2.2 Is the MT-2 HTLV-1 producer cell line (ATCC) a GMO? Under the GM contained use regulations genetically modified cell lines are counted as micro-organisms. If so it needs to be discussed and explained in the GM section.
2.10 How are the point mutations created in the HTLV1 and 2. If it is not by radiation or chemical means it will be classed as a GMO and needs explanation in the GM section.
2.15, 2.16 and 2.17 I understand from the explanation in 1.2 and elsewhere in the Bio1 that there are a number of different genetic modifications being carried out.
1. Knock outs of HTLV1 and 2 using shRNA knockdown and / or CRISPR,
2. Creation of replicating recombinant HIV incorporating fluorescent marker genes,
3. Creation of non-replicating retro virus pseudo-particles from transfected producer cells lines e.g. 293T cells.
4. Creation of recombinant derivatives of HIV and HTLV which you have classified as GM Class 2 HG2 in section 4.16.
5. Not described in 1.2 but mentioned in 2.15 The use of disabled retroviral MLV and HTLV described in 2.15 as ACDP HG1 GM Class 1, (although this might be subject to the host organisms and the inserts being used). If these are the typical commercially available 3rd generation retroviral vectors then this may be true. However if these are something that you are creating yourself then the committee will need to see that the disabling mutations are very robust and cannot be overcome by a recombination event with wild type HTLV or HIV.
Has all of this been comprehensively represented in 2.15, 2.16 and 2.17? e.g. I didn’t see mention of all of the components of the systems used to create the recombinant HIV?
I found it difficult to establish which hosts were being transfected or transduced with which vector and insert. Please could you make it clearer e.g. by identifying the various host vector insert systems with numbers or letters? It is really important that the Committee and the HSE can easily identify what GMO’s are Class 3, Class 2 and Class 1 and what vectors and inserts are associated with which hosts.
In 2.15 you mention non-pathogenic E.coli and insect cells lines used to express proteins. I don’t see plasmids mentioned in 2.16 or the genetic inserts mentioned in 2.17?
Are the disabled retroviral vectors all obtained from commercial sources where the disabling mutations have been quality controlled and verified as being robust and where, subject to the nature of the host and the insert, this could form part of a Class 1 GMO system?
4.6 and 4.14 How is the filtration accomplished? E.g. pressure, vacuum or centrifugation?
4.16 Classified by who? They are not wild type organisms, so their classification is subject to risk assessment. For these recombinant derivatives of the HG3 viruses HIV and HTLV to be classified as HG2 GM Class 2 The Committee
needs to be reassured that the disabling mutation is robust and there is a negligible chance of recombination with wild type virus leading to a return to full virulence and the ability to replicate.

4.19 4.10 I may have missed it but what is pACH. I don’t see it described in previous sections of this risk assessment.

5.1 Please be more specific about what work has to take place at CL3 and what is at CL2 and what elements of the work require an MSC. E.g. all handling of replication competent infectious HIV and HTLV virus whether recombinant or wild type including replication competent viral producer cell lines and all material suspected of being infected with these viral agents will take place in CL3 within a class 2 MSC.

5.4 Category A is PI 620 not 650. Only cultures of HIV are category A HTLV is likely to be B as exposure is unlikely to lead to permanent disability, life-threatening or fatal disease in otherwise healthy humans or animals.

5.5 Cultures of HIV are category A

5.12 Is the NP-40 or sds treatment of HTLV and HIV to inactivate it known to be effective? The HSE are insisting that these methodologies are validated or at least historically proven to be effective.

Comments: GM gave a brief description of the work.
PL checked with IH if all the BSO comments had been addressed.
IH confirmed that they had been but needed some additional refinement.
PL asked what the knockout genes were and what effects will these knockouts have on the virus?
GM explained the knock out mutant could not increase virulence. Rather it would decrease the fitness of the virus and it would be less virulent.
PL suggested that the knock out genes are all listed so far as is practical and the likely effects described.
IH pointed out that the risk assessment describes how any enhanced activity will be noticed and the work stopped. IH asked how enhancements would be recognised?
GM said that viral replication would be monitored by QPCR.
IH asked about daily visual observations and whether enhanced activity could be detected this way.
GM pointed out that this could not be done by looking at the cell, they will need to test by QPCR which would be done routinely as part of the work and would be recorded.
IH suggested adding this into the risk assessment and as a routine part of the process.
PL pointed out that HEK293T may be ACDP 2. Action: IH to check
PL agreed with IH BSO comments to make it more clear which hosts were being transfected or transduced with which vector and insert.
PL emphasised comments made by virtual reviewers that any non-waste related inactivation of HG3 or Class 3 material would need to be validated or supported by scientific papers.
IH pointed out that GM had referenced papers in the Bio1 and asked that they should be forwarded to the Safety Dept as part of the package for the HSE.
PL asked that the refresher training should be carried out at least annually. The committee agreed that this could be
part of the lab teams’ annual or termly meetings to review lab activities. The following amendments are requested prior to approval:

2.18 Remove ‘Other factors…’ and replace with a list of representative examples or classes of protein.

Forward papers to the safety dept referenced in the Bio1 regarding inactivation of material removed from the CL3 for further processing.

Review the arrangements for refresher training in the Bio1 and ensure that it is noted that it is completed at least annually.

The following comments are from committee member’s virtual review:

4.16 First paragraph ‘viruses’ needs a capital letter.

5.3 The word ‘primary’ in the first paragraph has a typo.

5.2 Second paragraph ‘lysis buffer’ is joined together and needs splitting.

10.1 First and second paragraph ‘mil’ has a ‘1’ after it which needs removing. Point 1 under large spillages has a typo in the word ‘involving’ and point 3 has a typo in the word cleaning.

I have a point to note regarding the SOPs- the HSE were very keen on the validation of inactivation procedures of infected material before removing from the CL3. Although these inactivation methods have been documented in the SOPs there is no ‘in house’ evidence to show that these inactivation methods work under the experimental conditions they are being used at i.e. no results tables. So I would suggest testing these methods in house and recording results for each inactivation procedure. Also you need to document how often you will validate and re-validate these SOPs.

With regards to the COP-Section 3 ‘Training’ - the HSE were also hot on refresher training. I suggest adding a note with regards including SOP specific training for each individual and then a section on refresher training for those people out of the lab for specific periods of time or who have not performed an SOP for a length of time e.g. 6 months.

Section 8- is the use of sharps prohibited – this has a question mark after it. Please amend.

Agreed: Class 3, Containment level 3. This is notifiable to the HSE.

IC reference number: GMIC-6945

</tr>
</tbody>
</table>
Endothelial cells infected with wild-type KSHV cannot be readily distinguished from uninfected endothelial cells without staining for KSHV antigens (such as the nuclear expressed latency-associated nuclear antigen, LANA-1). To circumvent this inconvenience, and to also allow a platform for genetic manipulation of KSHV, a novel recombinant KSHV (rKSHV.219) was generated and propagated in the primate Vero cell line. This virus was constructed using KSHV from the JSC-1 primary effusion lymphoma cell line and was engineered to expresses the green fluorescent protein (GFP) gene from the EF-1α promoter, as a marker of latent infection, and the red fluorescent protein (RFP) gene from the PAN RNA promoter, as a lytic cycle marker. The generation of this recombinant virus made the identification of ‘rKSHV.219-infected’ cells (GFP-positive) and ‘rKSHV.219 lytic’ cells (RFP-positive) very convenient. For these reasons my group will use rKSHV.219 to study the consequences of KSHV-infection on telomere maintenance.

Our aim is to understand how viral infection contributes to the maintenance of human telomeres. For this purpose, we will use the Open Biosystems TransLentiviral pGIPZ Packaging System to create replication-incompetent lentivirus that will be used to stably transduce human HeLa, 293, U2OS, endothelial cells, and fibroblasts with shRNAs that target the genes encoding either shelterin components (TRF1, TRF2, POT1, TPP1) telomere replication factors, DDR machinery components, and others. Transduced cells will be cultured in vitro and screened for viability, for sensitivity to DNA damaging agents, and for telomere structure and function upon KSHV infection. In addition, lentiviral CRISPR/Cas9 system will also be used to generate knock-out cell lines or introduce point-mutations into mammalian genes.

Recipient or parental organism

Hazard group 2 recipients.
Wild-type KSHV from JSC-1 strain as a recipient to generate rKSHV.219 recombinant virus.
Hazard group 1 (For information)
Human and murine cells and cell lines.
We will use the Open Biosystems TransLenti Viral pGIPZ and other third generation lentiviral lentiviral vectors (including CRISPR/CAS9). The lentiviral vectors to be used are self inactivating and replication incompetent, require three different vectors for packaging (they cannot package themselves), require upstream elements and trans complementation. They cannot survive outside of closed controlled cell culture conditions and are rapidly inactivated by dehydration or other environmental insult. They also require percutaneous inoculation for transmission. Thus, the risk to human health from the use of the pGIPZ lentiviral vector is very low and the risk of any spread into the wider community is very unlikely indeed.

Origin & function

Class 2 work with recombinant KSHV. Green fluorescent protein (GFP) gene from the EF-1α promoter, as a marker of latent infection, and the red fluorescent protein (RFP) gene from the PAN RNA promoter, as a lytic cycle marker. The generation of recombinant KSHV makes the identification of 'rKSHV.219-infected' cells (GFP-positive) and 'rKSHV.219 lytic' cells (RFP-positive) very convenient. For these reasons my group will use rKSHV.219 to study the consequences of KSHV-infection on telomere maintenance.

Work using attenuated lentiviral vectors. Experiments will involve silencing, mutation, or overexpression of cellular gene products, normally being responsible for telomere homeostasis, DNA damage response, and DNA repair. The specific genes that will be targeted are shelterin components and DDR machinery factors as well as other, so far unknown, genes (cellular and viral) to be discovered as key regulators involved in modulation of the telomere chromatin by KSHV.

Evaluation of foreseeable effects

Infectious virus rKSHV.219 is the only hazardous form and is readily inactivated with standard disinfectants such as 1% virkon. GM rKSHV.219 will be no more hazardous to human health or the environment than the wild-type KSHV. In immune-competent individuals, KSHV establishes asymptomatic life-long latency following acute infection, however, it can cause Kaposi's sarcoma or pleural effusion lymphoma in individuals with compromised immunity (HIV infected patients or transplant recipients). No risk to plants or animals.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not Applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid Waste
Treated with Virkon at a final concentration of 1% for 30 minutes before disposal to drains. Effective kill is in excess of a log 5 reduction in viable organisms. Information regarding virkon's effectiveness against herpes virus is available from Antec.

Solid Waste
solid waste will be placed in bin double lined with autoclave bags. The bags are sealed when 2/3rds full and
transferred to a pick up point in labs 451c or 327 for autoclaving by support staff. Autoclave waste cycle is set to hold the waste at 121 degrees for 15 minutes. The autoclaved waste is then sent for clinical waste disposal. The autoclave is validated annually with a representative waste load to ensure that these temperatures are reliably attained. Effective kill is in excess of a log 5 reduction in viable organisms. Sharps will be collected in sharpsafe bin, autoclaved and then incinerated.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

Respiratory syncytial virus (RSV) and Influenza are major causes of morbidity and mortality in early life. It is not fully understood why infections are more severe in some infants, but it is suggested that host genetics plays a role. Mammalian cells have a variety of mechanisms to reduce viral replication which are usually mediated by antiviral proteins. These can be present constitutively but a major element of the innate immune response to viral pathogens is the amplification of antiviral proteins, induced by the activity of type I interferons (IFNs).

The overarching aim of this research project is the investigation and functional characterisation of Interferon-stimulated genes (ISGs), and their role in the immune response to respiratory viral pathogens. This requires the development of cell lines deficient in the gene, and therefore protein, of interest. Further we intend to generate novel recombinant viral vectors that will be used to modulate gene expression in mouse models of infection. Following generation of modified cells or inoculation of mice with recombinant viral vectors, the application of respiratory viruses will be used to assess the role of the modified genes. This will require use of genetically-modified variants of RSV including variants encoding fluorescent/luminescent markers (GFP, RFP, luciferase, etc.) or host factors, and variants lacking certain viral genes.

This risk assessment applies to all work required to generate genetically modified mammalian cells, production and use of recombinant viral vectors, and subsequent infection in vitro or in vivo for ISG functional analysis.

**Recipient or parental organism**

1) Immortalised cell lines (Human - A549, HEp-2, Hek293T, Hek293. Monkey - Vero, Mouse - LA-4) and murine (C57BL/6, BALB/c, or similar strains) immune cells derived from bone marrow (macrophages/dendritic cells) will be genetically modified by transfection of plasmids encoding a Cas9 endonuclease. Depending on the targeting RNAs used in this study either indels or designed deletions of genes will be produced following cell-mediated repair of the DNA. The work will generally be limited to the production of cells with single genetic alterations.

2) Recombinant viral vectors - Recombinant Adeno-associated virus (AAV) and lentivirus will be produced using common triple transfection and purification protocols. Viral genomes will be produced that contain either shRNA
sequences or sgRNA along with a Cas9 cassette. Genomes will also contain a selectable or fluorescent marker including but not limited to GFP. Packaged viral genomes will be harvested, purified, and titrated using commercially sourced kits such as Clontech AAVpro Purification kit and AAVpro Titration kit. In-house qPCR assays will also be designed for titration. These vectors will then be validated in vitro for their ability to deliver shRNA or sgRNA expression before use in vivo.

3) Respiratory Syncytial Virus - Recombinant RSV (listed below) stocks have been produced previously by a collaborator and will be propagated and used for in vitro and in vivo infections to study the impact of human immune genes and viral genes on the intrinsic immune response. This will include use of these viruses in Cas9 modified cell lines and AAV/lenti infected mice to investigate impact in the context of ISG modification as described.

Murine cytokine -
RSV-mIFN-g - murine IFN-g gene inserted
RSV-mIL2 - murine IL-2 gene inserted
RSV-mIL4 - murine IL-4 gene inserted
RSV-mGMCSF - murine GM-CSF gene inserted
RSV-mIL-18 - murine IL-18 gene inserted
RSV-mIL-12 - murine IL-12 gene inserted

Additional RSV expressing alternative murine cytokines will be produced as necessary.

Reporter -
RSV-GFP - GFP gene inserted
RSV-RFP - RFP inserted

Gene deleted -
RSV-NS1ve - NS1 gene deleted
RSV-NS2ve - NS2 gene deleted
RSV-NS1NS2ve - NS1 and NS2 genes deleted
RSV-SHve - SH gene deleted

Gene mutated -
Point mutations in RSV genes to determine gene function

No recombinant Influenza will be used.

1) CRISPR-Cas9 modification of cells in vitro:
The vectors used for CRISPR-Cas9-mediated genome alteration in vitro will be non-mobilizable DNA plasmids. These will encode both bacterial selection markers (e.g. ampicillin resistance) and either additional selection markers (e.g. puromycin resistance for selection in mammalian cell culture) or encode fluorescent proteins for selection via FACS. Vectors will allow expression of the Cas9 endonuclease and Cas9-targeting guide RNA sequences. Cas9-expressing vectors may include commercially-available constructs such as pSpCas9(BB)-2A-Puro (PX459) V2.0 and pSpCas9(BB)-2A-GFP (PX458). Vectors are subject to change as required to optimise the production of the described GMMs, e.g. alternative Cas9 types, selection markers, or number of Cas9/DNA repair-targeting elements encoded on a single vector.

2) Adeno-associated virus vectors:
AAV particles will be produced in HEK293 cells via triple transfection protocols. A Recombinant AAV2-derived plasmid will be sourced from Addgene or Cambridge Biosciences (e.g. pAAV-sh(control) - Addgene #75438). This will contain the terminal repeat sequences of the AAV genome required for packaging but will not contain the Rep or Cap sequences found in wildtype AAV. This renders the particles unable to replicate. These repeats will instead flank a pol
III promoter upstream of an shRNA sequence or sgRNA sequence and a selectable marker (e.g. GFP) downstream of a pol II promoter. For CRISPR-mediated modifications Cas9 may be encoded as an additional element. For packaging of the above vector Rep and Cap elements will be supplied by an additional plasmid (e.g. pAAV-RC6 - Cambridge bioscience) and Adenovirus helper elements provided by a third plasmid (e.g. pHelper - Cambridge bioscience). These plasmids are not incorporated into the final virus particle. Recombinant AAV particles produced in this manner are able to infect dividing and non-dividing cells but are unable to become incorporated into the host genome or replicate in the host cells without the help of a co-infecting virus such as Adenovirus.

3) Lentivirus vectors:
Lentiviral particles will be produced using 3rd-generation packaging systems which split the required elements over 4 plasmids.

-> The transfer plasmid (e.g. pII3.7 - partial HIV type genome) contains the shRNA/sgRNA and a marker flanked by long terminal repeats required for packaging. These LTRs have been modified from wildtype to eliminate requirement for Tat co-activation of shRNA/sgRNA expression.
-> Packaging plasmid 1 - GAG-POL-RRE
-> Packaging plasmid 2 - REV

These two packaging plasmids encode elements required for virus replication and packaging. They are not incorporated into the virion progeny.
Endoence plasmid - The specific envelope protein to include on this final plasmid will vary and depend on the optimisation of the use of lentivirus particles in vivo for transduction. Different organs and tissues are better transduced by viruses with certain envelope proteins, e.g. GP64 has been shown to be more effective at transducing the murine lung than the classical VSV-G.

4) GM-RSV - RSV stocks as described above have been produced previously according to Bukreyev et al (J Virol. 1996 Oct;70(10):6634-41). Briefly RSV-specific gene-start and gene-end motifs were added to either end of a cDNA encoding the ORF of the gene of interest. This cassette was then inserted into the region between the G and F genes of complete positive-sense RSV antigenome. Recombinant virus was produced by transfecting HEP-2 cells with this antigenome and four plasmids encoding the N, P, L, and M2 ORFs separately.

Deletion mutants will be generated in genes involved in the type I IFN response. In addition to CRISPR-Cas9/shRNA use in vitro, AAV/lentivirus particles will be used to generate mutants and shRNA-knockdowns in vivo. Targeted genes include but is not limited to:

IFIC4L - Little characterisation
GBP1 - ISG and GTPase
GM RSV Murine cytokines involved in propagation and skewing of immune response - RSV-mIFN-g - murine IFN-g gene inserted.
RSV-mIL2 - murine IL-2 gene inserted
RSV-mIL4 - murine IL-4 gene inserted
RSV-mGMCSF - murine GM-CSF gene inserted
RSV-mIL-18 - murine IL-18 gene inserted
RSV-mIL-12 - murine IL-12 gene inserted
Additional RSV expressing alternative murine cytokines will be produced as necessary.

RSV-GFP - GFP gene inserted. Fluorescent reporter gene.
RSV-RFP - RFP inserted. Fluorescent reporter gene.

Gene deleted -
RSV-NS1ve - NS1 gene deleted. Viral gene involved in immune evasion.
RSV-NS2ve - NS2 gene deleted. Viral gene involved in immune evasion.
RSV-NS1NS2ve - NS1 and NS2 genes deleted

Gene mutated -
Point mutations in RSV genes to determine gene function
Deleted functional regions of RSV genes
No recombinant Influenza will be used.

Evaluation of foreseeable effects

1) All genetically modified human and murine cells will be loss of function mutants lacking an element of the intracellular immune response to pathogens. Human infection/colonisation by cultured cells is routinely mitigated by the use of microbiological safety cabinets, secondary containment during transport, and appropriate centrifuge spill/leak protocols. CRISPR-Cas9 vectors will be non-mobilisable. Environmental exposure of all GMMs will be limited. Any release of modified human or murine cells is unlikely to result in any damage to environmental organisms or spread of GMMs as they require supplementation with growth factors and specific temperature and atmospheric conditions.

2) AAV are generally non-pathogenic (Daya and Berns., 2008) and will be dead-end vectors unable to replicate upon infection.

3) Lentivirus vectors produced using 3rd generation systems (4-plasmid) are also unable to replicate but will retain the ability to integrate into the host genomic DNA. Modifications will not contain any known oncogenes or oncogenic sequences.

4) RSV is a human pathogen and may cause mild symptoms in humans and other primates. Human RSV is generally very species-specific. GM RSV to date have been recorded as less virulent than wt RSV. RSV may be present in mucosal secretions of experimental animals for a short time but is not able to spread to other animals due to low titre.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1) Liquid waste - Mammalian and bacterial culture waste will be treated with Distel at a final concentration of 1% for 10 minutes before disposal down the drain. RSV and Influenza have no known resistance to chemical disinfectants.

2) Solid waste - Tips and pipettes used to handle biological samples are soaked in 1% Distel for 10 minutes then placed in biobins and then into autoclave bags. All other plasticware used to culture biological material are placed directly into autoclave bags. All solid waste in contact with cells/tissue will be autoclaved at 121°C for 30 minutes.
All other solid waste such as tips, pipettes, tubes, and plasticware not used for either biological or GM material is placed in orange biobins or orange waste bags.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

Reviewer 1
2.14 GMIC – 01106 is referenced in this section and is on RADAR as a risk assessment which includes recombinant GFP RSV and various cytokines for Prof Peter Openshaw. I cannot see one for Dr Tregoning. Therefore the addition of the recombinant RSV to this project under Dr Tregonings name will unfortunately require notification to the HSE as a new GM class 2 project.
2.15 Please add the RSV as a recipient species for the GFP and cytokines.
2.16 How has the recombinant RSV been produced? Is that included here?
2.17 Please add the changes made to the RSV, including inserts and deletions.
7.1 How is the RSV and influenza treated?
14.1 Why is the recombinant AAV and lentivirus GM class 2? From the risk assessment it looked as if it was headed for being GM class 1? If it is class 2 please explain more fully the hazards to human health and the environment in section 2.14 to 2.18. If these viruses are suitably attenuated and disabled and the inserts are not hazardous then I am happy for them to be class1.
Agreed that recombinant RSV is GM class 2.

Reviewer 2
Change history should be completed as this is an update
2.10 ACDP classification needs to be completed
4.4-4.6 need to be completed
5.7-5.8: spills should be reported on SALUS.
5.8: Provided RSV is not involved and given the low risk from aerosols caused by a spill of these bacterial cultures (non-pathogenic E.coli for plasmid propagation) it should be safe to open the incubator for cleaning after one hour. If RSV is not involved the safety advisors should be informed but are perhaps not needed for a decision on whether to open the incubator.
10.2 Needlestick protocol required (possibility of needlestick whilst inoculating animals)

Reviewer 4
Can you ask John to check his room numbers for the CBS facility? As I think these will need updating. Section 1.3. I don’t think the rooms are mentioned anywhere else.

Project Containment

| Laboratory Activities | Glass Houses | Growth Rooms |

02/03/2022
In this project we aim to optimise and characterise the larvae of the wax moth, G. mellonella, as a novel infection model for mycobacteria to study host-pathogen interactions and assess the antimycobacterial activity of potential antimycobacterial agents.

Mycobacterium tuberculosis is a highly successful human pathogen that currently infects a third of the world's population, causing 9 million new cases of tuberculosis and 1.5 million deaths annually. The close association of tuberculosis (TB) with the human immunodeficiency virus (HIV) pandemic, and the rising problem of multi-drug and extreme drug resistance have created difficulties for TB control programmes worldwide. Furthermore the current BCG vaccine, although providing some protection against disseminated disease in childhood, is largely ineffective in preventing TB in adults. There is thus an urgent need for a greater understanding of host and M. tuberculosis interactions, improved vaccines to prevent infection, and novel therapies to shorten the duration of treatment and target latent TB infection (LTBI). However this has in part been hampered by the current inadequate, costly and timeconsuming in vivo infection models for TB.
M. tuberculosis is challenging to study in vivo due to its complex pathogenesis and disease progression. Animal models such as mice, guinea pigs, rabbits, zebra fish and non-human primates have previously been used to study M. tuberculosis infection. However, no single animal model can replicate all aspects of M. tuberculosis pathogenesis e.g. while the mouse model is widely used, it cannot replicate granuloma formation, vital for the study of TB infection; guinea pig and rabbit M. tuberculosis models do form granulomas yet they are expensive and time consuming. In addition, there are ethical concerns about the use of mammalian models (especially non-human primates) in TB research, and they are associated with high maintenance and cost.

To overcome these issues there is an urgent need for a rapid, well-characterised, low-cost, high-throughput model that mimics the key features of M. tuberculosis pathogenesis to further understand host-pathogen interactions, that can also be used to screen novel drug candidates and assess the efficacy of vaccine candidates in early stage development. Invertebrate models such as Caenorhabditis elegans, Drosophila melanogaster and Galleria mellonella are becoming more widely used as infection models as they are considerably cheaper and ethically more acceptable. The larvae of G. mellonella has increasingly been used as an infection model to study a range of bacterial and fungal infections. G. mellonella has a wide range of advantages that have made it a successful infection model. These include its sophisticated innate immune system, comprised of cellular and humoral defences, that shares a high degree of structural and functional similarity to that of vertebrates, and its ability to discriminate between bacterial and fungal pathogens as identified by the repertoire of immune defence peptides. Other advantages include, large size (2-3cm) for easy manipulation and infection, low cost and maintenance, large group sizes can be infected for reproducibility allowing robust statistical analyses, rapid results, survival at 37 degrees Celsius (allowing human pathogens to be investigated), and no Home Office licence is required for larvae infection.

G. mellonella will be infected with genetically modified mycobacterial species to optimise and characterise the insect larvae as an infection model for mycobacteria. We will undertake a range of experiments including survival curves of both mycobacterial species and G. mellonella over time, mycobacterial survival analysis in the presence and absence of standard antimycobacterial agents and novel therapeutic compounds, histopathology staining and transmission electron microscopy (TEM), transcriptomic, lipid and proteomic analysis, IVIS in vivo imaging and primary haemocyte (G. mellonella phagocytic cells) cell culture infection assays. These studies will aim to characterise G. mellonella as a novel infection model for mycobacteria.

**Recipient or parental organism**

Mycobacterium tuberculosis - hazard group 3
- Clinical isolates- drug sensitive and multi-drug resistant strains, but not extensively drug resistant.
- Fully drug sensitive laboratory strains such as H37Rv, Erdman, CDC1551, H37Ra

Other Mycobacterium species - hazard group 2
Mycobacterium bovis BCG pasteur (vaccine strain), M. bovis BCG is naturally resistant to pyrazinamide, but otherwise sensitive to TB drugs. Other vaccine strains of BCG such as Danish Moreau, Montreal etc may also be used.

Non tuberculous mycobacteria reference strains/clinical isolates including
Mycobacterium abscessus
Mycobacterium kansaii
Mycobacterium chelonae
Mycobacterium avium
Mycobacterium intracellulare
Mycobacterium marinum

- Attenuated Mycobacterium tuberculosis auxotrophic mutants - class 2 GMO. Refer to the BIO1 risk assessment, section 2.14 for details of these mutants and justification for their use at ACDP CL2.

M. tuberculosis Bleupan (ΔleuD ΔpanCD)
M. tuberculosis (mc2 6020 ΔlysA ΔpanCD)
M. tuberculosis (mc2 6030 ΔRD1 ΔpanCD)
M. tuberculosis (mc2 7000 ΔRD1 ΔpanCD)

Host/vector system

pSMT3 and derivatives - ColE1 and pAL500 origins of replication. Not mobilisable
pYUB854 and derivatives - OriE. Non mobilisable
pMV261 and derivatives - OriE Non mobilisable
pHAE159, pHAE87 and derivatives - Derivatives of the conditionally replicating mycobacteriophage PH101 (ts;Bardarov et al., 97)
pGS201, pGS202 - details at http://webhost.nts.jhu.edu/target/plasmids.aspx
pKINTA and derivatives - Non-mobilisable integrating vectors

Origin & function

Inserted genes are self cloning of mycobacterial genes either in the sense orientation to allow over expression, or in
the antisense orientation to allow down regulation, under the control of either an inducible or constitutive promoter e.g.
down-regulation and also over expression of the 19kDa lipoprotein gene (Rv3762, involved in immune subversion),
Acr2 gene (Rv0251c involved in bacilary defence against oxidant stress). Mycobacteria do not express any toxins
and there is little risk of altering pathogenicity by this method.
Selectable markers include hygromycin (not clinically used as toxic to humans), kanamycin, spectinomycin, zeocin
(not part of first line therapy), sometimes in combination with the sucrose and the SacB enzyme as a
counterselectable marker.
Reporter genes include a range of fluorescent reporters such as GFP or mCherry, luminescent reporters such as the
lux operon from Phorhabdus luminescens or Vibrio harveyi, or the luciferase genes from Firefly or Gaussia princeps.
Genes have been inserted into Mycobacterium tuberculosis clinical isolates that are present in the reference strain
H37Rv but naturally deleted in the clinical isolate. The pSMT3 vector has been used that encodes the open reading
frames for genes including Rv 0180 (Function unknown, probable conserved transmembrane protein), 1519 (probable
conserved hypothetical protein), 3019 (Function unknown - Secreted ESAT-6 like protein EsxR, 3020 (function
unknown - ESAT-6 like protein EsxS), 3516 (Could possibly oxidize fatty acids using specific components), 3517
(Function unknown - conserved hypothetical protein), 3738 (Function unknown - PPE family protein PPE66), 3739
(Function unknown - PPE family protein PPE67). Deleted genes in M. tuberculosis and M. bovis BCG will include
genes such as the DosS/ DosR (Rv3132c and 3133c) which is essential for dormancy survival and regulation.
We will also use live attenuated M. tuberculosis auxotrophic mutants that have the following gene deletions and
antibiotic resistance genes;
M. tuberculosis Bleupan ΔleuD ΔpanCD hygR (Sampson et al, Infection & Immunity
M. tuberculosis mc2 6030 ΔRD1 ΔpanCD hygR (Sambandamurthy et al, (2005) Infection & Immunity 73:1196-1203;
M. tuberculosis mc2 7000 ΔRD1 ΔpanCD unmarked (Sambandamurthy et al, (2005) Infection & Immunity 73:1196-

Evaluation of foreseeable effects

GMMs were created previously as detailed below and under reference GM77/16.
Mutants have been created by either the deletion of all or part of target genes and the introduction of a selectable marker, by double cross overs and homologous recombination. This has been done using mycobacteriophage or suicide plasmids, usually with a two-step selection procedure such as sucrose plus selection for an antibiotic marker such as kanamycin or hygromycin.

Reporters, such as genes for luminescence or fluorescence, have been introduced into class 2 and class 3 mycobacterial strains by electroporation of plasmid DNA which will be either maintained epimysally by a mycobacterial origin of replication or through integration into the attB phage attachment site. Reporters and mycobacterial genes have been over-expressed, or knocked down using antisense and inducible systems such as tetracycline or acetamide.

Genetic deletions in defined Mycobacterium tuberculosis clinical isolates (class 3) have also been complemented by introducing the intact genes present in the reference strain Mycobacterium tuberculosis H37Rv.

Deleted genes with known function such as DosS / DosR (Rv3132c and 3133c), essential for dormancy survival and regulation, and have been deleted from Mycobacterium bovis BCG (class 2) and M. tuberculosis H37Rv (class 3). We will also use genetically modified live attenuated Mycobacterium tuberculosis auxotrophic mutants (class 2 GMO) under containment Level 2. These defined M. tuberculosis strains with already targeted mutations render them highly attenuated and suitable for use under containment level 2 conditions. No further modification will be undertaken. All four of the strains carry two independent mutations, rendering them all auxotrophic for pantothenate, in combination with either leucine or lysine auxotrophy, or the deletion of the RD1 region responsible for the major attenuation of M. bovis BCG. The auxotrophic strains are well characterised and highly attenuated. Extensive safety testing has been performed on all the 4 strains; attenuated Mycobacterium tuberculosis leuD ΔpanCD hygR, attenuated Mycobacterium tuberculosis mc2 6020 ΔlysA ΔpanCD hygR, attenuated Mycobacterium tuberculosis mc2 6030 ΔRD1 ΔpanCD hygR, attenuated Mycobacterium tuberculosis mc2 7000 ΔRD1 ΔpanCD unmarked. (references Sampson et al, Infection & Immunity 2004 72:3031–3037; Sambandamurthy et al, Nature Medicine 2002 1171-1174; Sambandamurthy et al, 2005 Infection & Immunity 73:1196-1203.

There is no evidence that any of the recombinant mycobacteria made in this project is any more hazardous than parental strains.
Any liquid non-GM waste which is not infected with mycobacteria (e.g. unwanted haemocytes in CL2 tissue culture) is to be discarded with 2% virkon final concentration and left for 30 mins-1 hr before disposing via the drain. Any GM waste will be placed in autoclave bags and autoclaved. Any solid waste items not infected with mycobacteria or haemocytes will be discarded into orange bags for disposal via clinical waste.

All G. mellonella (whether infected or uninfected with mycobacteria) will be stored double contained at -80°C for a minimum of 24 hours to achieve a kill and then will be placed in autoclave bags and autoclaved at the desired sterilisation temperature of 121 degrees C for 15 minutes. Autoclaved waste is bagged as described as above. Autoclaves are serviced twice per year, and validated and insurance inspection once per year in accordance with Imperial College London regulations.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

02/03/2022

Page 2399 of 15326
Following the discussion of your proposal entitled “Galleria mellonella - a novel infection model for Mycobacteria tuberculosis aimed to replace animal infection models in experimentation.” (GMIC-8826) at the last GM Safety Committee meeting, the Committee request that the following amendments are made to the proposal prior to approval:

1. Move the last paragraph to the top.
1.1 Remove zebrafish from list of mammalian models.
2.16: Add vectors
2.17: Add inserts
5.9: Describe what actions will be taken should there be a needle stick injury include that Occupational Health will be contacted.

Comments: SN gave a brief description of the work.
MS asked what length of time would the larvae be holdings for?
SN answered 2 weeks.
MS queried what conditions are required for the larvae to develop into the Moth stage?
SN explained from larvae, to pupae, to moth they would require a temperature of 30-32 degrees Celsius. To prevent this, the larvae will be kept at 19 degrees Celsius, the pupae stage is 1-9 weeks and the infection will reduce maturity. This will give them enough time to notice development, at which point they will be moved to the -80 freezer for killing and then autoclaved.
MB asked if the larvae would be double contained?
SN confirmed that they would be and the petri dish would loosely taped to keep them closed.
MS checked if they will be using syringes and if they would be blunt.
SN explained they would be using Hamilton syringes. In the CL3, a sponge will be used to attach the larvae to and a disposable loop to hold them down before injecting.
MS asked if the needle part of the syringe be re-sheathed?
SN confirmed they would be.
MS asked about using a large falcon?
SN answered yes, 50ml.
MS wanted to know what was the process if there was a needle stick injury?
SN explained they would encourage it to bleed and run it under water.
MS suggested including that Occupational Health will be contacted in this process.
MB pointed out that boundaries between the strains/inserts and containment level 2/3 needed to be clear. The strain/inserts should also be listed in more details.
MB also asked what work would take place in Dr Brian Robertson’s lab?
SN will be using the IVIS in his lab.
Agreed: Class 3, Containment level 3. This is notifiable to the HSE.
Could you please ensure that the risk assessment is revised and the amendments

The aim of this project is to evaluate the innate immune responses during Zika virus (ZIKV) infection in vitro and investigate the determinants of inter-strain differences in virus modulation of those responses. Initially based on studying ZIKV inter-strain differences in innate immune responses (ex vivo and in vitro), the project needs to encompass GM construction and analysis of inter-strain (intra-species) chimaeras.

Recipient or parental organism

Zika virus (ZIKV)

Host/vector system

Infectious cDNA clones of pathogenic Brazilian ZIKV (HG2) strains Paraiba 01/2015 (Tsetsarkin et al., 2016, 2016 Volume 7 Issue 4 e01114-16) and/or BeH819015 (Mutso et al., Journal of General Virology 2017;98:2712–2724 DOI 10.1099/jgv.0.000938)

Origin & function

Homologous inserts from other strains/isolates of ZIKV (from cDNA or constructed synthetically) or directed
mutagenesis/editting (in vitro mutagenesis or CRISPR-mediated) to achieve same outcome.

**Evaluation of foreseeable effects**

ZIKV (pathogenic field or attenuated/vaccine strains) will be recovered from cDNA after transfection of permissive eukaryotic cells.

Knock-out or mutated versions of above ZIKV strains (by in vitro mutagenesis, including CRISPR, or by synDNA replacement); some will represent intra-species, inter-strain chimeras.

The mutations are found in different pathogenic strains which appear to share nearly identical clinical and epidemiological characteristics yet display subtle differences in innate immune responses (e.g. qualitative and quantitative differences in induction of IFN responses during in vivo and ex vivo infections). The aim is to associate these subtle differences with particular amino acid substitutions. Mutant viruses will have different combinations of mutations causing no more than a handful of amino acid substitutions (our comparison focuses on the Asian lineage). As such, none of the resultant viruses is expected to be more hazardous than parental pathogenic viruses.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid waste:
- Low titre/Low protein: High volumes (>250ml) of low titre, low protein liquid waste (e.g. PBS used to wash virus from cells or tissue samples) will be treated with 1% Distel (final concentration) for 30 minutes, then disposed of down the sink.
- High titre or high protein (e.g. following blood separation, discarded cells from viral stock culture): centrifuge tube used for procedure to be capped and tube placed in a sealable, hard plastic, leak-proof container ("sweetie jar") also used for solid waste produced in the MSC. In the case of residual tissue samples, excess tissue will be placed in a centrifuge tube, the lid sealed in place and the tube placed in the sweetie jar. Filled sweetie jars will be sealed and autoclaved.

Solid waste:
- Disposable plasticware (pipette tips/small tubes/tissue culture plates etc): will be placed in a sealable, hard plastic, leak-proof container ("sweetie jar") maintained in the hood. Sweetie jars will contain 200ml 1% Distel. Once filled, sweetie jars will be sealed ready to be autoclaved. The 1% Distel is present in case of a spill during transportation of sweetie jars between the CL3 and autoclave facility.
- Serological pipettes: All serological pipettes will be filled with 1% Distel in a 2L beaker maintained in the hood. At the end of the work period, pipettes will be removed into an autoclave bag, sealed and double bagged prior to autoclaving.
- Sharps: All surgical blade will be removed with a tamper-proof blade remover which will be placed in a standard rigid sharps container and sealed in a double bag. These will then be autoclaved.

**Is an emergency plan required according to regulation 20?** N

If yes, tick to confirm that it is attached to this form N
Following the discussion of your proposal entitled “ZIKV innate immunity.” (GMIC-9012) at the last GM Safety Committee meeting, the Committee request that the following amendments are made to the proposal prior to approval:

1.1. Is the virus infectious to humans from culture, for example by needle stick injury, or does it need to be activated or modified by transmission through a mosquito?

1.2. How long are the primary human cell lines cultured for?

2.18. What signs of a more hazards GM virus are you looking for? This needs to go into the COP

4.6. If this is a disposable scalpel why is the blade removed? If this is normal practice how is the blade removed without risk to the user?

4.6. How long are the primary tissue samples and CD4+ T cells from unscreened material cultured for? If over 96 hours is HIV propagation possible?

4.14. Isn’t the dissection of tissue from Zika patients using sharps the most hazardous process? Unless I am mistaken and according to your own text in 4.10 It isn’t an airborne pathogen so an aerosol isn’t a primary concern.

