<th>Purposes of the contained use</th>
</tr>
</thead>
<tbody>
<tr>
<td>To understand the fundamental determinants of virulence and the determination of fungal physiology and regulatory behaviours relevant to the ways in which C. albicans establishes and coordinate benign and pathogenic interactions with their hosts, as a framework for the development of novel diagnostic and therapeutic interventions</td>
</tr>
</tbody>
</table>

#### Recipient or parental organism

<table>
<thead>
<tr>
<th>Recipient or parental organism</th>
</tr>
</thead>
<tbody>
<tr>
<td>The strains used will be naturally occurring strains of C. albicans. These will be fully sequenced strains, where the manipulations are performed in highly determined genetic backgrounds</td>
</tr>
</tbody>
</table>

#### Host/vector system

<table>
<thead>
<tr>
<th>Host/vector system</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNA transformation, chromosomal insertion/deletion mutants will be generated by transformation</td>
</tr>
</tbody>
</table>

#### Origin & function

<table>
<thead>
<tr>
<th>Origin &amp; function</th>
</tr>
</thead>
<tbody>
<tr>
<td>The origins of the material used will be primarily from naturally occurring C. albicans strains. The only other genes will be widely used selectable markers and reporter genes. No marker or reporter will be used that is not widely used and known not to influence virulence. No selectable agent used for routine clinical treatment or prophylaxis will be used. The purpose of the experiments is primarily to explore the contributions of naturally occurring genes and gene combinations to virulence, in terms of gene complement and expression. Thus, the studied functions and genes are endogenous, and are primarily studied in a way that addressess naturally occurring functions, interactions, and evolutionary processes. The functions include filamentation and virulence factors that influence the interaction of C. albicans with the host</td>
</tr>
</tbody>
</table>

#### Evaluation of foreseeable effects

<table>

<th>Evaluation of foreseeable effects</th>
</tr>
</thead>
<tbody>
<tr>
<td>a) Risk assessment for human health and safety</td>
</tr>
<tr>
<td>The unmodified opportunistic pathogenic C. albicans included within this proposal is an ACDP hazard group 2 microorganism. In each instance the donor and recipient species are the same except during gene construction/manipulations in E. coli. Therefore, no new or additional potential risks will be created through the movement of any candidate virulence gene to a new potentially pathogenic species background.</td>
</tr>
<tr>
<td>C. albicans is the most common cause of candidates which encompasses infections that range from superficial to systemic diseases. It is normally a harmless human commensal and candidasis is often observed in immunocompromised individuals.</td>
</tr>
<tr>
<td>E.coli is a cause of urinary tract infections and occasionally infectious diarrhoea, although it normally exists as a harmless human commensal organism. Only disabled E. coli strains will be used.</td>
</tr>
</tbody>
</table>
The mutations that are to be introduced are each likely to result in a reduction rather than an increase in fitness and/or virulence. The majority of mutations will either delete or over-express genes.

Antibiotic markers will be used that are not normally the primary therapeutic agents. The reporter genes and selectable markers will be either neutral or lead to a reduction in fungal fitness. Gene transfer in these species does not necessitate the use of vectors that will increase the subsequent movement of altered genes.

After consideration of all factors, the assessment of risk to human health indicates no greater hazard than are likely with the 'wild-type' unmodified strains. Therefore, all work with these microorganisms will be undertaken at the AGCM Containment Level 2. There is a potential for generation of aerosols when working with C. albicans in suspension. Therefore, a microbiological safety cabinet will be used for all manipulations involving suspensions of C. albicans. All procedures will be conducted with good microbiological practice and good occupational safety and hygiene.

b) Nature of the work to be undertaken:

Constructs for altering the expression and phenotypes of the pathogens will be prepared in disabled E. coli strains. These will then be transformed into the experimental pathogen strains. The phenotypes of the altered strains will be determined using standard methods including direct studies of the cells by gel electrophoresis, and investigation of their altered behaviours under different environmental conditions.

The experiments proposed use small-scale cultures. Up to 100 ml maximum culture volumes will normally be used for disabled E. coli. Work on C. albicans will either be on solid media or in liquid culture no exceeding 100 ml.

No non-standard laboratory operations will be used.

c) Risk assessment for environmental harm

For the reasons described in the above section on risks to human health and safety, and in the 'Overview of the project' the modified strains are likely to be generally reduced in fitness compared to the wild-type organisms. Therefore, in each instance, the risks to the environment of the genetically modified organisms and their capacity to survive, establish and disseminate is likely to be equivalent to, or usually lower than that of the 'wild-type' strain. Mutants will be phenotypically and genetically stable and the potential for transfer of genetic material between GMOs and other organisms is negligible. The risk of transfer to humans is medium but the likelihood of a hazard being manifested is negligible because of the containment measures that will be employed and because the resistance markers that will be used are not primary therapeutic agents used against these organisms.

Containment level 2 will be applied for all laboratory work. A microbiological safety cabinet will be used for the manipulation of C. albicans in suspension/whenever aerosols could be created. All procedures will be conducted with Good Microbiological Practice and Good Occupational Safety and Hygiene.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125C for at least 15 minutes or 126-130C for at least 10 minutes or 134-138C for at least 3 minutes). Discharge any excess liquids to drains, solids will be collected and incinerated.
Liquids (eg samples, culture supernatants) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes, discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, solids will be collected and incinerated.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Degree of kill

Autoclaving: effectively 100% kill (annual validation by the manufacturer). Furthermore, the project leader will determine cell survival rate following autoclaving every 4 months.

Incineration: effectively 100% kill (annual validation).

Please enter comments on the GM safety committee on the risk assessment

Dr H - delivery of a presentation on the genetic modification of the human fungal pathogen C. albicans was well received by members of the Biological and Genetic Modification Safety Committee (BGMSC). The project is aimed at understanding virulence and how fungal infections become established.

The chair concluded by advising Dr H to produce a simplified risk assessment for submission to the Health & Safety Executive following discussions with Dr A S and to proceed if no other comments had come through from other Committee members.

02/03/2022
Molecular mechanisms of T cell mediated immune responses

The establishment of robust T cell immune response with memory function is critical for the development of novel vaccines for infections and cancers. Early growth response 2 (EGR2) has been shown to promote peripheral naïve T-cell proliferation and differentiation under infection condition, however, its role in generating and maintaining immunological memory during immune responses is still not clear. We would like to establish two chronic viral infection models for the mouse experiment to study the role of Egr2 in immunological memory during chronic viral infections.

Both models are provided very unique tools to study the role of Egr2 in immune response in viral infections, (1) recombinant replication deficient adenovirus - Classified as GM01 through risk assessment and(2) rMCMV - Classified as GM02 through risk Assessment.