4.18. Is the creation of the chimeric virus something that could occur naturally if African and Asian strains co infected the same human patient?

4.21. IS there a risk of airborne infection from Zika? In 4.10 you do not list this as being a route of infection.

5.3. Last paragraph missing the 3 from CL

5.7. Lab 45? Should this be 450?

5.12. With the exception of 3% paraformaldehyde have these methods been validated as effective?

5.13. Is the sorting with live virus? Is there an SOP?

6.4 3 missing after CL

6.5 and 6.6 " 3 lab " missing after CL

7.1 and 7.4. are there any large lumps of recognisable human tissue for disposal?

10.2. Check these emergency numbers especially the OH one

Amend 14.1

Agreed: GM Class 2. This is notifiable to the HSE.

---

## Project Additional Information

### Purposes of the contained use

To generate knockout, complementation and other relevant mutants e.g. fluorescence reporter mutants, of potential vaccine candidates identified via reverse vaccinology 2.0 (cloning of antibodies from patients recovering from disease/healthy volunteers). Mutants will be used to unequivocally identify/validate the targets of functional antibodies and confirm these targets as potential vaccine candidates.

### Recipient or parental organism

- Streptococcus pneumoniae
- Neisseria gonorrhoeae
- Acinetobacter baumanii
- Streptococcus pyogenes (Group A Streptococcus)

### Host/vector system

- pUC-based plasmids and derivatives (Col-E1 plasmid) - pGEM-T, pBluescript etc.
- pET-based expression vectors
- pACYC184 and derivatives
- pMIDG and derivatives
- Suicide vectors (e.g. pKNG101 or pEX series of plasmids).
- Transposons e.g. Mariner based transposon system or Tn5, Tn7 derivative plasmids.

### Origin & function

The inserts will primarily be genes encoding putative vaccine candidates of pathogens listed in section 7 above identified through antibody cloning work. Inserts will be genes inactivated by disrupting the reading frame i.e. deleting the gene and eliminating presence of its product in the cell.

Evaluation of foreseeable effects

No GMO is anticipated to be any more hazardous than wild-type strains. Genes will not be deleted if known to increase pathogenicity or host range. None of the genes of current interest to my group encodes a toxin or other product anticipated to increase the toxicity of any non-virulent recipient strain. Indeed, many strains produced will have deletions in genes, which are required for optimal growth and virulence of the organism, and mutants are expected to be less virulent than wild-type recipients. Genes conferring resistance to antibiotics used to treat clinical infections will not be used as markers.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be autoclaved (134°C for 10 minutes) or treated. Tissue culture waste will be treated with Virkon (Minimum 1% final concentration) for at least 1 hour before disposal down the sink.

Solid clinical waste (excluding microbiological waste) will be discarded into orange waste bags. Solid microbiological waste will be discarded into autoclave bags and sterilised by autoclaving (134°C for 10 minutes) before disposal.

Following autoclaving, solid waste will be transferred (double-bagged) into orange clinical waste bags and disposed following the route for clinical waste.

Packaged sterilised solid waste will be stored in waste collection bins prior to disposal.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

### Project Additional Information

**Purposes of the contained use**

Bacterial lung infections are a significant cause of morbidity and mortality. Particularly in individuals with underlying co-morbidities e.g. Cystic fibrosis, COPD, asthma and diabetes are more susceptible to bacterial lung infections. We are interested in the interactions between the bacteria and the host, looking at how the host tries to control the bacterial infection and how the bacteria tries to evade this. Using both in vitro and in vivo systems, we wish to define differences between healthy individuals and those with underlying co-morbidities that leads to greater disease susceptibility to bacterial lung infection. We will look at 4 bacterial pathogens: Staphylococcus aureus, Pseudomonas aeruginosa, Klebsiella pneumoniae and non-typeable Haemophilus influenzae - ntHi (hazard group 2 pathogens). All of these bacteria can be carried as part of the normal nasal/ host bacterial flora. We will also look at mouse pathogen citrobacter rodentium (ACDP hazard group 1).

Staphylococcus aureus is a major cause of hospital acquired infection, particularly bacterial pneumonia and wound infection. Bacterial pneumonia is a significant cause of morbidity and mortality. Attention has focussed in particular on hospital-acquired, antibiotic-resistant, bacterial infections, a government health priority. However, there is a lack of good in vivo models of bacterial infection in the lung. This project will develop in vivo models of S. aureus infection and then investigate the immune response to it and approaches to control it using vaccines or antimicrobial therapies. Both Methicillin Sensitive S. aureus (MSSA) and Methicillin Resistant S. aureus (MRSA) will be used.
Pseudomonas aeruginosa is able to infect a wide variety of hosts and tissues and is an excellent model for studying infection by gram-negative bacteria. It is particularly prevalent in cystic fibrosis patients. We will be using in vitro models of infection using airway epithelial cells and differentiated airway epithelia to assess the effect of altering physiological conditions on bacterial growth. We will then assess these conditions and drugs that can alter them using in vivo mouse models.

Haemophilus influenzae is serotyped according to the capsular antigens. Strains without a capsule are described as the non-typeable (ntHi). In general the non-capsulated strains are less virulent than the capsulated strains. Noncapsulated H. influenzae is often observed in the airways of patients with chronic obstructive pulmonary disease (COPD). We are interested in extending Haemophilus influenzae vaccination to ntHi strains. We will then assess protection of vaccines using in vivo mouse models. We will also assess ntHi as an agent of co-infection with other pathogens.

Klebsiella pneumoniae is primarily a hospital-acquired bacterial pathogen that causes pneumonia, urinary tract infections and septicemia. Its success is related to its ability to form biofilms on medical devices, such as catheters. We will investigate how Klebsiella biofilm formation effects virulence and how the metabolic profile changes. Citrobacter rodentium is a murine pathogen that belongs to a family of enteric pathogens, including enteropathogenic E. coli (EPEC) and enterohaemorrhagic E. coli (EHEC), which utilize attaching and effacing (A/E) lesions to colonize the gastrointestinal tract of the host.

Deletion mutants will be made, but genes will not be deleted if known to increase pathogenicity. Deletion mutants will be screened for the effect on pathogenicity in mouse models and if the mutants are more pathogenic than wild type they will be destroyed.

</tr>
<tr>
<td>2. Reporter gene expression. Mutants will be generated or acquired expressing reporter genes, for example (but not</td>
</tr>
</tbody>
</table>
limited to) luciferase or fluorescent proteins.

Evaluation of foreseeable effects

The mutants generated will either be loss of function mutants or carry non-toxic reporter genes. It is not anticipated that bacterial strains produced in the laboratory are more virulent than strains that already exist in the environment. Indeed, many strains produced will have deletions in genes, which are required for optimal growth and virulence of the organism. Also, antibiotic resistance markers (carbenicillin, gentamycin, chloramphenicol, tetracycline, kanamycin and streptomycin markers) used in the laboratory do already exist in the host strains found in the environment and hence there is no risk of introducing new resistance genes to environmental strains.

Non GM Citrobacter rodentium is a murine pathogen and hazard group 1 in terms of pathogenicity to humans but once genetically modified it is included in this submission as a class 2 GMO under the terms of the GM contained use regulations because of the risk of infection to wild murine populations in the event of an accidental release. However it is not anticipated that any of the modified organisms will be more hazardous than wild type and as explained above many will be less virulent.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid Waste: Tissue culture waste will be soaked in 1% (final concentration) Trigene / Distel solution for 30 minutes before disposal down the sink. Alternatively Virkon (minimum 1% final concentration) can be used.

Solid Waste: Plasticware including all tips, flasks, plates and pipettes used to handle biological samples are placed either in biobins, or directly into autoclave bags. All Solid waste in contact with cells/tissue will be autoclaved at 121°C for 30 minutes (cycle 3 mixed waste) total running time 1hr 30mins.

Please enter comments on the GM safety committee on the risk assessment
Following the discussion of your proposal entitled "Immunology of bacterial infection of the lungs", GMIC-2393 at the last GM Safety Committee meeting, the Committee request that the following amendments are made to the proposal prior to approval:

<table>
<thead>
<tr>
<th>Amendment</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.3</td>
<td>Room numbers for the 4th floor labs? These will need to be inspected by Safety Dept before work starts. Done</td>
</tr>
<tr>
<td>2.2</td>
<td>First line states Animal tissues. The rest of the statement lists human cell lines. Please make it more clear what tissues and cell lines are in use. It is important that the risk assessment sets the limits of the work. While some statements might be generic about types of cell line (especially where there are too many to list) it must be clear that they are all of the same type or risk group. Have increased information about the cells/ tissues, have also included PBMC. Have stated that the cells/ tissues will not be greater than CL2.</td>
</tr>
<tr>
<td>2.15</td>
<td>It is important that the risk assessment sets the limits for the work. It may be acceptable to have generic statements about the host strains but the limits must be clearly stated for example regarding MRSA you might want to mention that no strain used will be toxin producing, if this is the case then this must be stated in the risk assessment in this section. Will you be using clinical isolates or long term lab strains? It is worth stating which early on in the risk assessment. See response to comments below, have put both and said they are well characterised rather than lab adapted strains. Please state the ACDP bio Hazard group for each organism (2 by the look of it) done.</td>
</tr>
<tr>
<td>2.16</td>
<td>Vector and plasmid names please, if the list is too long please give some examples and set the limits of the work, e.g. Stating that they are non mobilizable, replication incompetent etc. Done.</td>
</tr>
<tr>
<td>2.17</td>
<td>Please give some examples of the types of genes you will be deleting. Also make sure that you mention all the types of genes you will be altering. Your current statement just says &quot;including&quot; and then lists some generic areas of functionality. Have put in a few examples, but still would like it to be broad. Also put a statement in 2.14 to the effect that if increased pathogenicity observed strains will be destroyed and that known increases will not be made. Again it is important that the limits are set. For example you may wish to state that no genes will be targeted whose deletion might lead to an increase in virulence, host range or pathogenicity. Done in 2.14 and stated we will not overexpress toxins.</td>
</tr>
<tr>
<td>5.1</td>
<td>Will you use an MSC at any stage other than cleaning up in the event of a rotor spill? Yes You identify several aerosol risks. Item 1. Substitute should for must. Done Item 2 Why use flip top tubes? If it is practicil to do so, why not remove the hazard and use screw top with an O ring.</td>
</tr>
</tbody>
</table>

02/03/2022
seal? This also reduces the risk of aerosol from leaks during centrifugation Done.

Item 3 How will you tell if there is a leak? Have put after an imbalance

After discussion all the above will be performed in an MSC

5.2 So material is always transported in the lab in conical screw cap flasks? Never in multi well plates, eppendrors, or petri dishes? This looks like the answer to a different question.

It was, have changed it to say: When moved within the lab, material with a liquid component will be moved in falcon tubes with sealed screw caps in tube racks or in flasks with screw cap lids.

Cultured biological material will be transferred from incubators to MSC in sealed vented flasks or plates with lids in secondary containers in the same laboratory. Petri dishes will be sealed with parafilm after incubation.

5.2 – how will this be contained in transport. See above

5.3 – add the term double contained? Done

5.6 Room number for the –80 lab. Done 463

-VOLUME OF STOCKS AND STORAGE CONTAINERS (BOTH PRIMARY/SECONDARY CONTAINERS)? Biological agents may be stored as glycerol stocks at -80 in lab 463. 2 aliquots of 1ml stored in cryovials will be stored per strain. The cryovials are stored in plastic lidded boxes.

5.7 Will rotors always be opened in the MSC? Is this practical for the fixed angle rotors? For swing out rotors with larger volumes (e.g. 50ml or 15ml falcons) the buckets will be opened in MSC. For fixed angled rotors, these will be opened on the bench or in the centrifuge.

Remove the term tissue culture cabinet and replace with microbiological safety cabinet or MSC. This applies to all uses of the term tissue culture cabinet.

Why 2% virkon but only 1% Trigene? Any spill will dilute this to less than 1% and below the manufacturers recommended minimum effective concentration. Changed to 2% throughout.

– First paragraph looks like the answer to the incubator question- have removed this and put in incubator section

- How are the flasks sealed? Screw cap. Tissue paper will not be a good secondary container in a spill.

5.10 Where are the animals infected with the bacteria, in cbs? In an MSC? Yes

5.10 - yes and no? Which is it? Yes

5.13 Any lone working? Should be as per the FoMed Lone Working Policy. Done

6.5 Use of Eye protection while working with P. aeruginosa at all times needs to be emphasised. (college has had several eye splash incidents) Put in 5.1and re-emphasised in 6.5

7.1 Virkon 2% is this diluted to 1% final concentration with waste liquid? Yes

7.2 – incomplete answer, need to answer the first question. Hopefully it is yes, Yes

8.1 MSC – KI once per year, airflow checks using a 100mm vane anemometer twice per year by an engineer and monthly by the operators where the MSC is used to provide operator protection. Added

-shaking incubator maintenance? Annual
9.1 – is competency assessed? Yes, put by me
10. Remove the term tissue culture cabinet and replace with microbiological safety cabinet or MSC. This applies to all uses of the term tissue culture cabinet.
Why 2% virkon but only 1% Trigene? Any spill will dilute this to less than 1% and below the manufacturers recommended minimum effective concentration. Changed throughout
13 Is all the work only carried out in one lab? Section 1.3 seems to indicate more labs are in use but does not list them. Done
14 Please complete this section. It is Class 2. Done
Comments: JT gave a brief description of the work. MS suggested building in a proviso to the risk assessment that no knockouts will be conducted that will knowingly increase virulence. Added
PF advised giving a few examples of the altered genes in 2.17. Added: 1. Deletion mutants. Mutants will be generated or acquired with deletions of genes in areas including those involved in modulation of the host immune response e.g. Pseudomonas PiA, S. aureus IEC; Chp, Sak, Sc, virulence factors including Pseudomonas AprA, Cif, and normal metabolic function, these include Pseudomonas gltK, Edd, Opr or antigenicity e.g. nTH protein D. Complementation studies may be performed to recover function.
PF Increased pathogenicity….Have mentioned this will not be done
PL suggested adding that Toxins will not be over-expressed, this should be mentioned in the form to set boundaries. He also recommended the mariner based transposon system for future collaborations with his group. Done
MS asked if the consequences of co-infections had been addressed and to give this some thought. Co-infections unlikely due to viral work occurring in MSC and bacterial work on bench.
PL Remove the term 'Lab adapted' and change to 'widely used' or 'well characterised' Done in 2.10 and 2.11
IH advised adding the current room numbers to the form and when moved to new location; a Form C can be completed to update. Done
PL pointed out that the statement about markers used for making mutants, should state "genes conferring resistance to antibiotics used to treat clinical infections will not be used as markers". Done
IH recommended adding the phrase to the hosts, "not using toxin producing strains." Also, to provide some examples for the vectors.
TN to check the formulations of distell. Trigene highly effective against strains described <log5 reduction at 1:200
IH suggested defining at what point in the experiment would the work be carried out in the MSC. I have put in 5.1 that work will be performed on the bench.
PL queried if JT had worked with the MRSA strain on the bench.
JT confirmed he had in the past, but not at ICL.
PL advised change the word ‘should’ to ‘must’ in 5.1 Done
Agreed: Class 2, Containment Level 2. This project is notifiable to the HSE.

02/03/2022
The aim of this project is to utilize a replication incompetent adenoviral vector to express inserted genes to elicit immune responses to the inserted gene products. The vectors under development will be based on the adenovirus family of respiratory viruses. Serotypes expected to be used include the Ad2, 4 and 5. All will be replication incompetent. Any serotype utilized will be gene E1a, E1b and E3 deleted, thereby preventing the replication of the adenovirus after cell entry. The adenoviral life cycle does not normally involve integration into the host genome, rather they replicate as episomal elements in the nucleus of the host cell and consequently there is no risk of insertional mutagenesis.

Unmodified Ad5 is classified in hazard group 2 under the COSHH regulations but the E1a gene deleted forms are classified as hazard group 1. Although recombination with an unmodified virus in vivo is a possibility the further deletion of the E3 gene renders it extremely unlikely that even in the event of such a rare recombination occurring that the recombinant will be packaged with viral coat proteins and secreted from the cell.

Host/vector system

Cells used to propagate the recombinant adenoviruses are 293 cells. These are human embryonic kidney cells that have been transformed with the adenovirus genes E1A.
and E1B, which are required for adenovirus propagation.

Origin & function

The genetic material to be inserted will be encode HIV proteins or natural murine cytokine proteins. In the case of murine derived genetic material, RNA will be isolated, first strand cDNA prepared and primers specific for the gene in question will be used in a polymerase chain reaction to amplify the target sequence. This material will then be inserted into the E3 region of the gene deleted adenoviruses. The selected genetic material will generally constitute an open reading frame of a particular protein that we expect to be fully transcribed using the host cell transcription machinery. Translation of the resulting RNA transcripts into fully functional murine protein is expected. We intend to use these expression vectors to produce physiologically relevant quantities of the murine proteins in vivo in the mouse. These proteins are expected to have various degrees of immuno-modulatory activity, although it is expected, based on current literature, that most will have no detectable effect.

HIV genetic material will be derived from current plasmid vectors that contain small parts of the HIV genome. This material can be sub-cloned from these plasmid vectors and inserted into the E3 region of the gene deleted replication incompetent adenoviral vector.

All the inserts that will be incorporated into the gene deleted adenoviral vector will not have any known oncogenic potential.

Evaluation of foreseeable effects

The adenoviral life cycle does not normally involve integration into the host genome, rather they replicate as episomal elements in the nucleus of the host cell and consequently there is no risk of insertional mutagenesis. Unmodified Ad5 is classified in hazard group 2 under the COSHH regulations but the E1a gene deleted forms are classified as hazard group 1. Although recombination with an unmodified virus in vivo is a possibility the further deletion of the E3 gene renders it extremely unlikely that even in the event of such a rare recombination the recombinant will be packaged with viral coat proteins and secreted from the cell. When injected into mice it is possible that the gene-deleted adenoviruses may come into contact in vivo with endogenous murine viruses. While it is extremely unlikely that these replication-deficient gene-deleted viruses will be transcomplimented by any known murine virus, we will utilise specific-pathogen free mice that do not harbour murine viruses of the papovaoviridae genus that contain both murine polyomaviruses as well as human papillomaviruses.

The adenovirus vaccine vector itself will consist of E1a and E3 gene deleted adenovirus and an insert consisting of a DNA sequence encoding for small parts of the HIV genome. Typically, the vaccine vector contains a DNA sequence that encodes individual viral proteins such as the env (structural envelope glycoprotein), gag (matrix and capsid structural protein), rev (regulator of viral protein expression) or tat (regulator of HIV genome transcription) molecules. These small parts of the virus are expressed in such a manner that the essential minimal components of an infectious retroviral particle will not be present, particularly the intact HIV/SIV viral genome, thus preventing any possibility of inadvertently generating an infectious viral particle. There is no perceivable risk inherent in these proteins.

Other inserted cDNA, that will encode for natural, non-modified, mouse proteins will belong to the murine cytokine/chemokine family of secreted proteins. Other insertions may include proteins that have been shown to stimulate the innate immune system, including those that act at the cell surface as well as internal cytoplasmic proteins. These proteins have not been described to have oncogenic attributes in the published literature and are indeed non-modified and identical to those proteins expressed by normal murine cells. The proteins expressed from these constructs have between 30 and 70% identity with the corresponding human cytokine. However, most are not active or have only partial activity on human cells (COPE cytokine Database).

It is not expected that any of the insertions detailed will have an effect on the tissue tropism. However, the deletion of E3 has been shown to increase the immune response due to less down-regulation of the host cell MHC Class 1. The addition of cytokine insertions may also increase the immune response. As these effects are the precise criteria under investigation in our studies, it is impossible to predict the effects of augmentation of the immune response. It is possible that the resulting inflammatory response will be harmful. However, none of the insertions will be human genes, although murine cytokine/chemokine products may have some activity upon human cells. (COPE Cytokine Database).

Evaluation of foreseeable effects

We do not intend to use any GM animals or plants.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

In view of the fact that all adenoviruses used will be replication incompetent but may have undetermined pathogenicity by virtue of the gene insert, it is appropriate for all manipulations involving this virus to be undertaken within a microbiological safety cabinet. It is expected that all large scale work with these GMOs will be done in a dedicated Category 3 facility, that has an autoclave within the lab. Small scale work (less than 100ml) may also be done within a microbiological safety cabinet in a category 2 laboratory. Liquid culture waste in both circumstances will initially be aspirated within the microbiological safety cabinet into a leak-proof container with Virkon S solution. The concentration of Virkon S will be maintained at greater than 1% - a concentration that has been validated as 100% virucidal for adenoviruses as well as most other viruses. Moreover, all waste materials (solid and Virkon S treated liquid) will be autoclaved in an autoclave maintained and appropriately certified to properly inactivate infectious waste. Autoclaved material is considered to be 100% effective at sterilization. The extra precaution of performing large scale preparative work in a category 3 laboratory with an internal autoclave ensures that large volumes of Virkon S treated culture solutions (which although almost certain to be 100% killed should be treated as potentially infectious material) cannot come into contact with other laboratory staff or any non-laboratory personnel. Any small volumes of culture performed in category will be treated with the Virkon S virucide and then contained within a leak-proof container for transport to the autoclave.

Any new staff would be specifically trained in the safety aspects of this work. Since the gene deleted replication incompetent virus is transmissible by an airborne route an inward microbiological cabinet airflow would be required.

The work involves standard laboratory protocols and there are no unusual procedures that require additional containment measures.

All work with these adenoviruses will be performed within a certified category 2 or 3 laboratory.

Mice injected with the replication-deficient gene-deleted recombinant adenoviruses will be maintained within isolators. All injections and handling of these animals after injection with the recombinant adenoviruses will be carried out entirely within a microbiological class 1 cabinet. Cells, blood and tissues harvested from these animals prior to schedule 1 euthanasia as well as post-mortem will be transported from the microbiological class 1 cabinet within the animal facility to a microbiological class 11 cabinet in our class II laboratory entirely sealed within a biohazard container. The exterior of the biohazard container will be sprayed with liquid Virkon disinfectant prior to removal from the microbiological class II cabinet to ensure no GMOs survive on the exterior of the container. Post-mortem, both the mouse carcass and the cage in which the mice lived will be autoclaved in an autoclave maintained and appropriately certified to properly inactivate infectious waste. Autoclaved material is considered to be 100% effective at sterilisation. The sterilized bedding contents of the cage and the mice carcasses will then be incinerated. The isolators that contained the cages will be fumigated.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

The risk assessment has been reviewed and approved by the St George's Hospital Medical School GMSC.

02/03/2022
**Project Ref** 79/01.1

**CU2 Project Title**
INVESTIGATION OF THE ROLE OF MOLECULES INVOLVED WITH CELL FATE DECISIONS

**Date Ackn’d**
11/01/2001

**Date Project Ceased**
10/09/2004

** Consent Granted**
not applicable

**Historical Significant Changes**
Gm 79/01.1 transferred to GM 541

**Recipient or parental organism**
1) Primary cells of mammalian original.
2) Immortalised cell lines.

**Host/vector system**
1) Retroviral vectors such as PMX and pMSCV (see attached risk assessment)
2) Packaging cell lines such as phoenix

**Purposes of the contained use**
To generate retroviral particles containing DNA sequences of molecules involved with cell fate decisions. To use these retroviruses to transfect mammalian primary or immortalised cells.

**Historical Date of Additional Info**
Gm 79/01.1 transferred to GM 541
Expression of retroviral vectors in packaging cell lines will generate replication-defective viruses. Once these viral particles have been used to transfect recipient cells, supernatants from these cells will be screened for the presence of infectious virus.

Origin & function

cDNA of mammalian origin coding for molecules involved with cell fate decisions
Including: notch molecules 1-4
  notch ligands jagged 1/2, delta
  notch signalling molecules delta, csl
  notch modulatory molecules - the fringe family
  mutant forms of the above molecules

Notch molecules are thought to be involved with cell fate decisions in the presence of certain cytokines, notch delays differentiation and promotes the proliferation of primitive cell types. Notch 1 is a known oncogene and truncated, constitutively active forms of notch 1 have been found in T lymphoblastic neoplasms. Molecules which potentiate notch signalling may be expected to delay differentiation also.

Evaluation of foreseeable effects

Following retroviral transfection, cells will be monitored for the presence of infectious retroviral particles on a regular basis. Once it has been established that no infectious particles are generated by host (or recipient) cells, then transfected cells will be used for experimentation. Primary cells are routinely screened for the presence of infectious agents to reduce the risk of co-infection with more than one retrovirus. Primary cells will not be used from lab workers or their family members to the risk of engraftment of transfected cells likely routes of transmission of replication-deficient virus include aerosols and sharps injuries. See attached risk assessment. Accidental inoculation with replication-deficient virus is likely to result in the destruction of virus by the host immune system and therefore long-term injury is unlikely. Experimental waste containing virus particles and transfected cells will be autoclaved to minimise any foreseeable environmental effects.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

See section 7. Analysis of transfected cells will be performed under category 1 conditions only when the absence of infectious viral particles has been established.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Packaging cell lines, cell culture supernatants containing retroviral particles and transfected target cells will be treated with 1% virkon solution which will destroy any retrovirus or retroviral containing cells. (A 0.05% virkon solution is sufficient for retroviral destruction according to the manufacturer). Solid waste is also treated with 1% virkon solution for a minimum of 1 hour. Both liquid and solid waste is autoclaved in order to ensure a 100% kill of GM material. Departmental autoclaves are serviced annually using a thermocouple. Refer to attached virkon data sheet for further information.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The local GMSC considered that the work using retroviral vectors required containment level 2 because of the potential oncogenic properties of the inserts. Other aspects of the project e.g. construction of plasmids in disabled Ecoli K12 strains have been assessed separately by the GMSC.

### Historical Significant Changes

- **Historical Date of Additional Info**: GM 79/01.2 transferred to GM 541

### Project Additional Information

**Purposes of the contained use**

The folate pathway is an essential but complex metabolic pathway in malaria parasites that is involved in DNA synthesis and amino-acid conversion. We have identified and characterised most of the genes involved in this pathway and now aim to investigate the individual roles of these genes by transformation experiments. This will encompass experiments where individual genes are disabled, to assess whether their activities are mandatory for survival, and experiments where certain of these genes are modified, to assess the role of naturally occurring polymorphisms in a controlled genetic background. We have evidence that different parasite lines differ in their ability
To make use of preformed folate from the host, and transformation provides a powerful route to investigate such a difference. This has been demonstrated in other laboratories where transformation is now routinely used to investigate basic questions about the biology of the parasite.

Recipient or parental organism

Laboratory strains of Plasmodium falciparum that have been in vitro culture for many years, both in this and numerous other laboratories will be used. The genetic modification introduced by transformation will render them more resistant to the drugs pyrimethamine, neomycin or blasticidin (used as the plasmid markers), but will have no effect on their susceptibility to a range of antimalarial drugs currently in clinical use. The risk of laboratory infection is extremely low, but such drugs will be able to clear infection rapidly. The targeted gene modifications in the folate pathway are likely to reduce their general viability relative to the untransformed host, or leave it unaffected. The modifications will not alter host specificity.

Host/vector system

The plasmid vectors to be used are derived from the commercially available pBluescript and pGEM series of E. coli vectors. These vectors are modified to include the necessary elements for targeting the genes of interest and introduced via electroporation. They are maintained by selection using the drugs mentioned above. If such selection is removed, plasmids are lost, unless integration has occurred at the target gene locus.

Origin & function

1. Plasmid sequences plus partial sequences of target P. falciparum folate pathway genes designed to disrupt the corresponding gene of the recipient cell.
2. Plasmid sequences plus sequences of target P. falciparum genes designed to alter the target gene at known polymorphic loci.
3. Plasmid sequences plus putative promoter regions of P. falciparum designed to test the effect of possible varying levels of expression on folate gene products.
4. Plasmid sequences that carry reporter activities such as Green Fluorescent Protein (GFP) or Chloramphenicol Acetyltransferase (CAT) to rapidly test for successful transformation.

All plasmids are constructed via cloning in standard disabled E.coli hosts (principally XL1-Blue, Stratagene)

Evaluation of foreseeable effects

No new potential hazards are identified as a result of the genetic modification. As with untransformed P. falciparum, the only route for transmission to humans will remain as direct inoculation into the bloodstream of the operator. The natural route of infection, via the bite of the Anopheles mosquito, is excluded by the complete absence of the latter from the working environment (mosquitoes are not bred in this Institute). Even if such a mosquito were present, it could not feed from culture flasks. Moreover, it would be unable to ingest sexual forms of the parasite for onward reproduction and transmission of the parasite, as only asexual forms will be cultured. Airborne contamination, e.g. by aerosol spread from cultures, is also not a risk with this organism, and there is no possible person to person transmission. Viability of these organisms for experimental purposes is totally dependent upon careful maintenance of stringent laboratory culture conditions and there is no known or foreseeable risk to the environment, as the parasite cannot survive in any environment outside of the tissue culture medium and the narrowly confined parameters of temperature, pH, and gas atmosphere (5% CO/5% O/90% N).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We request derogation from full Class 3 containment because the Risk Assessment indicates that the following features of level 3 containment are not required, given the absence of an airborne contamination risk when working with this organism - see section 2 (Growth and propagation of the parasite); 3 (Assessment of risks to human health), and 4 (Assessment of risk to the environment), of the Risk Assessment.

1. Fumigation, and thus a sealable laboratory.
2. Airlock entry to the laboratory.
3. Negative pressure relative to the surrounding laboratories, and HEPA filtered air extract.
4. Autoclave in the culture facility. Biological material is completely killed by verified disinfection procedures before removal from the facility in sealed plastic boxes. These
are transported directly to the nearby Departmental Autoclaving suite and the material sterilised in situ.

5. Specific measures to control aerosol dissemination.

6. Shower within the culture facility.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1) Parasite microscope slides are treated with methanol + flaming before staining with dye (also in methanol) and viewing, rendering material on the slide harmless. After use, the slide are routinely treated with bleach (Chloros, in appropriate dilution) before disposal and areas such as the microscope stage are wiped with 70% ethanol after use.

2) Disposal of solid culture materials (plastic pipettes/tips/tubes/tissue culture flasks) is by placing the items in a separate labelled double biohazard bag kept in the tissue culture room which is subsequently directly removed from autoclaving. In the case of liquid waste (culture supernatants and residual cells), treatment is for 16-24hrs in a solution of bleach (Chloros) dilute to a final volume containing 10% free chlorine (1:3 v/v) before disposal. The container is then placed for autoclaving. Spills for infected material must be attended to immediately. The volume is reduced by use of dry paper towels (which must be placed for autoclaving) followed by treatment of the affected area with diluted (1:3 v/v) Chloros bleach followed by a wipe with paper towel soaked in 70% ethanol. The latter is important, as bleach is detrimental to many surfaces including stainless steel; for such surfaces, Virkon disinfectant can be used in place of the bleach, either as a solution or as powder.

3) Degree of kill: the parasite is an extremely fastidious organism entirely dependant for viability upon careful maintenance within host red blood cells in a stringent tissue culture medium under the atmosphere of a special gas mix. Lysis of the red cells, removal of the medium, exposure to normal air (as opposed to the 5% CO/5% O mix needed for culture), increase in temperature above approx. 39C, small changes in pH away from physiological, all lead to parasite death within a very short time. As established in microscopy, Chloros lyses all host cell within a short period, penetrating the parasites and killing them 100%. It is not possible to restore a viable culture from infected red cells treated in this way. Autoclaving also kills the parasite 100%. Autoclaving is carried out in our central sterilising facility in equipment employing data logging of all autoclaving cycles. The autoclaves are also checked regularly by internal indicator tablets included in the items for disposal that confirm the proper length and temperature of the cycle. In addition, thermocouple tests of appropriate loads are carried out as part of the annual autoclave service that is carried out by the manufacturer.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

This project has been considered by the UMIST GMSC. The Committee believes that the containment measures and working practices described in the Risk Assessment are appropriate for this work on Plasmodium falciparum.

Animal Units Large Scale Activities Human Clinical Applications

02/03/2022
Project Additional Information

**Purposes of the contained use**

The application covers a range of specific projects with the overall goal to study the regulation and mechanisms of cell wall biosynthesis and its role in yeast-hypha morphogenesis of Candida albicans.

More specific goals:
1. Role of glycosylation
2. Role of the Ras/cAMP-dependent pathway
3. Role of specific O- and N-clycosylation enzymes in cell wall structure and adhesion

**Recipient or parental organism**

Recipient organisms include:
1. *E. coli* - many multiply disabled K12 derivatives
2. *S. cerevisiae* - many multiply disabled, non-pathogenic S288C derivatives
3. *C. albicans* (CA14, ura3; CA18, ura3 ade2 abd derivatives of these strains with further disabling markers (eg. glycosylation enzymes, components of the Ras/cAMP-dependent pathway).

**Host/vector system**

Vectors include:
1. Many non-mobilisable *E. coli* vectors (including pUC 18/19, pBLUESCRIPT, lac-based expression plasmids such as pET vectors)
**2/ Many non-mobilisable \textit{S.cerevisiae} vectors (including YEps, YCps, YIps and single-copy GAL-based expression vectors)**

**3/ Specific non-mobilisable \textit{C. albicans} vectors (single-copy integrating vectors PMB7, pDDB57, integrating expression vectors regulated by methionine pEXPa)**

**Origin & function**

The genetic materials in the modifications are all derived from naturally occurring organisms of \textit{E. coli}, \textit{S. cerevisiae} and \textit{C. albicans}. More specific Candida genes include:

1/ Glycosylation genes (eg. \textit{CaSRB1}, \textit{PMT1}, \textit{PMT2}, \textit{MNN1}, 2, 3, and 4)
2/ Regulated promoters (\textit{MET3}, \textit{MAL2})
3/ Auxotrophic markers (\textit{URA3}, \textit{ADE2}, \textit{LYS2})
4/ Components of the Ras/cAMP-dependent pathway (\textit{PDE1}, \textit{PDE2}, \textit{TPK1}, 2, 3, \textit{BCY1})
5/ \textit{Candida} genomic and cDNA libraries

**Evaluation of foreseeable effects**

\textit{Candida albicans} is a human pathogen in hazard group 2. \textit{Candida albicans} causes superficial infections of mucosal epithelia (thrush). However, at no time in the last 20 years since work with \textit{Candida} began, has a member of any lab had a thrush infection caused by a lab strain. \textit{C. albicans} also causes infections in severely immunocompromised patients and these can be fatal. However, it is important to remember that \textit{C. albicans} is widely distributed, being carried by over half of the population. It rarely affects healthy individuals. IOT only becomes a potential medical problem when the immune system of an individual is impaired. Furthermore, as with most pathogenic microorganisms, the virulence of \textit{Candida albicans} strains is likely to become attenuated rather than enhanced after prolonged laboratory culturing.

The strain \textit{Candida albicans} CA1-4 (\textit{ura3}) is the standard host for DNA transformation worldwide. Its uridine auxotrophy makes it avirulent (Leberer et al. 1996, PNAS, 93, 13217). Transformation with \textit{URA3} plasmids partially restores the virulence of CA1-4, but the restoration is not complete because the genes neighbouring \textit{URA3} remain inactivated. The \textit{URA3} marker is recycled for subsequent rounds of transformation (Fonzi and Irwin, 1993, Genetics, 134, 717). Therefore by necessity, some of the transformants we create are not genetically disabled, although their virulence is lower than the wild-type strains of \textit{C. albicans} carried by most individuals.

\textit{C. albicans} CA1-8 (\textit{ura3}, \textit{ade2}) is transformed with \textit{ADE2} or \textit{URA3} containing plasmids, leaving one remaining disabling mutation in the transformants. This is sufficient to render all of the transformants completely avirulent.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

We follow all safety guidelines for operation at containment level 2. Briefly:

All waste materials will be inactivated before disposal:

* liquid waste - autoclaving at 121 degrees C for 15 minutes (proven to effectively 100% kill fungal cells). The Department of Biomolecular sciences has two large autoclaves, one of which is to be replaced in January 2001. The next thermocouple tests will be carried out on both autoclaves when the engineers are in the department to install the new autoclave. The autoclaves have always been serviced annually by BMM Weston/Drayton Castle, thermocouple testing of various loads of waste is to be included in the annual service contract. The new autoclave will have a data logging system, the old autoclave has a chart recorder to monitor the conditions. Autoclave indicating rubes are placed in bins of contaminated materials each week.

* glass ware - soaked with Virkon (see attached information provided by the manufacturer) proven to effectively 100% kill fungal cells)

* plasticware - autoclaved under the conditions shown above. Before inactivation, plastics will be double-bagged for transport to autoclaves

* sharps will be minimised, but any contaminated sharps will be placed in separate CinBins, bagged and incinerated.
Once GMMs have been inactivated, normal routes of disposal will be used. These measures will reduce the likelihood of all hazards to negligible. The overall risk is therefore effectively zero with the proposed containment and control measures.

The UMIST GM safety committee has considered this project. The work with E. coli K12 and Saccharomyces cerevisiae is Class 1 but the Committee thought that the Candida albicans experiments required containment level 2 and were thus Class 2 activities.

Historical Significant Changes
### Project Additional Information

#### Purposes of the contained use

The application covers various specific projects which all have the overall aim of understanding the relationship between cellular proliferation and protein synthesis. More specific goals include an investigation of the control of translation initiation in response to stress as well as an analysis of downstream effects such as flocculence and colony morphology.

#### Recipient or parental organism

Recipient organisms include:

C. albicans - strains such as CA1-4 (ura3) and CA1-8 (ura3 ade2). These strains are standard lab strains with auxotrophic phenotypes and highly attenuated virulence. These strains cannot survive without media containing high concentrations of adenine and uracil, and given the stringent practices for autoclaving liquid and solid media prior to disposal in our institute, there is no possibility that these strains could escape into the environment.

#### Host/vector system

Vectors include:

Specific non-mobilisable C. albicans (single integrating vectors and integrating expression vectors regulated by methionine).

#### Origin & function

The genetic materials are all derived from naturally occurring organisms of E. coli, S. cerevisiae, and C. albicans. More specific Candida genes include:

1/ Protein synthetic genes (e.g. GCD1, GCD6, CDC33)
2/ mRNA decay genes (e.g. DCP1, CCR4)
3/ Auxotrophic markers (e.g. URA3, ADE2, LYS2)
4/ Candida genomic and cDNA libraries

These genes have homologues in all eukaryotic organisms. As a result there could be absolutely no effect of a gene transfer because the DNA sequences included in our constructs are part of the genomes of all known eukaryotic organisms.