Viruses that persist in their host have evolved different strategies to evade clearance by the immune system. In humans HIV leads to a persistent infection due to a high replication and mutation rate escaping the host's antibody and cytotoxic T lymphocyte (CTL) response and due to infection and destruction of CD4+ T cells further weakening the antiviral immune response. Cytomegaloviruses (CMV) persist in their host after CTL mediated control of the primary infection in a state of latency; they are not accessible to the immune system because no viral particles are produced. During states of immunosuppression (HIV, drugs, etc.) productive CMV replication and symptomatic CMV disease occurs frequently. It is not clear what the requirements are to maintain efficient CTL responses during persistent viral infection. Particularly, we want to address the question whether the maintenance of efficient CTL responses during a persistent viral infection is dependent on CD4+ T helper cells.

Recipients of MCMV are provided by collaborators from Oxford University, who originally received them from Munich (Germany) and are not generated in the UK.

They introduced the whole MCMV genome as a BAC into E.coli and transfected those with the respective sequences using standard techniques.
Purified, transfected BAC DNA was introduced into fibroblasts that start to produce MCMV particles within 5 days (For details: Messerle et al., PNAS 1997, 26:14759-63 and Wagner et al., J Virol. 1999, 73:7056-60)

**Origin & Function**

Mouse cytomegalovirus produces a spontaneous, persistent, subclinical infection in wild mice with a prevalence of greater than 65%. Infection of laboratory mice is thought to be uncommon. The susceptibility of mice to experimental infection varies with age, dose, route, virus strain and host genotype.

Mouse CMV is infectious only for mice, but it can replicate in cell cultures from several species including mouse, hamster, rabbit, sheep and primates. MCMV has been shown to infect human cells in vitro, but infection leads to an abortive cycle and is not thought to induce any disease.

Even though Mouse cytomegalovirus (MCMV) is a persistent infection in mice, there are no described epitopes of wild type MCMV presented by H-2Db (mouse Major Histocompatibility Complex). We will use recombinant MCMV (rMCMV), with inserts consisting of epitopes from Influenza A and lymphocytic choriomeningiti virus (LCMV) which are well-characterised and known to associate with H-2Db. Therefore cells infected with rMCMV will present known peptides with H-2Db to T cells. Mice deficient or depleted of CD4+ T cells will be infected with rMCMV experimentally. Thereafter we will follow their CTL response on a single cell level with tetramer complexes of H-2Db-peptide, and functionally with ELISpot and 51 Cr-release assays.

**Evaluation of foreseeable effects**

- **a) Risk Assessment for Human Health and Safety**

  The recipient microorganism, Mouse CMV (ACDP hazard group 1) does not infect humans (abonive replication in human cell lines), it doesn't produce any toxins, and there are no associated allergies known.

  The organism will not be produced at Brunel, but will be received from collaborators at Oxford University.

  Genetic modification of this organism will provide no replication advantage compared to wild type MCMV is expected; there will be no change in host range, pathogenicity or virulence; no infection of humans and no expected adverse effects from transfer of genetic material.

  **b) Risk Assessment for Environmental Harm**

  While viral persistence in the external environment would be likely, as mentioned above genetic modification of this organism will provide no replication advantage compared to wild type MCMV; there will be no change in host range, pathogenicity or virulence; no infection of humans and no expected adverse effects from transfer of genetic material. Infection of wild mice (prevalence of wild type MCMV infection in wild mice is 65-90%) would most likely lead to an asymptomatic infection.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

All of our mouse work is undertaken in a secure, Home Office approve animal facility on site at Brunel University. This includes compliance with the “Code of Practice for the Housing and Care of Animals Bred, Supplied or Used for Scientific Purposes”.

Work will be undertaken at containment level 2 within our secure animal facility.

MCMV transmission requires direct contact with contaminated excretion/secretion (although cross—contamination between cages has so far not been reported). Throughout the experiment the animals will be housed in ventilated cages (IVCs) all animal handling, including injections will be undertaken in Microbiological safety cabinets.

In order to minimise:

- spread of MCMY within the animal house,
- release of MCMY into the environment,
- and potential exposure of workers to MCMY

the following will be applied:

- All work involving animals to be undertaken at Animal Containment Level 2;
- laboratory work to be undertaken at Containment Level 2;
- gloves to be worn when handling any potentially infected materials, including animals;
- a microbiological safety cabinet to be used to minimise any aerosol dissemination of MCMY;
- access to areas where the MCMY is handled to be restricted to authorised personnel
- MCMV infected mice to be kept in filter top cages or individually ventilated cages; and
- sentinel mice will be kept in the same room and tested serologically for MCMY infection every 3 months.

Note: Risk assessment indicates there are no significant risk to human health and safety. The control measures specified are primarily to minimise risks to the environment.

These measures should reduce all risks to the environment and human health to zero.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

| Not Applicable |

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

**Consumables (mainly plasticware eg pipettes, flasks, tubes)**
- autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration.

**Liquids (eg samples, culture supernatants, tissue culture media)**
- autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-1380C for at least 3 minutes), discharge to drains.

**Sharps (eg needles, syringes, scalpels)**
- dispose of in sharps containers via clinical waste stream for incineration.

**Animal bedding**
- either autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), OR dispose via clinical waste stream for incineration.

**Animal carcasses**
- dispose via clinical waste stream for incineration.

**Degree of kill**
- Autoclaving, effectively 100% kill (annual validation)
- Incineration, effectively 100% kill (licensed incinerator)
Please see below with regards to your BGMSC application:

- Recombinant replication deficient adenovirus
  
  This particular strain has been attenuated by the removal of the E1/E3 genes. In general, in accordance with the Contained Use Regulations 2014 this strain can be classified as class GM 1 and doesn’t require any notification to the HSE. The virus cannot replicate in cells other than 293A cells.

- Recombinant murine cytomegalovirus (rMCMV)
  
  This particular strain does not infect humans, only mice, but could be transmitted between mice in containment, and in the wild. The wild type Murine Cytomegalovirus (MCMV) has been classified as ACDP Hazard Group 1 (reflecting human risk). Risk assessments indicate that there are no significant risks to human health and safety, but due to the fact the this particular strain could survive in the wild a GM2 classification should be placed upon it.

The rMCMV portion of the application will need to be notified to the HSE, and work should not commence until that notification has been acknowledged.

I am happy to discuss this further with you before proceeding, in case anything has been misunderstood. I will be out of office between the 9th and 13th of April, but will return to work on the 16th.

Kind Regards

D

www.brunel.ac.uk
Acinetobacter baumannii and Pseudomonas aeruginosa are opportunistic pathogens capable of infecting immunocompromised individuals. They represent excellent models to study infection and antimicrobial resistance in Gram-negative bacteria. The purpose of the use of these organisms will be to identify, evaluate and define key mechanisms involved in allowing these bacteria establish infection and display resistance to antibiotic therapy.

**Recipient or parental organism**

Escherichia coli (class 1):

E. coli K12 and derivatives will be used as a workhorse for cloning and as a recipient for gene overexpression and purification constructs. Most commonly used strains will be TG1, HB101, C600, DH5alpha, OP50, CC118, XL1blue, TOP10F, Rosetta, Shuffle, CE1224, DHM1, LEMO21, BL21, SM10,S17.1, Omnimax, Tuner, BL21 (DE3) and BL21 (DE3) pLysS. These strains have a widespread and long history of safe use.

Acinetobacter baumannii (class 2, opportunistic pathogen)
Most well studied and characterised laboratory strains will be used, this includes ATCC 19606, ATCC 17904, AB5075, European Clones I-III. Strains isolated from patients will also be collected and used in the course of the program. A collection of Tn T26 mutants will also be used (Gallagher et al., 2015, http://www.gs.washington.edu/labs/manoil/baumannii.htm) or other transposon mutant libraries may be used.

Pseudomonas aeruginosa (class 2, opportunistic pathogen):
Laboratory strains that have been extensively studied and characterised will be used, these include: PAO1, PA14, PAK, CHA, PA103, PA7, X13273, TB, SG17. A collection of Tn mutants (MAR2xT7) in the PA14 strain will be used (Liberati et al., PNAS, 2006, http://pa14.mgh.harvard.edu/cgi-bin/pa14/home.cgi) or other transposon libraries may be used.

Host/vector system

- pGEM-T: use in generating Acinetobacter allelic exchange constructs, AmpR f1 Ori.
- pKE229: use in generating Acinetobacter allelic exchange constructs, sacB oriR6K.
- pWH1266 (ATCC® 7792™) – constructed from pBR322, pWH1277, ampR, tetR.
- pLOF/Km: Suicide plasmid harbouring mini-Tn10Km; AmpR KmR.
- pWH1266: E. coli-Acinetobacter shuttle plasmid; AmpR TetR.
- pVK100: Cosmid cloning vector; KmR TetR.
- pME8032: TetR complementation vector.
- pTrc200 StrR, SpcR, pVS1 origin, lacql, trc promoter expression vector.
- pACYC184 and derivatives: ChiR, TetR.
- pMo130-TelR pMo130 plasmid and derivatives: Suicide plasmid, xylE+, sacB+, KmR contains 3.26 kb XmaI-digested telluriteresistance cassette from pwFRT-TelR.
- pEX100 and derivatives: SucR. Only replicate in E. coli lmbdapiir strain CC118
- pEX18Tc Suicide vector containing sacB, TcR.
- pSFS2A Containing kanR cassette, an FRT site, FLP1, and CaSAT1 as a SAT1 flipper
- pET22b/28c/28a and derivatives: ColE1 replicon, AmpR and KanR and capable of expressing Histidine N or C-terminal or duel tag.
- pET41a 3C protease, KmR, His GST Glutathion S-transferase) tag
- pSP56 ApR, GmR; the source of GmR cassette
- pQE30Xa and derivatives: Tag histidine (Qiagen). AmpR.
- pEGFP and derivatives: engineering of gfp fusion. AmpR.
- pGEX and derivatives: Tag GST (Glutathion S-transferase). AmpR.
- pBADmycHisA, B, C and derivatives: expression from an arabinose promoter, tag histidine and Myc. AmpR.
- pYZ4 and derivatives: KanR, Construction of phoA fusion.
- GATEWAY plasmids: InvitroGen. System including the entry vector pDONOR and the destination vectors (pDEST derivatives) for recloning and expressing tagged genes.
- pBAD and derivatives: arabinose promoter. AmpR.
- pTrc200 StrR, SpcR, pVS1 origin, lacql, trc promoter expression vector.
- pT7-1 to pT7-6 and derivatives: T7 promoter. AmpR. To be used together with pGP1-2 which carries the gene encoding RNA polymerase from T7 phage. KmR.
- pBAV1K-t5-gfp GFP expressing plasmid for use in Acinetobacter
- pEXT20 General cloning plasmid; AmpR
- pBAVMCS: pBAV1K-t5-gfp with GFP gene removed, E. coli–Acinetobacter shuttle plasmid; KanR
- pBAVMCS-tet pBAVMCS with tetracycline gene from pWH1266 inserted at SacI site
- pUT18c and pKT25 and derivatives: pUT18c, pUT18c, pUT18c+1 and pUT18c+2 (pUC19 derivative), AmpR, contains 3’ region of the gene encoding adenylate cyclase (cyaA), pKT25 (pSU40 derivative), KanR, contains 5’ region of cyaA (Houot et al., 2012).
- pMP190– Broad-host-range, low-copy-number promoter probe vector; IncQ replicon, lacZ CmrTra-
- pBS1479 and derivatives: AmpR. Tandem Affinity Purification (TAP). The TAP-Tag contains a domain CBP (Calmodulin Binding Protein) and a domain Protein A (Affinity for IgG).
- pLAFR1, pLAFR3 and derivatives : IncP, TetR. Cosmid with low copy number.
- pBK-CMV and its derivatives Dual eukaryotic and prokaryotic expression vector. KanR NeoR
- pBRRMC1-5 and derivatives : ChlR (1), TetR (3), KanR (2) AmpR (4), GentR (5).
- pUCP18/19 and derivatives : AmpR.
- p2lux- CmR Integrated lux vector (37-42C) not integrated at 30C
- pRK2073 Used as a helper in plasmid conjugation; Tpr
- pHp45 and derivatives : Interposons carrying resistances : KanR, TetR, HgR and ChlR.
- pSUP102 and derivatives : Tn5 –B10 (KanR), -B11 et -B12 (GentR), -B13 (TetR), -B20 (KanR), -B21 (TetR), -B22 (GentR), -B30 (TetR), -B40 (KanR) et –B41 (TetR).
- pUT-Tn5 and derivatives: TetR.
- pBK-miniTn7 and gfp derivatives. pUC19 based vectors with various resistance for delivery of gfp on the chromosome.
- pML1 (GmR) and pLR27 (KmR) and pALMAR3 (TnR) for Tn5 delivery on the chromosome.
- Mini-CTX1, Mini-CTX_luxCDABE , Mini-Tn5-luxCDABE and Mini-CTX2 (TetR, pMB1 origin, CTX integrase) for engineering lacZ transcriptional fusion on the chromosome.
- pFLP2 for excision of CTX backbone from the chromosom (AmpR, sacB).
- pMo130 Suicide vector for allelic exchange in Acinetobacter; ColE1 ori, RK2 oriT, xyIE, sacB, KmR
- pMH487; pUCP22Not-RNase III-gfp(mut3)-T0-T1, AmpR Gmr

Origin & function

Because of the nature of this project, we could potentially need to use any of the annotated genes available from the genome sequence of the University of Washington laboratory strain of Acinetobacter baumannii (http://tools.uwgenomics.org/cgi-bin/pgat_acinetobacter/elementlist.cgi?id=AB5075UW) or orthologues of these genes found in other strains of Acinetobacter baumannii. A similar approach will be required for Pseudomonas aeruginosa where genes from the lab adapted strains PAO1 and PA14 strains (http://pseudomonas.com), as well as homologous of these genes found in other strains.