#### Evaluation of foreseeable effects

Candida albicans is a human fungal pathogen in Hazard Group 2. It is a micro-organism of a very low pathogenic potential that very rarely affects healthy individuals. It becomes infectious, however, in severely immunocompromised patients like HIV positive individuals or organ transplant patients. Candida albicans can cause superficial infections of mucosal epithelia (thrush). However, in the 20 or more years that C. albicans has been studied in labs, there has never been a thrush infection caused by a laboratory derived strain. In fact the lab strain CA1-4 which is the standard lab strain worldwide is auxotrophic for uracil. This strain cannot therefore survive in the absence of high concentrations of uracil and this makes the strain avirulent. It might be anticipated that transformation of this strain with plasmids bearing the URA3 gene restores the virulence of CA1-4, but the strain is still severely disabled (e.g. Chen et al., 2004. Mol Microbiol. 51:551-65). The lab strain CA1-8 is auxotrophic for both uracil and adenine. Transformation of this strain therefore would only ever complement one of these auxotrophies, thus this is sufficient to render all transformed strains avirulent. Even though these strains are avirulent, the stringent practices for autoclaving liquid and solid cultures prior to disposal eliminates the possibility of strains escaping into the environment alive.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

NA

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

NA

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

We follow all safety guidelines for operation at containment level 2. Briefly:

- All waste materials will be inactivated prior to disposal.
- Liquid - autoclaving at 121 degrees centigrade for 15 minutes which has been proven to effectively kill 100% of fungal cells. The Department of Biomolecular Sciences has a large autoclave which replaced two autoclaves in January 2001. The autoclave is serviced annually by BMM Weston/Drayton Castle and thermocouple testing of various loads of waste is included in the annual service contract. The autoclave has a data logging system and autoclave indicator tubes are placed in bins of contaminated waste on a weekly basis.
- Glassware - soaked with 1% Virkon (see information provided by the manufacturer - proven to effectively kill fungal cells)
- Plasticware - autoclaved under the conditions described above. Before inactivation plastics will be double-bagged for transport to the autoclave.
- The use of sharps will be minimised, but any contaminated sharps will be placed in separate CinBins, bagged and incinerated.

Once GMMs have been inactivated, normal routes of disposal will be used. The proposed containment and control measures will eliminate the hazards, making the overall risk effectively zero (see risk assessment).

**Project Ref 173/04.1**

**Date Ackn’d**: 21/06/2007  
**CU2 Project Title**: Identification of genes conferring drug resistance to Ovarian cancer.

**Class**  
Class 2

**Culture Vol Class**  
< 1 Litre

**Non-GMM Consent Granted**  
Not Applicable

**Project notified under transitional arrangements**: N

**Withdrawn**: N

**Tick if notifying a connected programme of work**: N

**Historical Significant Changes**: PROJECT MOVED FROM GM 173 (21/6/07).

**Recipient or parental organism**

Commercially available replication-defective serotype V adenoviral expression system (eg Becton Dickson AdenoX system) lacking E1 and E3 genes.

HEK 293 cells which express E1 genes necessary for packaging the virus will be transfected with adenoviral DNA to generate a replication-defective adenovirus.

The virus will be used to infect primary cultures ovarian cancer and cancer cell lines.

**Origin & function**

Adenovirus as described above.
Adenovirus as described above.

**Evaluation of foreseeable effects**

No foreseeable effects are anticipated with the use of replication-defective adenovirus type V per se. Adenovirus type V is a common respiratory pathogen, and immunity in humans is believed to be lifelong. The parental virus is considered a class 1 agent.

Therefore, any hazard that arises will depend on the nature of the insert. The insert will be shRNA directed to genes identified through micro-array analysis of avarian cancers and the work to identify these genes is ongoing. A risk assessment will be conducted for each gene which we intend to knockdown, once the identity of the genes is known. However, since the genes identified by the microarray studies are expected to promote a malignant phenotype, interfering with their expression by RNAi is unlikely to promote malignancy. Nevertheless, we may chose to inhibit the expression of genes whose function is not fully understood and for which the effects are not wholly foreseeable.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not relevant.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Work will be conducted within a containment level 2 laboratory using a class 2 microbiological safety cabinet. Liquid waste will be treated with chloros at a final concentration of 3% for 12 hours prior to sterilisation by autoclave. Solid waste will be soaked in 10% chloros overnight. Both solid and liquid waste will be collected by the central sterile supplies department and sterilised by autoclave.

02/03/2022
The aim of the project is to use genetically engineered Lentiviruses to produce metastatic models that express a Luciferase marker enzyme and enable the tumours to be visualised in vivo. Cell signalling pathways that are involved in maintaining the metastatic phenotype will be

---

**Project Additional Information**

**Purposes of the contained use**

To prevent exposure of the workers to Class 2 GMM.

**Recipient or parental organism**

- E.Coli (recA)
- DH5 alpha
  
  A commonly used strain with a long history of safe use.

**Host/vector system**

The following plasmids will be utilised

- pFIV-34N
- PVSV-G
- pSIF1-H1-Puro™shRNA Expression Vector

**Origin & function**

Our intention is to introduce the luciferase gene into the appropriate established tumour cell lines using an Expression system based upon a Feline Immunodeficiency Virus (FIV) obtained from a commercial source (System Biosciences Inc). The FIV lentiviral expression systems circumvent the possible recombinant issues that normally arise with the use of HIV vectors. We also intend to use the FIV-based short hairpin RNA and double promoter – siRNA Cloning and Expression Vectors that will target selected...
gene sequences and enable us to produce stable tumour cell lines.

To create functional pseudoviral particles, the lentivector containing the expression construct is co-transfected with the packaging plasmids into the producer cell line. The packaging cells replicate the expression construct and package it into the pseudoviral particles. The pseudoviral particles will then be used to infect (or transduce) target cells and express effector or reporter molecules but cannot replicate within target cells because the viral structural genes are absent and the LTRs are designed to be self-inactivating upon transduction.

Following transduction into the target cells, the expression cassette is reverse transcribed and integrated into the genome of the target cell. After integration, the expression cassette continuously and stably produces high levels of effector or reporter molecules in target cells. Target cells stably expressing the effector molecule will be isolated using the selectable marker contained in the expression vector construct (e.g. puromycin or copGFP). The transduced cells will be assayed for gene breakdown or luciferase production using specific assays, immunoblotting or by flow cytometry. Infected cells will be assayed in vitro and in vivo to determine the effect of knock down or expressed genes on their metastatic potential.

The cell lines that will be transduced are all established human tumour cell lines either derived by the Tumour Biology and Metastasis Team or from ATCC. These will include MDAMB435 (breast), DU145 (prostate), MTSP 12-H (mesothelioma).

Evaluation of foreseeable effects

The feline immunodeficiency virus (FIV) was originally isolated from cat blood. Despite common close exposure of humans to FIV through contact with domestic cats (including bites, scratches, etc), no human infection or disease has ever been associated with FIV.

The lentiviral expression systems are made with a split-genome conditional packaging system which acts as a built in device against the generation of productive recombinants. The number of lentiviral genes necessary for packaging, replication and transduction is reduced to three (gag, pol, rev), and the corresponding proteins are expressed from different plasmids (for HIV-based packaging plasmids) lacking packaging signals and share no significant homology to any of the expression lentivectors, pVSV-G expression vector, or any other vector, to prevent generation of recombinant replication-competent virus. None of the HIV-1 genes (gag, pol, rev) will be present in the packaged viral genome, as they are expressed from packaging plasmids lacking packaging signal – therefore, the lentiviral particles generated are replication-incompetent.

The packaging plasmids are transfected into the 293TN producer Cell Line. In the unlikely event these cells were accidentally injected the risk of pathogenesis is very low due to the recognition of the cells by the immune system as being foreign.

A deletion in the enhancer of the U3 region of 3' LTR ensures self-inactivation of the lentiviral construct after transduction and integration into genomic DNA of the target cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Evaluation of foreseeable events:

The feline immunodeficiency virus (FIV) was originally isolated from cat blood. Despite common close exposure of humans to FIV through contact with domestic cats (including bites, scratches, etc), no human infection or disease has ever been associated with FIV.

The lentiviral expression system are made with a split-genome conditional packaging system which acts as a built in device against the generation of productive recombinants. The number of lentiviral genes necessary for packaging, replication and transduction is reduced to three (gag, pol, rev), and the corresponding proteins are expressed from different plasmids (for HIV-based packaging plasmids) lacking packaging signals and share no significant homology to any of the expression lentivectors, pVSV-G expression vector, or any other vector, to prevent generation of recombinant replication virus. None of the HIV-1 genes (gag, Pol, rev) will be present in the packaged viral genome, as they are expressed from packaging plasmids lacking packaging signal - therefore, the lentiviral particles generated are replication- incompetent. The packaging plasmids are transfected into the 293TN Producer Cell Line. In the unlikely event these cells were accidentally injected the risk of pathogenesis is very low.
due to the recognition of the cells by the immune system as being foreign. The infected human cells would be unlikely to be pathogenic due to rapid complement mediated lysis of these cells when recognized by the immune system as of non-self origin. Cells would not be shedding virus as they are replication-defective and therefore do not pose a risk to human health or the environment. In our risk assessment, the modified viruses should not pose a serious risk to the environment. These viruses are extremely unstable, inactivated by detergent, UV light and ethanol, and would not survive outside of the laboratory environment. Animals containing the previously infected human cells are safe to the environment as they would be unlikely to survive outside the laboratory because of their severe immune defect. There is no potential to transfer the GMO to other organisms outside of the experimentally manipulated procedures outlined.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Protective clothing and gloves will be worn at all times. All staff are trained in the good laboratory practise and are fully aware of the Institute local rules for containment level 2 laboratories. Work surfaces, including the inside of microbiological safety cabinets, will be suitably disinfected after use. Centrifugation will only be performed in sealed tubes to prevent aerosols. Sharps will not be used. Liquid waste, such as cell culture medium, which may contain virus or cells, will be rendered safe for disposal by overnight treatment with a QAC based disinfectant (Tresolin K). Plastic pipettes will be soaked in 5% Chloros prior to removal by CSSD. Solid waste will be placed in autoclave bags for collection by CSSD. Material collected by CSSD will be autoclaved on site. The cleaning, disinfecting and disposal procedures will be documented and displayed. The biological spillage procedure will be displayed and HAZ-TAB disinfectants will be available for immediate use. Supernatant will be collected and human tumour and epithelial cells will be exposed to the supernatant in conditions to promote infection. Virus preparation will be certified free of replication competent virus (see below). These cells will then be assayed in vitro and/or injected into animals to measure their oncogenic potential.

Once the lentivirus has infected the cells it should not be able to replicate. In order to test this we will plate NIH3T3 (murine) or ECV304 (Human) cells into 6 well plates (5x104/well). Next day we will add 1ml of either fresh or frozen (-70°C) viral supernatant (supernatant 1) (Vector+gene+GFP) plus 2g of polybrene (8mg/ml stock) and incubate overnight. The following day the cells are washed with medium and replaced with fresh medium. After 24 to 48 hours the infectivity will be assessed by assaying the % positive GFP cells. The cells will grow for a further 4 to 6 days (splitting cells if necessary) and overnight supernatant harvested (supernatant 2) from confluent cells. This will allow amplification of the virus.

Plate NIH3T3 or ECV304 cells in a 6 well plate (5x104/well) and leave overnight. Add supernatant 2 plus polybrene as before. In addition include as a positive control supernatant 1 plus polybrene. Wash cells next day and add fresh

Is an emergency plan required according to regulation 20? N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Question: why are NIH3T3 or EC304 cells being used for the viral activity assay? Are these the cell lines in which studies will be performed?

I thought human tumour cell lines were going to be used for these studies in which case shouldn’t these be the cell lines tested for viral activity?

Answer:
Your assumption is correct that no viral particles should be present. This assay is about ensuring that any viral particles there would be detected. I understand that these cell lines are highly sensitive to infection by any virus. DH5 α

It is not clear to me from the proposal what their animal models or the cell lines actually are.

I am only being vague on this issue because we have many animal models and cell lines that we hope to use and I don't wish to be limited by naming just a few.

Initially there will be MDA MB435 (breast), DU145 (prostate), MSTO 12-H (mesothelioma)

The work is categorised as containment level 2 and yet there are not any level 2 labs in the McElwain.

The proposed laboratory (room 019) has been inspected by members of ICR's Health and Safety and has been

| Recipient or parental organism | HSV1 vectors deleted for ICP34.5 (neurovirulence factor) and ICP47 have been engineered to express human GM-CSF and/or TNF-alpha. These vectors are designed to replicate in tumours but not surrounding tissues (considerable literature demonstrates such a phenotype for HSV1 and 2 ICP34.5 and ICP47 deleted viruses) with the additional delivery of immunostimulatory and/or radiosensitising factors. Each of the deletions in ICP34.5 and ICP47 has been shown individually to generate a non-pathogenic, though still replication competent virus. |

<table>

| Please enter comments on the GM safety committee on the risk assessment | The GMSC opinion is that the viruses to be used are probably Class 1, although as risks are low, Class 1 could be considered appropriate. |
THE USE OF SPECIFICALLY DESIGNED SMALL INTERFERING RNA (SIRNA) AGAINST GENES AND ANALYSIS OF THE EFFECTS THESE HAVE ON CELLULAR PHENOTYPE.

Recipient or parental organism

Split-genome MLV-based systems (eg. Cosset, F.L. et al., J Virol. 69: 7430-6 (1995)) or lentiviral-based systems (eg. Ikeda, Y. et al., Nat Biotechnol. 21: 569-72 (2003)) to generate non-replication competent virus. These enable virus to be harvested from the supernatant of these cells in a safe and well characterised manner which can then be used to infect cells in order to get stable expression of a packaged transgene.
Host/vector system

Murine Leukaemia Virus and Human Immunodeficiency Virus - based systems.

Origin & function

The inserted genetic material will typically be of the form of the pSUPER system that delivers an siRNA-like transcript which forms a 19-base pair stem-loop structure in order to knock-down gene expression (Brummelkamp, T.R. et al., Science 296: 550-3). These will be specifically designed against a gene of from a library of 8000 siRNA vectors being widely distributed throughout the UK under the auspices of Cancer Research UK.

Evaluation of foreseeable effects

Both types of virus will be produced from split-genome packaging cells whereby the components required for virus for production have been split onto 3 separate plasmids to prevent recombination and generation of replication competent virus. The generated viruses will only have packaged the gene of interest and their tropism will be largely defined by the envelope protein expressed in the packaging cell line. For ecotropic virus this will only enable infection of rodent cells whilst the host range for amphotropic virus includes human cells.

MLV is a type-C retrovirus and none of this class have been shown to have pathogenicity in humans. HIV leads to acquired immune deficiency syndrome (AIDS). However components of the human immunodeficiency virus, which are used in the lentiviral cells, will not lead to the generation of replication competent virus. Both are unlikely to survive outside of the laboratory, where suitable growth conditions are provided.

The normal transmission route of retro and lenti viruses is either by injection or exchange of bodily fluids so rapidly degrade once outside the body. Should the packaging cells be accidentally injected, the risk of pathogenicity is very low in an immunocompetent individual due to the recognition of the cells as foreign and the subsequent induced complement mediated lysis. However only plastic disposable ware will be used, with no sharps or needles being required.

siRNA will be generated to a large number of specific targets and per se these small inserts and transcripts provide little hazard. However the targets are likely to be wide ranging and may include a range of different classes of targets in order to screen many genes as possible targets.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Work within the containment level 2 laboratory will be conducted using a class II microbiological safety cabinet. Liquid wastes, such as cell culture medium, which may contain virus or cells, will be rendered safe for disposal by overnight treatment with a QAC based disinfectant. Pipette tips, simplettes etc will be similarly soaked in disinfectant and the tips collected for disposal in solid bins by CSSD. These measures provide at least 4 magnitudes of protection against retrovirus whilst the cells are effectively killed. Plastic pipettes will be soaked in 5% Chloros prior to removal by CSSD. Material collected by CSSD will be autoclaved on site.

1. Lentiviral-based systems (eg Ikeda, Y., et al, Nat Biotechnol 21:569-72 (2003) will be used to generate non-replication competent virus. These systems enable virus to be harvested from cell supernatant in a safe and well-characterised manner which can then be used to infect cells in order to get stable expression of a packaged...
transgene.

ii). MoLV production: Viral supernatant will be made from the cell line Moloney NIH3T3 clone 4. Supernatant will be harvested from these cells and used to infect neonatal mice.

Host/vector system

I) Human Immunodeficiency virus-based systems.

ii) Wild-type MoLV

Origin & function

I) Vectors: Lentiviral vectors will be HIV-derived and replication defective. For siRNA expression, we plan to use pSico (Ventura et al (2004) Proc Nat Acad Scu USA 101:10380-10385) or similar vectors, and for cDNA expression, the LV series of vectors (Pfeifer et al (2002) Proc Nat Acad Sci USA 99:2140-2145) or similar. All vectors are replication defective and are self-inactivating as they contain mutations resulting in deletion of the LTR promoter. No vectors contain the WPRE sequence.

ii) shRNA inserts: shRNAs generated against a large number of targets in the human or mouse genome will either be introduced as a library (eg Paddison et al (2004) Nature 428:427-431), or as individual sequences. They will be used to achieve knockdown of endogenous cellular genes.

iii) Other inserts: cDNAs or mutants thereof encoding a large number of genes will be individually introduced to explore the effects of their expression on cell phenotype. Inserts are likely to include genes involved in cell cycle control, differentiation, apoptosis and control of cell movement.

iv) Wild-type MoLV will be used as an insertional mutagen to infect neonatal mice for studies on cooperation between different oncogenes.

Evaluation of foreseeable effects

Lentiviral work: All virus will be produced from split genome packaging cells whereby the components required for virus production have been split onto separate plasmids to prevent recombination and generation of replication competent virus. The generated viruses will only have packaged the gene of interest and their tropism will be largely defined by the envelope protein expressed in the packaging cell line. The host range of amphotropic lentivirus will include human cells. However, whilst HIV infection leads to AIDS, the components of the HIV virus used in the lentiviral packaging cells cannot lead to the generation of replication competent virus, as shown by Ikeda et al (2003) Nat Biotech 21:569-572. The packaging line also uses the MLV4070A envelope protein rather than HIV envelope. The viruses are unlikely to survive outside the laboratory, as suitable growth conditions will not exist.

The normal transmission route of lentiviral vectors is either by injection or exchange of bodily fluids. Should the packaging cells be injected accidentally, the risk of pathogenesis is very low in an immunocompetent individual due to the recognition of the cells as foreign. Any persons involved in the project who become immunocompromised must report this immediately and may be restricted from working on this part of the project. Only plastic disposable ware will be used, and no sharps or needles are required.

The recombinant viruses are also low risk as they are replication incompetent and cannot generate more virus in infected cells or mobile endogenous viruses in either humans or mice. Similarly, due to their route of transmission these viruses are rapidly degraded once outside the body.

MoLV work: for MoLV infection of neonatal mice, virus will be infectious but ecotropic, and therefore of negligible risk to human health. For MoLV supernatant production, the virus may potentially contaminate other murine cell lines, and so it will be grown under level 2 containment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable. Injection of MoLV viral supernatant and maintenance of mouse strains only requires level 1 containment as there is no known evidence for horizontal transmission (J. Jonkers, pers comm.)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Work within the containment level 2 laboratory will be conducted using a class II microbiological safety cabinet. Liquid wastes, such as cell culture medium, which may contain virus or cells, will be rendered safe for disposal by overnight treatment with a QAC based disinfectant (Tresolin K). Pipette tips, simplettes etc will be similarly soaked in disinfectant and the tips collected for disposal in solid bins by CSSD. Plastic pipettes will be soaked in 5% Chloros prior to removal by CSSD. Sharps will not be used in connection with this work. These measures provide at least four magnitudes of protection against virus whilst the cells are effectively killed. Material collected by CSSD will be autoclaved on site.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

The risk assessment form has been distributed to members of the genetic modification safety committee who have approved the use of these class 2 GMMs.

Project Ref  80/05.2

Date Ackn’d  14/10/2005

Date Project Ceased

CU2 Project Title  An exploratory study of the safety and biological activity of oncovey (GM-CSF) in combination with radiotherapy and cisplatin in the treatment of locally advanced epithelial cancer of the head and neck

Class  Class 2

Consent Granted  Not Applicable

CultureVolClass2  < 1 Litre

CultureVolumeClass3-4

02/03/2022
The study will be a single arm, open label upward titration of up to three dose levels of OncoVEX(GM-CSF) in combination with radiotherapy and concomitant cisplatin in the treatment of patients with locally advanced stage III and IV head and neck cancer with one or more nodal metastasis in the neck (N2-N3).

Recipient or parental organism

Replication competent herpes simplex type-1 virus that is derived from HSV1 strain JS-1 (ECACC No. 01010209). The OncoVEX(GM-CSF) vector is deleted for the neurovirulence factor, ICP34.5. Deletion of this gene provides a virus that is non-pathogenic while providing the property of tumour selective replication. The vector is also deleted for ICP47, which blocks antigen presentation by blocking the transporter associated with antigen processing (TAP1 and TAP2). The vector also contains the coding sequence for human GM-CSF, a cytokine involved in the stimulation of T-cells. Human GM-CSF gene was cloned from an IMAGE clone 2340997/5808-K14 (UK HGMP Resource Centre). GM-CSF expression is under the control of the human cytomegalovirus immediate early promoter (HCMV IE). GM-CSF occurs normally in the human body. This cytokine is a licensed pharmaceutical product that is used to aid myeloid recovery following bone marrow transplant and chemotherapy, GM-CSF rarely causes anaphylaxis and cardiovascular disorders. Patients with congestive cardiac failure and renal insufficiency will be excluded from the clinical trial. However, only very low-level systemic levels of GM-CSF are expected following intra-tumoural inoculation of the virus where GM-CSF will be locally produced. Thus toxic effects associated with high levels of systemic GM-CSF are not anticipated.

The deletion of ICP47 and the expression of GM-CSF should enhance the immune response towards tumour cells. GM-CSF expression is under the control of the human cytomegalovirus immediate early promoter (HCMV IE). This is an infectious gene therapy product that replicates selectively in rapidly dividing eukaryotic cells. The parent vector is ACDP category 2 and ACGM level 2 containment is appropriate for OncoVEX(GM-CSF) vector due to the conditional replication competence of the vector, and the expression of a biologically active cytokine.

Host/vector system

Replication competent herpes simplex type-1 virus that is derived from HSV1 strain JS-1 (ECACC No. 01010209). The OncoVEX(GM-CSF) vector is deleted for the neurovirulence factor, ICP34.5. Deletion of this gene provides a virus that is non-pathogenic while providing the property of tumour selective replication. The vector is also deleted for ICP47, which blocks antigen presentation by blocking the transporter associated with antigen processing (TAP1 and TAP2). The vector also contains the coding sequence for human GM-CSF, a cytokine involved in the stimulation of T-cells. Human GM-CSF gene was cloned from an IMAGE clone 2340997/5808-K14 (UK HGMP Resource Centre). GM-CSF expression is under the control of the human cytomegalovirus immediate early promoter (HCMV IE). GM-CSF occurs normally in the human body. Patients with congestive cardiac failure and renal insufficiency will be excluded from the clinical trial. However, only very low-level systemic levels of GM-CSF are expected following intra-tumoural inoculation of the virus where GM-CSF will be locally produced. Thus toxic effects associated with high levels of systemic GM-CSF are not anticipated.

The deletion of ICP47 and the expression of GM-CSF should enhance the immune response towards tumour cells. GM-CSF expression is under the control of the human cytomegalovirus immediate early promoter (HCMV IE). This is an infectious gene therapy product that replicates selectively in rapidly dividing eukaryotic cells. The parent vector is ACDP category 2 and ACGM level 2 containment is appropriate for OncoVEX(GM-CSF) vector due to the conditional replication competence of the vector, and the expression of a biologically active cytokine.
cytomegalovirus immediate early promoter (HCMV IE). This is an infectious gene therapy product that replicates selectively in rapidly dividing eukaryotic cells. The parent vector is ACDP category 2 and ACGM level 2 containment is appropriate for OncoVEX(GM-CSF) vector due to the conditional replication competence of the vector, and the expression of a biologically active cytokine.

As regards the safety of this vector, there are a number of specific relevant points:

* The vector is deleted for ICP34.5 & ICP47, deletion of both of which renders the virus non-pathogenic.
* HSV and HSV vectors do not to integrate into the host DNA.
* The HSV thymidine kinase (TK) gene is intact in OncoVEX (GM-CSF) and expressed from the vector. This renders the viruses sensitive to anti-viral agents such as acyclovir, which can be used to block virus replication in the unlikely event that this is required.

There is no anticipated hazards should release of OncoVEX(GM-CSF) into the environment occur. However, procedures will be used to prevent contamination of the environment with OncoVEX(GM-CSF) even though (i) there is no anticipated hazard of OncoVEX(GM-CSF) to the environment and (ii) OncoVEX(GM-CSF) would not be expected to be able to survive in the environment if release occurred.

**Origin & function**

Replication competent herpes simplex type-1 virus that is derived from HSV1 strain JS-1 (ECACC No. 01010209). The OncoVEX(GM-CSF) vector is deleted for the neurovirulence factor, ICP34.5. Deletion of this gene provides a virus that is non-pathogenic while providing the property of tumour selective replication. The vector is also deleted for ICP47, which blocks antigen presentation by blocking the transporter associated with antigen processing (TAP1 and TAP2). The vector also contains the coding sequence for human GM-CSF, a cytokine involved in the stimulation of T-cells. Human GM-CSF gene was cloned from an IMAGE clone 2340997/5809-K14 (UK HGMP Resource Centre). GM-CSF expression is under the control of the human cytomegalovirus immediate early promoter (HCMV IE). GM-CSF occurs normally in the human body. This cytokine is a licensed pharmaceutical product that is used to aid myeloid recovery following bone marrow transplant and chemotherapy, GM-CSF rarely causes anaphylaxis and cardiovascular disorders. Patients with congestive cardiac failure and renal insufficiency will be excluded from the clinical trial. However, only very low-level systemic levels of GM-CSF are expected following intra-tumoural inoculation of the virus where GM-CSF will be locally produced. Thus toxic effects associated with high levels of systemic GM-CSF are not anticipated.

The deletion of ICP47 and the expression of GM-CSF should enhance the immune response towards tumour cells. GM-CSF expression is under the control of the human cytomegalovirus immediate early promoter (HCMV IE). This is an infectious gene therapy product that replicates selectively in rapidly dividing eukaryotic cells. The parent vector is ACDP category 2 and ACGM level 2 containment is appropriate for OncoVEX(GM-CSF) vector due to the conditional replication competence of the vector, and the expression of a biologically active cytokine.

The study will be a single arm open label upward titration of up to three dose levels of OncoVEX(GM-CSF) in combination with radiotherapy and concomitant cisplatin in the treatment of patients with locally advanced stage III and IV head and neck cancer with one or more nodal metastasis in the neck (N3-N3). Treatment with OncoVEX(GM-CSF) will be scheduled to commence on the day on which chemoradiotherapy begins. Patients will be admitted to the outpatients department or a day ward for all injections of virus. The injections will always be performed in a side room where the trial subjects can be segregated from other patients for safety reasons. Groups of four evaluable patients will be treated with dose levels of 10 (to the power of 6) pfu/mL on four occasions, 10 (to the power of 6) pfu/mL on one occasion followed by 10 (to the power of 7) pfu/mL on three occasions and 10 (to the power of 6) pfu/mL on one occasion followed by 10 (to the power of 8) pfu/mL on three occasions. The first dose of virus will be up to 2 mL per tumour (4 mL in total) of the dosage strength 10 (to the power of 6) pfu/mL given on the same day that treatment with cisplatin and radiation begins. Subsequent doses of virus (which will always be administered to the same nodes) will consist of a volume of up to 4 mL in weeks 3 (day 21), 6 (day 42) and 9 at a dosage strength of either 10 (to the power of 6), 10 (to the power of 7), or 10 (to the power of 8) pfu/mL depending on the dose level to which the patient is allocated. The timing of these doses is designed to avoid chemotherapy-induced nadirs in the white cell count. The initial dose strength of 10 (to the power of 6) pfu/mL will be used in order to allow the patient to become tolerant to HSV1. Each injection will then be made, under local anaesthetic, along multiple tracks in order to disperse the vector throughout the tumour. Following injection, the injected tumour will be covered with a double occlusive dressing (Tegaderm) that must be kept in place for 24 hours. The injected tumour(s) will be swabbed 24 and 48 hours after injection in order to ensure that there is no shedding of virus from the injection site. If shedding or weeping is detected, the dressing must be replaced and changed every 24 hours, with the swabs repeated every 24 hours until shedding has ceased for at least 72 hours.

During the chemoradiotherapy the following clinical safety laboratory tests will be obtained at weekly intervals (including those tests taken prior to OncoVEX(GM-CSF)
injection): Haematology (full blood count), clinical chemistry (including urea, creatinine and electrolytes, liver function tests). The following immunology laboratory tests will be obtained before the second, third and fourth injections of OncoVEX(GM-CSF): HSV-antibodies, antinuclear antibody (autoantibody). There will be a final follow-up visit one month after the week 10 investigations or one month after surgery. At this time, a physical examination will be conducted and blood samples will be obtained for haematology (full blood count), clinical chemistry (including urea, creatinine and electrolytes, liver function tests) and HSV-1 antibodies, antinuclear antibody (autoantibody). Adverse events and concomitant medications will be documented from the time of screening until the patient comes off study.

Evaluation of foreseeable effects

Treatment with OncoVEX(GM-CSF) will be scheduled to commence on the day on which chemoradiotherapy begins. Patients will be admitted to the outpatients department or a day ward for all injections of virus. The injections will always be performed in a side room where the trial subjects can be segregated from other patients for safety reasons. Before each injection, the ECOG score will be recorded. Vital signs (core temperature, heart rate, blood pressure) will be measured and recorded. The patients will be examined for the presence of active herpes labialis. If this is present, the injection must be delayed until healing occurs. Blood will be obtained for clinical chemistry and haematology. The patients will also be questioned about any symptoms that they are experiencing at the time and any medications they may be taking. Before the first injection, the node(s) that will be injected will be identified and allocated a tumour number. Where appropriate, the node(s) that will not be injected will also be identified and numbered. All nodes will be palpated and evaluated for injection site reaction prior to injection.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste generated by trial will be autoclaved prior to being incinerated as clinical waste by the Trust wast contractor White Rose. All small materials (eg syringes, sharps) will be soaked in a virucidal agent (such as Virkon 10%) for 30 minutes prior to autoclaving.

Is an emergency plan required according to regulation 20? Y

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
## GSCM - Action points

HSV-GMCSF

- HSE also aware of trial. Would like a full report to the HSE - Actioned
- Dressing type to be confirmed on patient information letter - actioned
- Final version of patient letter to be confirmed - actioned
- BG discussed concerns over blood samples taken for staff from Occ Health and where these may be stored. Also how staff with needlestick injuries will be monitored KH felt that the risk is minimal, however will confirm action. MG felt that a swab should be taken if an abnormal lesion should develop on a staff member - actioned
- KH to amend paragraph two on the first page of GMCSF study relation to deletions - actioned
- SOP's to be made available on Weston Ward, Labs and Radiotherapy - actioned

## Purpose of the contained use

**Prevention of Class 2 GMMs being a hazard to workers**

## Recipient or parental organism

**Lentiviral-based systems** (e.g., Ikeda, Y., et al, Nat Biotechnol 21:569-72 (2003)) will be used to generate non-replication competent virus. These systems enable virus to be harvested from cell supernatent in a safe and well-characterised manner which can then be used to infect cells in order to get stable expression of a packaged transgene.

## Host/vector system

**Human Immunodeficiency Virus-based systems**

## Origin & function

Vectors: For Aurora-A cDNA expression, the LV series of vectors (Pfeifer et al (2002) Proc Nat Acad Sci USA 99:2140-2145) or similar will be used. All vectors are replication defective and are self-inactivating. Other inserts: expression on cell phenotype. Inserts are likely to be involved in cell control.

## Evaluation of foreseeable effects

Lentiviral work: All virus will be produced from split genome packaging cells whereby the components required for virus production have been split onto separate plasmids to prevent recombination and generation of replication competent virus. The generated virus will only have packaged the gene of interest and their tropism will be largely defined by the envelope protein expressed in the packaging cell line. The host range for amphotropic lentivirus will include human cells. However, whilst HIV infection leads to AIDS, the components of the HIV Virus used in the lentiviral packaging cells cannot lead to the generation of replication competent virus, as shown by Ikeda et al (2003) Nat Biotech 21:569-572. The packaging line also uses the Vesicular Stomatitis Virus (VSV-G) envelope protein rather than HIV envelope. The viruses are unlikely to survive outside the laboratory, as suitable growth conditions will not exist. The normal transmission route of lentiviral vectors is either by injection or exchange of bodily fluids. Should the packaging cells be injected accidentally, the risk of pathogenesis is very low in an immunocompetent individual due to the recognition of the cells as foreign. Only plastic disposable ware will be used, and no sharps or needles are required. The recombinant viruses are also low risk as they are replication incompetent and cannot generate more virus in the infected cells or mobilise endogenous viruses in either humans or mice. Similarly, due to their route of transmission these viruses are rapidly degraded once outside the body.

## Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

No.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Work within the containment level 2 laboratory will be conducted using a class II microbiological safety cabinet. Liquid wastes, such as cell culture medium, which may contain virus or cells, will be rendered safe for disposal by overnight treatment with a QAC based disinfectant (Tresolin K). Pipette tips, simplettes etc will be similarly soaked in disinfectant and the tips collected for disposal in solid bins by CSSD. Plastic pipettes will be soaked in 5% Chloros prior to removal by CSSD. Sharps will not be used in connection with this work. These measures provide at least four magnitudes of protection against virus whilst the cells are effectively killed. Material collected by CSSD will be autoclaved on site.

## Project Additional Information

### Purposes of the contained use

To prevent the GMM being a hazard to workers.

### Recipient or parental organism

Human and non-human cancer cell lines, which are commercially available, have been maintained in culture for many years and are not known sources of human pathogens.

### Host/vector system

We will engineer attenuated vaccinia viruses (VV) and mutations (tk-, vgf-) targeted to reduce their virulence and restrict the viral replication to tumours vs normal tissues (Puhlmann et al., 2000; McCart et al., 2001).

### Origin & function

We will insert the genes encoding for luciferase, green fluorescent protein (GFP) or carboxypeptidase G2 (CPG2) into the VV vectors. The gene products are not harmful to any organism. Gene expression will only occur in cancer cells, however, a small fraction of non-cancer cells supporting transgene expression cannot be excluded. Luciferase and GFP are commonly used reporter enzymes to monitor gene expression. Both genes are commercially available and have been used extensively without any reported adverse effects. CPG2 is a naturally occurring bacterial enzyme. The enzyme has been assessed in a clinical trial (Napier et al., 2000) and is used in the clinic as a therapeutic drug for the treatment of methotrexate poisoning. CPG2 is non-toxic. In this study, CPG2 will be used to activate a prodrug into a cytotoxic drug in cancer cells.

### Evaluation of foreseeable effects

Wild-type VV may cause disease in people with active skin disorders, during pregnancy or in immuno-compromised people. However, in this study, we will use attenuated, tumour selective VV vectors. There is no risk of insertional mutagenesis as VV spends its entire life cycle in the cytoplasm and cannot transfer its viral DNA into the genome of infected cells.

Wild-type VV is categorised as ACDP hazard group 2 and the ACGM compendium of guidance states in Part 2B Annex III "Tk-minus phenotype is believed to reduce the virulence of the virus in mice but it is debatable whether this should be taken to imply lower virulance in man, or whether this should allow a down-grading of categorisation."

VV have been used clinically as tumour vaccines (Kwak et al., 2000) and a tk-deleted VV vector has safely completed a clinical trial in patients with cutaneous melanoma (Mastrangelo et al., 1999).

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be placed in clear autoclave bags and disposed of by autoclaving on site - this has a 100% degree of kill.

Pipettes, containers and plasticware contaminated with viruses will be left completely submerged in 1% Virkon before disposal. Virkon has been validated as being effective within 5 minutes at this concentration and Virkon stocks are routinely tested by the manufacturer (http://www.antecint.co.uk/go.htm). The website will be monitored for any change.

02/03/2022
Cells and growth medium will be treated with 1% Virkon before disposal.

The Fulham Road GMSC reviewed and discussed this project they advised the work be conducted at containment level 2. Although the pathogenicity is reduced in respect of the wild type there remains a risk of infection to certain workers. The committee requested that the work conducted at the Sutton site be considered and included in the assessment.

Please enter comments on the GM safety committee on the risk assessment

Project Ref  80/07.1

Date Ackn’d  30/05/2007

CU2 Project Title  Study of RAS GTPases and their downstream effectors during intracellular signalling in human tumours.

Date Project Ceased

Consent Granted  Not Applicable

Tick if notifying a connected programme of work  N

Historical Significant Changes  N

02/03/2022
The aim of this project is to assess the role small GTPases, in particular those encoded by the ras family of genes and their downstream effectors, play in intracellular signalling in human cancer.

All the recipient cell lines used in this study come from the American Tissue Culture Collection (ATCC) (www.atcc.org/) and include the following (tissue origin, mutation and ATCC identifier have been provided between brackets): MiaPaCa-2 (pancreatic, K-ras, CRL-1420), CAPAN-1 (pancreatic, K-ras, HTB-79), CAPAN-2 (pancreatic K-ras, HTB-80), ASPC-1 (pancreatic K-ras, CRL-1682), PANC-1 (pancreatic, K-ras, CRL-1469) SK-MEL-2 (skin, N-ras, HTB-68), A549 (lung, K-ras, CCL-185), A427 (lung, K-ras, HTB-53) and HS766T (pancreatic, wild type, HTB-134).

For packaging of the viral particles the following two cell lines will be used Human Embryonic Kidney cells HEK 293T (for use with Sigma’s Mission shRNA libraries) and Human Embryonic Kidney cells HEK 293FT (for use with Invitrogen’s BLOCK-it™ Lentiviral Pol II miR RNAi Expression system).

To the best of our knowledge all these cell lines, recipient and packaging, are routinely and widely used in laboratories around the world and are thought not to harbour any adventitious agents to human health and or environment.

The vectors will be obtained from commercial sources, including Sigma and Invitrogen. If the vectors are obtained from Sigma, these will accompany a lentiviral library known as MISSION shRNA (http://www.sigmaaldrich.com/Area_of_Interest/Life_Science/Functional_Genomics_and_RNAi.html). The library includes the following three vectors pLKO.1-puro Vector, MISSION™ shRNA Envelope Vector and MISSION™ shRNA Packaging Vector. If the vectors are outsourced from Invitrogen, they will be included in the BLOCK-it™ Lentiviral Pol II miR RNAi Expression System (Catalogue numbers K4935-00, K4936-00, K4937-00 and K4938-00). Vectors included in these kits are: pcDNA™6.2-GW/miR, and/or pcDNA™6.2-GW/miR neg control plasmid and/or pcDNA™6.2-GW/EmGFPMiR neg control plasmid, pLenti6/V5-DEST Gateway Vector, pLenti6/V5-GW/lacZ control and pDONR™221 Vector.

During this study we plan to knock-down and re-introduce the following genes (MIM between brackets):
- H-ras (190020): potential oncogene, GTPase, member of mammalian ras gene family
- K-ras (190070): potential oncogene, GTPase, member of mammalian ras gene family
- N-ras (164790): potential oncogene, GTPase, member of mammalian ras gene family
- PLCε (608414): phospholipase C epsilon, belongs to the phospholipase family that catalyzes the hydrolysis of polyphosphoinositides such as phosphatidylinositol-4,5-bisphosphate (PI(4,5)P2) to generate the second messengers IP3 and DAG
- RAF family of genes:
  - A-raf (311010), potential downstream effector for ras family of genes
  - B-raf (164757), potential downstream effector for ras family of genes
  - C-raf (164760), MAPKK which function downstream of the ras family of genes
- NORE-1A (607020), member of the ras association domain family. It functions as a tumour suppressor
- RALGDS (601619), ral guanine nucleotide dissociation stimulator
**P13Kp110β (171834), catalytic subunit alpha of P13K**

**P13Kp110γ (601232), catalytic subunit gamma of P13K**

**Evaluation of foreseeable effects**

The lentiviruses are made with a split-genome conditional packaging system. This conditional packaging system acts as a build-in device against the generation of productive recombinants. The gene of interest will be under the control of the human cytomegalovirus (CMV) promoter. The vector also contains elements to allow packaging into virions. The packaging plasmids supply the helper functions in conjunction with structural and replication proteins (in trans) required to produce lentivirus. The HEK 293T/293FT lines stably expresses the SV40 large T antigen under the control of the CMV promoter. When packaging plasmids and lentiviral vector are co-transfected into the HEK 293T/293FT cells a replication defective virus is produced. If packaging cells were injected accidentally the risk of pathogenesis is very low due to the recognition of the cells as foreign. This virus can then be used to transduce both actively cycling and dormant mammalian cells but will not replicate in the host cells. Once inside the cell, the RNA of interest can be studied. However since the genes expressed in these vectors are potential oncogenes, they themselves may cause the host cells to proliferate.

The viral particles will in principle carry DNA encoding oncogenes, but as mentioned above the risk of any potential harm to operatives can be considered negligible as lentiviruses are incapable of replication due to its split-genome conditional packaging system. The infected human cells would be unlikely to be pathogenic due to rapid complement mediated lysis of these cells when recognized by the immune system as of non-self origin. Cells would not be shedding virus as they are replication-defective and therefore do not pose a risk to human health or the environment.

Although the lentiviral particles that will be used on this study belong to the broader Retroviridae group, none of them are listed under the approved list of biological agents by the ACDP.

In our risk assessment, the modified viruses should not pose a serious risk to the environment. These viruses are extremely unstable, inactivated by detergent, UV light and ethanol, and would not survive outside of the laboratory environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Protective clothing and gloves will be worn at all times. The individual performing theses experiments is trained in good laboratory practice and is fully aware of The Institute local rules for containment level 2 laboratories. Work surfaces, including the inside of microbiological safety cabinets, will be suitably disinfected after use. Aerosol will not be generated in this project. Centrifugation will be done in sealed tubes. Sharps will not be used. Liquid wastes, such as cell culture medium, which may contain virus or cells, will be rendered safe for disposal by overnight treatment with 1% Virkon or other approved disinfectant. Plastic pipettes will be soaked in 5% Chloros prior to removal by CSSD. Solid waste will be placed in autoclave bags for collection by CSSD. Material collected by CSSD will be autoclaved on site. The cleaning, disinfecting and disposal procedures will be documented and displayed. The biological spillage procedure will be displayed and HAZ-TAB disinfectants will be available for immediate use. Supernatant will be collected and human tumour cells will be exposed to the supernatant in conditions to promote infection. Virus preparation will be certified free of replication competent virus. These cells will then be assayed in vitro to measure their oncogenic potential.

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

The aim of this project is to assess the role of small GTPases, their activators and downstream effectors, in intracellular signalling in human cancers. We wish to target these genes in human and mouse cancer cell lines as well as in mouse primary cell cultures. This procedure requires the generation of replication defective recombinant
lentiviruses capable of infecting human and mouse cells. The recombinant virus will contain genetically modified viruses that will alter the expression of specific genes, which will allow to study their function in tumorigenesis.

Recipient or parental organism

HEK 293, HEK 293T and HEK 293FT (human embryonic kidney cells) will be used to produce the lentiviruses. The following cell lines will be infected with lentiviruses: A549, H441: Human lung carcinoma; Lim 1215, Human colon carcinoma; HeLa, Human cervical carcinoma, MDA-MB-231, Human breast carcinoma; HUVEC, Human umbilical vein endothelial cells.

Primary cells from mouse tissues and mouse tumours.

Host/vector system

pLKO. 1-puro Vector, mission shRNA Envelope Vector and mission shRNA Packaging vector (sigma).
BLOCK-iT Lentiviral Pol II miRNA Expression System (invitrogen).
pMD2.G and pCMV delta R8.2 plasmids (Professor Didier Trono, EPFL, Switzerland and distributed by addgene Cambridge, USA).

Origin & function

GFP: Green fluorescent protein reporter gene
H-ras, K-ras, N-ras, RAIA, RAIB: proto-oncogenes, small GTPases RAIBP1: Effector of al small GTPases
Rac1, RhoA, RhoC: Small GTPases involved in cytoskeleton remodelling
ROCK I, ROCK II: Kinases involved in cytoskeleton remodelling
MT1-MMP: Proteases involved in degradation of extracellular matrices.

The modified genes need to be introduced into appropriate cellular model systems to assess their role in oncogenic signalling. One of the more efficient model systems uses lentiviral vectors to introduce these genes into a wide variety of cell types. The vectors currently in world-wide use, are modified non-replicating RNA viruses derived from the Murine Moloney Leukaemia Virus (MoLV), the Myeloproliferative Sarcoma Virus (MPSV), the Murine Stem Cell Virus (MSCV) and third generation Lentivirus vectors (with biosafety features). They are all designed to transmit inserted genes at high titres with a choice of various selectable marker genes. The introduced genes are driven either by the viral LTR or an internal eukaryotic promoter. Some vectors allow the expression of polycystronic transcripts with internal ribosomal entry sites to allow dual expression of the introduced potential oncogenic transcript and selectable marker which may be either a drug-resistance marker or a green fluorescent protein gene. The recombinant lentiviruses will contain shRNA directed against genes such as the ones mentioned above. To address the oncogenicity of the constructs directly, we will introduce them into the appropriate human cell lines that are already under investigation in our laboratory. In the case of the lentivirus vectors, the number of HIV genes used in the system is three (gag, pol and rev). The VSV-G gene from vesicular stomatitis virus replaces the HIV envelope. Two or Three packaging plasmids will be co-transfected along with the lentivirus vector (containing the gene of interest) into the Human Embryonic Kidney (HEK) 293, 293T or 293FT packaging cell lines. The packaging line also uses the Vesicular Stomatitis (VSV-G) envelope protein rather than HIV envelope. The viruses are replication defective and are unlikely to survive outside the laboratory, as suitable growth conditions will not exist. Supernatant from the packaging cell lines co-expressing the retroviral construct of interest will be used to infect the cell line or primary cell culture of interest.

Evaluation of foreseeable effects

The lentiviruses are made with a split-genome conditional packaging system. This conditional packaging system acts as a build-in device against the generation of productive recombinants. The gene of interest will be under the control of the human cytomegalovirus. The HEK 293T/293FT lines stably express the SV40 large T antigen under the control of the CMV promoter When packaging plasmids and lentiviral vector are co-transfected accidentally the risk of pathogenesis is very low due to the recognition of the cells as foreign. This virus can then be used to transduce both actively cycling and dormant mammalian cells but will not replicate in the host cells. Once inside the cell, the RNA virus is reverse transcribed, becomes stably integrated into the host genome and the effect of expression of the gene of interest can be studied.

The viral particles will in principle carry DNA encoding proto-oncogenes, but as mentioned above the risk of any potential harm to operatives can be considered negligible as lentiviruses are incapable of replication due to its split-genome conditional packaging system. The infected human cells would be unlikely to be pathogenic due to rapid
Complement mediated lysis of these cells when recognized by the immune system as of non-self origin. Cells would not be shedding virus as they are replication-defective and therefore do not pose a risk to human health or the environment. Although the lentiviral particles that will be used on this study belong to the broader Retroviridae group, none of them are listed under the approved list of biological agents drawn by the ACDP.

**Project Additional Information**

**Purposes of the contained use**

The aim of the project is to assess the effect of blocking the expression of B-Raf and related signalling proteins on the growth of melanoma cell lines in a 3-dimensional model which more closely replicates the tumour microenvironment. We have previously shown that siRNA-mediated gene knockdown of B-Raf inhibits melanoma cell growth. However, this culture model is not compatible with siRNA oligonucleotides. Therefore, we wish to create melanoma cell lines which stably integrate shRNA sequences into their genome for long-term gene knockdown.

**Recipient or parental organism**

The recipient cell lines will be primary human melanocytes or immortalized human melanoma cell lines. Each of these cell lines are commercially available, have been maintained in cell culture for many years, are not known sources of human pathogens, and are unlikely to survive outside the laboratory environment.

**Host/vector system**

The vector to be used is a lentivirus derived from HIV-1. However the vector has been modified in several ways to ensure that the virus is replication-defective, and will not form active viral particles unless it is co-transfected into a packaging cell line with helper plasmids.

**Origin & function**

The genetic material that will be cloned into the lentiviral vector will be DNA that encodes a short hairpin RNA molecule directed against B-Raf or related genes which...
support melanoma progression. Expression of the shRNA molecule will result in gene-specific knockdown, most likely promoting growth inhibition or cell death in the transfected cells. We also propose to use a lentiviral vector encoding the bacterial Tet-repressor protein, so we can achieve inducible expression of shRNA in the cell lines under study. Once Tet-repressor and shRNA constructs have been stably introduced into cells, shRNA expression and subsequent gene knockdown will only occur if tetracycline is added to the culture medium.

**Evaluation of foreseeable effects**

The lentiviral vectors which we propose to use do have the potential for infecting any human cell. Through good lab 1’ practise (GLP) the risk of these vectors affecting the user or others in the laboratory is extremely low. In the unlikely event of infection, the viral particles will not replicate, as discussed above, The expression of these shRNA molecules is hypothesized to target the growth of melanoma cells, and would likely induce cell death. In the case of infection with a lentivirus encoding the Tet-repressor, expression of this protein would have little effect on human cells, as Tet-repressor promoter elements are not present in human genes.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

n/a

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

We are not requesting derogation.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All transfections and infections of cells will be performed in a designated Class II biohazard safety cabinet, which will be disinfected with 1% Virkon after use. Virkon is a chemical disinfectant that kills 99.999% of organisms in less than 10 minutes. The cabinet will prevent unwanted infection of the cell cultures as well as release of the viruses into the environment. Infected cells will be grown in a designated incubator. Pipettes, containers and plasticware contaminated with viruses will be left completely submerged in 1% Virkon before disposal. Cells and growth medium will be treated with 1% Virkon before disposal according to the Institute’s Waste Index and Disinfection protocols. HIV-1 is transmitted through blood and a limited number of bodily fluids, none of which will be encountered in the course of this work. Further, sharps will not be used. To date, no one has been identified as infected with HIV due to contact with an environmental surface (see http://www.cdc.gov/hiv/resources/qa/qa35.htm). No living material infected with HIV-1 derived lentivirus will be transported other than between cabinet, microscope and incubator in the tissue culture room 5C10.1 (ACGM2), but cell extracts will be transported between room 5C10.1, laboratories 4N19-21 (ACGM1) and the equipment room on the 4th floor (ACGM1). Viral preparations will be double-contained and transported between room 5C10.1 and the —80°C freezer (room 4S4, ACGM1) for storage. In the event of a spillage, chlorine-releasing disinfectant granules (HAZ-TAB) or 1% Virkon will be used for immediate disinfection.

**Project Additional Information**

**Purposes of the contained use**

Generation of replication-defective lentiviruses (with biosafety features) for overexpression or inhibition of genes which may play a role in mammary gland development and/or genes for labelling cells with fluorescent proteins or luciferase.

**Recipient or parental organism**

DNA will be propagated in DH5a (disabled, recombination deficient (recA)) E. coil. 

Replication defection viruses will be generated in HEK293T cells.

**Host/vector system**

Trono laboratory split genome, conditional packaging lentiviral system (pWPl, pMD2.G, p5PAX2) for overexpression studies.

Split genome lentiviral SEW expression vector, pCMVR8.91 packaging construct and pMD2.VSVG pseudotyping vector for inhibition studies.
The aim of this project is to use new methods to enable the in vivo assessment of gene overexpression or knockdown on mammary development without the need to generate transgenic or knockbut animals. The project will use viral vectors to transduce primary mouse mammary cells in culture and then transplant them back into mammary fat pads. Previously, similar work has been carried out using retroviral transduction. However, the requirement for proliferation in the target cell in order to maximise retroviral genomic integration has meant mammary epithelial cells can only be transduced with very variable, and usually poor, success. Lentiviral vectors, which do not require proliferation in the target cells, enable much higher rates of transduction to be achieved.

The expression vectors (pWPI and SEW) contain elements to allow packaging into virions. The packaging plasmids supply the helper functions in conjunction with structural and replication proteins (in trans) required to produce the lentivirus. The 293T line stably expresses the 5V40 large T antigen under the control of the CMV promoter. When packaging plasmids and lentiviral vector are co-transfected into the 293T cells a replication defective virus is produced. This virus can then be used to transduce both actively cycling and dormant mammalian cells but will not replicate in the host cells. Once inside the cell, the RNA virus is reverse transcribed, becomes stably integrated into the host genome and the effect of expression of the gene of interest can be studied.

Genes of interest to be studied include:

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

The vectors may also carry marker genes such as luciferase or fluorescent proteins.

**Origin & function**

There is a negligible hazard to human health from disable E. coli host strains. DH5a has a proven history of safe use, has been well characterised and is known to be free from harmful sequences.

The infected packaging cells would be unlikely to be pathogenic due to rapid complement mediated lysis of these cells when recognized by the immune system as of non-self origin. Transduced cells would not be shedding virus as they are replication-defective and therefore do not pose a risk to human health or the environment. The risk that the vector could be rescued in the mouse is negligible (there is no known means for murine retrovirus rescue of such vectors) so there is negligible risk of spread to other cages or to staff. Mouse cells will be unable to survive in the human in the event of accidental inoculation due to the species barrier and immune response.

The only risk is from lentiviral-mediated insertion of an oncogene or knockdown sequence into a human host during handling of viral supernatants. However, insertion of an oncogene into the human cells is not enough to create by itself cancer because it needs a combination of additional alterations. We will not use sequences which knockdown p53, Rb or their regulators. The vectors will be replication defective and potential exposure will be controlled by following containment level 2 local rules and use of good microbiological practice.

The viruses are unlikely to survive outside the laboratory, as suitable growth conditions will not exist. The packaging cells and any transduced cells cannot survive outside the laboratory.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Transfection of packaging cells and harvesting and testing of viral supernatants will be carried out at Level 2. Each batch of viral supernatant will be tested to ensure it is free from replication proficient virus by transducing a target cell population with the virus, waiting up to one week and then harvesting supernatants from the target cell population. These supernatants will then be used to ‘transduce’ a fresh batch of target cells. Failure to transduce the target cell population in the second round of transductions (as indicated by lack of expression of the marker gene carried by the virus) will demonstrate that the virus was unable to replicate after the first round of transduction, is therefore replication defective and no cells transduced with the virus can shed live virus. Furthermore, there is no known mechanism for endogenous mouse viruses to rescue a replication-deficient biosafety engineered lentivirus (mouse cells will be the target cells for transduction). Therefore, once target cells have been transduced with the virus and been free of viral supernatants for 24 hours, they may be considered Level 1 GMMs.
Work surfaces, including the inside of microbiological safety cabinets, will be suitably disinfected after use (Trigene). Aerosols will not be generated. Centrifugation will be done in sealed tubes. Liquid wastes will be rendered safe for disposal by overnight treatment with an approved disinfectant according the ICR Waste Index (Virkon). Plastic pipettes will be soaked in an approved disinfectant (Virkon) prior to removal by Central Services Department (CSSD). Solid waste will be placed in autoclave bags for collection by CSSD. Material collected by CSSD will be autoclaved on site. The cleaning, disinfecting and disposal procedures will be documented and displayed. The biological spillage procedure will be displayed and HAZ-TAB disinfectants will be available for immediate use. Any incidents and accidents will be reported.

Once the lentivirus has infected the cells it should not be able to replicate. All new batches of virus will be tested for replication competence. Murine NIH3T3 or 3T3-L1 cells will be transduced with fresh or frozen (-700°C) viral supernatant (supernatant 1) (virus containing the gene of interest plus either a selectable marker or GFP) plus 2 ug/ml of polybrene and incubated overnight. The following day, cells will be washed with medium and refed. After 24 to 48 hours check the number of GFP positive cells will be assessed (or the cells will be put under selection). Cells will be grown for a further 4 to 6 days (splitting cells if necessary) and an overnight supernatant (supernatant 2) harvested from confluent cells. The supernatant will be passed through a 0.45 micron filter and either used straight away or stored frozen at -700°C. NIH3T3 or 3T3-L1 cells will then be transduced with supernatant 2 plus polybrene. A positive control consisting of supernatant 1 plus polybrene will be included. The cells will be washed the next day and fresh medium added. The cultures will be checked for GFP positive cells 24 to 48 hours later (or put under selection). In the absence of virus in supernatant 2 no green (GFP positive) cells (or resistant colonies if a selectable marker is used) should be seen whereas green cells should be present in cells transfected with positive control supernatant 1.

Is an emergency plan required according to regulation 20?

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

Comment from the committee:

Is the work in the BSU really ACGMI? Surely it is ACGM 2 since you are putting cells into mice that have been infected with a virus?

The answer from the proposer:  
‘Once primary or cell lines have been transduced with a proven replication defective virus but have been free of viral supernatants for 24 hours, they can be taken from Class 2 containment. Subsequent work with cells transduced with virus can be carried out at Class 1, as they will be no more hazardous than any cell type which has been genetically modified with an alternative strategy. The virus will have been proven to be replication defective, therefore the transduced cells cannot produce more virus. There is no known method for endogenous mouse viruses to rescue such replication defective sequences, so work in the BSU with the transduced cells can also be carried out at Class 1.’

Just to expand on this, my assessment is that as the cells for transplant will have been transduced with a replication defective virus, they cannot themselves produce virus and they are no more hazardous than cells which have been stably transfected with any other sort of gene. As I say, there is no known mechanism by which endogenous viruses can rescue these sequences. My assessment of the risks of this project is that whilst working with virus producer cells and viral supernatants is level 2, once the cells have been transduced with proven replication deficient virus, the risks associated with those cells is level 1.

Project Additional Information

Purposes of the contained use
The aim of the project is to assess the effects of blocking the expression of lysyl oxidase family members on tumour cell growth and progression using established cancer cell lines.

Recipient or parental organism
The lentiviral vectors will be used for growth studies on established cancer cell lines: MDA-MB-231 human breast cancer cells, and B16 mouse melanoma cells. Each of these cell lines is commercially available, have been maintained in cell culture for many years and are not known sources of human pathogens. All cell types used in this study are unlikely to survive outside the laboratory environment.

Host/vector system
We will use the commercially available pLKO.1 lentiviral vector that is classified as a Biosafety Level 2. pLKO.1 is derived from the HIV-1 virus. None of the HIV-1 structural
genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced. The lentiviral particles produced in this system are replication-incompetent and only carry the gene of interest. No other viral species are produced.

Origin & function

The inserted genes will be various shRNA constructs that knock-down expression of LOX and LOXL2 mRNA. LOX and LOXL2 are extracellular enzymes that are required for breast cancer cell survival, proliferation, invasion and metastasis. We have previously shown that genetic knockdown will abrogate these activities. Subsequent experiments will produce shRNA constructs that target genes that co-operate with LOX and LOXL2 to promote breast cancer tumour growth and progression. Previous shRNA experiments by Dr Erler using retroviral delivery have established sequences which specifically target LOX and LOXL2, without affecting other proteins including other LOX family members.

Evaluation of foreseeable effects

Despite the inclusion of the safety features, the lentivirus produced with this system can still pose some biohazardous risk since it can transduce primary human cells. Control measures to be used will include good laboratory practice, wearing of lab coats, wearing of two pairs of gloves, and all work to be performed in a designated Class II biohazard safety cabinet, which will be disinfected with 2% Virkon after use.

The lentivirus produced with this system can infect all primary human cells, but is replication deficient. In addition, the envelope protein of I-IIV-1 has been replaced with that of VSV-1, to avoid providing resistance to host defence mechanism. HIV-1 survival outside of the intracellular compartment is extremely limited, and is unlikely to recombine with related microorganisms. Survival of the recombinant lentiviral vectors will be similar to the wild-type virus, which is extremely low outside of a cellular host, or within human blood and a limited number of bodily fluids. HIV-1 is a human pathogen, but is not known to have any pathogenicity to agricultural animals, plants or other microorganisms.

To date, no one has been identified as infected with HIV-1 due to contact with an environmental surface.

The system to be used results in the production of a replication-defective virus. The inserted gene product is highly specific for knockdown of LOX and LOXL2. Since the inserted gene will result in the knockdown of genes known to promote tumour growth/progression upon expression, it is very unlikely to result in harmful biological activity. The safety and containment procedures in place should prevent transmission of the virus to the environment by air or drains.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Transfections and infections of cells will be performed in a designated Class II biohazard safety cabinet, which will be disinfected with 2% Virkon after use. The cabinet will prevent unwanted infection of the cell cultures as well as release of the viruses into the environment. Infected cells will be grown in a designated incubator. Pipettes, containers and plasticware contaminated with viruses will be left completely submerged in 2% TriGene before incineration. Cells and growth medium will be treated with 1% Virkon before disposal according to the Institute’s Waste Index and Disinfection protocols. Virkon has been validated as being effective within 5 minutes at these concentrations and stocks are routinely tested. HIV-1 is transmitted through blood and a limited number of bodily fluids, none of which will be encountered in the course of this work. No living material infected with HIV-1 derived lentivirus will be transported other than between cabinet, microscope and incubator in the tissue culture room. Once infected, the cells and cell extracts will no longer contain productive virus. In the event of a spillage, chlorine-releasing disinfectant granules (HAZ-TAB) or 1% Virkon will be used for immediate disinfection.

Virus will be produced and collected in a designated Class II biohazard safety room. All batches collected will be tested to confirm that no replication competent virus is present. Cells will be transduced in the designated room and will be kept there until they are virus-free for 24 hours. All subsequent work will be level 1. Transduced virus-free cells will be cultured in level 1 tissue culture and cell samples will be tested in the level 1 labs.
The ICR genetic modification safety committee are happy with this risk assessment.

Please enter comments on the GM safety committee on the risk assessment

**Project Additional Information**

**Purposes of the contained use**

- Vaccinia virus is classified as a group 2 biological agent under ACDP. GL-ONC1 is a highly attenuated derivative of vaccinia virus Lister (LIVP) from the Institute of Research on Viral Preparations, Moscow. LIVP has been used extensively as a vaccine for smallpox during the smallpox eradication campaign. For smallpox vaccines most adverse effects were common cold-like symptoms and only rarely were severe complications seen. Typically a lesion at point of inoculation at 1 week post vaccination was seen and rarely, generalised vaccinia 5-10 days later. The virus may be transmitted to contacts of inoculated individuals. See action sheet and document. The genetic modifications found in GL-ONC1 (insertion of Luciferase, GFP, GUS and lac-Z) are not expected to alter the pathogenicity of the virus and are themselves not hazardous to human health. Vaccinia virus does not integrate into the genome and the naked DNA is not hazardous.

**Recipient or parental organism**

CV-1 cells (African green monkey kidney) will be used for vaccinia virus culture, plaque assays and the neutralisation assay. Head and Neck, melanoma, and colorectal cell lines will be used to assess the oncolytic potential of GLONC1.

**Host/vector system**

Vaccinia virus LIVP was used as a vaccine for smallpox. The host range of this virus is humans, rabbit, cows and river buffaloes.

**Origin & function**

GL-ONC1 has a number of reporter gene inserted into its genome. A Renilla Luciferase-Green Florescent Protein (GFP) fusion, Escherichia coli (E. coli) beta-galactosidase (Lac Z), E. coli glucuronidase (GUS) have been inserted into the F14.5L, thymidine kinase (tk) and haemagglutinin (ha) loci in LIVP respectively. The transferring receptor (TFR) has also been inserted in the J2R locus but is not expressed as it is in the reverse orientation to a synthetic vaccinia early late promoter. GL-ONC1 was described by Zhang et al., in 2007 under the nomenclature (GLV-1 h68). The Renilla luciferase gene originates from the Renilla reniformis (sea pansy). The Renilla luciferase gene encodes a protein that can catalyse the oxidation of coelenterazine (coelenterate-luciferin) generating light which can be visualised using an IVIS imaging system. GFP is a commonly used reporter gene originally isolated from the jelly fish Aequorea victoria. GFP has a major excitation peak at 395nm and a minor peak at 475nm and an emission peak at 509nm in the lower green portion of the visible spectrum. The luciferase-GFP fusion is not expected to have any adverse effects if expressed in humans. beta-galactosidase hydrolyses a range of sugar molecules to generate a coloured product that can be measured to determine the amount of enzyme activity. Similarly, beta-glucuronidase cleaves the substrate X-Gluc (5-bromo-4-chloro-3-indolyl-beta-D-glucuronic acid), to produce colorless glucuronic acid and an intense blue precipitate of chloro-bromoindigo. Expression of beta-galactosidase and betaglucuronidase can be detected in situ or in a variety of colourmetric assays. It is not anticipated that expression of beta-galactosidase or betaglucuronidase would have any adverse effects if expressed in humans.

**Evaluation of foreseeable effects**

- GL-ONC1 has been extensively used as a smallpox vaccine. For less attenuated smallpox vaccines most adverse effects were related to common cold-like symptoms. Rarely severe complications were encountered. Typically 1 week after vaccination, vaccination lesions appear at point of inoculation, which resolve within 28 days, and rarely as a severe complication, generalised vaccinia. Vaccinia does not ordinarily cause disease in humans, it is not a natural human pathogen, disease is a rare complication of vaccination. The greatest risk of vaccination is transmittal of the virus to unvaccinated contacts or to other sites on the vaccinated individual.

- GL-ONC1 is stable for up to 6 days when dried at room temperature, although infectivity decreases exponentially with time. Vaccinia is not pathogenic for plants, microorganisms or other animals beyond its host range. Although GL-ONC1isa replicating virus the expression of the marker genes and inactivation of the ha and tk genes are likely to produce an attenuated phenotype. There is no evidence that vaccinia virus can insert its DNA into the host genome. The safety and containment procedures in place should be sufficient to prevent release of the virus to the environment by drains or air. Animals that have been infected with the GL-ONC1 are unlikely to escape from the Biological Service Unit (BSU).
Normal working practice is only to open cages in hoods (as part of laboratory animal allergy prevention) and to record the number of occupants on each cage label. In addition, lab animals are unlikely to survive in the environment as they have no natural resistance to environmental pathogens.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Biological liquid waste will be subject to inactivation with 1% Virkon for 24 hours prior to disposal to drains with plenty of water. This has been documented as being sufficient for inactivation of the virus according to RelyOn Virkon® Efficacy Data. Surface contaminated plastic waste will be rinsed with 1% Trigene laboratory disinfectant or 1% Virkon and then autoclaved prior to disposal. Pipettes and pipette tips will be treated with either 1% Virkon or 2% Trigene for 24 hours prior to autoclaving and disposal. Trigene also breaks down and inactivates DNA and RNA and is a DEFRA approved disinfectant. Trigene will also be used for decontamination of laboratory surfaces. All clinical material will be placed in plastic Sharps/Cm bins labelled with the following ‘ACGM2 waste, 5C10.1, FOR AUTOCLAVING AND INCINERATION’ in addition to standard ICR waste index. Any biological spills will immediately be treated with Virkon granules. Vaccinia virus is also susceptible to a range of chemicals including 1% sodium hypochlorite, 2% glutaraldehyde, forraldehyde and household bleach. For example, in experiments where infected cells are fixed (with formaldehyde and glutaraldehyde) prior to staining to assess lacZ expression, infectious virus will be inactivated by this procedure but the infected material will still be disposed by the approved waste route i.e. treatment with Virkon or Trigene and autoclaving.

All animal work will be performed in the BSU and in accordance with the local rules for ACDP level 2 working in the BSU. In the BSU standard cleaning and disinfection of the work area and equipment such as beakers and balances will be carried out using Virkon or Trigene. There is a theoretical risk of virus excretion therefore cages used for animal work will be of a disposable type. The cages will not be cleaned whilst occupied by animals as all studies proposed are of short duration. At the end of the work the cage in its entirety will be placed into a yellow plastic bag and the contents sealed with a plastic tie. The sealed yellow bag will be placed into a red 60 litre leak-proof plastic container supplied by a registered and approved waste contractor (Grundon Waste Management) and later will be collected by the waste contractor, who will incinerate the waste offsite. Sharps/Cm bin waste from BSU projects will be labelled with ‘ACGM2 waste, BSU, FOR INCINERATION’ and will be collected by the approved waste contractor and incinerated offsite.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The genetic modification safety committee were happy that this risk assessment addressed all the issues. The contractor, Grundon Waste Management is registered to take GM waste.

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

Generation of replication-defective lentiviruses (with biosafety features) for overexpression or inhibition of genes which may play a role in mammary gland development and/or genes for labelling cells with fluorescent proteins or lucifrase. The project will use viral vectors to transduce primary mouse mammary cells in culture and then transplant them back into mammary fat pads to enable the in vivo assessment of gene overexpression or knockdown on mammary development without the need to generate transgenic or knockout animals.

**Recipient or parental organism**

DNA will be propagated in DH5a (disabled, recombination deficient (recA) E.coli. Replication defection viruses will be generated in HEK293T cells. Viruses will be used to infect mouse 3T3 fibroblasts, C57MG, NMuMG, CommaD and HC11 mouse mammary cell lines (these are widely used and none are known to
carry adventitious agents) together with primary mouse mammary epithelial cells.

Host/vector system

This is a connected programme enabling different lentiviral vector systems to be used providing all conform to minimum biosafety standards, namely all must be split-genome (on a minimum of three vectors) replication defective viruses. The initial vectors to be used will be Trono laboratory split genome, conditional packaging lentiviral system \( pWPI, pMD2.G, pSAX2 \); split genome lentiviral SEW expression vector. \( pCMVR8.91 \) packaging construct and \( pMD2.VSVG \) pseudotyping vector; GIPZ lentiviral shRNA/mir system (six vector split genome VSV-G pseudotyped).

Origin & function

The aim of this connected programme submission is to establish minimum biosafety features and standards that will be used with this work so that additional vector systems being used for the same project and which meet these safety criteria may be added to this risk assessment without the need for resubmission to the HSE. For example, we have previously had approved risk assessment for two lentiviral systems, one for over-expression of genes and one for gene knockdown. However, recent collaborators who wished to work with us doing exactly the same experiments as described above, but with their gene of interest, had their over-expression and knockdown sequences cloned into different vectors. We did not have approval for these systems, even though they had equivalent third generation features with the viral elements split between three plasmids. We therefore had to spend a considerable amount of time recloning into our own vector systems. A second example of the need for this Connected Programme is that a number of viral libraries are now available through commercial companies from which genes of interest can be "cherry picked". Again, they usually have the same high biosafety features but in different packaging systems. It makes no sense to have to apply to the HSE every time one wants to use a different system form a different company.

Genes of interest to be studied include:

- ID4 - abHLH protein involved in regulating differentiation (no known oncogenic function)
- Myb - a transcription factor involved in cell lineage switching (oncogene)
- Msx2 - a transcription factor involved in cell lineage switching (potential oncogene)
- Sox6 - a transcription factor involved in cell lineage switching (no known oncogenic function).
- Ttk - Ttk protein kinase (potential oncogene).
- Wee1 - Wee1 tyrosine kinase homolog (potential oncogene).

The vectors may also carry marker genes such as luciferase or fluorescent proteins.

Evaluation of foreseeable effects

There is a negligible hazard to human health from disable E.coli host strains. DH5a has a proven history of safe use, has been characterized and is known to be free from harmful sequences.

The infected packaging cells would be unlikely to be pathogenic due to rapid complement mediated lysis of these cells when recognized by the immune system as of non-self origin. Transduced cells would not be shedding virus as they are replication-defective and therefore do not pose a risk to human health or the environment. The risk that the vector could be rescued in the mouse is negligible (there is no known means for murine retrovirus rescue of such vectors) so there is negligible risk of spread to other cages or to staff. Mouse cells will be unable to survive in the human in the event of accidental inoculation due to the species barrier and immune response.

The only risk is from lentiviral-mediated insertion of an oncogene or knockdown sequence into a human host during handling of viral supernatants. However, insertion of an oncogene into the human cells is not enough to create by itself cancer because it needs a combination of additional alterations. We will not use sequences which knockdown p53, Rb or their regulators. The vectors will be replication defective and potential exposure will be controlled by following containment level 2 local rules and use of good micro-biological practice.

The viruses are unlikely to survive outside the laboratory, as suitable growth conditions will not exist. The packaging cells and any transduced cells cannot survive outside
of the laboratory.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Work surfaces, including the inside of microbiological safety cabinets will be suitably disinfected after use (trigene). Centrifugation will be done in sealed tubes. Liquid wastes will be rendered safe for disposal by overnight treatment with an approved disinfectant according the ICR Waste Index (Virkon). Plastic pipettes will be soaked in an approved disinfectant (Virkon) prior to removal by Central Services Department (CSSD). Solid waste will be placed in autoclave bags for collection by CSSD. Material collected by CSSD will be autoclaved on site. The cleaning, disinfecting and disposal procedures will be documented and displayed. The biological spillage procedure will be displayed and HAZ-TAB disinfectants will be available for immediate use. Any incidents and accidents will be reported.

Once the lentivirus has infected the cells it should not be able to replicate. All new batches of virus will be tested for replication competence. Murine NIH3T3 or 3T3-L1 cells will be transduced with fresh or frozen (-70oC) viral supernatant (supernatant 1) (virus containing the gene of interest plus either a selectable marker or GFP) plus 2 ug/ml of polybrene and incubated overnight. The following day, cells will be washed with medium and refed. After 24 to 48 hours check the number of GFP positive cells will be assessed (or the cells will be put under selection). Cells will be grown for a further 4 to 6 days (splitting cells if necessary) and an overnight supernatant (supernatant 2) harvested from confluent cells. The supernatant will be passed through a 0.45 micron filter and either used straight away or stored frozen at -70oC. NIH3T3 or 3T3-L1 cells will then be transduced with supernatant 2 plus polybrene. A positive control consisting of supernatant 1 plus polybrene will be included. The cells will be washed the next day and fresh medium added. The cultures will be checked for GFP positive cells 24 to 48 hours later (or put under selection). In the absence of virus in supernatant 2 no green (GFP positive) cells (or resistant colonies if a selectable marker is used) should be seen whereas green cells should be present in cells transfected with positive control supernatant 1.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

02/03/2022
## Measles virus and measles virus vectors for in vitro and in vivo study.

**Project Additional Information**

### Purposes of the contained use

Wildtype MV is listed in ACDP as a Hazard Group 2 biological agent therefore Containment Level 2 is appropriate for MV-Edm and MV-Edm derived vectors. MV does not integrate into host DNA. Naked MV DNA is also not hazardous. The manipulations to MV-Edm are unlikely to alter the tropism or pathogenicity of the virus. (NIS and GFP genes are not potentially hazardous to human health).

### Recipient or parental organism

Mouse and rat tumour models.

### Host/vector system

The MV-Edm virus and vectors are derived from the attenuated Edmonston vaccine strain of MV(MV-Edm). The genetic basis of attenuation is unknown, however, as this is a widely used vaccine strain it is known to pose no risk to health. The manipulations to MV-Edm are unlikely to alter the tropism or pathogenicity of the virus. MV has no known transforming abilities and does not integrate into the host DNA; naked MV DNA is also not hazardous.

### Origin & function

The NIS and GFP genes, driven by constitutive CMV promoters, have been inserted into the full length MV-Edm genome downstream of the viral hemagglutinin gene. NIS is an integral plasma membrane glycoprotein which acts as an ion pump that transports iodide (I-) into cells. It has been most commonly studied and discussed in...
connection with the thyroid gland, in which NIS mediates the active transport of I- into the thyroid follicular cells as the crucial first step for thyroid hormone biosynthesis. The trapping of I- in cells, mediated by NIS, allows the delivery or radioiodine (131-I) and this method has been used effectively in the clinic as an ablative therapy for thyroid cancer for many years. NIS gene delivery into non-thyroidal tumour cells is also capable of inducing accumulation of therapeutically effective doses of 131-I and therefore has potential as a therapy for extrathyroidal tumours. In addition, the accumulation of 131-I allows scintigraphic imaging of tumours in order to assess tumour progression or regression, metastatic disease and recurrence. NIS occurs normally in the human body and, if expressed in humans, is not expected to have any adverse effects. The green fluorescent protein (GFP) is a protein that derives from the jellyfish Aequoreo Victoria. It is commonly used as a reporter gene. GFP is not expected to have any adverse effects if expressed in humans.

**Evaluation of foreseeable effects**

MV has no known transforming abilities and does not integrate into the host DNA. The MV-Edm virus and vectors are derived from the attenuated Edmonston vaccine strain of MV (MV-Edm). Although the genetic basis of attenuation is unknown, this is a widely used vaccine strain that is known to pose no risk to health. The manipulations to MV-Edm are unlikely to alter the tropism or pathogenicity of the virus. Naked MV DNA is also not hazardous.

Expression of NIS and GFP genes are not potentially hazardous to human health.

The safety and containment procedures in place should prevent transmission of the virus to the environment by air or drains. It is unlikely that the mutations introduced into MV could be stably maintained outside the laboratory conditions as the virus requires a host to replicate in. Animals that have been infected with the MV vectors are unlikely to escape from the Biological Service Unit (BSU). Normal working practice is only to open cages in hoods (as part of laboratory animal allergy prevention) and to record the number of occupants on each cage label. In addition, lab animals are unlikely to survive in the environment as they have no natural resistance to environmental pathogens.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Pippettes will be disposed of into pipette bins containing 2% TriGene, which inactivates nucleic acid, and contaminated plasticware will be soaked in a 1% Virkon solution for at least 12 hours prior to removal from containment. Following removal, plasticware will be autoclaved onsite. Biological liquid waste will be treated with 1% Virkon for at least 24 hours prior to disposal to the drain with plenty of water. A 1% Virkon solution has been shown to be sufficient for decontamination of VSV in tissue. In the event of a spillage Virkon granules will be used to immediately inactivate the virus. This treatment has been shown to kill VSV vectors effectively. All cages used for animal work will be of a disposable type. The cages will not be cleaned whilst occupied by animals as all studies proposed are of short duration. At the end of the work the cage in its entirety will be placed into a yellow plastic bag and contents sealed with a plastic tie. The sealed yellow bag will be placed into a red 60 litre leak-proof plastic container supplied by a registered and approved waste contractor (Grundon Waste Management) and later will be collected by the waste contractor, who will incinerate the waste onsite.

N
1) There should only be one proposer on each risk assessment. (It is fine to have just you)
Answer from Proposer:
I have changed the proposer on each risk assessment to me.

2) I am a bit confused. It states that all work will be in one room apart from transport to the freezer, but it lists rooms CBO37, 5C10.1, 4S4.1, 4S4.1, rm46.4 of BSU for use?
- I guess one of these rooms is for the irradiation part of the procedure? How will they transport the virus since it looks to me like they may actually be going from room to room? It might be useful to state what each room is being used for?
Answer from proposer:
I have removed CBO37
5C10.1 is the Category II lab
The radiation activities will take place in Room 19.2
4S4.1 and 4S5.1 refer to rooms where -80C storage will take place.
There is no designated room number in the BSU for animal work of this kind.
Answer from proposer:
The virus will be transported from room to room in a sealed tube in a sealed container.