Evaluation of foreseeable effects

Host range, tissue tropism and susceptibility to host defense mechanisms are not expected to be altered significantly by any of the genetic modifications expected to be carried out in this project. The GMMs generated in this project are likely to have comparable properties to the wild type recipient isolates, or to have an attenuated phenotype due to reduced fitness and/or reduced antibiotic resistance profile. Some transfer of non-toxic genes between P. aeruginosa and A. baumannii will take place to establish conserved regulatory networks, however the genes in questions are well defined and not expected to significantly alter acute virulence. As such, the risk associated with the GMMs is considered to be the same as those posed by the wild type organisms. The vast majority of all gene insertions will be associated with complementation of previously generated mutants, in which case the hazards will be no more than wild type strains, as they will have reverted to the full wild type genetic cohort. Any fusion constructs or tagging experiments will only involve the insertion of innocuous reporter DNA sequences (His, GST, GFP) none of which will increase the

02/03/2022 Page 5569 of 15326
virulence of recipient strains. All protein expression experiments will take place in an E.coli K12 background. The vast majority of potential proteins that may be overexpressed will be non-toxic enzymes. In the rare instances where a toxin may be expressed for purification, the toxin will have anti-bacterial activity rather than any anti-eukaryotic activity. The probability of this research leading to the need to clone a bacterial toxin with anti-eukaryotic activity is small. Some transfer of non-toxic genes between P. aeruginosa and A. baumannii will take place to establish conserved regulatory networks, however the genes in question are well defined and not expected to significantly alter virulence. GMM could alter the expression of genes associated with motility, biofilm formation, secretion systems, antibiotic resistance and quorum sensing which may affect virulence. Data from the published literature highlights that artificial alteration in expression of these genes comes at a fitness cost and while certain virulence traits may be increased, the overall fecundity of the GMM will likely be reduced as a result. The probability of creating a mutant strain with a genuine increased virulence profile is diminishingly small as these mutants should have already arisen in the global bacterial population. As most of the strains to be used in this project are laboratory adapted strains infection in healthy individuals is not a particular concern. In addition to this no procedure in the laboratory will require direct contact with any of the potential pathogens. In addition, personal protective equipment (PPE) including lab coat and gloves will be worn when working with these strains to further minimize the risk of direct contact with the organism.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

NA

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

There will not be any anticipated derogation from full containment.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Local waste streams are currently in place to deal with all GMM waste.

Solid Waste: All contaminated solid waste in placed in autoclave bags which are subsequently sealed and autoclaved on standard sterilisation cycles (121-135°C for at least 10 minutes).

Liquid waste: All liquid waste will be treated wil either 1% virkon or PRESEPT effervescent disinfecting tablets (2.5g) for a minimum of 6 hours before disposed of down the laboratory sink.

Sharps: Disposed of in designated sharps bins prior to sterilisation via autoclaving.

Surface: Post working with GMMs all surface will be decontaminated with 70% EtOH, virkon or Presept.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Dr M's project was discussed and reviewed at the Biological and Genetic Modification Safety Committee at Brunel University. The risk assessments and procedures were deemed appropriate for the work planned.

02/03/2022
For these activities, the maximum culture volume that could be released at one time would be 2 litres. Established methods are used to inactivate waste. Liquid bacterial waste is inactivated by recognised chemical methods: overnight treatment in freshly-made chlorine-releasing solutions or bleach (1000 ppm available chlorine). For monitoring, samples are placed in a neutralising broth and subjected to liquid and agar plate culture. Solid waste, for example culture flasks and petri dishes, are inactivated by heat sterilisation, and the waste is incinerated. The autoclave used for sterilisation is regularly maintained and Brown's tubes are used to monitor each batch of waste. In each laboratory carrying out GM work, a log book is kept for the monitoring procedures.

### Project Additional Information

#### Purposes of the contained use

The aim of the project is to evaluate the role of specific Campylobacter genes associated with the physiology and pathogenicity of the bacterium in vivo. To do this gene sequences and their promoters will be reintegrated into the bacterial genome in order to knock-out or alter their function. Campylobacter genes for which we can ascribe a role will be manipulated in an attempt to express them in laboratory strains of E. coli to study the structure and function of the proteins they encode.

#### Recipient or parental organism

<table>
<thead>
<tr>
<th>Host</th>
<th>Vector</th>
</tr>
</thead>
<tbody>
<tr>
<td>E. coli Top10 cells (Invitrogen)</td>
<td>pCR2.1 Topo plasmid (Invitrogen)</td>
</tr>
<tr>
<td>E. coli BL21(DE3) (Novagen)</td>
<td>Approved vectors based on colE1 replicating plasmids (eg pUC18, pBS and pBC)</td>
</tr>
<tr>
<td>Campylobacter jejuni (ACDP 2)</td>
<td>pET series of expression plasmid vectors (Novagen)</td>
</tr>
<tr>
<td>Campylobacter coli (ACDP 2)</td>
<td></td>
</tr>
<tr>
<td>Campylobacter lari (ACDP 2)</td>
<td></td>
</tr>
<tr>
<td>Campylobacter upsaliensis (ACDP 2)</td>
<td></td>
</tr>
</tbody>
</table>

All the recipient Campylobacter species to be used in this study are wild type ACDP group 2 organisms. No multiply-antibiotic resistant isolates will be used which would preclude therapy with standard antibiotic regimes should infection occur.

#### Host/vector system

- **Genomic DNAs of the following:**
  - Campylobacter jejuni (ACDP 2)
  - Campylobacter coli (ACDP 2)
  - Campylobacter lari (ACDP 2)
  - Campylobacter upsaliensis (ACDP 2)
  - Campylobacter bacteriophage DNA

The target gene sequences are expected to encode bacterial cell-surface associated proteins or be responsible for the biosynthesis of surface associated components (e.g., lipopolysaccharide, capsular polysaccharide, lipid and glycosylation modifications of proteins). Gene functions may also include products responsible for intracellular DNA modifications.