3) I note that both of this group submissions list the BSU on the location room numbers, but neither list any BSU activities. Maybe all their locations could be reconfirmed to ensure accuracy?
Answer from Proposer:
I had originally planned to submit a separate BSU risk assessment, however, I have updated the risk assessments to include BSU activities.

4) There is mention of Room 46.4 of BSU Fulham being used for this work. I assume this is the Procedure room located just inside the barrier which is labelled Room 44. If this is the case this room is NOT a containment level 2 facility. The BSU's at Sutton and CBL do not have facilities for Category 2 containment work.
Answer from proposer:
Where animals are infected with virus all materials will be disposed of by approved routes (see risk assessment)

5) I have just one question regarding the GMO Proposal. It refers to the use of irradiation on infected cell lines. Will this occur in the Class II room or in a radioactivity area, and if it is the latter what measures, if any are needed, will be used to contain the infected cells or ensure there is no live virus in the cell culture.
Answer from proposer:
Irradiation of infected cell lines will take place in a controlled radiation area (Room 19.2). This irradiation will take place on cultures in sealed tissue culture containers.

6) 07-09 only. And also they should change MV to VSV on pages 7 and 8.
Answer from proposer:
Done
7) 07-08 only. I would like to see more details of how the virus will be produced, will scalpel blades be used for existing bands from gels, and do infected cells themselves produce infective viral particles?
Answer from proposer:
No scalpel blades will be used in the production or purification of these viruses. For virus production cells are infected with virus, harvested and subjected to centrifugation. Where needles are used for harvesting bands from sucrose gradients this will be done using a retort stand fitted with Perspex safety blocks (approved by H&S for previous virus purification protocols) produced specifically for this application.

8) 07-09 only. More detail required. How will virus be produced? Will sharps be used for cutting gels? It is stated that the virus is replication competent - will cells infected with it be transplanted into animals? Will the animals then be giving off virus and if so, will they be contained?
Answer from proposer:
See point 7) re scalpel blades. Where animals are infected with virus all materials will be disposed of by approved routes (see BSU risk assessment).

Please add the name preferably a reference for the vector to be used. Is there a bacterial host for the propagation of the viral vectors? This should be named. Could the proposer name which cancer cell lines they plan to use.

MV vectors will be obtained from the lab of Department of Immunology, Mayo Clinic, Rochester, Minnesota. The available relevant references for virus production are:

VSV vectors will be obtained from the lab, Department of Immunology, Mayo Clinic, Rochester, Minnesota. The available relevant references for virus production are:

No bacterial host is used for the propagation of measles virus.

Cell lines used will be Vero (African Green Monkey), LA7 (mouse mammary epithelial tumour), RG2 (rat glioma) and 9LlacZ (rat gliosarcoma). Other commonly used cell lines from other cancer types may also be tested. These cell lines are used routinely in the laboratory and pose no risk to human health. The cells used in this study pose no environmental hazard as they are unlikely to survive outside the laboratory.

9) If people with eczema/impaired immunity are to be excluded from working on this project, perhaps pregnant women should also be excluded??On a similar note, is it worth checking the measles immune status of staff on this project prior to exposure to this live, attenuated virus?
Answer from Proposer:
Previously the procedure for handling virus has been that pregnant women should not handle high titre stocks of virus but are permitted to handle diluted virus as the risk of infection is minimal. The measles virus and vectors used is an attenuated vaccine strain.
Investigating the effect of wild-type and mutant receptor tyrosine kinases on receptor-tyrosine kinase inhibition using retroviral vectors.

The aim of our project is to assess the effect of expression of wildtype and mutant receptor tyrosine kinase expression in paediatric and adult glioma cell-lines on cell growth, migration and RTK inhibitor sensitivity. It has previously been shown that in glionblastoma mutations in the EGFR gene have multiple effects on this and therefore we will assess if mutations in other receptor tyrosine kinases have a similar effect. We aim to express these wildtype and mutant genes using retroviral (MMLV based) vectors.

The recipient cell lines will be paediatric and adult glioblastoma cell-lines, as well as mouse fibroblast cell-line NIH-3T3. These cell-lines have been extensively characterised, have been maintained in cell culture for many years, are not a known source of pathogens, and are unlikely to survive outside the laboratory environment.
The vector that will be used is based on the Murine Moloney Leukemia virus (pBabe-puro). The vector has been modified in several ways to ensure that the virus is replication-defective, and will not form active viral particles unless it is co-transfected into a packaging cell-line with helper plasmids.

Origin & function

The genetic material that will be cloned into the retroviral vector will be DNA encoding wildtype and mutant versions of several receptor tyrosine kinases, such as EGFR, PDGFRα, PDGFRβ, IGF1R, ERBB2, KIT, VEGFR2 and MET. We also will clone fusion genes involving these receptors. The material will either be cloned from universal human reference RNA, with the mutations being introduced using site directed mutagenesis, or will be cloned from RNA extracted from patient material.

Evaluation of foreseeable effects

The retroviral vectors that we propose to use do have the potential for infecting any human cell. Through good lab practice the risk of these vectors affecting the user or others in the laboratory is extremely low. In the unlikely event of infection, the viral particles will not be able to replicate as they lack the gene encoding the envelope protein, which is required for cell entry. It is very unlikely that receptor tyrosine kinase expression will lead to cells that are able to survive outside the laboratory environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

There will be no derogation

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All transfections and transductions will be performed in a designated Class II biohazard safety cabinet, which will be disinfected with 1% Virkon after use. Virkon is a chemical disinfectant that kills 99.999% of organisms in less than 10 minutes. The cabinet will prevent unwanted infection of the cell-cultures as well as release of the viruses into the environment. Infected cells will be grown in a designated incubator. Pipettes, containers and plasticware contaminated with viruses will be left completely submerged in 1% virkon before disposal. Cells and growth medium will be treated with 1% virkon before disposal according to the Institute's Waste Index and Disinfection protocols. Sharps will not be used. Solid waste will be collected separately from any other biological waste, using a separate waste management system which involves autoclaving the waste in the building, after which it will be disposed of as biological waste which will be incinerated.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The genetic modification safety committee had some minor comments at the initial risk assessment:
- eye protection should be worn when working with the virus, even when working in a biological safety cabinet.
- details of method to detect helper virus formation in transduced cells were asked
- they asked to state that good laboratory practice will be used when working with oncogenic DNA

All these points were addressed in the final version of the risk assessment, which was approved and is attached to this application.
### Project Containment

#### Laboratory Activities

#### Project Additional Information

#### Purposes of the contained use
The generation and use of recombinant lentiviruses for overexpression or knockdown of genes or miRNA that may be involved in the development of cancer. The project will use third generation lentiviral vectors to transduce a range of target cells to generate stable cell lines expressing a defined phenotype for evaluation both in vivo and in vitro.

#### Recipient or parental organism
DNA will be propagated in DH5a (disabled, recombination deficient (recA)) E.coli or Stbl3 E. coli

#### Liposarcoma cell lines:

---

02/03/2022
**DDLPS: FU-DDLS-1, LPS6, LPS695, LPS853, LPS510, DDLS8817, T1000, 93-4496, 94-778, RDD8107 WDPDS: GOT3 SW 872 (HTB 92) (lacks MDM2 amplification), LiSa-2 (WLS-160, HS-18).**

**Rhabdosarcoma:**
- RH3, RH4*, RH5, RH18*, RH28, RH30, RH41, RH30-Birch*
- CCA CT10, RD*, JR-1*, CT-T, RUCH3, RUCH-2 (Botryoid), RMS-YM*, A204/HTB82, RH7, RH10, RH13, A673, Hs729T

**Ewings sarcomas**
- A673, TC-71, SK-ES-1, A4573, STAET2.1, TTC466, SKNMC, STAET1, RM82, WE68, CADOES, SJRH.

**Desmoplastic small round tumour**
- JN-DSRCT-1.

**Models:**
- C2C12 - myoblasts, osteoblasts and adipocytes.
- C3H10T1/2 - myoblasts, osteoblasts, chondrocytes and adipocytes.
- 3T3-L1 - pre-adipocytic murine cells model.
- LPS in xenograft.
- Shep, Kelly and IMR32 Neuroblastoma.
- Primary mesenchymal stem cells.
- Human tumour cell lines and established metastatic variants.
- HEK293T packaging cells.

### Host/vector system

This is a connected programme to enable the use of different lentiviral systems that are all split genome third generation. The following vectors or derivatives will be employed. Tronolab pWPI system; split genome lentiviral SEW expression vector; GIPZ and TRIPZ lentiviral shRNAmir system (six vector split genome VSV-G pseudotyped); pLVUT-TR-KRAB (Aebischer); Sigma MISSION shRNA pre-packaged lentiviral particles; pCDF cDNA Cloning and Expression Lentivectors. (System Biosciences); Retro-X Tet on Advanced Inducible Expression System (Clontech); Virapower TREX and BlockIT Inducible RNAi Lentiviral expression system (Invitrogen).

### Origin & function

The aim of this connected programme is to allow those groups employing lentiviral systems for determining the validity of gene targets in a drug development program to do so without the need for resubmission to the HSE validity of gene targets in a drug development program to do so without the need for resubmission to the HSE.

The genes of interest that are being studied include:
- **MAP4K4** - Serine/threonine kinase that may play a role in the response to the environmental stress and cytokines such as TNF-alpha.
- **MYCN** - A Proto-oncogene. Amplification of this gene is associated with a variety of tumors, most notably neuroblastomas.
- **ALK-Orphan receptor with a tyrosine-protein kinase activity**
- **HIF1alpha** - The protein is a master transcriptional regulator of the adaptive response to hypoxia.
- **ILT8** - Chemokine that functions as a chemoattractant, and is also a potent angiogenic factor.
- **GMCSF** - The protein encoded by this gene is a cytokine that controls the production, differentiation, and function of granulocytes and macrophages.
- **TIMP-1** - The proteins encoded by this gene family are natural inhibitors of the matrix metalloproteinases (MMPs), a group of peptidases involved in degradation of the extracellular matrix.
- **TNFalpha** - This cytokine is involved in the regulation of a wide spectrum of biological processes including cell proliferation, differentiation, apoptosis and lipid metabolism.
- **WNT** - A proto-oncogene. These proteins have been implicated in oncogenesis and in several developmental processes, including regulation of cell fate.
- **DVL1** - The human homolog of the Drosophila dishevelled gene (dsh) encodes a cytoplasmic phosphoprotein that regulates cell proliferation.
- **SHH** - The hedgehog (Hh) signalling pathway is crucial in the development of all known animals.
- **Siah 1 and 2** - These genes encode proteins that are E3 ligases and are involved in ubiquitination and proteasome-mediated degradation of specific proteins.
- **B Catenin** - Mutations in this gene are a cause of colorectal cancer (CRC), pilomatrixcoma (PTM), medulloblastoma (MBD), and ovarian cancer.
- **THAIP1 and 2** - Threonine aldolase 1 pseudogenes.
- **bFGF** - FGF family members bind heparin and possess broad mitogenic and angiogenic activities.
- **AKT 1-3** - Serine/threonine kinases that plays a key in regulating cell survival, insulin signalling, angiogenesis and tumor formation. Akt is a downstream mediator of the PI 3-K pathway.
- **VEGF** - This gene encodes a protein that specifically acts on endothelial cells and has various effects, including mediating increased vascular permeability, inducing
angiogenesis, vasculogenesis and endothelial cell growth, promoting cell migration, and inhibiting apoptosis.
mTOR Rictor and Raptor These kinases mediate cellular responses to stresses such as DNA damage and nutrient deprivation
HSP90 isoforms. HSP90 proteins are highly conserved molecular chaperones that have key roles in signal transduction, protein folding and protein degradation.
GSK3B Participates in the Wnt signalling pathway
Aurora kinase A and B. Aurora kinases are a family of highly homologous serine/threonine kinases that play a critical role in regulating many of the processes that are pivotal to mitosis.
Pik3CA, B, D, G Lipid kinases that are responsible for coordinating a diverse range of cell functions including proliferation, cell survival, degranulation, vesicular trafficking and cell migration. Potentially oncogenic
Gly1 and 2 Threonine aldolases involved in glycine biosynthesis
Chk1 and 2 Required for checkpoint mediated cell cycle arrest in response to DNA damage
FLT1-3 These genes encode proteins that bind to VEGFR-A, VEGFR-B and placental growth factor and play an important role in angiogenesis and vasculogenesis.
RPS6KB1 and 2 Downstream effectors of the mTOR signaling pathway
PAK4 PAK proteins are critical effectors that link Rho GTPases to cytoskeleton reorganization and nuclear signaling
FOXO1 forkhead box A10/O26/04/2011 Transcription factor. Multiple targets. Might play a role in myogenic differentiation.
NELL1 NEL-1. This gene encodes a cytoplasmic protein that contains epidermal growth factor (EGF)-like repeats. The encoded heterotrimeric protein may be involved in cell growth regulation and differentiation.
PAX3-FOXO1 Fusion gene, Rhabdomyosarcoma, Transcription Factor: Multiple targets.

The following genes encode proteins that are involved in the epigenetic control of demethylating histones:
FBX10 FBXL11 FBXL19 HR HSPB JARID1A JARID1B JARID1C JARID1D JARID2 JHDM1D JMJD1A JMJD1B JMJD1C JMJD2A JMJD2B JMJD2C JMJD2D JMJD3 JMJD4 JMJD5 JMJD6 LSD1 PHF2 PHF8 UTX UTY ASH1 ASH2L CARM1 DOT1L EHMT1 EHMT2 EZH1 EZH2 LCMT2 METT10D METT11D1 METT5D1 MLL MLL2 MLL3 MLL4 MLL5 NSD1 PRDM1 PRDM2 PRDM5 PRMT1 PRMT2 PRMT5 PRMT6 PRMT7 PRMT8 SET7/9 SET8 SETD1A SETD2 SETD3 SETD4 SETD5 SETD6 SETDB1 SETD2B SETMAR SMYD2 SMYD3 SMYD5 SUV39H1 SUV39H2 SUV420H1 SUV420H2 SUZ12 WHSC1 WHSC1L1

IGF1R IGF1R homodimers are activated by IGF-I and IGF-II and mediate pre- and postnatal growth. Mediate action via PI3K.
MET MET is a cell surface receptor that is involved in initiating cell migration.
MYC A transcription factor with multiple targets and known oncogenic function.
ALK A signalling kinase critical in cell survival and proliferation.
ERK1 A signalling kinase critical in cell survival and proliferation.
EEK2 A signalling kinase critical in cell survival and proliferation
PLK1 A signalling kinase critical in cell survival and proliferation
RAF1 This gene is the cellular homolog of viral raf gene. Functions downstream of the Ras family of membrane associated GTPases to which it binds directly.
GPC3 Heparan sulfate proteoglycan involved in growth factor signalling.
GPC3 Heparan sulfate proteoglycan involved in growth factor signalling.
SULF1 Sulatase with heparin-degrading endosulfatase activity.
SULF2 Sulatase with heparin-degrading endosulfatase activity

Their functions are mostly unknown with following exceptions:

- hsa-miR-19a and b. Known oncogenic function. Activated by cMYC
- hsa-miR-181b. Involved in myogenic differentiation through modulation of HOX genes
- hsa-miR-21 known oncogenic function. Targets and represses PTEN
- hsa-miR-9 Oncogenic function. Activated by cMYC and MYCN. Promotes metastasis
- hsa-miR-20a. Oncogenic activated by cMYC and MYCN
- hsa-miR-17a, 18a, 92a and 378 Known oncogenic function activated by cMYC
- hsa-miR-25 Known onogenic function
- hsa-miR-183 Targets PTEN

Further genes and miRNAs will be added to this risk assessment in the future by means of local updates when new ones of further interest are identified.

### Evaluation of foreseeable effects

There is a negligible hazard to human health from disabled E. coli host strains. DH5a has a proven history of safe use, has been well characterised and is known to be free from harmful sequences.

The infected packaging cells would be unlikely to be pathogenic due to rapid complement mediated lysis of theses cells when recognized by the immun system as of non-self origin. Transduced cells would not be shedding irus as they are replication-defective and therefore do not pose a risk to human health or the environment. The risk that the vector could be rescued in the mouse is negligible (there is no known means for murine retrovirus rescue of such vectors) so there is negligible risk of spread to other cages or to staff. Mouse cells will be unable to survive in the human in the event of accidental inoculation due to the species barrier and immune response.

The only risk is from lentiviral-mediated insertion of an oncogene or knockdown sequence into a human host during handling of viral supernatants. However, insertion of an oncogen intot he human cells is not enough to create by itself cancer because it needs a combination of additional alterations. The vectors will be replication defective and potential exposure will be controlled by following containment level 2 rules and use of good microbiological practice.

The viruses are unlikely to survive outside the laboratory, as suitable growth conditions will ot exist. The packaging cells and any transduced cells cannot survive outside the laboratory.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

- Work surfaces, including the inside of microbiological safety cabinets, will be suitable disinfected after use (Trigene). Centrifugation will be done in sealed tubes. Liquid wastes will be rendered safe for disposal by overnight treatment with an approved disinfectant according to ICR Waste Index (Virkon or Chloros). Plastic pipettes will be...
soaked in an approved disinfectant (Virkon) prior to removal by Central Services Department (CSSD). Solid waste will be placed in autoclave bags for collection by CC+SSD. Material collected by CSSD will be autoclaved on site. The cleaning, disinfecting and disposal procedures will be documented and displayed. The biological spillage procedure will be displayed and HAZ-TAB disinfectants will be available for immediate use. Any incidents and accidents will be reported.

Once the lentivirus has infected the cells it should not be able to replicate. All new batches of virus will be tested for replication competence. Where appropriate with HIV based vectors this may be done by the use of a p24 assay on the tissue culture medium. Alternatively Murine NIH3T3 or 3T3-L1 cells will be transduced with fresh or frozen (-70°C) viral supernatant (supernatant 1) (virus containing the gene of interest plus either a selectable marker or GFP) plus 2ug/ml of polybrene and incubated overnight. The following day, cells will be washed with medium and refed. After 24 to 48 hours check the number of GFP positive cells will be assessed (or the cells will be put under selection). Cells will be grown for a further 4 to 6 days (splitting cells if necessary) and an overnight supernatant (supernatant 2) harvested from confluent cells. The supernatant will be passed through a 0.45 micron filter and either used straight away or stored frozen at -70°. NIH3T3 or 3T3-L1 cells will then be transduced with supernatant 2 plus polybrene. A positive control consisting of supernatant 1 plus polybrene will be included. The cell will be washed the next day and fresh medium added/ the cultures will be checked for GFP positive cells 24 to 48 hours later ( or put under selection). In the absence of virus in supernatant 2 no green (GFP positive) cells (or resistant colonies if a selectable marker is used) should be seen whereas green cells should be present in cells transfected with positive control supernatant 1.

Purposes of the contained use

Our laboratory has active interests in the use of viral and other biotherapeutic agents, both as treatment for cancer and for improving response rates to, and toxicity of, existing cancer therapies. At present we utilise oncolytic viruses (detailed in a previous GMSC/HSE GM80/08.3 in the treatment of cancer. We also have a significant interest in radiosensitisation by both viral and standard chemical chemotherapeutic agents. Doses of radiotherapy that can be clinically administered to cancer patients are limited by local toxicity to joints and other tissues. The administration of novel radioprotective agents is one established technique to protect normal tissue against toxicity whilst allowing target tumour cells to exhibit sensitivity; an alternative mechanism is to use biotherapeutic agents which have synergy with radiotherapy to enhance the sensitivity of tumour cells to radiation. The agents which are the subject of this application will therefore be used in existing in vitro and in vivo models to assess their efficacy in protecting normal tissues (lentivirus work) or sensitising tumour cells (listeria work). This will involve testing the agents alone and in combination with radiotherapy and chemotherapy.

Note that this application is submitted as a Connected Programme. The aim of this submission is to establish minimum biosafety features and standards that will be used with this work so that additional vector systems and genes being used for the same project and which meet these safety criteria may be added to this risk assessment without the need for resubmission to the HSE.

Recipient or parental organism

Listeria monocytogenes EDGE
Class 2 Listeria monocytogenes yyCh
For the Listeria, standard plasmid vector systems designed for use in Gram positive bacteria or shuttle vectors that replicate in both Gram negative and Gram positives hosts (Listeria, Bifidobacteria and Lactococcus). The vector systems used in this project are commercially supplied, have a history of safe use and are not likely to endow any pathogenic traits.

Lentivirus:
We will use commercially available lentiviral plasmids, with appropriate packaging systems (2nd or 3rd generation or higher) or ready-made lentiviral particles. For generation of lentiviral plasmids within the institute we will propagate cDNA in DH5a (disabled, recombination deficient (recA)) E. coli or Stbl3 E.coli), which are designed to minimise recombination in lentiviral vectors. All virus will be replication incompetent and we will routinely screen stable cell lines, and produced titres of virus, for replication competence.

cDNA will be propagated in DH5a (disabled, recombination deficient (recA)) E. coli or Stbl3 E.coli), which are designed to minimise recombination in lentiviral vectors.

All the vector systems described below are split vector systems with a minimum of three elements:

1) The expression vector into which the gene of interest is cloned and which also usually contains a fluorescence and/or selectable marker. The expression vectors also contain elements to allow packaging into virions.

2) A packaging plasmid supplying the helper functions in conjunction with structural and replication proteins (in trans) required to produce the lentivirus. In some more advanced biosafety systems, these functions are also split between more than one vector.

3) A plasmid supplying an envelope protein that gives broad tropism (usually VSV-G).

VECTOR SYSTEM 1: pLV-CMV-X-GFP-2A-puro (3rd generation LV backbone with 2nd generation packaging plasmids)

VECTOR SYSTEM 2: pGIPZ SYSTEM (2nd generation)

VECTOR SYSTEM 3: pLV-fLuc (firefly luciferase) (3rd generation)

VECTOR SYSTEM 4: pLV105-eGFP (3rd generation)

Additional vector systems with the same minimal safety features will be added as required.

For listeria:

i) lux: The inserted genes of interest for each bacterial strain encode the luxABCDE operon, which is a synthetic operon encoding a fatty acid reductase complex (LuxCDE) involved in synthesis of the fatty aldehyde substrate for the bioluminescence reaction catalyzed by the LuxAB luciferase. Its function is to serve as a reporter system to monitor bacterial viability and growth both in vivo and in vitro.

ii) fLuc: Firefly luciferase gene. Expression of the luciferase gene is driven by the human cytomegalovirus immediate early gene (CMV) promoter. The reporter gene has been used extensively in research and poses no risk to animal health or the environment.
Evaluation of foreseeable effects

Lentivirus
Accidental human inoculation with lentivirus is unlikely to result in the development of any human disease, acute or chronic, as the vectors are replication deficient and any inoculated virus will be rapidly destroyed by the human immune system.

The infected packaging cells would be unlikely to be pathogenic due to rapid complement mediated lysis of these cells when recognized by the immune system as of non-self origin. Transduced cells would not be shedding virus as they are replication-defective and therefore do not pose a risk to human health or the environment. The risk that the vector could be rescued in the rat is negligible so there is negligible risk of spread to other cages or to BSU staff.

There is a small risk from lentiviral-mediated insertion of an oncogene or knockdown sequence into a human host. However, insertion of an oncogene into the human cells is not enough to create by itself cancer because it needs a combination of additional alterations. We will not use sequences which knockdown p53, Rb or their regulators. The vectors will be replication defective, potential exposure will be controlled by following containment level 2 local rules and use of good microbiological practice. The viruses are unlikely to survive outside the laboratory, as suitable growth conditions will not exist.

Listeria monocytogenes
In healthy individuals, infection by L. monocytogenes causes the disease listeriosis, which is generally a foodborne disease, with as few as 1000 organisms having the potential to invade the gastrointestinal epithelium in susceptible individuals. Clinical treatment of wild-type L monocytogenes is with ampicillin, to which these organisms are almost universally sensitive, and produces cure.

The EDGe strain is the wild-type strain and yycH is a safety-modified derivative with further increased sensitivity to ampicillin, allowing it to be easily cleared systemically following administration of the antibiotic. Routes of infection include inoculation, ingestion, inhalation and contact with mucous membranes. Individuals working with listeria will be required to wear personal protective equipment (eye guard, face mask, gloves) to reduce the risk of transmission.

DH5-alpha strain E. coli will be used to perform transformations. Hazards to human health are non-pathogenic to human health.

Superoxide dismustase 2 is involved in the regulation of cellular oxidative stress and as such is not considered an oncogene. Similarly, CTGF knockdown is unlikely to result in de-differentiation on it's own. The hazards from over-expression or knock-down are therefore, negligible. Hazards from potential oncogenes are minimal as they can rarely act as single transforming agents in normal cells.
Listeria
The inserted gene products encode a reporter system. The genetic insert is a synthetic luxABCDE operon encoding a fatty acid reductase complex (LuxCDE) involved in synthesis of the fatty aldehyde substrate for the bioluminescence reaction catalyzed by the LuxAB luciferase. It poses no risk to animal or human health. Another gene is firefly luciferase gene. Expression of the luciferase gene is driven by the human cytomegalovirus immediate early gene (CMV) promoter. The reporter gene has been used extensively in research and poses no risk to animal health or the environment.
Hazards from alteration of existing traits:
Lentivirus
The proposed vectors are reduced in pathogenicity as they lack certain wildtype elements and are replication deficient.
Listeria
L. monocytogenes EGDe is not altered in any way in regard to its pathogenicity, host range, tropism, transmission or immunity and will behave exactly as wild-type species would so poses no increased threat to human or environmental health when compared to the parental strain.
L. monocytogenes yycH is a safety-modified derivative with increased sensitivity to ampicillin allowing it to be easily cleared systemically following administration of the antibiotic.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Lentivirus will be cultured using standard culture techniques in a dedicated incubator in a containment level 2 laboratory. Following this the viral particles will be concentrated and aliquoted for administration in our established in vivo model. Transport between the CL2 laboratory and the CL2 BSU facility in which our existing work takes place will be transported in 2 containers with sealed lids.
The listeria will be cultured using standard bacterial culture techniques in a dedicated incubator in a containment level 2 laboratory. Following this the bacteria will be concentrated and aliquoted for administration in our established in vivo model. Transport between the CL2 laboratory and the CL2 BSU facility in which our existing work takes place will be transported in 2 containers with sealed lids.

Animals are housed singly in Individually Ventilated Cages (IVCs).

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid wastes will be rendered safe for disposal by overnight treatment with an approved disinfectant according to the ICR Waste Index (1% Virkon). Plastic pipettes will be soaked in an approved disinfectant (2% Trigene) for 24 hours prior to removal by CSSD (Central Sterile Services Department). Solid wastewill be placed in autoclave bags for collection by CSSD. Material collected by CSSD will be autoclaved on site. The cleaning, disinfecting and disposal procedures will be documented and

13. Emergency Plan - Public Register
14. Risk Assessment - Public Register
I confirm that I have attached a risk assessment to this form.
I am not claiming exemption from disclosure for sections of the risk assessment.

Summary of files attached to this notification

Attachments Uploaded
15. Comments of the genetic modification safety committee on the risk assessment - Public Register
16. Personal information for person responsible for supervision and safety of GM activities at the premises
17. Non Disclosure of Information
18. Declaration displayed.

All GMM waste material is sealed and autoclaved on-site. Animals used in procedures involving GMMs will not be permitted to rejoin the general animal population. Only staff with appropriate training will be allowed to perform procedures using GMM's in animals. All staff must wear disposable PPE during every visit. BSU waste and culled animals that have received lentiviral/listeria inoculation will be incinerated as per routine practice. There is no expected risk of recovering infectious virus or bacteria from culled animals and frozen carcasses will be incinerated within 24 hours of death.

The ICR Genetic Modification Safety Committee have approved the attached risk assessment for submission to the HSE.

<td>THE USE OF AN RPOS-LUX CDABE REPORTER PLASMID IN E.COLI AND</td>
<td>Class 2</td>
<td>&lt; 1 litre</td>
<td></td>
</tr>
</tbody>
</table>
Purposes of the contained use

The plasmid pSB367 is a pUC based vector which contains a fusion of the Salmonella dublin spvRA promotor with the luxCDABE genes from Photorhabdus luminescens. This plasmid, which has been constructed elsewhere, will be introduced into a non-pathogenic bur colonising strain of E coli (Krogfelt KA et Infect Immun 68(5):2518-24) and Salmonella Typhimurium strains to monitor rpoS mediated gene expression.

Recipient or parental organism

The recipient bacteria will be a non pathogenic gastro-intestinal E coli strain and Salmonella Typhimurium strains. The E coli strain will be non-pathogenic yet will be able to colonise the GI-tract. Salmonella Typhimurium is an ACDP group 2 pathogen which is able to colonise the gastrointestinal tract of humans and cause a self-limiting gastrointestinal illness in healthy individuals. The route of transmission is via the oral route. The GMOs will contain a pUC based plasmid which leads to the expression of luxCDABE. These are widely used reporter genes and encode a luciferase complex that results in the production of bioluminescence. Other than the production of blue green light no other foreseeable effect is likely to be associated with the GMOs. The introduction of this plasmid will not affect pathogenicity or tissue tropism.

Host/vector system

The plasmid has been constructed elsewhere (University of Nottingham). It is a pUC based vector containing an ampicillin resistance gene. In E coli and Salmonella this vector is considered to be non-mobilisable and gene transfer is thus a remote possibility.

Origin & function

This project will involve the introduction of a plasmid into E. coli and Salmonella Typhimurium. This will represent the only genetic modification carried out. The Plasmid pSB367 is a pUC based vector which contains a fusion of the Salmonella dublin spvRA promotor with the luxCDABE genes from Photorhabdus luminescens. The spvRA promotor is a non-coding region that is active in response to levels of the alternative sigma factor RpoS. The luxCDABE genes are derived from a non-pathogenic bacterium (Photorhabdus luminescens) and will function solely as a reporter gene such that cells containing the plasmid will express bioluminescence in response to levels of RpoS.

Evaluation of foreseeable effects

Bacterial luciferase catalyses the oxidation of reduced flavin mononucleotide (FMNH2) and a long chain aldehyde by molecular oxygen to yield FMN, the corresponding acid, water and light. the luxC, luxD, and luxE encode for a multi-enzyme reductase complex that produces decanal the substrate for the luciferase reaction. These genes are not implicated in pathogenicity and have no known function other than the production of bioluminescence. Consequently, the expressed gene products can be
considered to be non-harmful. The strain of E.coli, whilst not pathogenic, will colonise the GI-tract. The recipient Salmonella Typhimurium strains will be enteropathogenic and may cause a self-limiting gastrointestinal illness in health individuals if the organisms enter the mouth. However, the GMOs will not be altered in existing pathogenic traits and there is no reason to suspect that the disease caused will be different to that of the wildtype organisms.

The GMMs may survive in the environment for a limited period. However, since the modification is not likely to confer survival advantages no specific environmental hazard is likely. Animals are frequently, colonised by the non-GM recipient organisms and these are continually shed into the environment as a result of faecal contamination. Given that no specific hazard has been identified, it is not thought that the modified organisms would present a greater risk to the environment than the wildtype.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None applied for

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste including liquid 100 ml cultures, 1 ml samples taken for growth measurements, and solid agar plates will be inactivated using the school waste autoclave. Inactivation will use the routine cycle which operates at 121 C for 30 min. No viable cells of the GMMs will survive this process. The inactivation process is monitored by a trained technician.

Is an emergency plan required according to regulation 20? N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

JWD asked if attenuated strains of Salmonella Typhimurium were available, and if so, could these be used to lower risk. SFP replied yes attenuated strains were available (such as LT2) but these have rpoS mutations. Since they do not produce RpoS they could not be used to monitor it's level which is the purpose of the planned experiments. The risk assessment was then approved for submission to the HSE.

The purpose of this project is to measure circadian rhythms in cultured primary cells (of human or rodent origin) by means of real-time reporter imaging. The reporter constructs will be inserted into the cultured cells by use of a lentiviral transfection system.

Recipient or parental organism

All plasmids will be grown up in a standard disabled E.coli strain (e.g. JM109, DH5alpha; ACDP Hazard Group 1). The E.coli cloning strain used (e.g. JM109, DH5alpha) will be disabled and thus presents very low risk and should not survive outside the laboratory. Transfected E.coli will become insensitive to ampicillin for selection purposes, but will be destroyed either in the recovery of the inserted plasmids or by use of a standard detergent (e.g. wiskon). No alteration in pathogenicity of E.coli host will be caused.

Lentiviral constructs will be made using commercially available HEK293T cells which are produced by stably expressing the SV40 large T antigen in a standard HEK293 cell line. The SV40 large T antigen facilitates production of high viral titres. HEK cells are commonly used human-derived cells that pose little risk and should not survive outside the laboratory. All HEK293T cells used within an experiment will be destroyed either in the recovery of the lentiviral particles or by use of a detergent.

Host/vector system

The lentiviral particles to be used are 'second generation' vectors, in which the core and enzymatic components of the virion come from HIV-1 but have been manipulated...
To delete all viral auxiliary genes (i.e. vpr, vif, vpu and nef) and thus reduce pathogenicity.

Reporter constructs are considered harmless and there is no evidence that they will alter the pathogenic nature of the lentivirus.

Origin & function

Production of lentivectors will be based around the psPAX2 (2nd generation) packaging system and pMD2G envelope plasmid, which originate from the Trono laboratory (http://tronolab.epfl.ch/page58114.html). Reporter vectors will be cloned into a standard commercial reporter vector (e.g. pGL3). Plasmid vectors will contain an ampicillin resistance gene.

Lentivectors will be based on HIV-1, but modified to reduce pathogenicity (as described under "Host/vector system" section above).

We will initially use a reporter construct produced by fusing the firefly luciferase gene to the promoter region of the mouse Bmal1 gene, which is a rare component of circadian clock. This construct has been provided by Professor Steven Brown (http://www.pharma.uzh.ch/research/chronobiology/areas/chronobiology/projects/genetics.html), University of Geneva. In future experiments, we will likely produce additional reporter constructs, which will have a similar basis, i.e. a standard, non-hazardous reporter gene controlled by appropriate mammalian promoter/enhancer elements.

Evaluation of foreseeable effects

Details of the foreseeable effects are given above. In brief,

Preparation of the lentiviral particles will pose minimal risk and would by itself come under Class 1.

Preparation of the lentiviral particles will involve transfecting a human-derived cell line (HEK293T) with a combination of plasmids. The lentiviral system to be used takes advantage of genetic manipulation to greatly reduce pathogenicity. The reporter constructs that the lentivirus will deliver to our target cells is considered harmless and thus there is very low risk associated with this work.

The final part of the work will involve using the lentivirus to transfict human and rodent primary cell cultures. These primary cells are not considered pathogenic per se. There is very small risk that human cells may contain infectious material. However, the human volunteers for our work will be put through health screens during the selection procedure and workers with human primary cultures will be encouraged to take a course of vaccination against Hepatitis B.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only cultured cells will be used in this programme of work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We will conduct this work according to the full Class 2 containment regulations.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Treatment/inactivation of liquid waste and spills during the cell culture process will be conducted by treatment with suitable detergent (e.g. Virkon) or bleach. Liquid waste will be treated for 24 hours before being washed down the sink with plenty of water.

Solid waste will be autoclaved prior to disposal.

Centrifugation in closed vessels will minimise aerosol formation.
At the end of an experiment, cells will be destroyed using standard detergent (e.g. virkon).

The GMM committee was satisfied that the lentivirus vector system proposed in this research incorporates sufficient safety features for work at containment category 2.

The main risks associated with HIV-1 based vectors are:

1. The generation of replication competent lentivirus.
   Safety measure assessment - The vector system proposed contains only the core and enzymatic HIV-1 genes with auxiliary genes deleted. It is extremely unlikely to generate the capacity of replication by recombination events. Work at containment level 2.

2. Potential for tumourgenicity and insertional mutagenesis of lentiviral vector (this has not been well defined).
   Safety measure assessment - Work at containment level 2.

The inserted reporter genes were not oncogenic.

Please enter comments on the GM safety committee on the risk assessment

</tbody>
</table>
The primary objective is to expand the safety profile of an attenuated vaccinia virus when administered intravenously to subjects with advanced solid tumours. Secondary objectives include the detection of virus delivery to primary and/or metastatic tumours by Polymerase Chain Reaction (PCR), viral plaque assay (VPA) and immunohistochemistry; and evaluation of anti-vaccinia virus immune response (e.g. antibody responses); evaluation of viral delivery by imaging of GFP expression. A recommended dose and schedule for future investigation will be made. Any evidence of anti-tumour activity will be described. Kinetic studies of virus in serum will be conducted.

Vaccinia viruses are of high genetic stability. The whole life cycle is restricted to the cytoplasm of infected cells thus recombination with host genomes located in the nucleus are very unlikely to occur. Since poxviruses are not endemic in human populations, it is further unlikely that these viruses would recombine with a wild-type virus to produce a more virulent strain; and, despite worldwide use of the live virus vaccine, no reported adverse events due to mutations to a more aggressive phenotype have ever been reported.

Consequences of accidental exposure as auto-inoculation of mucous membranes or abraded skin may result in a benign rash; needle sticks may most likely be restricted to local reactions as development of vesicular or pustular lesion, area induration or erythema surrounding a scab or ulcer at inoculation site. Flu-like symptoms may occur.

GL-ONC1 has a number of reporter genes inserted into its genome.

- RUC-GFP: Synthetoc vaccinia early/late promoter (pE/L), followed by sea pansy Renilla reniformis luciferase and humanized Aequorea victoria green fluorescent protein fusion gene.
- LacZ: Vaccinia virus Western reserve (WR) early/late P7.5 promoter, followed by the bacterial E. coli beta-galactosidase gene.
- gusA: Vaccinia virus WR late P11 promoter followed by the bacterial E. coli beta-D-glucuronidase gene
- hTRF: Synthetic vaccinia early/late promoter (pE/L), followed by human transferrin receptor sequences in reverse orientation to the promoter, thus the hTFR is not expressed.
The inserted genes serve several purposes:
Disruption of the viral nonessential genes (F14.5L, TK and HA) by insertion of the respective genes not only attenuated the virus but also enhanced its tumour-specific targeting.

Furthermore, the three inserted diagnostic marker genes (ruc-gfp, LacZ, gusA) will be used to monitor virus replication in vivo and in vitro for the detection of virus in biopsies:
RUC-GFP allows for direct in vivo monitoring of tumour targeting, e.g. in the pleural cavity and the detection of metastases, as well as the staging of human subjects by imaging of regional lymph nodes to determine degree of metastases.

X-Gal and X-Glu allow for histopathological staining of tumour biopsies, and thus for monitoring of tumour targeting and oncolytic effects of the virus, which can be carried out in tumours that are not easily accessible by fluorescence. The procedures can also be performed in clinics that do not have this special equipment.

The circulating beta-glucuronidase will be used for monitoring the presence/release of GL-ONC1.

The vaccinia specific promoter sequences are needed for expression of the different markers.