#### Evaluation of foreseeable effects

Campylobacter enteritis is the most common form of bacterial food poisoning in the world. Campylobacter infection occurs through ingestion (fecal oral route) and results in a self-limiting diarrhoeal disease. A few rare post-infection cases have been associated with the later development of a paralysing autoimmune disease (Gillian Barre syndrome). There is no specific risk of transmission by aerosol known for these organisms. Campylobacter jejuni is known to encode a cytolethal distending toxin.
However, the toxin contains multiple sub-units all of which would have to be co-expressed. The host Campylobacter species are initially wild type and have the potential to cause human disease. It is therefore proposed that all experiments will be performed under containment conditions ACDP 2. The resulting GMMs are unlikely to pose any further risk to human health as they will contain DNAs of similar origin and that the ACGM containment level be 2, consistent with the host and donor DNAs.

Birds carry thermophilic Campylobacters in their gut without any known detrimental affect, such that most wild birds and domestic poultry are colonised. It is possible that the modified Campylobacters could survive in avian species if they were to be released into the environment. Therefore it is proposed that all experiments will be performed under containment conditions ACGM 2.

When expressing the Campylobacter genes in E. coli it is possible that some of these genes could increase their fitness and/or human or animal colonisation potential. However, the auxotrophically crippled organisms (E. coli K-12 ACDP 1) will still retain limited survivability in the environment. The majority of genes are not known to be toxic, and when expressed in isolation form the remaining Campylobacter host genes are unlikely to produce any deleterious effects over the parental organism. Owing to the potential for increased expression levels in E. coli the containment level for this work is proposed to be ACGM level 2 consistent with the ACDP level of the donor organisms.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Local Incineration: solid wastes are incinerated at 1000 degrees C for 360 minutes until ash (100% kill). These are discarded as solid waste.

Autoclave: Liquid waste is autoclaved at 121 degrees C for 30 minutes until to achieve 100% kill (internal temp and pressure monitors) and discarded to the drains once cool. These measures are coupled with condesate thermocouples and thermologue test strips.

Chemical Treatment: 2% Virkon is used to remove contamination from solid surfaces. This concentration will kill the bacterial rapidly as recommended by the supplier. After 15 minutes contact the disinfectant is diluted and the liquid waste discarded to drain.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Project approved at Containment level 2 by GM Safety Committee, which includes representatives of all University employees. The project details were assessed by expert members of the committee and the decision was reported to the general safety committee.

All small-scale cultures eg. petri dish plates, liquid cultures (max volume 200 ml) are disposed of by autoclaving at 121 degrees C (15 psi) in the centre of the load for 30 minutes. Efficiency of autoclaving is tested in each treatment using heat sensitive tape, periodically by plating out from treated cultures, and annually by manufacturer's inspection.

Transgenic plant material, all growing media and posts are disposed of by incineration. All GMO plant material is no longer viable when it leaves the site for incineration.

## Project Additional Information

### Purposes of the contained use

Increasing basic understanding of the mechanisms underlying bacterial pathogenicity.

### Recipient or parental organism

Genes cloned from one pathovar of *Pseudomonas syringae* (parent) will be transferred into *E. coli* DH5a and into other pathovars of *Pseudomonas syringae*.

### Host/vector system

Vectors used will be broad host range plasmids such as pLAFR3 and CoIE1 replicon based pBluescript.

### Origin & function

Genes transfer will be used to identify genes for avirulence and virulence by function, using altered pathogenicity as the test. Following detection of activity in cosmid clones (up to 30 Kb) sub-cloning will allow functional open reading frames to be analysed. Proteins will be expressed from vector promoters.

### Evaluation of foreseeable effects

The GMOs are not considered a significant risk to human health. Release of the GM *Pseudomonas syringae* strain with altered virulence is unlikely to result in the infection of plants. The bacteria are spread by seed and through rainsplash onto infected leaves. They are not soil-borne pathogens. Nevertheless the *Pseudomonas syringae* strains will not be specifically disabled.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Plants infected with GMOs will be maintained in designated growth rooms as specified in the MAFF (now DEFRA), Plant Health Licence, no PHL30A/37554/2001).

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1. Autoclaving at 121°C for 30 mins to destroy broth and petri cultures and infected plant material (leaves and pods).
2. Soaking in a presept bath 140ppm chlorine, overnight to decontaminate glassware and plasticware.
3. Incineration of contaminated soil and pots organised by "Whiterose" No GMOs should survive.

Non-GMM Consent Granted Not Applicable

Project notified under transitional arrangements N

Historical Significant Changes GM 235 MERGED WITH GM 386 & PROJECT TRANSFERRED TO GM 3

Project Additional Information

Purposes of the contained use

The studies proposed are based on the use of recombinant viral vectors for gene delivery in vitro in primary neuronal cultures to investigate the pathogenic mechanisms involved in neurodegenerative disorders, including Alzheimer’s disease and amyotrophic lateral sclerosis (ALS). Two viral delivery systems will be used: lentiviral vectors and adeno-associated viral vectors to over-express proteins encoded by genes mutated in familial forms of AD and ALS or protein accumulating in affected neurons, as well as modifying enzymes and interacting partners and to silence the expression of the above proteins using RNA interference.

Recipient or parental organism

E. coli - K12 or B derivatives (e.g. SURE 2, Stratagene and DB3.1 ccdB gene tolerant cells). Human HEK 293T cells for packaging, NIH3T3 cells, HT1 080 cells or equivalent for virus titration. Experiments will be conducted in nonneuronal (e.g. COS-7 and CHO cells) of neuronal (e.g SH-SY5Y and N2a neuroblastoma cell lines as well as in primary rat or mouse neuronal cultures (cortical neurons, motor neurons, dorsal root ganglion neurons, Purkinje cells), including neurons derived from transgenic mice.

Host/vector system
The inserted genetic material will be cloned into the plasmids: pAMICBA-pl-WPRE-BGH for adeno-associated virus construction or into the self-inactivating lentiviral plasmids: pLenti-DEST1TOPO or pLentiLox3.7. Genes encoding the components required for packaging the viral genome are separated onto three plasmids for the lentiviral vectors (pLP1, pLP2, pLPNSVG). The lentiviral plasmids do not contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus.