**Evaluation of foreseeable effects**

Hazards arising from the alteration of existing pathogenic trails: GL-ONC1 is expected to have reduced virulence compared to wild-type vaccinia strains due to the insertional inactivation of a number of viral genes. It is anticipated that these deletions will render the virus tumour selective. The inserted genes do not have any expected biological activity on the human recipient.

The risk that GL-ONC1 will revert into more virulent mutants is very low, as the parental UVP strain, a descendant of the Lister strain, was attenuated by frequent passages on calf skin (more than 500 times) and was widely used as a vaccine, with excellent documented safety, during the WHO smallpox eradication program. In addition, because orthopoxviruses are not endemic in the human population, it is unlikely that GL-ONC1, as a clonal strain, will recombine with a wild-type orthopoxvirus to produce a more virulent strain; and, despite worldwide use of the live virus vaccine, no reported adverse events due to mutation to a more aggressive phenotype has ever been reported.

Potential hazards if the genes being transferred to another micro-organism: Vaccinia virus is non-pathogenic to other micro-organisms or plants, and it does not transfer its DNA to the host genome on infection. The inserted genes are marker genes to allow assessment of viral trafficking in tissue and imaging and are unlikely to be transferred to other micro-organisms or cause harm.

Consideration of the predicted properties of the GMO to determine whether there are any mechanisms by which it could represent a hazard to the environment. Samples of Good Laboratory Practice (GLP) and Good Manufacturing Practices (GMP) produced GL-ONC1 were spotted onto filter paper to examine the stability after release into environment. At the respective tie points, the virus samples were retrieved from the filter paper and the amount of active virus was analysed by plaque assay. The sponsors experimental results showed that the titres of both GLP and GMP manufactured GL-ONC1 were decreased by 99.99% within 24 hrs when released into the environment at room temperature. By days 6-7, all viruses were disintegrate. Therefore, we do not believe that virus shed from patients will be of significant environmental concerns or health concerns to the others.

Precautions are in place to isolate patients on the treatment ward at CRC which is a locked ward with swipe-card access, to avoid environmental contamination. Vaccinia virus is non-pathogenic to other micro-organisms or plants, and it does not transfer its DNA to the host genome on infection. Transfer of DNA has not been reported. Deletions of a number of genes in GL-ONC1 mean that the virus cannot replicate without a suitable host.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A
Derogation is sought to use an autoclave located in a different building to inactivate items generated in the class 2 activity within the Clinical Research Centre. It is proposed that items that require inactivation by autoclaving will be autoclaved at the Leggett Building (previously known as the Postgraduate Medical School) which is immediately adjacent to the Clinical Research Centre, approximately 80 metres away. The Leggett building is owned and operated by the University of Surrey and is on the University Manor Farm campus together with the Clinical Research Centre. The campus is monitored by the University Security and Estates department. Access to laboratory areas (including the area in which the autoclave is situated) in the Leggett Building is controlled at all times by swipe-cards, and access to the entire building is swipe-card controlled outside working hours. All items will be transported by University staff in plastic bags placed within a rigid, leak-proof box. The outside of the box will be disinfected with 1% Virkon before transport.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

(1) In this connected programme of work all activities involving storage, preparation and administration of the GMM will take place within the University of Surrey Clinical Research Centre, using the following procedures:

Virkon is used to decontaminate all areas where GL-ONC1 virus is handled, stored and transported. After patients have been discharged floors, walls, beds, mattresses and furniture in the rooms and patients' area will be wiped-down with 1% Virkon. All equipment (ECG machines, infusion pumps) will be cleaned with 1% Virkon after use.

All GMM spills will be treated in accordance with CRC Work Instruction 0903: large volume liquid spills covered with Virkon powder and then scraped up, smaller spills and all surfaces or fabrics sprayed with 1% Virkon and wiped-down. Toilets will be disinfected with bleach.

Cups and plates used by patients will be washed in 1% Virkon and then palced in the dishwasher on a high temperature cycle.

The blood samples taken for viral testing are labelled with biohazard stickers and will be handled with universal precautions against blood-borne viruses.

All PPE and potentially contaminated clinical waste, sharps, vials and infusions sets will be placed in yellow-bags or Sharpsafes and inactivated by autoclaving before leaving the site for destruction by incineration by an external contractor. The autoclave cycle will be recorded and the autoclave undergoes regular maintenance and testing for compliance with required inactivation parameters. Derogation is sought to use an autoclave in an adjacent building.

All patients linen will be inactivated by autoclaving before being sent for laundering using an external contractor.

(2) In addition, tissue biopsies will be taken from tumours at the Royal Surrey County Hospital as radiology facilities are required. All equipment will be disposable and will be disposed of in the hospital clinical sharps waste stream. Biopsy samples will be labelled with biohazard labels and handled with universal precautions against blood-borne viruses within the hospital. All biopsies will be disposed of in the hospital clinical waste stream.

Blood samples collected at Surrey Clinical Research Centre will be sent to Roayl Surrey County Hospital for analysis. Urine samples will be sent from Royal Surrey County Hospital to Frimley Park Hospital if microscopy analysis is required. Blood and urine samples will be placed within two sealed plastic bags (double bagged), which will be marked with hazard stickers, before they are transported to Royal Surrey County Hospital in a closed rigid container. The samples will be handled with universal precautions against blood-borne viruses within the hospital. Samples will be disposed of in the hospital clinical waste stream.

3) Some blood samples collected at Surrey Clinical Research Centre will be sent to the Leggett Building (formerly the Postgraduate Medical School), for analysis. Samples will be placed in two sealable plastic bags (double bagged), which will be marked with hazard stickers, before they are transported to the Leggett Building in a closed rigid container. The samples will be handled with universal precautions against blood-borne viruses within the Leggett Building. Samples will be disposed of in the laboratory clinical waste stream.

Purposes of the contained use

In vitro infection studies of cells with recombinant strains of KSHV for investigation into the biology and pathogenesis of the virus, including aspects such as entry and replication processes and the significance of virus-host interactions e.g. functions and mechanisms of KSHV immune proteins.

Recipient or parental organism

KSHV is a human gamma herpesvirus that is the aetiological agent of Kaposi's sarcoma (KS) and primary effusion lymphoma (PEL). The incidence of KSHV is 3.5% in the general population of the U.S and the United Kingdom. However, in those geographical areas where KS is endemic, the incidence is much higher, e.g. - 11.5% in western Sicily and 29% in South Africa. Overwhelming serological and molecular data justify KSHV in the aetiology of KS, but infection with the virus alone is not sufficient for the development of KS and additional factors are required, including immune suppression and perhaps host genotype.

The opinion in the KSHV field is that the virus is either not transforming, or is poorly transforming. In this regard, KS is also not considered a true monoclonal neoplasm, but rather a hyperplasia in which KSHV and environmental cofactors such as inflammatory cytokines, promote cell proliferation. Late stage KS tumours may eventually develop into true sarcoma, since there is then some evidence of clonality.

Host/vector system

Donor/vector
KSHV, E. coli and associated plasmids, Aequorea victoria (green fluorescent protein & enhanced green fluorescent protein), Discosoma (Ds red fluorescent protein).

Vector
Mobilization-defective transfer vector plasmids in which one or more genes of interest can be inserted e.g. F plasmid pMBO131: F factor-based prokaryotic replicon that carries the F factor origin of replication, the chloramphenicol-resistance gene, and the partitioning proteins A and B. It is self-replicating and limits its copy number to one or two copies/cell.

Host
Disabled E. coli for plasmid construction, 293 and other cells, human and non-human (such as Vero), to generate infectious particles and to study infection processes. PEL cell lines for production of KSH. Target cells: human cell lines, primary cells of endothelial, epithelial and lymphoid origin (liver, gut, stomach, thymus, B- and T-lymphocytes, monocytes).

Origin & function

The present programme of work will include the manipulation of the KSHV bacterial artificial chromosomes (BACs) and other recombinant strains as technologies evolve to manipulate the genomes of large DNA viruses. Selected ORF's will be deleted, mutated or reintroduced and resulting recombinant virions will be purified or infection of various cell types. We will infect cells with recombinant KSHV derivatives in which one or several viral genes involved in virus infection and/or pathogenesis have been deleted/mutated or placed under an inducible promoter (e.g. -oestrogen receptor, tetraculcine inducible promoters). In case of very low virus titres, concentration by centrifugation will be performed.

Evaluation of foreseeable effects

Wild type KSHV is ACDP category 2

However, recombinant KSHV plasmids will be propagated in disabled E. coli strains derived from K-12 which are non-pathogenic, and the viral genes of the insert and hygromycin gene are not expressed in these cells. The vector and the insert are not self-transmissible and are poorly mobilisable. The genetically modified KSHV strains and derivatives in E. coli are therefore unlikely to cause any disease to humans, animals or plants. Transmission of either naked plasmid DNA or the plasmid from bacteria to humans is highly unlikely, and with expected consequences no worse than an ACDP level 2 virus already present in the population, and quite prevalent in some areas.

Experimental infection of cells in vitro with KSHV is only usually achieved at low efficiency. The infection is then latent, unless the lytic switch protein encoded by ORF50 is
provided in trans. Several published reports claim that experimental KSHV infection of endothelial cells results in extended lifespan allowing their prolonged passage in vitro. In vivo, KSHV replication in tumour cells is predominantly latent, suggesting that the proteins encoded by the latency genes may be involved in pathogenesis. None of these genes is active on its own in the endothelial cell proliferation assay. The present study encompasses these KSHV genes and the proteins they encode. The aim of the programme of work is to create mutant viruses, deficient in one or more of these genes, and to analyse their phenotype. The creation of such a mutant requires cloning of either part or all of the target gene. Once the mutant virus is constructed, a 'revertant' must be created from that mutant. Again, this process may involve cloning the gene of interest. The revertant virus is re-engineered to express the gene deleted in the mutant virus, in order to ensure phenotypic differences observed in the mutant virus are solely due to deletion of the target gene, and not to erroneous changes made elsewhere in the virus genome. In some strategies to recreate wild type virus, the mutated gene will be complemented in trans, from an expression vector transfected into the mutant-virus-producing cells.

None of the KSHV genes, or the proteins they encode, presents a high risk to workers, particularly given that KSHV is, in the worst case scenario, only poorly transforming. Nevertheless, cell transformation has been observed in studies with certain individual KSHV proteins, e.g. - K1, vGCR and viRF-1. Should a worker be exposed to one of these protein, an immune response would be anticipated, but is unlikely to confound diagnostic assays, since KSHV infection is not screened for routinely.

The antibiotic resistance genes (e.g. - hygromycin, chloramphenicol) and the reporter genes (GFP, RFP) and other selection and reporter genes are not associated with any likely hazards.

Wild type KSHV replicates of low levels in vitro. Recombinant strains are expected to replicate to similar levels.

The genes encoded by the KSHV BAC are not expressed in the bacterial host. Hence, there is no potential to increase the pathogenicity of the host. The BAC-derived virus mutants are expected to have a decreased ability to infect and replicate in target cells compared to wild type KSHV. Mutated recombinant KSHV strains are expected to be less harmful than their wild type counterparts. The reporter genes are not expected to affect the pathogenicity of the virus. None of the primary cells or cell lines used in these studies will be derived from the worker. In addition protein, even in the context of the BAC-derived virion, their inoculation into the worker will induce a strong allogenic immune response, which will protect the individual. Hence, handling of cells expressing either individual or few KSHV proteins poses no greater threat that that of culturing cell lines infected with wild type KSHV.

The reporter genes are not expected to affect the pathogenicity of the virus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not Applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid and liquid contaminated waste is treated by autoclaving at 121°C for 15 minutes in a mixed load validated cycle.

Post autoclaving: Solid waste is further disposed of into a tiger stripe bag and sent off site for incineration via Grundons Waste Management Company. Liquid waste is disposed of down the sink with copious amounts of water. This flows to the main foul drain and onto a waste water treatment facility owned by Thames Water.

Liquid disinfection may also be performed by treating the solution with 1% (weight/volume) Virkon overnight at room temperature. The solution is then disposed of to the laboratory drain flushed with copious amounts of water at a maximum volume of 2L per day. This flows to the main foul drain and onto a waste water treatment facility oned by Thames Water.

Expected degree of kill:
Autoclaving achieves effectively 100% kill of all GMMs.

1% Virkon solution can be used for disinfection when necessary. 1% Virkon solution is validated for disinfection of most herpesviruses, including herpes simplex virus (HSV). Equine herpesvirus, feline herpesvirus, turkey herpesvirus and Marek's disease virus. Virkon acts by oxidative disruption of proteins and lipids vital to normal virus infectivity. By definition KSHV shares the same structure with that of those herpesviruses for which Virkon has been validated. Moreover, KSHV titres are several orders of magnitude lower than those of HSV. Taken together, these data indicate complete inactivation of KSHV is expected.

Tick if notifying a connected programme of work  N
The aim for this project is to utilise a Campylobacter jejuni mutant libraries (obtained from Prof. Duncan Maskell and his team at the University of Cambridge) in a series of genotypic and phenotypic assays to further elucidate the role of biofilms in the pathobiology of Campylobacter infections. The libraries contain a mutant in every non-essential gene of the Campylobacter jejuni type strain NCTC 11168/M1/a wildtype C. jejuni chicken isolate. The mutants will be entered into biofilm assays and biolog phenotypic arrays.

Recipient or parental organism

The recipient organism will be Campylobacter jejuni (ACD) hazard Group 2) which is a food borne pathogen able to colonise the gastro-intestinal tract of humans and animals. Although Campylobacter jejuni is a harmless gut commensal to animals, the organism is pathogenic to humans, causing self-limiting gastro-enteritis. The organism would therefore pose a hazard to human health if ingested. The vast majority of infections in humans are caused by the consumption of contaminated poultry products. There are currently no vaccines for Campylobacter available for humans. Erythromycin and Ciprofloxacin are the preferred antibiotic treatment.

Host/vector system

The mutant libraries were constructed by using an in vitro transposon protocol. Chromosomal DNA of the bacterial strain of interest serves as the acceptor for incorporation of the mariner transposon element. During the in vitro transposon mutagenesis the mariner transposon element is sliced out of the donor plasmid (pSV006 for Campylobacter jejuni) by Himar1 transposase and inserted into TA-dinucleotide sites in the acceptor DNA. During the in vitro transposition gaps are created at the site of insertion; these are repaired by filling in by DNA polymerase followed by a ligation step. The transposon is marked with a chloramphenicol or kanamycin resistance gene.

The transposase enzyme is expressed from the pMALC9 plasmid that contains the hyperactive from of Himar1 transposase cloned into the maltose-binding protein (MBP) fusion plasmid (ampicillin resistance) in Escherichia coli BL21 pLYsS (chloramphenicol resistance). Protein expression is induced with IPTG and the E. coli cells are lysed by one freeze-thaw cycle followed by sonication. After centrifugation the Himar1-MBP fusion protein (present in the supernatant) is allowed to bind to amylose resin and after several wash steps eluted through competition with maltose. Thereafter, the purified Himar1 enzyme is ready to be used in in vitro transposon mutagenesis protocols stored at -80°C.

It must be noted that the mutant library will contain a mutant in every non-essential gene in th Campylobacter genome. This included mutations in genes which may code for regulatory proteins or enzymes that regulate the virulence of the pathogen.

The mutations caused by the insertion of transposons in this mutant library will attenuate the strain. However, given the nature of tranposons, there is a possibility that the mutation could be reversed by the excision of the transposon in the intended insertion site to another location in the genome. However, for this to occur, the specific transposases for the removal of the transposon have to be present in the bacterial cell.
The method for the construction of the mutant libraries uses a mariner-based transposon derived from Himar1. This type of transposon is active in a wide range of hosts and has simple requirements for transposition. It is possible for transposition to occur in vitro with only its purified transposase. Himar1 is active in E. coli, and hyperactive transposase mutants are used in the methodologies for the construction of these mutant libraries to provide transposases required to transposon insertion into the Campylobacter jejuni genome. Himar1 is not active in Campylobacter, therefore host transposases in the C. jejuni genome should therefore not be able to move the position of the transposon. Regardless of this, transposons by nature are not permanent mutations and extra caution should be taken to ensure attenuated GMOs do not revert to wild type.

Having a mutant in every non-essential gene will further elucidate the genes responsible for biofilm formation in Campylobacter jejuni. Again, the mutations caused by the insertion of transposons in this mutant library will attenuate the strain.

**Origin & function**

The plasmid sequence containing the transposon will with the inserted transposon contains a chloramphenicol resistance gene which is used as a selective marker. However, this antibiotic is not used for therapeutic purposes, so potential therapies are not compromised.

Gene transfer to other bacterial species is a remote possibility. Certain Campylobacter strains are naturally competent so there is a possibility that the DNA could be transferred to other Campylobacter strains of the same species. However, there would be no hazard associated with this since this process would be common in the environment as a result of natural animal carriage and faecal shedding of bacteria into the environment.

It is also likely that any mutation will reduce the organism’s ability to survive in the environment, and therefore acquiring the mutant gene will have the same effect in the recipient cell.

Gene transfer from the mutant Campylobacter strain to a wild type organism is made difficult due to the organism’s lack of ability to grow below 30°C and will not replicate in environment outside of warm blooded animals. Campylobacter are considered to be very fragile organisms and do not survive for extended periods on surfaces or the environment.

The transposon does not code for a specific toxin or other virulence gene, and will only silence the gene that it is inserted into and this will attenuate the test Campylobacter strain. However, as mentioned previously, mutations will occur in all non-essential Campylobacter jejuni genes, including ones that may regulate virulence. Thus, care must be taken when working with the organisms since certain mutants may be slightly more virulent than the wild type.

The mutations are likely to reduce the organism’s ability to survive and therefore are unlikely to increase infectivity or pathogenicity. There is no evidence to suggest such mutations will increase host range or tissue tropism. Moreover, mutations are likely to attenuate the cells ability to produce adhesins or other surface proteins to increase pathogenicity.

**Evaluation of foreseeable effects**

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

No plant or animal work is planned.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste
All contaminated solid waste, such as pipette tips and petri dishes, will be placed in Disposafe containers and sealed. These will then be autoculled at 121°C for 15 minutes.
Liquid waste
Liquid waste will be collected in a glass Duran bottle and placed in a plastic autoclave bin. Volumes larger than 500ml will be split into two bottles to allow effective steam transfer at 121°C for 15 minutes.

Non-contaminated waste will be disposed of separately. After autoclaving, GMO contaminated waste will be labelled with 'UN3245' and private contractors 'Grundon Waste Management' will collect and dispose of waste by incineration.

Virkon S will be used as a surface disinfectant at 1% with a minimum contact time of 1 hour. Virkon S has been validated for disinfection of Campylobacter jejuni in a 1:100 dilution. Virkon S achieves deactivation and destruction of the target organisms through a broad-spectrum, non-selective range of oxidation reactions. 70% ethanol will also be used for a surface disinfectant.

The Biosafety committee approved this risk assessment on 26th February 2014 on the condition that minor amendments to wording were made to confirm controls used.

Please enter comments on the GM safety committee on the risk assessment

CU2 Project Title: Genetic modification of class II poxviruses - Maluquer Lab (connected programme of works).

Class: Class 2
Culture Vol Class 2: < 1 litre
Consent Granted: Non-GMM

Date Project: 02/03/2022
The overall aim of this project is to modify class II poxviruses to understand how these viruses interact with the host immune system, how they manipulate cellular resources and signalling pathways, and how these contribute to virulence. The class II poxviruses to be studied are vaccinia virus and ectromelia virus.

Vaccinia virus (VACV) is the prototypic and most studied member of the Poxviridae family. VACV was used as live vaccine to eradicate smallpox, and soon after became a useful expression vector for the expression of heterologous genes. Given the high immunogenicity generated by VACV infection, recombinant VACV expressing heterologous antigens have the potential to become powerful vaccines. Ectromelia virus (ECTV) is the causative agent of mousepox. Genetically it is closely related to Variola virus and monkeypox virus. ECTV infects only mice (so far, laboratory mice only) which develop a pustular rash reminiscent of smallpox disease in humans. Given the existence of an effective animal model, ECTV is an excellent model to study smallpox and exanthematous diseases, as well as host-pathogen interactions.

VACV is considered a hazard group 2 agent. ECTV is a mouse pathogen and it is not known to infect man. For the purpose of these rules, both should be treated as hazard group 2 agents.

VACV and ECTV are lytic viruses that replicate in the cytoplasm. This implies that chances of recombination or integration into the mammalian chromosomes are extremely rare, because the viral genome does not travel to the cell nucleus and the infected cell is eventually killed by the virus. Expression of oncogenes in VACV or ECTV is not expected in this project, but it would not likely to be hazardous because the virus kills all the cells it infects and therefore there is no potential for tumour development.

There are many distinct strains of VACV. In my laboratory most work with VACV will be conducted with the Western Reserve (WR) strain of VACV, but some work is also done using other strains such as Copenhagen, Lister, and IHOJ, that are of similar or lower virulence than WR. In addition we use some attenuated strains such as v811 (a strain lacking 55 genes from the VACV Copenhagen strain) and modified vaccinia virus Ankara (MVA). Most VACV strains are classified by ACOP as hazard group 2 pathogens. but the MVA strain is a category 1 organism due to its inability to replicate in most mammalian cells. Two strains of ECTV are described, Naval and Moscow, with almost identical properties.
VACV/ECTV genes will be expressed heterologously in a wide range of cloning and expression vectors, including (1) mammalian expression and cloning vectors that are non-mobilisable and only replicative in bacterial hosts such as pcDNA3 or pCI, (2) bacterial vectors such as pET or pGEX, (3) baculovirus vectors based on Autographa californica nuclear polyhedrosis virus (AcNPV), and (4) self-inactivating (SIN) lentivirus vectors.

A baculovirus vector based on AcMNPV will be used for high level expression of structural proteins in insect sf9 cells. This vector lacks the baculovirus polyhedrin gene and is therefore non-pathogenic for insects. Gene expression is driven by the insect cell specific polyhedrin promoter, producing fusion proteins with well-characterised tags such as glutathione-S-transferase (GST) or polyhistidine to aid purification.

SIN lentiviral vectors are categorized by the Advisory Committee for Dangerous Pathogens as a hazard group 1 biological agent. SIN lentiviral vectors are 3rd generation lentiviruses where the U3 region of the 3’ LTR has been deleted. This region contains the major viral promoters and enhancers of the virus and is copied to the 5’ end of the provirus during reverse transcription. SIN constructs result then in a provirus that is devoid of U3 enhancer sequences, therefore reducing the potential for mobilisation of the vector once inserted and the potential of transactivation of cellular genes as a result of insertion.

All systems and vectors described here are well-characterised, and pose minimal hazard to human health or to the environment.

Origin & function
We intend to clone genes from VACV and ECTV and express them in a number of delivery systems (see above) to study their activity ectopically in mammalian cells. In addition, some of these genes may be expressed in bacteria or baculovirus to produce soluble protein. That material will be used to obtain reactive sera. Finally, some constructs will be used to delete genes in VACV or ECTV using genetic methods based on recombination.

Particular genes of interest involve genes of unknown function located at the termini of the viral genome. These genes are likely to be involved in virus-host interactions aimed at evading the host immune response. Consequently, recombinant viruses engineered to lack such genes are likely to be attenuated compared to its parental strain.

Evaluation of foreseeable effects
VACV or ECTV will be modified to either express reporter genes (luciferase or fluorescent proteins) or to lack expression of a natural gene. The virulence of these modified viruses is expected to be reduced or similar to its parental virus. There is no intention to insert oncogenic foreign genes in VACV or ECTV, or to introduce antigens from other pathogens.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
N/A.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
None.

Please note that CL3 animal facilities will be used when working with EClV in the animal model. This facility is removed by geography from other facilities to ensure appropriate quarantine processes. The work is only designated as a class 2 activity.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All solid and liquid contaminated waste generated in the containment level 2 laboratory is treated by autoclaving at...
121°C for 15 minutes on a mixed load validated cycle. Liquid disinfection may also be performed by treating the solution with 1% (weight / volume) Virkon for at least 30 mins at room temperature. The solution is then disposed of to the laboratory drain flushed with copious amounts of water at a maximum volume of 2l per day. This flows to the main foul drain and onto a waste water treatment facility owned by Thames Water.

In the CI2 animal facility, solid waste is disposed of into a yellow burn bin and sent off site for incineration via Grundons Waste Management Company. liquid waste is disinfected by treating the solution with 1% (weight / volume) Virkon for at least 30 mins at room temperature before disposing of down the sink with copious amounts of water. This flows to the main foul drain and onto a waste water treatment facility owned by Thames Water.

In the CL3 animal facility waste will be disposed of via autoclaving at 121°C for at least 15 minutes on a validated cycle.

Post autoclaving: Solid waste is further disposed of into a yellow burn bin and sent off site for incineration via Grundons Waste Management Company. liquid waste is disinfected by treating the solution with 1% (weight / volume) Virkon for at least 30 mins at room temperature before disposing of down the sink with copious amounts of water. This flows to the main foul drain and onto a waste water treatment facility owned by Thames Water.

The Safety committee met on 12th November 2014 and approved this assessment. The committee requested that the assessment was reviewed by the animal facility manager to ensure specific quarantine procedures were developed for staff working on this project. The committee also requested that Occupational Health review the assessment to confirm the health surveillance required for personnel to work on this project.

Please enter comments on the GM safety committee on the risk assessment

Project Additional Information

Purposes of the contained use

The Phenomics core facility offers expertise in phenotyping bacteria within the University of Surrey and for external establishments. This technology is applicable to both wild-type and genetically modified organisms. This risk assessment covers the handling, storage and culture of ACDP Hazard Group 1 and 2 bacteria at the University of Surrey.

Recipient or parental organism

The recipient bacteria will be ACDP hazard group 1 or 2. Genetically modified bacteria will be supplied by the collaborative institute to the University of Surrey. No genetic modifications will be undertaken at the University of Surrey. The modes of transmission will vary according to the specific bacteria. However, all experiments involving live bacteria will be conducted in line with the safety regulations relevant to dealing with ACDP 1 and 2 bacterial species.

Host/vector system

This application will include the use of any ACDP Hazard group 1 or 2 bacteria. The bacteria will depend on the proposed study being undertaken by the collaborating institute. A variety of vectors are available for use in different bacterial species. These are usually non-mobilisable or mobilisation-defective vectors from commercial or academic sources.

Origin & function

Numerous methods are employed to create genetically modified bacteria. The method selected will depend on the purpose of the studies and species of bacteria. Generation of a mutant typically involves the insertion of nonreplicating DNA (suicide plasmid, transposon, bacteriophage, PCR product), which may or may not integrate into the chromosome. Where complete ablation of the gene function is required, the mutated DNA may contain a copy of the
Evaluation of foreseeable effects

The GMO's are unlikely to have increased pathogenic potential. It is therefore anticipated that there will no ecologically disruptive effects to other organisms. All the GMO's will be worked on in containment and only one species of organism will be worked on at anyone time. However, any addition risks (if any) will be considered following a review of the GMO risk assessment for the particular mutant strains as detailed by the collaborating institute before receipt of the isolates by the University of Surrey.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No Plant or animal work is planned.

9.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid and liquid contaminated waste is treated by autoclaving at 121°C for 15 minutes on a mixed load validated cycle.
Post autoclaving: Solid waste is further disposed of into a tiger stripe bag and sent off site for incineration via Grundons Waste Management Company. Liquid waste is disposed of down the sink with copious amounts of water. This flows to the main foul drain and onto a waste water treatment facility owned by Thames Water. Liquid disinfection may also be performed by treating the solution with 1% (weight/volume) Virkon S overnight at room temperature. The solution will then be disposed of to the laboratory drain flushed with copious amounts of water at a maximum volume of 2L per day. This flows to the main foul drain and onto a waste water treatment facility owned by Thames Water.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The Biosafety committee approved this risk assessment on the 17th June 2015 on the condition that minor amendments to wording were made.

### Project Ref 81/16.1

**Date Ackn'd**: 06/04/2016

**CU2 Project Title**: Handling (storage and culture) of genetically modified ACDP Hazard 2 Oncolytic virus sent from other institutions

**Class**: Class 2

**CultureVolClass2**: < 1 Litre

**CultureVolumeClass3-4**: Consent Granted

**Non-GMM**: Consent Granted

**Project notified under transitional arrangements**: N

**Withdrawn**: N

**Tick if notifying a connected programme of work**: Y

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

### Project Additional Information

**Purposes of the contained use**

The primary objective of our research projects is to investigate oncolytic inflammation, and the enhancement of antitumour immune responses seen with oncolytic virus (OV). We also wish to combine OVs with immune modulating drug such as immune-checkpoint inhibitor antibodies to explorer immunological "danger" signals using In vitro and In vivo models. All viral vectors are attenuated resulting in tumour selective tropism.

**Recipient or parental organism**

Adenovirus (replication-defective) - ACDP Hazard group 2 - Human
Adenovirus (replication-competent, attenuated) - ACDP Hazard group 2 - Human
Maraba Virus (MaraV) (replication-competent, attenuated) - ACDP Hazard Group 2 - Sand flies
Vaccinia virus (replication-competent, attenuated) - ACDP Hazard group 2 cattle
HSV-1 (replication-competent, attenuated) - ACDP Hazard group 2 - Human

Host/vector system

Adenovirus (replication-defective or competent, attenuated)
Adenoviruses were first discovered in the 1950’s and have since been studied in detail thus much is known about their biology and pathology. Ad5 has a long history of use as a therapeutic oncolytic agent both as wild-type virus and as a gene therapy vector and has an excellent safety record with many cancer patients having been treated at high doses without adverse effects [1 7-19][20, 21, 29].

General information
Type: non-enveloped double stranded DNA virus [17]. Size: 32-40kb [1 7].
Family serotype group C, human Adenoviridae (Mastadenoviridae) [17]

Mutagenic effects

Infectivity
Natural host - humans [20,21]. Other hosts - rodent, swine and rabbit [20,21 ]. Tropism - eyes, respiratory and gastrointestinal tracts [22]. Route of transmission - aerosol [22].

Transduction capability
Normal and tumour, dividing and non-dividing cells[1 8, 23, 24].

Mechanism of cell death
Necrosis or apoptosis, dependent on cell type [25J.

Pathogenesis

Health and Safety
Executive
Commonly: well-characterized, mild, self-limiting disease (mild respiratory disease, gastroenteritis, conjunctivitis) [4].
Rarely: In infants and children pertussis-like syndrome, acute febrile pharyngitis and hepatitis[22].

Toxicity (side effects of treatment)

Human - Commonly: Minimal grade 3 and no grade 4 toxicity (observed across trials in a wide variety of cancers at doses of up to 2 x 1013 viral particles) [19J. Rarely: hepatotoxicity, acute inflammatory responses and one case of morbidly with very high doses (26). Pregnancy: extremely small risk of foetal abnormalities [27J. Immunocompromised individuals: extremely small risk to the foetus [27J.

Mouse
Dose and variant-dependent hepatotoxicity in athymic and immunocompetent mice [5, 28J.

Risk to the environment - Very low/negligible
Although release of Ad5dl309, Ad5d1922-947 or Ad5 CMV GFP to surrounding areas would increase the risk of exposure to rodents, rabbits and pigs, due to their greater immunogenicity and/or compromised replicative abilities relative to wtAd5 these 3 vectors are highly unlikely to cause disease in healthy or immuno-compromised animals. As all work using these viruses will be carried out in containment level 5 facilities the risk to the environment would be considered negligible.

Adenovirus (replication-defective or competent, attenuated) - Summary

Risk to normal, healthy immuno-competent individuals Very low. Exposure to Ad5dl309, Ad5d1922-947 or Ad5-CMV GFP
is highly unlikely to result in toxicity. In comparison to wt Ad 5, Ad5dl309 is more immunogenic [29, 30].
Ad5d1922-947 is both more immunogenic and replication restricted [5]. and Ad5-CMV-GFP is unable to replicate.
Immune recognition and activation would control viral pathogenesis in all cases.
Maraba Virus (MaraV) (replication-competent, attenuated)
Maraba Virus is from the Rhabdoviridae family one of eight set type vesicular stomatitis virus (VSV).
General information
Type: ssRNA virus (negative strand) comprising a "bullet-shaped" nucleocapsid and a lipid envelope, populated by the
viral glycoprotein (G). Maraba Virus is from Rhabdoviridae family one of eight set type VSV.
Mutagenic effects
Oncogenicity: non-oncogenic [7]. Genome integration none [7]. Mutagenesis risk very low. Vertical transmission none [7].
Transduction capability
Normal and tumour, dividing and non-dividing cells [7].
Pathogenesis
No pathogenicity has been documented in humans with Maraba virus
Maraba virus is listed as a distinct species (ICTV: http://ictvdb.bio-mirror.cn/ictv/fs_rhabd.htm) within the
Rhabdoviridae and, whilst closely related to strains of VSV such as Indiana, does not cause vesicular disease with
symptoms overlapping with FMDV in cattle or other ruminants [31].
Infectivity
Maraba virus has been shown to have limited spread outside of sandflies [31] and no natural mammalian host has
been identified, with only one documented example of human seropositivity. Vectors based on Maraba virus contain
two attenuating mutations in the glycoprotein (G) and matrix (M) proteins. The M mutation limits evasion of innate
antiviral immunity but the mechanism of action of the G-protein mutation is not known. Genetic modification of MG1
comprises an insertion site between the G and M open reading frames (ORFS), resulting in expression from an
internal transcription initiation site. Attenuations mean that high titre growth of MG1 is only possible in tumour cell
lines. This property has resulted in MG1 being proposed for use as a highly selective oncolytic virus. This virus is not
listed as a SAPO
Toxicity (side effects of treatment)
Health and Safety
Executive
Genetically modified and tumor-targeted Maraba virus, MG1 (mutations in M protein L 123W and G protein Q242R),
has been established as a superior OV compared to VSV [7]. MG1 had a 100-fold greater maximum tolerable dose
than wild-type Maraba in vivo and resulted in durable cures when administered in syngeneic and xenograft models.
Direct cranial injection does result in neurotoxicity and fatal encephalitis, but this only occurs via this invasive route of
delivery Shedding and spreading of MG1 from infected Macaques is minimal, viral genomes only being detectable in
tissues via PCR, not by the less sensitive IHC or plaque assay (personal communication D. Stojdl, CHEO Research
Institute, Ottawa).
Risk to the environment: Very low/negligible
Maraba virus has been shown to have limited spread outside of sandflies [31]. Whilst closely related to strains of VSV
such as Indiana, does not cause vesicular disease with symptoms overlapping with FMDV in cattle or other ruminants
[31].
Maraba Virus (MaraV) (replication-competent, attenuated)-summary
Maraba Virus has no known natural mammalian host and pathogenesis has not been documented in humans.

Genetic modification of MG1 results in a highly selective oncolytic virus.

Vaccinia virus (replication-competent, attenuated)

Vaccinia has been studied in detail over many years and much is known about its biology and pathology. It has a long history of safe use as a live vaccine in human smallpox vaccination programs [32J, and in addition a good safety record in clinical immunotherapy trials [1 2J.

General information

Type: enveloped double-stranded DNA virus [12, 32J. Size -192kb [12, 32J Family Poxviridae [1 2, 32J.

Mutagenic effects

Oncogenicity: non-oncogenic [12J. Genome integration: none [12]. Mutagenesis risk: very low - virus remains within the cytoplasm of the host cell and has little interaction with the host cellular proteins [12]. Vertical transmission: none [12J.

Infectivity

Natural host: none. Other hosts: human, buffalo, cattle, rabbits, mice. Route of contact: possibility of aerosol transmission [33, 34][58, '59J.

Tropism

Mucosal tissues [33, 34][58].

Transduction capability

Normal and transformed cells; is capable of infecting almost all cell types including a range of tumours including melanoma, glioma, bladder and colorectal cancer.

Pathogenesis

Human: Commonly: treatable, clinically mild disease (rashes, accidental implantations) [35J. Very rarely: potentially fatal disease (post-vaccinial central nervous disease, progressive vaccina aka vaccina necrosum, eczema vaccinatum) [35J.

Toxicity (side effects of treatment)-Human

The level of vaccinia induced human toxicity is strain-dependent [8J. Commonly: Minimal grade 3 and no grade 4 toxicity (observed across immunotherapy trials in a wide variety of cancers with administration via intramuscular, intratumoural, intravesical and subcutaneous routes. Doses of up to 109 viral particles) [6, 12, 36, 37J. Very rarely: Progressive vaccinia, eczema vaccinatum, post-vaccination encephalomyelitis [37J. Immunocompromised individuals and infants: higher incidence of adverse effects (5 deaths/106 under 1 year old vaccinees versus 0.5 deaths/1061-4 year old vaccinees in 1968) [35J.

Mice: Toxicity and mortality in immuno-competent mice are dependent upon strain [66]. Extremely virulent infection with high toxicity and mortality can occur on systemic injection of high doses of wild type vaccinia into immunocompetent or nude mice but the attenuated virus highly unlikely to cause disease in healthy or immuno-compromised animals. [11 , 38J.

Hazard identification for viral vectors- vvDD-GFP & vv-GMCSF (JX-594)

Health and Safety

Executive

Risk to normal, healthy immuno-competent individuals Very low Exposure to vvDD-GFP or vv-GMCSF(JX-594 is highly unlikely to result in toxicity. In comparison to wtWR, vvDD-GFP [12J is replication restricted and vv-GMCSF (JX-594) [39J is both replication restricted and more immunogenic. Immune recognition and activation would control viral pathogenesis in all cases.

Risk to the environment: Very low/negligible
Although release of vvDD-GFP or vv-GMCSF(JX-594) to surrounding areas would increase the risk of exposure to rabbits, cows and mice, due to their compromised replicative abilities and/or greater immunogenicity [12, 39] relative to wt-WR, these 2 vectors are highly unlikely to cause disease in healthy or immuno-compromised animals. As all work using these viruses will be carried out in containment level II facilities the risk to the environment would be considered negligible.

Vaccinia virus (replication-competent, attenuated)-summary
Vaccinia has been studied in detail over many years and much is known about its biology and pathology. It has a long history of safe use as a live vaccine in human smallpox vaccination programs [35], and in addition a good safety record in clinical immunotherapy trials [12, 28]. Disease as a result of vaccination is rare and well-characterized with treatments being readily available.

HSV-1 (replication-competent, attenuated)
Herpes simplex virus (HSV) is one of the most widely clinically used oncolytic agents. Clinical experiments have demonstrated that intravascular delivery of HSV is a safe and effective way to produce oncolytic effects.

T-VEC (talimogene laherparepvec) [40]
General information
Type: enveloped double stranded DNA virus [32]. Size -152kb [32] Family Herpesviridae.
Mutagenic effects
Oncogenicity: none reported. Genome integration: none [41]. Mutagenesis risk: none [41].
Vertical transmission: none reported. HSV1 has been widely investigated for several decades with no instances or evidence of oncogenicity or vertical transmission having been reported.