**Origin & function**

Full-length and truncated cDNA (Homo sapiens and rodents) or cloned genomic fragments encoding the protein known to be mutated or accumulating and aggregating in neurodegenerative diseases as well as sequences designed to silence these proteins by RNA interference. Some examples are listed below.
- Tau, a neuronal microtubule associated protein that stabilises axonal microtubules. Mutations in tau cause a form of fronto-temporal degeneration.
- Sodium calcium exchanger, NCX2, Sodium calcium exchanger, calpain cleaved, NCX3
- Kinases: GSK3alpha and beta, Casein kinase 1, Cdk5 and its activators, CPRK family
- ALS2/alsin, a protein that contains several domains characteristic of GTP exchange factors. Mutations of the ALS2 gene are linked to juvenile familial forms of amyotrophic lateral sclerosis (ALS).
- VAPB (vesicle associated protein B —mutated in familial ALS) and its interacting partners.
- Standard reporter genes (e.g. GFP, Luciferase, -galactosidase) will also be already present or cloned into these vectors.
- Superoxide dismutase 1 (SOD1) mutations in which cause familial ALS

**Evaluation of foreseeable effects**

Transformed E.coli: No significant hazards have been identified. Insertion of the foreign sequences into E coli is not expected to result in harmful physiological or pharmacological properties or to affect the pathogenicity of the host or normal human defence mechanisms. The resulting GMM’s are not expected to carry any additional risks compared to that of the un-modified recipients. Virally transfected HEK293FTIT cells could pose a risk to human health associated with the production of recombinant infectious lentiviral particles. However, as they are self-inactivating replication deficient vectors the risk is only from the insertion of the genetic material, described above. None of the genetic inserts are likely to cause significant effect on an individual as their potential toxic effect is limited to neurons have no known oncogenic properties.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Consumables (mainly plasticware e.g. pipettes, flasks, tubes) — soaked in hypochlorite solution before autoclaving using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-l2SoC for at least 15 minutes or 126-l3OoC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids placed in a clinical waste bag for incineration by external contractors.

Liquids (e.g. samples, culture supernatants, tissue culture media) — Disinfectant - Trigene left overnight, then dispose of to drain with running water

Safety cabinet - will be washed down with Trigene solution after use.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least :15 minutes or 126-13OoC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids in a clinical waste bag for incineration by external contractors.

Sharps (e.g. needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Degree of kill

**Autoclaving, effectively 100% kill (annual validation)**
Incineration, effectively 100% kill (licensed incinerator)
Chemical disinfection with Trigene, used according to manufacturers instructions under standard conditions, manufacturers validation (e.g. 99.998 % kill).

Is an emergency plan required according to regulation 20? N

Project Additional Information

**Purposes of the contained use**

The project involves the construction of replication incompetent viruses encoding DNA sequences enabling siRNA-mediated gene silencing or gene overexpression, with the aim of studying the role of given candidate genes in psychiatric disorders, neurodegeneration, neurological disease and neutral development. Three viral delivery systems will be used: lentiviral vectors, adenoviral vectors and adeno-associated viral vectors. These will be used to investigate the function of gene products thought to be involved in development and pathophysiology in vitro in primary neuronal cultures. (see 17).

**Recipient or parental organism**

E14, HM2 stem cells; PC12 pheochromocytoma, NG108-15, SH, SYSY, Neuro2A, HD7/7, HD7/109, HD109/109 neuroblastoma; NS5, MHP36 neutral stem cells, HEK, HeLa, HT1080 endothelia, 3T3, COS-7, CHO, MEF fibroblasts, CG4, O2A glioma. E.coli - K12 or B derivatives. Primary murine neutral cells.

**Host/vector system**

The inserted genetic material will be cloned into the plasmids: pAAV-IREShrGFP for adeno-associated virus construction or into the self-inactivating lentiviral plasmids: LeDo-G pSiEW or pLK. Genes encoding the components required for packaging the viral genome are separated into three plasmids for the lentiviral vectors (pLP1, pLP2, pLPVS VG or pLKO.1, PIKO.1-CMV-GFP, PCMV-VSV-G). The lentiviral plasmids do not contain any regions of homology with each other to prevent undesirable.

**Origin & function**

Full-length and truncated cDNA (Homo sapiens and rodents) or cloned genomic fragments encoding the protein known to be mutated or deregulated in psychiatric disorders, neurodegeneration, neurological disease and neutral development as well as sequences designed to silence these proteins by RNA interference.

**Evaluation of foreseeable effects**

Transferred E.coli: No significant hazards have been identified. Insertion of the gene sequences into E.coli is not expected to result in harmful physiological properties or to affect the pathogenicity of the host or normal human defence mechanisms. The resulting GMMs are not expected to carry any additional risks compared to that of the un-modified recipients.

Vira ly transfected HEK293T cells could pose a risk to human health associated with the production of recombinant infectious lentiviral particles. However, as they are self-inactivating replication deficient vectors the risk is only from the insertion of the genetic material, described above. None of the genetic inserts are likely to cause significant effect on an individual as their potential toxic effect is limited to neurons and have no known oncogenic properties.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All materials that have been in contact with genetically modified material will be sterilized. Consumable (mainly plasticware e.g. pipettes, flasks, tubes) will be soaked in hypochlorite solution before autoclaving using a make safe cycle (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or plates will be autoclaved.
at 121 degrees C for at least 15 minutes before removal form the building in double bags for incineration, thereby ensuring 100% kill.
To achieve 100% kill of liquid material, waste will be treated with Virkon 1% (w/v) or Trigene (2% w/v) and incubated overnight in accordance with manufacturer's recommendations before disposal down a sink. We have opted not to autoclave liquid waste in light of concerns about delays to autoclave availability for this purpose, coupled with the undesirability of autoclaving bleach-treated waste.

Sharps (eg needles, syringes, scalpels) will be autoclaved disposed of as for solid waste.
All animal carcasses will be incinerated.
Safety cabinet will be washed down with Trigene solution after use.
Autoclaves are serviced and validated annually by the manufacturer or an approved contractor

Degree of Kill:
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incineration)
Chemical disinfectant with Trigene, used according to manufacturers instructions under standard conditions, manufacturers validation (eg 99.998% kill).

The IOP GMSC (GM235) discussed the project and approved the projects with minor amendments.

Project Ref 235/09.1

Date Ackn'd 03/06/2009

CU2 Project Title Reprogramming of human somatic cells into induced pluripotent stem cells for

Class CultureVolClass2 CultureVolumeClass3-4

Class 2 < 1 Litre
The project involves the construction of replication incompetent viruses containing DNA sequences that encode four human transcription factors. These transcription factors will be introduced into primary human somatic cells with the objective of reprogramming them into induced pluripotent stem cells (iPSC). The resulting iPSC lines will be subjected to various differentiation protocols to convert them into desired somatic cell lineages. Of particular interest will be iPSC lines made from primary cells obtained from patients suffering from a range of monogenic and polygenic diseases. The research is expected to shed light on the pathophysiology of early human disease development as well as providing cellular reagents for drug screening and discovery. Two viral delivery systems will be used: lentiviral and retroviral vectors. The transcription factors in the lentiviral vectors will be under the control of doxycycline-inducible promoters.

Recipient or parental organism

Human embryonic kidney packaging cells for making infective lentivirus or retro-viruses. A variety of human primary somatic cell cultures of which skin fibroblasts will make up the most frequent use

Host/vector system

Lenti-x Expression System (Clontech) In this lentiviral system, the final vector [assembled through independent transformation of packaging cells (HEK293T cells) with three plasmids] is a VSV-G pseudotyped, replication incompetent retrovirus derived from HIV-1. The virus does not encode Tat and the inserted transcription factor (Oct4 or Sox2 or Klf4 or c-myc) is under the control of doxycycline. The presence of added doxycycline will be needed for activation of the inserted transcription factors. LVX-Tight-Puro Vector from Clonetech is need to mediate the doxycycline control.

pCMV-VSVG are all retroviruses containing the inserted DNAs indicated. In order to assemble infectious retroviruses, these DNAs and two other plasmids are introduced into human 293T packaging cell lines to create a VSV-G pseudotyped, replication incompetent retrovirus derived from the Moloney Murine Leukemia Virus.

All assembled viruses can infect human and mouse cells. The pMX and pLVX retroviral constructs have ampicillin resistance for bacterial selection. pLVX also has puromycin resistance for mammalian cell line selection

HEK293T cells will be used for packaging

Origin & function
Full length human cDNAs encoding the transcription factors Oct 4, Sox 2, Klf 4, c-myc, and Sall 4 have been selected. The first four of these will be used to reprogram cells. Sall4 has been included because there are rumours that it alone can reprogramme cells. However this technology is moving very fast and it is eminently possible that fewer and different human gene inserts will be required in the future. New and even safer vector delivery systems are being developed and we would like to suggest that HSE permission, if granted, will also cover new vector systems and unspecified human sequences that can reprogram human somatic cells efficiently (subject of course to the caveat that any changes will receive the approval of the local risk assessment committee and will be notified to HSE).

Evaluation of foreseeable effects

Virally transfected HEK293T cells could pose a risk to human health associated with the production of recombinant infectious lentiviral particles. However, as they are self-inactivating replication deficient vectors the risk is only from the insertion of the genetic material, described above. Special note should be made regarding the use of the c-myc insert. C-myc is a known oncogene however in iPSC generation it greatly improves reprogramming efficiency. Since this goes down considerably with age of donor, we think it essential to include in the protocol.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Uncontaminated and contaminated waste will be segregated. Uncontaminated waste will be put in yellow bags for disposal and subsequent incineration. All materials that have been contaminated with genetically modified material will be inactivated by autoclave or chemical sterilisation, prior to disposal via clinical waste route and incineration.

i) All sharps, disposable plastic pipettes and tips contaminated with GM material will be put into Sharpsafe bins, clearly labelled as “GM WASTE”. These will be autoclaved at 121°C for at least 20 minutes before disposal and subsequent incineration. Contaminated sharps will be treated with 2% Trigene for at least 30 minutes before discarding into the sharp safe bin to prevent the build-up of contaminated material.

ii) Plasticware (e.g. tissue culture flasks, petri dishes, tubes) and other solid waste (e.g. gloves, paper towels, solid media) contaminated with GM material will be collected in a clear autoclave bag and autoclaved at 121°C for at least 20 minutes at the end of each day. The waste will then be placed in yellow bags for disposal and subsequent incineration.

iii) Liquid waste contaminated with GM material will be treated with Trigene for at least 30 minutes. This will be done by adding the waste to an appropriate volume of the neat disinfection solution and making up to a final concentration of 2%.

iv) Any reusable containers contaminated with GM material will be left to soak in 2% Trigene for at least 30 minutes before washing. This will be done by addition of the disinfection solution directly into the container or by immersion of the contaminated equipment in a larger vessel containing the disinfection solution.

Degree of kill:
Autoclave waste cycle at 121 for 20 minutes. 100% kill confirmed by annual validation.
Chemical disinfection with Trigene, used according to manufacturers instructions under standard conditions, manufacturers validation (e.g. 99.998 % kill).
Incineration, effectively 100% kill (licensed incinerator).
The Committee had minor comments which have been covered in the signed risk assessment form.

Primary human fibroblasts, epithelial and endothelial cells - pBabeNeo/hygro/puromycin, pZipNeoSV(X)1, pLHCX, pLNCX- retroviral vectors.

Origin & function

This project aims to develop amphotropic viruses for transducing various immortalising genes into primary human somatic cells.

The immortalising genes are derived from the Papovaviruses SV40 and Polyoma, Human Papilloma virus 16/18, a human cellular gene induced by the Human Papilloma virus 16/18 E6 protein, a fragment of the human p53 gene and the catalytic subunit of the human telomerase gene.

SV40 large T antigen is an immortalising gene that has the potential to extend the lifespan of human cells. It can inactivate the p53 and RB (Retinoblastoma protein family) pathways.

Polyoma large T antigen is also an immortalising gene that can inactivate the RB pathway.

HPV E6 protein is an immortalising gene derived from the Human Papilloma virus 16/18 that inactivates p53, can induce telomerase in human somatic cells, induce the IITF gene and can extend lifespan of primary human cells.

The IITF gene can induce telomerase activity in human cells and thus has the potential to be an immortalising gene.

The catalytic subunit of telomerase can be used to reconstitute telomerase activity in human somatic cells that are null for telomerase and this maintain their telomeres. Maintenance of telomeres is a critical step in the immortalisation of primary human somatic cells.

Evaluation of foreseeable effects

These viruses either singly or in combination with telomere maintenance as induced by E6, IITF or hTERT have the potential to induce immortalisation of human cells. Therefore these viruses do have the potential to induce immortalisation if the operator is exposed to them by inoculation. Thus safety procedures have been put in place so that the risk of a worker infecting their own cells with the retroviruses is extremely low. Moreover since the viruses produced are defective and helper free they should not be able to spread by themselves from the site of infection.

Cultures of human cells after transduction should produce immortal human cell lines which can be propagated indefinitely and should not produce any infectious virus because the viruses that are being prepared are defective and helper free. Such cells should be rejected by the immune system if accidentally inoculated.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The virus producer cells and the viruses will be handled and maintained in a level 3 containment facility to ensure there is no accidental release or exposure.