Infectivity
Natural host: Human [42] Other hosts: Mice, rat, rabbit, non-human primates, guinea pig [43]
Route of transmission
Direct contact [44]
Tropism
Oral and genital mucosa, nervous system, eyes [44]
Transduction capability
Tumour cells [15, 45]
Toxicity and Pathogenicity
Mechanism of cell death: Cytolysis due to viral replication [41]
Pathogenesis
Commonly: None [15] Rarely: Pyrexia, inflammation, nausea, anorexia [46]
Toxicity (side effects of treatment)
Commonly: Grade 1 and minimal grade 2 toxicity (observed in phase 1 trial in a range of cancers at doses of up to 108 viral particles) [46]. Rarely: Low-grade hepatotoxicity, ulceration [46]
Hazard identification for JS1/34.5-/47- and OncoVexGM-CSF (T-VEC [talimogene laherparepvec])
Risk to normal, healthy immuno-competent individuals Very low Exposure to JS1/34.5-/47- or OncoVexGM-CSF (TVEC) is highly unlikely to result in toxicity as both viruses are non-pathogenic [15].
Risk 10 the environment Very low/negligible

Health and Safety
Executive
Release of JS1/34.5-/47- or OncoVexGM-CSF 10 surrounding areas would increase the risk of exposure to rodents and rabbits. However as JS1/34.5-/47- and OncoVexGM-CSF are non-pathogenic the likelihood of any infection or disease is negligible. All work carried out using this virus will be carried out in containment level II facilities thus the risk to the environment would also be considered negligible.
Adenovirus (replication-defective) - ACDP Hazard group 2
Replication-defective Ad vectors contain deletions in their E1 region, thus requiring helper cell lines which are modified to encode these regions (e.g. HEK293) in order to complete a full infectious cycle. In all other cells, these vectors are limited to single-round infections.

Adenovirus (replication-competent, attenuated) - ACDP Hazard group 2
Replication-competent Ad vectors have a long history of use as a therapeutic oncolytic agent both as wild-type virus and as a gene therapy vector. They have an excellent safety record with many cancer patients having been treated at high doses without adverse effects [2-4].

Ad5d1922-947 derived from Ad5d1309; replication is confined to tumour cells with a non-functional retinoblastoma pathway. Ad5d1922-947 lacks a functional CR2 region in the E1A protein [5, 6], rendering the virus unable to switch on host cell proliferation mechanisms in cells with a functioning retinoblastoma pathway. It combines the immunogenic properties of Ad5d1309 with an inability to replicate in normal non-proliferating cells.

Maraba Virus (MarabV) (replication-competent, attenuated) - ACDP Hazard Group 2
Marab V MGl vectors contain two stable attenuations [7]; one in the glycoprotein (G) ORF, and one in matrix (M).

Vaccinia virus (replication-competent, attenuated) - ACDP Hazard group 2
Replication-competent vaccinia virus has a long history of safe use as a live vaccine in human smallpox vaccination programs [8], and in addition a good safety record in clinical immunotherapy trials [1, 9, 10].

ddW-GFP
Genetically modified; A double-deleted, replication-restricted mutant vaccinia virus (vvDD) expressing EGFP, derived from the Western Reserve strain. The coding sequences for both thymidine kinase (TK) and vaccinia growth factor (VGF) have been deleted and EGFP inserted into the TK locus; ddW-GFP has been shown to replicate only in tumour. Created by McCart et al [11, 12].

vv-GMCSF (JX-594)
JX-594, a single-deleted, replication-restricted mutant vaccinia virus (vVDD) expressing human GMCSF gene (encoding granulocyte macrophage colony-stimulating factor or GM-CSF; driven by a synthetic early/late promoter) and lacZ gene (encoding I3-galactosidase or I3-gal; driven by the p7.5 early/late promoter) inserted into the TK gene (encoding thymidine kinase or TK) in the J segment of the Wyeth strain vaccinia virus. [8, 13] Elimination of TK from the JX-594 genome restricts viral replication to tumour cells, whereas GM-CSF production facilitates tumour immune response, and I3-gal is included for virus tracking purposes. [1, 3]

HSV-l (replication-competent, attenuated) - ACDP Hazard group 2
A genetically modified strain of HSVl in which the coding sequences for ICP34.5 and ICP47 are deleted [14]. Deletion of ICP34.5 causes the loss of viral neurovirulence and the ability to establish latency together with confining viral replication to tumour cells [14, 15]. Deletion of ICP47 prevents virus inhibition of cell surface presentation of viral antigens increasing viral immunogenicity in comparison to wtHSVl and enhances tumour-specific viral replication [16].

Evaluation of foreseeable effects
All viral vectors are attenuated resulting in tumour selective tropism.

Adenovirus
Health and Safety Executive
AdSd1922-947 derived from AdSd1309; replication is confined to tumour cells with a non-functional retinoblastoma pathway. AdSd1922-947 lacks a functional CR2 region in the E1A protein [5], rendering the virus unable to switch on...
host cell proliferation mechanisms in cells with a functioning retinoblastoma pathway. AdSd1922-947 is both more immunogenic and replication restricted [S] compared to wild type. Clinical studies with replication-competent, attenuated adenovirus have shown safety with limited toxicity.

Maraba Virus (MaraV)
Maraba MG1 vectors contain two stable attenuations [7], one in the glycoprotein (G) ORF, and one in the matrix (M). These have been demonstrated to render MG1 capable of replicating only in tumour cell lines. The M mutation limits evasion of innate antiviral immunity [7].

Vaccinia virus
Vaccinia has been studied in detail over many years and much is known about its biology and pathology. It has a long history of safe use as a live vaccine in human smallpox vaccination programs [35], and in addition a good safety record in clinical immunotherapy trials [12]. Risk to normal, healthy immuno-competent individuals: Very low Exposure to vvDD-GFP or vv-GMCSF (JX-963) is highly unlikely to result in toxicity. In comparison to wtWR, vvDDGFP [11, 12] is replication restricted and vv-GMCSF (JX-S94) [39] is both replication restricted and more immunogenic. Immune recognition and activation would control viral pathogenesis in all cases.

HSV-1
Herpes simplex virus (HSV) is one of the most widely clinically used oncolytic agent. Clinical experiments have demonstrated that intravascular delivery of HSV is a safe and effective way to produce oncolytic effects. Risk to normal, healthy immuno-competent individuals: Very low Exposure to JS1/34.S-/-47- or OncoVexGM-CSF (T-VEC) is highly unlikely to result in toxicity as both viruses are non-pathogenic [15].

Hazards to the Environment
The potential hazards of sequences within the GMO being transferred to related organisms:
Factors to consider include whether widespread dissemination of the inserted gene as a result, for example, of either gene transfer or recombination of the GMO with a wild-type microorganism, would be a matter of concern. If this is the case an important consideration will be whether, in the event of a breach of containment the GMO could survive in the environment for long enough for such a gene transfer to take place.

Hundreds of patients have been treated with oncolytic virus recombination between wild type and attenuated virus has not been documented. Contact with wild type is almost impossible in a lab environment, the wild type viruses have never been grown in the lab. If recombination were to take place the attenuate gene would be passed on to the wild type virus. This would result in the wild type virus having a tumour select phenotype and be harmless to normal tissue. Adenovirus (replication-defective or competent, attenuated) Risk to the environment: Very low/negligible. Although release of AdSd1309, AdSd1922-947 or AdS CMV GFP to surrounding areas would increase the risk of exposure to rodents, rabbits and pigs, due to their greater immunogenicity and/or compromised replicative abilities relative to wtAdS these 3 vectors are highly unlikely to cause disease in healthy or immuno-compromised animals. As all work using these viruses will be carried out in containment level II facilities the risk to the environment would be considered negligible.

Maraba Virus (MaraV) (replication-competent, attenuated). Risk to the environment: Very low/negligible. Maraba virus has been shown to have limited spread outside of sandflies [31]. Whilst closely related to strains of VSV such as Indiana, does not cause vesicular disease with symptoms overlapping with FMDV in cattle or other ruminants [31].

Vaccinia virus (replication-competent, attenuated). Risk to the environment: Very low/negligible Although release of vvDD-GFP or vv-GMCSF (JX-S94) to surrounding areas would increase the risk of exposure to rabbits, cows and mice, due to their compromised replicative abilities and/or greater immunogenicity [11, 12, 39] relative to wt-WR these 2 vectors are highly unlikely to cause disease in healthy or immuno-compromised animals. As all work using these viruses will be carried out in containment level II
facilities the risk to the environment would be considered negligible.

HSV-1 (replication-competent, attenuated). Risk to the environment: Very low/negligible

Release of JS1/34.5-47- or OncoVexGM-CSF to surrounding areas would increase the risk of exposure to rodents and rabbits. However as JS1/34.5-47- and OncoVexGM-CSF are non-pathogenic the likelihood of any infection or disease is negligible. All work carried out using this virus will be carried out in containment level II facilities thus the risk to the environment would also be considered negligible.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Animal work will be carried out under conditions stated in the Animal Scientific Procedures Act (Pandha project
licence 70/7347) and is under constant review by the University of Surrey's Animal Welfare Ethical Review Board.
Clinical data shows that oncolytic virus are shed from patients post treatment but due to attenuation of the viral vector
reinfection of normal tissue is not possible. As per animal house procedures all bedding waste will be sent for
incineration. Derogation for disposal GM Class 2 animal waste is detailed and accepted by the HSE in GM notification
GM81/15.1. All proceduces wil l be performed in a class 2 Biosafety cabinet

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
There is no autoclave within the building, so inactivation is by a validated disinfectant. Inactivation will be via a 1 %
(WN) Virkon S for at least 24hrs at Room Temperature.
Inactivated fluids will then be flushed to laboratory drain with copious amounts of water as below for liquid Waste as
described below
Solid plastic waste will be inactivated by immersion in 1 %(WN) Virkon S for at least 24hrs at room temperature and
then placed into a yellow bag which is sealed. This bag in turn is placed into a second yellow bag and sealed.
The double yellow bag is then sealed in a burn bin containing 1-2inches of vermiculite granuales.
This is then tagged, recorded and sent off site for incineration via Grundons Waste Management Company. The burn
bins will be labelled with UN3291. Upon collection the burnbins will be placed into a 770L taylor bin and transported to
the Clinical waste incinerator. Here the taylor bin is tipped into the hopper which feeds the incineration chamber.
Waste in the primary combustion chamber burns for a minimum of six hours and then passes to a secondary

02/03/2022
A combustion chamber which reaches temperatures of 1100 degrees C. The Colnbrook facility is licenced to process class 1 and class 2 GM waste and is registered under GM reference centre number GM782. A certificate of destruction will be provided for waste sent under derogation to Grundons. Derogation for disposal GM Class 2 animal waste is detailed and accepted by the HSE as part of GM notification GM81/15.1.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid disinfection will be performed by treating Liquid waste with a solution of 1% (weight/volume) Virkon S for at least 24 hours at room temperature. The Inactivated Liquid waste will then be disposed of down the laboratory Sink. The Inactivated Liquid waste will be flushed with copious amounts of water at a maximum volume of 2L Inactivated waste per day. This flows to the main foul drain and into a waste water treatment facility owned by Thames Water. Solid plastic waste is inactivated by immersion in 1% virkon for 24hrs then further disposed of into a bag, bag, bin, burn system as follows:

1. Solid Inactivated waste is placed into a bag which is sealed.
2. This bag in turn is placed into a yellow bag and sealed.
3. The yellow bag is then sealed in a burns bin containing 1-2inches of vermiculite granuales.
4. This is then tagged, recorded and sent off site for incineration via University Waste route currently Grundons Waste Management Company.

Tumour Slices will be blocked for cutting, fixed in formalin, then, disposed of in a sealed clinical waste bin that is tagged, recorded and disposed of by separated incineration in accordance with HTA rules and regulations. Via University waste route currently Grundons Waste Management Company.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The Biosafety university of surrey committee has approved this risk assessment on the Tuesday 19th January 2016 on the condition that minor amendments to wording were made.

02/03/2022
Project Additional Information

Purposes of the contained use
To develop live attenuated vaccine candidates for the specific protection of poultry against the diseases and pathologies caused by Avian Pathogenic E. coli (APEC) and potentially suppress the carriage of these organisms in at risk animals.

Recipient or parental organism
The recipient organisms in this study are veterinary isolates of Avian Pathogenic E. coli (APEC). These bacteria are ACDP Hazard Group 2 organisms. E. coli is a gram-negative, facultatively anaerobic, rod-shaped bacterium of the genus Escherichia that is commonly found in the lower intestine of warm-blooded organisms. Avian Pathogenic E. coli (APEC) are a diverse group of E. coli that cause a number of differing disease outcomes in susceptible birds. Pathologies associated with these organisms include airsacculitis, polyserositis, septicaemia and other mainly extraintestinal diseases. APEC are found in the intestinal microflora of healthy birds and most of the diseases associated with them are secondary to environmental and host predisposing factors.

Host/vector system
pCM433kanT is a plasmid vector that is currently within the plasmid collection at the School of Veterinary Medicine. This plasmid was developed in the Lab of Dr Mary Lindstrom at Iowa State University (Puri et al2014). The plasmid encodes the kanamycin resistance cassette and the sacB gene. pCM433kanT is propagated in E. coli DH5 alpha.
This strain of E. coli is not a pathogen, and was developed for laboratory cloning use with multiple mutations that enable high-efficiency transformations. pCM433kanT is the source of the kanamycin resistance cassette and the sacB gene from Bacillus subtilis, two genetic markers that will be used in this study for selection and counterselection of genetically transformed E. coli isolates. The gene products arising from this construct pose no direct hazard to human health.

Origin & function

The genetic material involved in this study are the kanamycin resistance gene and sacB gene from pCM433kanT as well as the genomic flanking regions of the aroA gene of various veterinary isolates of Avian pathogenic E. coli. aroA in E. coli encodes the 3-phosphoshikimate 1-carboxyvinyltransferase (also known as 5-enolpyruvylshikimate-3-phosphate synthase) enzyme catalyses the six 1h step in the biosynthesis from chorismate of the aromatic amino acids (the shikimate pathway) in bacteria. Since the shikimate pathway is not present in vertebrates but is essential for the life of plants, fungi and bacteria, it is commonly viewed as a target for antimicrobial drug development.

Using the PCR amplified flanking regions of the aroA gene as well as the kanamycin resistance cassette and sacB gene from pCM433kanT, the aroA gene will be deleted by induction of homologous recombination. This deletion method will make use of standard mutagenesis, cloning and PCR techniques and the use of suicide vectors. In detail, a vector will be constructed containing a kanamycin resistance cassette and the sacB gene from Bacillus subtilis conferring sucrose sensitivity flanked by the genomic regions -1OOObp either side of the aroA gene (encoding the phosphoserine aminotransferase gene and Zn-dependent protease genes). Separate genetic constructs will be made for each candidate isolate.

In the first instance, these genetic constructs will be transformed into the target strains from which they are derived resulting in a kanamycin-resistant, sucrose-sensitive derivative for each isolate of APEC selected. Successfully clones will be subjected to a second transformation event in order to excise the kanamycin resistance and sucrose sensitivity cassettes, resulting in a clean, unmarked deletion of aroA.

Evaluation of foreseeable effects

Deletion of the aroA gene causes the target organism to become auxotrophic i.e. to be dependent on certain aromatic compounds for growth. Aromatic amino acids are not synthesized by vertebrates, and are only present in tissues at very low and well-controlled levels. The loss of aroA gene function results in attenuation of in vivo growth without compromising potential cellular and humoral immune responses by the avian host. The mutations described in this study are specifically intended to attenuate this organisms. Deletion of the aroA gene will render these APEC isolates auxotrophic and dependent on host-derived aromatic amino acids which are not synthesized by vertebrates. Reversion or gene recovery of deletion has never been seen with aroA deletion vaccines. Therefore, the mutations described herein, will not pose a risk to human health.

The mutation described here will likely reduce the ability of these strains to survive within the environment. Deletion of the aroA gene is a disabling mutation that will abolish the ability of the wildtype avian pathogenic E. coli strains to colonise vertebrate hosts and other animals in the environment. Reversion of a deletion in aroA has never been observed.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No Larger GMOs will be used in this study

For only GMOs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
All solid and liquid contaminated waste is treated by autoclaving for at least 15 minutes at 121 °C on a validated cycle resulting in 100% kill.

Post autoclaving: Solid waste is further disposed of into a tiger stripe bag and sent off site for incineration via Grundons Waste Management Company. Liquid waste is disposed of down the sink with copious amounts of water. This flows to the main foul drain and onto a waste water treatment facility owned by Thames Water.

Liquid disinfection may also be performed by treating the solution with 1% (weight/volume) VirkonS for 16hrs at room temperature. The solution is then disposed of to the laboratory drain flushed with copious amounts of water at a maximum volume of 2L per day. This flows to the main foul drain and onto a waste water treatment facility owned by Thames Water.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The University Biosafety committee requested additional information to confirm the classification of the activity as a Class 2. The information was accepted and incorporated into the risk assessment. Other minor changes in text were recommended regarding waste disposal to provide full clarification.

Pexa-Vec is currently in clinical development for the treatment of Hepatocellular Carcinoma. The proposed contained use will be the administration of the investigational product, in a hospital or clinic setting, by intratumoral (IT) injections to patients as part of an international, multicenter clinical trial. This clinical trial is a Phase III trial in patients with Advanced Hepatocellular Carcinoma (HCC) without prior systemic therapy. Results from this pivotal trial will determine whether Pexa-Vec followed by sorafenib increases survival duration in advanced HCC patients compared to treatment with sorafenib alone, and whether sequential dosing with Pexa-Vec followed by sorafenib has a favourable safety profile.

Approximately 40 clinical sites in the EU will enroll patients in the JX594-HEP024 (PHOCUS) study. Additional clinical sites in Australia, Canada, China, Israel, Korea (Republic of), New Zealand, Singapore, Taiwan, Thailand and the USA will also participate in the study. A total of 600 patients will be recruited in this clinical trial with an expectation to enroll 200 patients in EU countries. In the control arm, the 300 patients will not receive Pexa-Vec. After study completion, all patients will be followed up for survival. Among them, 300 patients (i.e. approximately 100 patients in EU) will receive Pexa-Vec by IT injections.

Pexa-Vec is a replicative oncolytic recombinant vaccinia virus (W) derived from the commonly used vaccine Wyeth strain, DryvaxTM. W is a member of the Poxviridae family (genus Orthopoxvirus). Multiple strains of W exist that have different levels of virulence for humans and animals. The New York City Board of Health (NYCBOH) strain, from which the Wyeth strain of the Dryvax® vaccine was derived, has low pathogenicity in humans (Fenner F. et al., 1988). W has a long and extensive history of use in humans. Following injection into the skin, the virus typically establishes only a brief and limited subcutaneous (SC) infection. As W contains antigens that stimulate an immune response that are cross-reactive with smallpox antigens, the vaccine thereby confers protection from the human smallpox disease. W may cause local reactions including erythema, edema and systemic reactions such as fever and malaise, as has been observed with conventional vaccination to smallpox. During the smallpox vaccination campaign, serious complications had occurred in less than 1 in 4,000 individuals, mainly in immunosuppressed and extremely young individuals. Pexa-Vec is even further attenuated as the thymidine kinase gene has been disrupted which makes

Recipient or parental organism

Pexa-Vec is a replicative oncolytic recombinant vaccinia virus (W) derived from the commonly used vaccine Wyeth strain, DryvaxTM. W is a member of the Poxviridae family (genus Orthopoxvirus). Multiple strains of W exist that have different levels of virulence for humans and animals. The New York City Board of Health (NYCBOH) strain, from which the Wyeth strain of the Dryvax® vaccine was derived, has low pathogenicity in humans (Fenner F. et al., 1988). W has a long and extensive history of use in humans. Following injection into the skin, the virus typically establishes only a brief and limited subcutaneous (SC) infection. As W contains antigens that stimulate an immune response that are cross-reactive with smallpox antigens, the vaccine thereby confers protection from the human smallpox disease. W may cause local reactions including erythema, edema and systemic reactions such as fever and malaise, as has been observed with conventional vaccination to smallpox. During the smallpox vaccination campaign, serious complications had occurred in less than 1 in 4,000 individuals, mainly in immunosuppressed and extremely young individuals. Pexa-Vec is even further attenuated as the thymidine kinase gene has been disrupted which makes
replication in normal cells more difficult than the small pox vaccine. Rare complications included eczema vaccinatum (patients with eczema), disseminated vaccinia rash, progressive vaccinia (in T-cell-deficient individuals) and encephalitis (1-2 per million vaccinated) (Fields B.N., 1996). Recent studies of smallpox vaccines have identified cardiac injury including pericarditis and myocarditis as a potential risk (Halsell J.S. et al., 2003).

W replication exclusively occurs in the cytoplasm thus eliminating any risk of integration of the viral DNA into the host genome (Moss B., 2007).

In terms of classification of hazard, W is considered as a Group 2 biological agent as per Directive (2000/54/EC). W is also classified as a Biosafety Level 2 (BSL-2) infectious substance by the US Centers for Disease Control and Prevention (CDC) (CDC, 2009) and as a risk group 2 organism by the US NIH Guidelines (NIH).

Host/vector system

Pexa-Vec was generated by co-transfection of CV-1 cells (Monkey kidney cells) with W (Wyeth strain obtained from the Center for Disease Control, Atlanta, Georgia) and the plasmid pSC65/hGM-CSF. The vector pSC65/hGM-CSF contains DNA sequences coding for the hGM-CSF and ~galactosidase proteins and for their respective promoters. In addition, the transgene sequences are flanked by two W genomic regions (TKL and TKR) that allow homologous recombination between the transfer plasmid and VV.

The plasmid pSC65/hGM-CSF is generated from the plasmid pSC65 which was provided by Dr. B. Moss, National Institute of Allergy and Infectious Diseases, Bethesda, Maryland (Chakrabarti 1997).

The plasmid pSC65/hGM-CSF is inserted into VV. The insertion of pSC65/hGM-CSF into VV can be detected by using colorimetric identification of plaques containing recombinants expressing ~galactosidase.

The pSC65 vector when provided by Dr. B. Moss contains the LacZ gene. The LacZ gene is a reporter gene, under control of the W p7.5 early/late promoter. The additional donor gene (i.e. gene coding for hGM-CSF) is inserted in pSC65 as follows.

The plasmid pCSF-1 (No. 39754) was obtained from American Type Culture Collection and comprises the full-length cDNA for hGM-CSF (Wong 1985). The hGM-CSF gene was cloned first into the EcoR1 site of pBLUESCRIPTII SK (Stratagene, La Jolla, California), generating plasmid pBLUE/hGM-CSF, and providing restriction enzyme sites to allow cloning of the hGM-CSF gene into the Sail and Bglli sites of pSC65. This positioned the hGM-CSF gene downstream of a synthetic promoter (PsE/L) designed by Dr Moss’ laboratory to give maximal levels of transcription during both the early and late phases of vaccinia infection (Chakrabarti 1997).

Origin & function

Pexa-Vec contains three genetic modifications compared to the wild type Wyeth strain: 1) disruption of the viral thymidine kinase (TK) gene by, 2) insertion of the human granulocyte macrophage-colony stimulating factor (hGMCSF) gene and 3) insertion of the LacZ gene.

Due to the insertion of the transgenes, the TK gene is inactivated. This decreases W virulence (Buller R. et al., 1985) by restricting viral replication to proliferating cells. This also targets dissemination of the virus to tumors (Puhlmann M. et al., 2000).

The plasmid pCSF-1 (No. 39754, American Type Tissue Culture Collection, Rockville, Maryland) contains the fulllength cDNA for hGM-CSF (Wong G.G. et al., 1985). The cDNA for the hGM-CSF gene was inserted into the TK gene to help elicit an immune response to tumor cells both at the site of viral replication and in distant metastases.

The cytokine hGM-CSF was chosen because it was the most potent stimulator of systemic anti-tumor immunity among many tested (Dranoff G. et al., 1993), probably due to its unique ability to promote differentiation of hematopoietic precursors into dendritic cells (Pardoll D.M., 1995). Dendritic cells are professional antigen presenting cells that may take up and present released tumor antigens as the tumor cells are killed by the W.

The LacZ gene is contained in the pSC65 plasmid which was provided by Dr. B. Moss, National Institute of Allergy and Infectious Diseases.
and Infectious Diseases, Bethesda, Maryland. The LacZ gene encodes for β-galactosidase which is a hydrolase enzyme that catalyzes the hydrolysis of β-galactosides into monosaccharides.

Of note, following recombination between the W and pSC65/hGM-CSF, the antibiotic resistance gene contained in pSC65 is not part of the insert. The final GMO does thus not contain any genes conferring resistance to antibiotics.

Evaluation of foreseeable effects

Pexa-Vec is non-integrative, and replicative and propagative characteristics of W have been attenuated in Pexa-Vec, which makes the virus replication dependent on actively dividing cells such as cancer cells. Therapy with a replicating virus can theoretically lead to shedding of the virus into the environment, and potentially to the public, although controls are used in this trial to minimize this occurrence. The clinical information available to date suggests that Pexa-Vec is safe at the clinical dose of 1 x 10^9 pfu (10,000-fold higher than smallpox vaccine dose) and has not spread to caregivers in contact with the treated patients. Should shedding occur, the level of exposure would be predicted to be low compared to the doses received by patients in the proposed trial, and extremely low compared to doses of non-attenuated vaccines administered to the public (e.g. vaccines against smallpox). In addition, exposed individuals over the age of 35 will likely have been previously immunized with vaccinia. In the highly unlikely event that an exposed individual were to demonstrate virus-associated toxicity, therapy could be initiated with VIG and/or cidofovir. Therefore, public health risks with this virus are extremely low and in fact should be lower than with standard vaccination procedures. To date, no reports of transmission to health care personnel from vaccinia recipients have been published. Routine barriers nursing approaches should be used per institutional guidelines for infectious organisms (e.g. such as for M. tuberculosis, Pseudomonas).

The genetic modification of the virus is not expected to result in any post-release shift in biological interactions or host range or in any known or predictable effects on non-target organisms in the environment. It is also not expected that the release of the recombinant virus would result in any increase in pathogenicity as compared to the parental virus strain and/or in any increase in the capacity to recombine with other related viruses.

Therefore, under the conditions for use in the proposed clinical trial, Pexa-Vec is not considered to represent a risk for the environment and for the public health.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable,

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Under Schedule 8 of the Genetically Modified Organisms (Contained Use) Regulations 2014 Table 2 details the containment measures to be applied for non laboratory type facilities. Line 20 requires that inactivation of GMMs in contaminated material and waste is required by validated means at containment level 2. The waste is such that it cannot be disinfected and there is no available autoclave. All waste will be packaged to send directly to incineration. Therefore a derogation is requested. Please see section below detailing how waste will be handled.
The Pexa Vec literature states 'Fabrics (e.g., clothing, sheets, towels) that have touched an uncovered pustule can be laundered in hot water with detergent'.

The SCRC laundry service via White Knight washes bedding at 90°C. Current procedures allow for soiled bedding to be bagged in a red dissolvable washing bag. The bag is placed directly into the washing machine so no contact by third persons is made when handling the laundry.

The red bag system should be used for all bedding from participants in this clinical trial.

Please see attached separate document detailing the risk assessment for this derogation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- The waste is such that it cannot be disinfected and there is no available autoclave. The information detailed indicates how the waste will be packaged to send directly to incineration.
  - All waste will be placed inside a yellow hazardous waste bag. This bag will be sealed with a plain cable tie. The bag is then placed inside a second yellow hazardous waste bag and sealed with another cable tie. The double bagged waste is then placed inside a 30L yellow hazardous waste burn bin containing at least 2 inches of vermiculite to act as spillage absorbent material. This burn bin is sealed by clicking the lid closed. The yellow burn bin is a UN approved biohazard waste bin used for transport of waste on public highways. The maximum weight of each burn bin must not exceed 20Kg. Operationally, the yellow burn bin containing 2 inches of vermiculite in its base and 2 yellow bags (one inside each other) will be placed out at the start of each day. At the end of each day or when the container is three quarters full, the first bag will be sealed, the second bag sealed and then the lid of the burn bin closed. This will be performed in the room where the waste has been generated. Each burn bin is tagged with a uniquely numbered locking plastic tag. The tag reference is recorded.
  - The burn bin is labelled with a UN3373 label. Regular collections are arranged with the waste management contractor Grundons. During collection the unique tag reference numbers on the will be noted onto the consignment note and confirmed to the hazardous waste safety advisor in order for a certificate of destruction to be requested.

This waste must remain segregated from other burn bin waste generated from the building.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [Y]

Please enter comments on the GM safety committee on the risk assessment

The University Biosafety Committee approved this project on 12th January 2017.

The committee did request additional information to be added into the risk assessment to make more explicit the PPE requirements during administration of the product. The committee also asked about the information provided to the patient and was satisfied that the items were documented within the risk assessment.

Date of Significant Change

Project Additional Information

Purposes of the contained use

The goal of these studies is to i) identify and characterise sequences in mobile genetic elements (MGE) (e.g. plasmids, transposons) that promote their spread or persistence under different environmental conditions (e.g. in vitro - in planktonic culture, on surfaces, in biofilms; ex vivo - using organ culture models, bioreactor gut models; and in vivo - using mammalian and insect models of infection); ii) construct mutants harbouring deletions or insertions to disrupt sequences of interest using standard genetic techniques based on homologous recombination, CRISPR-Cas systems or transposon mutagenesis; iii) construct restoration of function mutants in knock out strains using gene complementation approaches; iv) clone and express 'marker' tags (e.g. fluorescent proteins, enzymes such as methyltransferases, short random sequences of nucleotides (barcodes)) on MGE and/or resistant bacteria to track their movement; v) insert reporter genes to study gene expression and/or protein localisation in prokaryotic and immortalised eukaryotic cell lines.
MGE harbouring drug resistance genes will be obtained from nature, either sourced from published literature or from
internal or external collections of resistant bacteria organically isolated from clinics, the environment or animals.

'Recipients' are any species that are capable of harbouring the genetically modified MGE. It is not possible to list
every potential 'recipient' (or donor) species due to the complexity of the natural microbial communities that are
typically found in settings such as the mammalian intestine, in soil or in waste-water samples, that may be used in our
studies. However, the genetic modification is unlikely to significantly affect the virulence of any particular recipient
strain but if the MGE is stably maintained, it could affect our ability to treat any infection that the recipient is able to
cause because it also naturally carries genes coding for resistance to antibiotics.

In some cases, we may use clinical isolates of Escherichia coli or other ACDP Biohazard group 2 pathogens e.g.
Klebsiella pneumoniae, both as a source of MGE carrying drug resistance genes, and as a potential recipient of
genetically-modified MGEs. Certain strains of E. coli are capable of causing infections and are typically transmitted by
the faecal-oral route of transmission. Infection could lead to signs of gastrointestinal disease (typically self-limiting
diarrhoea in otherwise healthy individuals) or extra-intestinal infections (e.g. bladder infections). K. pneumoniae is a
commensal in healthy individuals but is capable of causing extra-intestinal infections (e.g. urinary tract infections,
pneumonia) in individuals with underlying medical issues.

Recipient or parental organism

Bacterial 'donor' species are those that naturally carry MGE harbouring drug resistance genes, such as E. coli
(pathogenic and K-12 strains). In addition, Citrobacter rodentium (a natural murine pathogen) may be used as the
'host' species during in vivo mouse challenge experiments as unlike E. coli, this organism is capable of colonising the
murine intestine to high levels. However, any species within the complex microbiota capable of taking up the MGE
could potentially be a 'donor' and used in subsequent experiments.

A range of different plasmid vectors will be used during the genetic modification processes including:
1. cloning, gene editing and suicide plasmids for basic genetic manipulation in bacteria (e.g. pCVD442, pRRS,
pCRISPR-Cas systems); 2. bacterial expression plasmids for gene complementation and functional analysis studies
(e.g. pSEVA621, pBAD-TOPO), 3. plasmids carrying transposons to facilitate the insertion of marker tags (e.g. pBAM)
or the generation of mutant libraries in bacteria (e.g. EZ-TnS, pSAM) and 4. transfection vectors to allow genes of
interest to be expressed in eukaryotic host cells to aid assignment of function (e.g. pACGFPN1, pCMV-HA).

Host/vector system

The inserted gene products code for fluorescent proteins (e.g. GFP - green fluorescent protein) enzymatic activity (e.g.
methyltransferase (MTase)) or no known product (aka short nucleotide sequences or 'barcodes'). None of these are
Toxins or are oncogenic.

Genes coding for fluorescent proteins are found in nature and if expressed, confer fluorescence in target cells. Some
variants have been adapted to confer higher levels of fluorescence in target bacterial species - these are available
from the published literature.

Genes coding for methyltransferase (MTase) activity are also found in nature. These are enzymes that add a methyl
group to specific nucleotides in the genome of organisms. This results in methylation of DNA, which in turn protects it
from cleavage by cognate restriction endonucleases. This has been recognised as a mechanism via which bacteria
protect themselves from the effects of incoming foreign DNA. Changes in the methylation status of genomic DNA can
result in widespread changes in gene expression including those involved in general celluar activity and virulence in a
species-specific manner.

'Barcodes' or short sequences of nucleotides confer no product but can be used to help differentiate different sources

Origin & function
of DNA during high throughput sequencing reactions. Barcodes are chemically synthesised and have been previously described in the literature.

**Evaluation of foreseeable effects**

The genetically-modified MGE will be harboured in ACDP Hazard group 1 or 2 strains. While the inserted sequences do not encode pathogenicity determinants, it is possible that expression of the MTase could lead to change in the expression of other genes in the genome. It is not possible to predict which genes may be affected for each species (without performing the experiment) but it is highly unlikely that changes will significantly increase the virulence of the organism over its original ACDP classification.

The genetically modified MGE could be transferred to other organisms under the right conditions because this property defines this type of genetic element (i.e., that it is mobile). Transfer is most likely to occur under conditions where there is a high localised density of donor and potential recipient cells as it is normally an infrequent event. However, specific-pathogen free mice or decontaminated research-grade Galleria mellonella larvae are unlikely to contain members of the normal microbiota that are pathogenic to humans. Thus, transfer to other members of the microbiota are unlikely to pose a problem for human health.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

A derogation is in place to allow disposal of waste from the animal facility without autoclaving on-site. Derogation for sending waste direct to incineration has been approved under notified assessment GM81/15.1. All waste from the animal facility is double-contained within yellow hazardous waste bags and then placed inside a yellow hazardous waste burn bin. The bin is sealed by clicking the lid shut. The outside of the bin is disinfected with 1% bleach solution (or equivalent disinfectant) and labelled with a UN3373 Category B Biological Material sticker prior to removal from the unit. The bins will only be removed from the facility when able to be handed directly to Grundons Waste management personnel, where they will be immediately placed into a 770L ‘taylor’ style bin. The waste will then be transported to Grundons Coinbrook facility where it is processed direct through their High Temperature Clinical waste incinerator. Grundon’s Coinbrook facility is licensed to process class 1 and class 2 GM waste and is registered with the HSE (GM Centre #GM782).

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All solid and liquid contaminated waste generated outside of the animal facility is treated by autoclaving at 121 °C for at least 15 minutes on a mixed load validated cycle.

Post autoclaving: Solid waste is further disposed of into a tiger stripe bag and sent off site for incineration via Grundon’s Waste Management Company. Liquid waste is disposed of down the sink with copious amounts of water. This flows to the main foul drain and onto a waste water treatment facility owned by Thames Water.

Liquid disinfection may also be performed by treating the solution with 1% (weight/volume) Virkon overnight at room temperature. The solution is then disposed of to the laboratory drain flushed with copious amounts of water at a maximum volume of 2L per day. This flows to the main foul drain and onto a waste water treatment facility owned by Thames Water.

In the insect larvae studies, larvae will be disposed of, after killing by placing at -80°C for 24 hours, by autoclaving at 121 °C for at least 15 minutes on a mixed load validated cycle. Larvae will be contained in sealed, plastic tubes (e.g. 50 ml falcon tubes) during freezing and autoclaving steps.

In the animal facility, any solid or liquid waste generated can be disposed of without autoclaving on-site. Derogation
for sending waste direct to incineration has been approved under notified assessment GM81/15.1. All waste is doublecontained within yellow hazardous waste bags and then placed inside a yellow hazardous waste burn bin. The bin is sealed by clicking the lid shut. The outside of the bin will be disinfected with 1% bleach solution (or equivalent disinfectant) and labelled with a UN3373 Category B Biological Material sticker. The bins will be removed from the facility and handed to Grundons Waste management personnel, where they will be directly placed into a 770L 'taylor' style bin. The waste will then be transported to Grundons Coin brook facility where it is processed direct through their High Temperature Clinical waste incinerator. Grundon's Coin brook facility is licenced to process class 1 and class 2 GM waste and is registered with the HSE (GM Centre #GM782).

Project Ref 81/20.1

Date Ackn'd 22/01/2020

CU2 Project Title The role of mobile genetic elements in spreading antibiotic resistance: evolution

Class 2

CultureVolClass2 1 Litre

CultureVolumeClass3-4 < 1 Litre
The main aim of this work will be to limit the spread of antimicrobial resistance (AMR) by sensitising resistant bacteria, blocking transfer of mobile genetic elements (MGEs) or preventing bacterial transmission. For that purpose, the following steps will be performed:

- Select the most prevalent MGEs spreading critical important priority AMR genes, especially species of Enterobacteriaceae carrying carbapenemase and ESBL genes.
- Analyse fitness, transfer and evolution of selected MGEs under different conditions. This step could provide information useful to identify host or MGE sequences subject of further experiments that could involve generation of genetically modified MGEs or bacterial hosts (via deletion, disruption or insertion of sequences of interest involved in MGE biology).
- Develop a method to study in detail the evolutionary dynamics of selected MGEs in complex microbial communities. This step could include the generation of genetically modified MGEs or bacterial hosts carrying tracking genes, such as fluorescent proteins, barcode tags, etc.
- Design a CRISPR-Cas delivery vector to remodel complex communities by sensitising bacteria carrying AMR genes. To carry out this step, a broad host range vector will be genetically modified by standard genetic techniques to carry a CRISPR array with spacers targeting MGEs-derived sequences, a Cas nuclease, and a tracking gene. Both the vector and the donor bacteria used to deliver the vector could be subject to further modification to improve delivery characteristics, such as transfer frequency or host range, or to increase the potential use (e.g. expression of antigens to use as a vaccine, or addition of spacers to the CRISPR array with other targets to use as antimicrobials against pathogenic bacteria).
- Study the evolutionary dynamics of the selected MGEs in the presence and absence of the CRISPR-Cas vector to test its sensitising ability pre- and post-infection and to understand the risks associated with the emergence of resistance from single species to complex bacterial communities (such as in vitro gut models or in vivo infection models, where a high number of bacterial species within the community will be potential recipients and new donors of the CRISPR-Cas vector and MGE targeted).
The genetically-modified organism will be mainly Escherichia coli or other species of Enterobacteriaceae classified as ACDP Biohazard group 2. They are typically commensal bacteria found in the gut of healthy humans and animals. However, some strains can cause gastrointestinal disease or extra-intestinal infections, especially in immunocompromised individuals.

Potential recipients (and new donors) of genetically-modified MGEs could include different commensal bacteria found in the gut microbiome of different species (e.g. pig, chicken, horse, human faeces used in in vitro gut models, or decontaminated research-grade Galleria mellonella larvae used in animal studies). It is highly unlikely that members of the normal microbiota of these hosts will be pathogenic to humans or animals. No Biohazard group 3 or 4 organisms will be used in this work.