The transduction and selection of the primary human cells will be carried out in the level 3 containment facility. They will then be tested to determine whether they are producing retroviruses by using the culture medium for transduction of control cells. Once they have shown to be negative for virus production, they will then be transferred to a level 2 containment facility for routine culture and subcloning. They will be tested every 3 months to ensure that they remain negative for virus production.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Non requested.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be treated with chloros for >24 hours at >10% (10,000 ppm). (Validated experimentally 100% kill) Inactivated liquid waste will be disposed of in dedicated drains leading directly to sewer waste.
The committee feels that even though this is initially a level 2 project, the potential hazards involved in constructing and using viruses that can infect human cells and are transducing gene(s) that have the potential to immortalise human cells warrants the extra containment provided by a level 3 facility.

### Purposes of the contained use

To generate high titre pseudotyped lentiviral vector systems containing genes that can be used for the immortalisation of non-dividing primary cells derived from P1 3-kinase gene-targeted mice.

### Recipient or parental organism

**E. coli JS4-rec A-derived from E.coli MC 1061.** This is disabled E. coli

293T kidney cells - produced from human embryonic 293 kidney cells by transformation with SV40T. (Studies on in vitro transformation by DNA and DNA fragments of human adenoviruses and simian virus 40. Graham, FL; Abrahams, PJ; Mulder, C; Heijneker, HL; Warnaar, SO; De Vries, FA; Fiers, W; Van Der Eb, AJ. Cold Spring Harb Symp Quant Biol. 1975; 39 Pt 1: 637-50). These cells have a history of safe use for the production of lentiviruses.

Mouse embryonic fibroblasts (MEFs).

### Host/vector system

**E.coli JS4/p8.91, pVSV-G, pHR, pRETR0-SUPER, pHR containing lacZ, SV40T, p85 alpha, p85beta, p55gamma, p110alpha, p110beta, p110delta, pRETRO-SUPER containing a p53-specific short hairpin oligonucleotide.**

293T will be transduced with the 3 plasmids pVSV-G, p8.91 and pHR into which is inserted lacZ, SV40T, p85alpha, p85beta, p55gamma, p110alpha, p110dbeta, p110delta or pRETRO-SUPER into which is inserted a p53-specific short hairpin oligonucleotide to produce the lentivirus.

Mouse embryonic fibroblasts will be transduced with the VSV-G pseudotyped minimal lentiviral vector containing lacZ, SV40T, p85alpha, p85beta, p55gamma, p110alpha, p110beta, p110delta, a p53-specific short hairpin oligonucleotide.

### Origin & function

**Minimal HIV1-based lentiviral vectors tranducing genes corresponding to the reporter enzyme beta-galactosidase (lacZ), wild type SV40T-antigen (U19), the regulatory subunits of the enzyme P13-kinase (p85 alpha, p85beta, p55gamma), the catalytic subunits of P130-kinase (p110alpha, p110beta, p110delta)**

LacZ is an E.coli gene for beta-galactosidase, which is used as a reporter of localised expression. There is no hazard associated with the expression of this gene.

SV40 large T antigen is an immortalising gene derived from the Papovavirus SV40 that has the potential to extend the lifespan of human cells. It can inactivate the p53 and RB pathways.

p53-specific short hairpin oligonucleotide. Expression of this sequence in mouse cells causes suppression of p53 expression (by RNA interference) that results in extended life span-immortalisation of mouse cells.

p85alpha, p85beta, p55gamma, regulatory subunits for P1-3 kinase (P13K). They form heterodimers and stabilise the p110 catalytic subunits. There are no indications that the full length P13K regulatory subunits constitute a potential hazard.

p110alpha, p110beta, p110delta in native or constitutively active (membrane targeted) form (CAAX form). They will be used to "rescue" the proliferative defect caused by inactivation of the respective genes in targeted mouse cells. The wild-type P13K catalytic subunits could be considered as proto-oncogenes that become oncogenic for
Evaluation of foreseeable effects

The E. coli cells are non-colonising and disabled (recA-) and the inserted sequences are driven by eukaryotic specific promoters (eg CMV). Therefore there is no risk from this part of the work.

The 293T cells will produce a lentivirus containing the inserted genes. The production of a lentivirus increases the risk compared to a simple retrovirus as these can enter non-dividing cells. Also pseudotyping the lentivirus with VSV-G increases the risk as this enables the virus to bind to multiple cell types. However, the virus is replication defective and like all retroviruses these lentiviral particles have a limited survival capacity (half-life of 2-4 hours). The main risk to the worker as for HIV1 is from needlestick injury and by operating in a sharps-free environment and using a class II hood in a level 3 environment the risk to the worker is very low.

Primary mouse cells once tested for absence of replication competent virus have no risk.

The main hazard is from the inserts which are potentially immortalised oncogenes. These can immortalise, but not transform, human cells and therefore, in principle create a pre-neoplastic clone in vivo in a worker exposed to them. However, it has been shown (Lundberg et al Oncogene 2002; 21: 4577-4586) that further genetic modifications such as introduction of mutant ras is necessary for full malignant transformation of cells expressing SV40 large T plus telomerase. Also, p53 inactivation alone is not sufficient to mediate stable reversion of senescence in primary human fibroblasts (Shay et al., 1991, Exp. Cell Res., 196:33-39). Finally, oncogenicity of membrane targeted forms of the p1 3-kinase has only been demonstrated in chicken cells, and published evidence shows that a similar phenomenon does not occur in mammalian cells.

Also the virus prepared with the inserts is replication defective and therefore cannot be self-propagating, further reducing the risk from these inserts, but in any event naturally occurring lentiviruses are not transmitted via aerosols.

The main risk comes from needlestick injury or via an open wound or from an aerosol of these high titre viruses. To minimise these risks the work is carried out in a class II laminar flow cabinet in a level 3 room and working in a sharps-free environment. Any wounds will be covered and gloves and laboratory coats will be worn at all times. Aerosol is minimised by not using a vacuum for aspiration of medium.

Therefore although the consequences of the hazard of transfer of the sequence to the worker could be severe, resulting in the generation of a pre-neoplastic cone(s) in the worker, with the application of the described control measures the risk of the foreseeable effects is extremely low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The transfection of plasmids in 293T cells and transduction of virus to human primary cells and cell lines will be carried out in a class II hood in a level 3 containment facility. The recipient mouse cells will be tested to determine whether they are producing lentivirus by taking culture medium from the transduced cells and placing on control cells, and testing for gene transfer. Once they have been shown to be negative for virus production, they will then be transferred to a level 1 containment facility for routine culture and subcloning.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested.