**Host/vector system**

Original MGEs carrying AMR genes will be obtained from nature, either sourced from published literature or from internal or external collections of resistant bacteria isolated from clinics, animals or the environment. The AMR genes naturally present in these elements could affect our ability to treat potential infections caused by the bacterial host. Modification of the MGEs or host bacteria will be performed using standard genetic techniques, such as homologous recombination, Gibson assembly or transposition, employing strains and vectors commonly used for basic genetic manipulation of bacteria (e.g. E. coli DY380, E. coli DH5α, E. coli MFD-pir, pCas, pTargetF, RP4, pRRS, pBAM, pBAD, pSEVA, pLOF, etc.).

**Origin & function**

The MGE-related gene products that will be inserted to study MGE biology, and tracking products such as fluorescent proteins (e.g. gfp from jellyfish), are not toxic, oncogenic or predicted to alter bacterial virulence found in nature and extensively used in the literature.

The Cas nuclease inserted as part of the CRISPR-Cas delivery vector is considered a “selective toxin” that will cut DNA complementary to the spacers included in the CRISPR array. The spacers will be specifically selected to target MGE-born sequences, with the aim of sensitising the host bacteria without causing bacterial death, thus avoiding high selective pressures that would increase emergence of resistance. Alternative strategies include designing CRISPR arrays to target specific pathogenic bacteria with the aim of triggering bacterial cell death of those pathogens with complementary sequences in their genomes that have received the CRISPR-Cas vector. This strategy is nowadays a common alternative to antibiotics with great potential and effectively used in the literature, and it is also widely found in many Bacteria and Archaea as a defence mechanism against viral infection.

**Evaluation of foreseeable effects**

None of the traits inserted will be pathogenicity determinants or predicted to alter bacterial virulence. It is highly unlikely that the genetic modifications introduced affect the virulence of the host bacteria, but it cannot be fully discarded (bacteria can mutate and produce more virulent variants regardless of any inserted sequence).

The presence of the MGEs harbouring antibiotic resistance genes, both the original and the genetically-modified versions, could affect the ability to treat infections caused by the bacterial hosts acquiring these vectors and increase their survival in environments containing antibiotics. The presence of the MGEs containing CRISPR-Cas systems with bactericidal effects could also increase their ability to compete with other bacteria increasing their survival.

The purpose of the broad host range vector carrying CRISPR-Cas is the decontamination of AMR genes from the highest possible diversity of bacteria present in the gut, as well as preventing the acquisition of new AMR-harbouring MGEs. The extent of spreading of these MGEs in the bacterial community will also be tested to understand the risks of transmission of specific MGEs and how to prevent it.

It is difficult to anticipate the specific bacteria that will receive the genetically-modified MGE due to the high diversity of
bacterial species in the gut, but they will be generally commensals, only able to produce infections in very specific circumstances (such as to immunocompromised individuals). All these experiments will be carried out in contained environments and all potential donors and recipients will be inactivated after each procedure. In the event of a breach of containment, the genetically-modified MGE could be transferred to other bacteria because this property defines this type of genetic element (i.e. that it is mobile). Transfer is most likely to occur under conditions where there is a high localised density of donors, potential recipient bacteria, and nutrients (like the gut). In the unlikely event that transmission occurred, the resulting genetically-modified microorganism would be able to decontaminate the environment from resistant bacteria.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applied for

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid and liquid contaminated waste is treated by autoclaving at 121°C for at least 15 minutes on a mixed load validated cycle.
Post autoclaving: Solid waste is further disposed of into a tiger stripe bag and sent off site for incineration via Grundons Waste Management Company. Liquid waste is disposed of down the sink with copious amounts of water. This flows to the main foul drain and onto a waste water treatment facility owned by Thames Water. Liquid disinfection may also be performed by treating the solution with 1% (weight/ volume) Virkon overnight at room temperature. The solution is then disposed of to the laboratory drain flushed with copious amounts of water at a maximum volume of 2 l per day. This flows to the main foul drain and onto a waste water treatment facility owned by Thames Water.
For the insect larvae studies, larvae will be disposed of, after killing by placing at -80°C for 24 hours, by autoclaving at 121°C for at least 15 minutes on a mixed load validated cycle. Larvae will be contained in sealed, plastic tubes (e.g. 50 ml falcon tubes) during the freezing and autoclaving steps.

Is an emergency plan required according to regulation 20? N

Please enter comments on the GM safety committee on the risk assessment

The University Biosafety Committee met to discuss the risk assessment on 21/10/2019. GM2019/06 was approved at GM Class 2 with no amedments or comments.
Use of genetically modified ACDP hazard group 1 and 2 bacteria within in vitro animal gut models and in vitro organ culture (IVOC) experiments, and curing of naturally occurring plasmids. Genetically modified E. coli will be used to study the transfer of antimicrobial resistance genes between bacteria in-vitro. The recipient organisms will include Eschericia coli, Klebsiella species and non-typoidal Salmonella, isolated from humans and animals. These bacteria are ACDP Hazard Group 2 organisms. E. coli, Klebsiella and Salmonella are Gram-negative, facultatively anaerobic, rod-shaped bacterium of the genus that are commonly found in the lower intestine of warm-blooded organisms. The organisms have the potential to cause a range of diseases in both animals and humans, but the GMO organisms should not be more virulent than the parental organism.
All genetic modifications will be done by Friedrich Loeffler Institut (FLI) in Germany and strains will be sent to Surrey for use in in vitro gut models and in vitro organ culture.

Transposon mutagenesis will be performed either using a custom commercial vector such as pMOD-2 EZ-Tn5 <MCS> from Epicentre Biotechnologies, OR a Tn5 transposon and transposase on a custom conjugative or mobilisable suicide plasmid. Both methodologies will result in the Tn5 transposon and an antibiotic (ampicillin, kanamycin or chloramphenicol) resistance encoding gene being inserted into the chromosome, by a transposase enzyme, of the host species (namely non-typhoidal Salmonella serotypes in the first instance).

The Epicentre Biotechnologies method uses a linearised non-replicating piece of DNA (a “transposome”) within the delivery system, and as such the transposase gene is lost during natural replication of the bacterial cells. In the case where a custom suicide plasmid is used, this plasmid (encoding the transposase) will contain the levansucrase gene sacB, which acts as a counter selection marker to aid the selection of transposon mutant strains that have lost the plasmid vector. Cells that have acquired the Tn5 transposon will be resistant to the named antibiotic. These cells are then grown in the presence of sucrose in order to obtain Tn transposon mutant cells that have lost the plasmid vector and thus have lost the transposase and levansucrase encoding genes.

Host/vector system

The nature of genetic modification include insertion of ~100 bp random DNA barcode marker into the chromosome (at the dif locus), insertion of a transposon e.g. Tn5 into the chromosome to disrupt gene function (creating a transposon mutant library to be used for Transposon Directed Insertion Sequencing (TraDIS)), and the removal of naturally occurring extended spectrum beta-lactamase (ESBL) encoding plasmids.

DNA barcode markers are to be used to enable the identification of an E. coli strain of interest from the mixed natural population within the animal gut model, by using PCR, qPCR or colony hybridisation (using streptavidin detection) techniques. A ~100 bp random DNA sequence is firstly synthesised using biotinylated nucleotides incorporating desired restriction enzyme sites at each end. This is inserted into the delivery plasmid (pBD62 or derivative thereof) by conventional cloning, resulting in the DNA barcode being flanked by transcription terminator elements (TrrnB from E. coli and TtL3 from coliphage λ). The delivery plasmid (encoding zeocin resistance) is transferred into the E. coli strain of interest by conjugation, and is inserted into the chromosome at the dif locus via the integration element from choleraphage CTX–phi (the XBS site). A Cre recombinase encoding plasmid is then transformed into the zeocin resistance cells to remove the backbone of the delivery vector by recombination at the loxP sites. The final cells therefore contain the DNA barcode (flanked by the two transcriptional terminators to prevent any possible transcriptional read-through from adjacent promoters) and a single loxP site, flanked by dif sites.

Origin & function

The nature of genetic modification include insertion of ~100 bp random DNA barcode marker into the chromosome (at the dif locus), insertion of a transposon e.g. Tn5 into the chromosome to disrupt gene function (creating a transposon mutant library to be used for Transposon Directed Insertion Sequencing (TraDIS)), and the removal of naturally occurring extended spectrum beta-lactamase (ESBL) encoding plasmids.

DNA barcode markers are to be used to enable the identification of an E. coli strain of interest from the mixed natural population within the animal gut model, by using PCR, qPCR or colony hybridisation (using streptavidin detection) techniques. A ~100 bp random DNA sequence is firstly synthesised using biotinylated nucleotides incorporating desired restriction enzyme sites at each end. This is inserted into the delivery plasmid (pBD62 or derivative thereof) by conventional cloning, resulting in the DNA barcode being flanked by transcription terminator elements (TrrnB from E. coli and TtL3 from coliphage λ). The delivery plasmid (encoding zeocin resistance) is transferred into the E. coli strain of interest by conjugation, and is inserted into the chromosome at the dif locus via the integration element from choleraphage CTX–phi (the XBS site). A Cre recombinase encoding plasmid is then transformed into the zeocin resistance cells to remove the backbone of the delivery vector by recombination at the loxP sites. The final cells therefore contain the DNA barcode (flanked by the two transcriptional terminators to prevent any possible transcriptional read-through from adjacent promoters) and a single loxP site, flanked by dif sites.

Evaluation of foreseeable effects

Genetic modifications will not increase infectious potential or the survivability of the bacteria. No genes of known toxins, oncogenic proteins, allergens or modulators of growth or differentiation will have been added to an organism. Any antibiotic resistance genes will not be connected to first or second-line antibiotics used for treatment in humans. No genes of known adhesins, envelope proteins or capsid proteins will have been added to an organism. Bacterial strains in which DNA sequences have been manipulated are unlikely to be more virulent than the wild-type strains, and indeed in most cases will be attenuated. As the GMO is likely to be less virulent than its pathogenic progenitor it can therefore be handled at the ACDP category relevant to the wild-type.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No larger GMOs will be used in this study.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogations applied for

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid and liquid contaminated waste is treated by autoclaving for at least 15 minutes at 121°C on a validated cycle resulting in 100% kill.
Post autoclaving: Solid waste is further disposed of into a tiger stripe bag and sent off site for incineration via Grundons Waste Management Company. Liquid waste is disposed of down the sink with copious amounts of water.
This flows to the main foul drain and onto a waste water treatment facility owned by Thames Water.
Any spill will be cleaned using liquid disinfection by treating the solution with 1% (weight/ volume) VirkonS for 16hrs at room temperature. The solution is then disposed of to the laboratory drain flushed with copious amounts of water at a maximum volume of 2L per day. This flows to the main foul drain and onto a waste water treatment facility owned by Thames Water.

The main aim is to investigate the role of extracellular DNA and trace elements on antimicrobial resistance gene transfer by transformation and conjugation. E. coli will be used as a model organism for transformation while C. difficile will be a model organism for monitoring conjugation events.

**Recipient or parental organism**

The recipient organisms include Escherichia coli, Clostridioides difficile, Yersinia species, Klebsiella species, nontyphoidal Salmonella serotypes and other ACDP hazard group 1 and 2 bacteria. Primary experiments will be conducted using E. coli and C. difficile as recipient or parental organisms.

**Host/vector system**

Several standard non-viral vector systems such as pUC18/19, pBR322, pEK499 plasmid and plasmids isolated from E. coli or other Gram-negative bacteria maybe used. The host organism is E. coli.

**Origin & function**

The origin of the GM material is from E. coli or C. difficile strains. The GM material encodes for antimicrobial resistance genes such as rifampicin resistance (rpoB), erythromycin resistance (Erm), ESBL genes, tetracycline resistance (Tn5397) and pathogenicity island (tcdB).

**Evaluation of foreseeable effects**

E. coli transformants will carry antimicrobial resistance genes. Infection with these strains may cause urinary tract infections with a strain that is either rifampicin or cefotaxime resistant. C. difficile transconjugates will carry plasmids from the parental strain encoding for antimicrobial resistance genes. Infection with these strains may cause severe diarrhoea and dehydration due to exposure to C. difficile toxins. It is possible that the mutated DNA could transfer to other bacteria, by recombination or on mobile genetic elements capable of transferring to chromosomal DNA. This could occur within the experiment or the environment. In the event of a breach of containment, the genetically-modified plasmid could be transferred to other bacteria because of its
properties as a mobile genetic element. Transfer is most likely to occur under conditions where there is a high localised density of donors, potential recipient bacteria, and nutrients (like the gut). It is unlikely for genetically modified bacterial DNA to be transferred to others when in low concentrations, there is a lack of nutrient media and without selective pressure (antibiotics/herbicides).

Most of these bacteria are typically found in the gut of healthy individuals; however, some strains e.g. E. coli can become opportunistic pathogens in certain conditions, causing gastrointestinal disease or extra-intestinal infections (e.g. urinary tract infections). Infection by C. difficile may result in exposure to C. difficile toxins causing severe diarrhoea and dehydration. Exposure to toxin A can provoke C. difficile infection symptoms. All strains will only be used in the laboratory under containment conditions with appropriate decontamination procedures. Therefore, the likelihood of environmental contamination is negligible.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

| NA |

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

For solid waste, all surfaces and equipment will be disinfected with ANIGENE HLD4V diluted at 1:100 with a contact time of 2 minutes. Plastics will be placed in a “Bio Bin”, which is sealed in the MSC. Waste will be held in autoclave bags in the laboratory for collection by the Technical Team at an agreed time (maximum of over weekend in lab). Waste will be autoclaved at 121°C for 15 minutes hold time. Autoclaved waste will then be sent for incineration by a licensed contractor via the yellow clinical waste route.

Contaminated liquid within the gut model fermentation vessels and any other liquid waste will be decontaminated by autoclaving at 121°C for 15 minutes on a validated cycle before the liquid waste is disposed of.

In the event of a spillage:

Spills caused as a result of collection and transport of faecal/gut samples will be dealt with using ANIGENE HLD4V diluted at 1:100 with a contact time of 2 minutes. Absorbent materials will be used to mop up the spill. The materials used to mop up the spill will be treated as contaminated waste and placed into autoclave waste stream for treatment. The area of the spill must be wiped with ANIGENE HLD4V diluted at 1:100 with a contact time of 2 minutes to remove any residual contamination. Any equipment that has become contaminated during the spill must be decontaminated using ANIGENE HLD4V diluted at 1:100. All significant spills will be reported on the University electronic accident reporting system.

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

We are using genetically modified (GM) bacteria to enable us to monitor the bacterial response to cellular & environmental changes as single and as mixed cultures. We are running a range of projects where bacteria are exposed to different environmental (cell cultures, temperature, acidity, oxygen) and/or stress (plasma, cold pasteurisation, ultrasounds, biomaterials) conditions and thereafter we are monitoring their growth/survival and/or their metabolic activity. To do that we are using classic microbiological techniques like plate counting or flow.
cytometry and at the same time advanced microscopy techniques (fluorescent or confocal) which enable us to
determine spatially the location and distribution of bacteria. GM strains of different colours will let us generate a better
imaging when we have co-cultures (mixed cultures) of multiple bacteria. We are following this general approach for
bacteria relevant to food safety and wound healing (skin bacteria)
Current projects under this notification are titled:
Project 1 - Biofilm formation on complex 3D food model systems
Project 2 - Understanding the molecular and cellular mechanisms that phosphate glasses and cold plasma regulate to
inhibit bacterial growth.
Project 3 - Behaviour and biofilm formation of Listeria monocytogenes missing stress regulating genes of SigmaB to
various environmental conditions and induced stresses on different food models

Recipient or parental organism

Project 1: All HG2, sourced from ATCC.
P. aeruginosa ATCC 15692-GFP (previously modified)
P. aeruginosa ATCC 10145
GFP-expressing strains are used for visualising bacteria in food-based systems. Both have infection potential.
Project 2: All sourced from ECCAC
HG1 bacteria, reference strains and strains that are resistant to antibiotics:
• Escherichia coli K12_seva631_14F_2RBS_GmR_MSFGFP
• E. coli K12_seva631_14F_2RBS_GmR_EcFbFP
• E. coli K12_seva631_14F_2RBS_GmR_mcherry
• E. coli K12_seva631_14F_2RBS_GmR_CFP
• E. coli K12_seva631_14F_2RBS_GmR_YFP
• E. coli K12_seva631_14F_2RBS_GmR
• E.coil DC10b_pTH100_AmpR_sGFP (sourced from Addgene)
• E.coli DC10b_pRN11_AmpR_mCherry (sourced from Addgene)

HG2 bacteria, reference strains and strains that are resistant to antibiotics:
• Pseudomonas aeruginosa PAO1_seva631_14F_2RBS_GmR_MSFGFP
• P. aeruginosa PAO1_seva631_14F_2RBS_GmR_EcFbFP
• P. aeruginosa PAO1_seva631_14F_2RBS_GmR_mCherry
• P. aeruginosa PAO1_seva631_14F_2RBS_GmR_CFP
• P. aeruginosa PAO1_seva631_14F_2RBS_GmR_YFP
• P. aeruginosa PAO1_seva631_14F_2RBS_GmR
• Enterococcus faecalis OG1RF_pMV158_TetR_GFP (sourced from Academic Centre for Dentistry Amsterdam
(ACTA))
• Staphylococcus aureus NCTC 8325 (sourced from Public Health England)
The HG2 bacteria rarely usually affect healthy people but may cause infections including bacteraemia, endocarditis,
meningitis and infections of bones, eyes, skin, urinary, gastrointestinal and respiratory tract in people with a
compromised immune system.
Project 3: Listeria monocytogenes strains, HG2 (University of Reading)
L. monocytogenes EGD-e
L. monocytogenes 10403S
L. monocytogenes LO28
All strains have similar infectious potential to wildtype strains and can cause listeriosis if ingested.
All have had the sigB gene deletion. SigB affects the response of Listeria to oxidative stress, without this gene the
bacteria are expected to be much more sensitive to the environment and after treatment (e.g. plasma disinfection and sterilisation) it would die faster. The deletion has been conducted to enable greater understanding of the role of SigB in responses to processing techniques.

Project 1:
pUCP18-MCS-gfp-mut3 plasmid, shuttle vector encoding the GFP variant mut3 to be used with P. aeruginosa ATCC 10145. No modifications of P. aeruginosa ATCC 15692-GFP at the University of Surrey. Systems used not known, however the modifications are only GFP labelling.

Project 2:
All bacterial strains have been modified previously at other organisations. No further modifications have been or will be done in the lab. The seva831 and pMV128 plasmids that are inserted in E.coli, P. aeruginosa and E. faecalis respectively, only carry fluorescent proteins (e.g. GFP); therefore, any gene deletion on these plasmids would not revert pathogenicity features to the strains.

Project 3:
All L. monocytogenes strains have been previously modified. Systems used unknown, however the modifications are only GFP labelling. No further modifications to be done at the University of Surrey.

Project 2:
Some survival expected in the environment and the plasmid can mobilise to environmental bacteria. The recombinant plasmid contains an antibiotic resistance gene but since the work will involve small numbers of bacteria generated in cultures up to 50 millilitres in volume, the risk of transfer of antibiotic resistance to environmental bacteria is low.

Risk of infection if ingested or into open wounds is similar to wildtype strains. No expected increased infection potential in the event of exposure in any of the modified strains.

Project 3:
The L. monocytogenes SigB is responsible for stress functions. Its deletion has no safety implications, the mutants have lower stress resistance and lower virulence and are expected to be more sensitive, grow slower and die faster than the wildtype.
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid cultures will be treated with either Chemegene (5% v/v) or Virkon (1% w/v) with overnight contact time. Treated culture will be poured to drain with copious amounts of water which flows to foul drain and waste water treatment facility owned by Thames Water. Solid waste is treated by autoclaving for at least 15 minutes at 121°C on a validated waste treatment cycle. Autoclaved waste is dispatched for incineration as Offensive waste (Tiger stipe) by Grundon Waste Management Company.

Historical Significant Changes
Implications of cathepsin S in the pathogenesis of degenerative diseases and the interest in developing inhibitors as potential therapeutics, make this enzyme an attractive target for structural investigations for Celltech R&D Ltd.

Full length human cathepsin S will be obtained by PCR from an image clone #3610589 supplied from Research Genetics (Invitrogen).

Recipient or parental organism

Full length human cathepsin S will be obtained by PCR from an image clone #3610589 supplied from Research Genetics (Invitrogen).

Host/vector system

Initial PCR products will be ligated into TOPO vectors (Invitrogen) and then transformed into E.coli TOP10 cells (Invitrogen). Expression is unlikely at this stage. Culture volumes are small at this stage also (<5mls). Plasmid DNA will be prepared from these and sequenced. Only those cloned with the correct full-length sequences will be pursued. Other cultures will be destroyed by autoclaving at 103KPA for 20 mins. Clones that are shown to contain the correct full-length sequence of human cathepsin S will be selectively removed from the TOPO cloning vector, and ligated into suitable restriction sites within appropriate expression vectors eg pBlueBac 4.5 (Baculoviral expression system, Invitrogen) or pMT/V5-His vectors (Drosophila expression system, Invitrogen).

The baculoviral expression will be effected within suitable insect cell host cell lines eg High Five, SF9 and SF21. (All supplied from Invitrogen).

Material ligated into the pMT vectors will be used to transfect Drosophila S2 insect cells. Stable transfectants will be selected, and these will be used for expression studies. The Drosophila S2 insect cells are supplied from Invitrogen.

Origin & function

Full length human cathepsin S will be obtained by PCR from an image clone #3610589 supplied from Research Genetics (Invitrogen)

The products of the gene will be assessed using western blotting and purified, and then used in a screening programme.

Cathepsin S is a highly active lysosomal cysteine proteinase (E.C. 3.4.22.27). It belongs to the papain super family. It is a single chain enzyme, (M, 24000), with no known glycosylation sites in the mature sequence. It is unique amongst the other known lysosomal cysteine proteinases, in that it is highly stable at neutral and slightly alkaline pH.

Cathepsin S is found mainly in lymph nodes, spleen and macrophages, including rat glial cells. It is absent or expressed only at very low levels in kidney, liver, heart, pancreas, ovary and small intestine. The limited occurrence of this enzyme has prompted speculation concerning a special function for cathepsin S in normal and diseased
tissues. The high concentration of cathepsin S in rat brain glial cells may indicate an involvement of the enzyme in Alzheimer's disease. In addition, the high elastinolytic activity of cathepsin S in lung macrophages at neutral pH suggests a participation in the pathogenesis of emphysema. (Bromme 1996). This elastinolytic activity may play a role in tissue damage associated with inflammation. (Kirschke et al., 1989, Shi et al., 1992). Additionally, newly synthesised MHC class II a & B chains associate with a protein chaperone, the invariant chain (Il), which promotes the proper assembly of MHC class II complexes and their trafficking through cells and prevents untimely loading with peptides. Efficient loading of MHC class II heterodimers with antigenic peptides requires concurrent processing of both the Il chain and endocytosed proteins. Present data indicates that Cathepsin S is involved in the degradation of the Il chain and thereby regulating the convergence of processed antigen and MHC class II dimmers competent for peptide loading. In short, it facilitates antigen presentation in the MHC class II system by degradation of the Il chain (Driessen et al., 1999) and may therefore be a target for attenuation of immune response.

Implications of cathepsin S in the pathogenesis of degenerative diseases and the interest in developing inhibitors as potential therapeutics, makes this enzyme an attractive target for structural investigations.

Previous investigators have succeeded in cloning and expressing significant quantities of human cathepsin S using the baculovirus expression system. (Bromme 1996).

Evaluation of foreseeable effects

Overexpression of Cathepsin S would be unlikely to have a negative impact on the environment. Overexpression is unlikely to increase the ability of the expression hosts to survive outside of the laboratory. The baculoviral hosts (SF9, SF21 and High Five cells) and the S2 Drosophila cells have very stringent physiological requirements to sustain growth (a very narrow temperature range, and highly specific nutrient requirements), which would prevent them from proliferating in the environment. Standard microbiological containment procedures (screw top flasks fitted with 0.2 uM filters and similar filters fitted to exhaust lines for a Biostat insect cell fermenter) would prevent any release of recombinant Drosophila into the laboratory or environment. It is recognised that baculoviral particles will not be contained by such measures, but their highly restrictive host range (ie High five, SF9 and SF21 cells) dictates that this should not pose any particular risk to human health nor to the environment. Thus the risk to both human health and the environment at this stage is negligible.

It is recognised that by applying standard good microbiological practice, that this can contain any recombinant material being produced during the initial growth stages. However it is recognised that the objective of this work is to create a quantity of recombinant biomass, which in turn can be collected in a safe manner. The issue as to why this process requires containment level 2 is detailed below.

Cathepsin S has a proteolytic role in the degradation of the invariant chains, and also an elastinolytic activity resulting in tissue damage and remodelling. Expression of the recombinant full-length material results in the production of an inactive form of the protein. Activation occurs when the pH is reduced to r.r, whereupon the proenzyme is then activated. With these physiological properties in mind, it would be advisable to ensure that good microbiological practice is followed throughout this work, and precautions taken to ensure that any aerosols generated during the fermentation process be suitably contained. Growth of the recombinant GMOs can be contained by applying routine GMP (as detailed above). It is the downstream processing of any recombinant biomass, where sonication is applied to disrupt recombinant biomass, (and where aerosols would be generated) is where it is recognised that containment within a microbiological cabinet is required to prevent inadvertent inhalation of the cathepsin S. This containment can be achieved by sonication within a class 2 microbiological flow cabinet. Exhaust is filtered through HEPA filters prior to being exhausted out of the building via a stack on the roof.

02/03/2022
### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Shake flask fermentations are effected in disposable flasks. After use, contents (ie recombinant biomass) will be recovered by centrifugation and stored in polythene bags in dedicated freezers identified with biohazard warning signs. Centrifugation containers will be sterilised by autoclaving at 103Kpa for 30 minutes, and then sent for hot washing in an industrial dish washing machine. Empty flasks will be sterilised by autoclaving at 103Kpa for 30 minutes and then sent for disposal by incineration. Spent fermentation broth will be collected, and autoclaved in a Rodwell Herald autoclave location in the laboratory. (103Kpa, 30 mins). The presence of viable recombinant baculoviral particles and viable drosophila cells could be assessed by experimentation. (Previous work with recombinant baculovirus and drosophila, involving the expression of containment level 1 products has shown that this process is 100% effective at destroying viable recombinant material.) Sterilised broth will then be run to waste down the drain.

5 litre fermentations runs within the Biostat 2 fermentation vessel will be effected with 0.2uM air filters on both the air inlet and exhaust lines. This is standard practice. This provides for the same levels of protection to human health and the environment as described for the shake-flasks. Following the recovery of recombinant biomass by centrifugation, spent fermentation broth will be decanted back into the fermentation vessel, and the complete unit will be autoclaved at 103Kpa for 1 hr (extended time to accommodate for the increased volumes). Sterilised broth will then be run to waste down the drain. Broth could be tested for viable recombinant baculoviral particles and viable drosophila cells.

All disposables (ie tips, pipettes) used during the process will be soaked in a 1% w/v solution of Vircon prior to collection and subsequent autoclaving at 103KPA for 30 minutes, prior to disposal via incineration. Any spillages will be treated with solid Vircon, and material then soaked up onto paper towels, and subsequently autoclaved at 103Kpa for 30 minutes prior to disposal.

**Project Containment**

---

02/03/2022
Myelin/oligodendrocyte glycoprotein (MOG) is a candidate autoantigen in multiple sclerosis. Novel approaches that have the potential to interrupt either the processing and presentation or the immune effector response to this antigen may have therapeutic potential in MS, making this pathway an attractive target for Celltech R&D Ltd.

Rat MOG residues 1-125 (extracellular domain) will be obtained from a rat brain cDNA library (Clontech) by PCR.

Initial PCR products will be ligated into TOPO vectors (Invitrogen) and then transformed into E. coli TOP10 cells (Invitrogen). Expression is unlikely at this stage. Culture volumes are small at this stage also (<5mls). Plasmid DNA will be prepared from these and sequenced. Only those clones with the correct full-length sequence will be pursued. Other cultures will be destroyed by autoclaving at 103KPA for 20 mins. Clones that are shown to contain the correct full-length sequence of rat MOG, will be selectively removed from the TOPO cloning vector, and ligated into suitable restriction sites within appropriate expression vectors, e.g., pet, pCal vectors (which are mobilisation defective and utilise the T7 RNA polymerase based expression system). Vectors will then be transferred into the appropriate host cells for large-scale protein production.
Full-length rat MOG will be obtained by PCR from a rat brain cDNA library (Clontech). This will be cloned into a non-expression vector eg TA cloning vectors. After verification of the correct sequence, the gene will be transferred into a relevant mobilisation defective T7 promoter-driven expression vector. Vectors will then be transferred into the appropriate host cells for large-scale protein production eg E. coli BL21 codon plus (DE3) cells. The products of the gene will be assessed using Western blotting and purified, and then used in EAE models.

MOG is a CNS-specific, qualitatively minor myelin component expressed on oligodendrocyte surfaces and the outermost lamellae of the myelin sheaths. 1,2,3. Amongst the many myelin components proposed as specific autoantigens in MS, MOG is the only one able to induce both an inflammatory T-cell and demyelinating antibody response in a range of laboratory animal species 4,5,6,7. In MS patients, elevated autoreactive T-cell and B-cell responses have been demonstrated in blood 8,9 and CSF 10 and the presence of circulating anti-MOG Ab's may predict disease progression 11. Furthermore, post-mortem tissue from MS patients, areas of demyelination are often associated with the deposition of anti-MOG antibodies 12.

Recombinant MOG may be used for a variety of experimental purposes, such as crystallography, the generation of anti-MOG antibodies in vitro, the isolation of MOG-specific CD4+ and CD8+ T-cell lines in vitro, investigation into the MOG processing amd MHC II interaction on CD4+ T-cells, generation of encephalitogenic T-cell lines and as an antigen in animal models such as AEA. In MS patients changes in the circulating MOG-specific T-cells and in anti-MOG antibody titres have been associated with the pathophysiology of the disease and may be useful clinical markers of disease progression.

Previous investigators have succeeded in cloning and expressing significant quantities or rat MOG in an E. coli expression system 2.

Reference list:

Evaluation of foreseeable effects

Overexpression of MOG would be unlikely to have any negative impact on the environment. Over-expression is unlikely to increase the ability of the strain to survive outside of the laboratory. It is therefore estimated that both the likelihood of and the consequence of hazard to the environment is negligible. The overall estimation of risk is therefore assessed as "effectively zero". The scale of the work within the Applikon fermenters would not exceed 4*2 litres. Should all of this material be inadvertently released from the vessel, then the GMO would be contained within an aseptic access room, that has sealed floors. Material could not leach into other rooms or into the environment. Spillages would be treated with solid Vircon, and the material soaked up onto paper towels, and subsequently autoclaved at 103Kpa for 30 mins, prior to disposal.

The recombinant biomass generated will be obtained after centrifugation of the fermentation broth. This biomass will be soted at -20 degrees C, in polythene bottles or bags, depending upon the yield of the recombinant biomass. Spent fermentation broth will be autoclaved at 103Kpa for 60 mins prior to disposal down the drain.

Recombinant biomass will be resuspended in a suitable extraction buffer, and disrupted by sonication. The sonicator will be located in a class 2 microbiological flow cabinet. Sonication will only be effected when the flow cabinet is operating to ensure that any aerosols generated, do not vent into the general microbiology laboratory. Exhaust is filtered through HEPA filters prior to being exhausted out of the building via a stack on the roof. The cabinet is maintained by the manufacturers (Envair), and is serviced annually.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Shake flask fermentations are effected in reusable pyrex flasks, with single use foam bungs at the enclosures. After use, contents (ie recombinant biomass) will be recovered by centrifugation and stored in polythene bags in dedicated freezers identified with biohazard warning signs. Spent fermentation broth will be collected, and autoclaved in a Rodwell Herald autoclave located in the laboratory. (103Kpa, 30 mins). Sterilised broth will then be run to waste down the drain. Centrifugation containers will be sterilised by autoclaving at 103Kpa for 30 mins, and then sent for hot washing in an industrial glass washing machine. Empty flasks will be sterilised by autoclaving at 103Kpa for 30 minutes and then cleaned within an industrial glasswash machine.

4*2 litre fermentation runs within the Applikon fermentation vessels will be effected with 0.2 M air filters on both the air inlet and exhaust lines. This is standard practice. This provides for the same levels of protection to human health and the environment as described for the shake - flasks. Following the recovery of recombinant biomass by centrifugation, spent fermentation broth will be decanted back into the fermentation vessels, and the units will be autoclaved at 103Kpa for 1 hr. Sterilised broth will then be
run to waste down the drain. Broth could be tested for viable recombinant bacterial cells if necessary.

All disposables (ie tips, pipettes) used during the process will be soaked in a 1% w/v solution of Vircon prior to collection and subsequent autoclaving at 103Kpa for 30 minutes, prior to disposal via incineration. Any spillages will be treated with solid Vircon, and material then soaked up onto paper towels, and subsequently autoclaved at 103Kpa for 30 minutes prior to disposal.

Please enter comments on the GM safety committee on the risk assessment

This project was presented to members of the Celltech R&D Ltd Genetic Modification Advisory Committee & Biological Safety Committee on the 22/5/2003, at a meeting convened at the request of the proposer. The biological safety officer (Dr Alastair Durrant) noted that there was a requirement for containment level 2 for processing of the recombinant biomass as a consequence of the biological activity of MOG. Advice was sought by AD from both the head of the department where the work is intended to take place and also from the site R&D director, with respect to the biological activities of the MOG, prior to AD instigating the notification process to the HSE.

Project notified under transitional arrangements N
One of the major protein constituents of the synaptic vesicle is the family of proteins SV2. They are integral glycosylated membrane proteins with an approximate size of 90Kd and are present on all synaptic vesicles, such as calcium or ATP. We have identified SV2A as the binding site of the anti-epileptic drug, Keppra. This study is intended to characterise the molecular actions of SV2 proteins and to ascertain whether the antiseizure potency of Keppra is as a consequence of modulating the function of SV2A.

PRC products (relating to SV2A, SV2B and SV2C) will be recovered from mammalian brain specific total RNA (Ambion) using specific primers.

PCR products will be typically cloned into TA or TOPO TA cloning vectors and used to transform One Shot E.coli cells. Expression of any recombinant product at this stage is very unlikely.

In addition to the above described work with native SV2 variants, mutant versions of the gene, comprised either of chimeras between the different isoforms (EG SV2A/C chimeras) or site specific mutants of the different isoforms, where individual residues are replaced, will be cloned and expressed. Recombinant genetic material at this stage will be sequenced and only when it is shown to be the correct sequence will it then be moved into an expression vector with an aim of placing it deliberately in frame with a promoter. Typical expression vectors (which are mobilisation defective) would be from the pET, pCal-S, pGEX4T2, pLV1393, pFastBac-Mam, pLentiPst, PIE, pIND, pIRES, pD40 expression series. These will then be transferred into the appropriate host cells.

Examples of expression hosts include; SF9 & T.ni (Baculoviral expression), E.coli BL21 (DE3), BL21 (DE3) pLysS, Origami (Bacterial expression), CHO, PC12, HEK293, COS-7 (Mammalian cell line expression).

PCR products recovered from mammalian brain specific total RNA (Ambion) using specific primers will be cloned initially into PCR Cloning vectors hosted by disabled expression hosts. After verification of the correct sequence, the gene will be transferred into the relevant expression vector and then used to transform or transfect host cells.

The products of the gene will be assessed using western blotting and purified, and then used in a screening programme. Defined mutants of the SV2 gene would also be cloned and expressed.

One of the major protein constituents of the synaptic vesicle is the family of proteins SV2. They are integral glycosylated membrane proteins with an approximate size of 90Kd and are present on all synaptic vesicles. The molecular action of SV2 proteins is unknown. The SV2s are twelve transmembrane proteins with a significant homology to the major facilitator superfamily (MFS) of transporters found in both bacteria and eukaryotes. Given their universal presence in synaptic vesicle, it has been proposed that the SV2s might transport a common constituent of the vesicles, such as calcium or ATP. The small gene family consists of three isoforms, designated SV2A, SV2B, and SV2C. SV2A is the most widely distributed isoform, being nearly ubiquitous in the central nervous system as well as being present in endocrine cells. SV2B is brain specific, with a wide but not ubiquitous distribution, and SV2C is even less prevalent with a very restricted localization in old brain regions like the substantia nigra and...
striatum, the midbrain, the brainstem and the olfactory bulb. SV2C was undetectable in the cerebral cortex and the hippocampus, and found at low levels in the cerebellar cortex. SV2A -/- and SV2A/B -/- knockout (KO) mice have been reported and exhibit a severe seizure phenotype, while the SV2B -/- Kos are reported to have no phenotype. No SV2C KO have been reported so far (but are being prepared by UCB). KO studies indicate that SV2A plays an important role in modulating synaptic vesicle fusion. We have identified SV2A as the binding site of LEV (Keppra) and analogues in the brain while SV2B does not recognise LBS ligands. The observed correlation between ligand binding affinity to SV2A and anti-seizure potency suggests that LEV (Keppra) and analogues might act by altering this modulatory function of SV2A.

Lynch et al., PNAS June 29 2004 101 (26) pp9861-9866

Evaluation of foreseeable effects

SV2 proteins levels are not altered in association with any pathological conditions. They are believed to play a role in regulation of exocytosis of synaptic vesicles in the CNS. The anti-epileptic drug, Keppra that target SV2 has shown a good toxiological profile in animal models and in clinical trials. Given that this activity is common to vertebrates, it is highly unlikely that overexpression of the individual native or mutant recombinant forms would be expected to have any negative impact on the environment. Overexpression is unlikely to increase the ability of the strain to survive outside of the laboratory. It is therefore estimated that both the likelihood of and the consequence of hazard to the environment is negligible. The overall estimation of risk is therefore assessed as "effectively zero".

Use of COS-7 cell lines necessitates containment level 2. The scale of the growth of these cells will be restricted to tissue culture flasks. In the event of a spillage of cells (transfer from class 2 cabinet to incubator within the same laboratory), then the scale of spillage would be minimal (<1 litre). The spillage would be treated with solid Vircon, and the material then soaked up onto paper towels, autoclaved at 103Kpa for 30 minutes and then disposed of. The laboratory has restricted access, and has sealed floors. Material could not leach into other rooms or into the environment. Exhaust from the class 2 cabinet is HEPA filtered. Spent media (after separating the biomass by centrifugation) will be treated with Vircon, prior to disposal down the drain.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For work not involving COS-7 cells, good microbial practice will be followed throughout this work. All waste generated will be autoclaved prior to disposal. For work involving COS-7 cells the following procedures will be deployed. The cells will be passaged and maintained in a tissue culture laboratory within a class 2 microbiological flow cabinet dedicated for the use of COS-7 cells. Exhaust from this unit is HEPA filtered. The unit is maintained by the manufacturers (Envair) and is serviced annually. Face velocity testing and containment efficiency certificates are up to date and indicate maximal performance with respect to user protection. Transfection of the cells will occur in the class 2 hood. Cells will be maintained in sealed tissue culture vessels, and incubated in a dedicated incubator. Cell harvesting will be carried out 24-48hrs-post transfection. The culture vessels will be transferred to the class 2 cabinet, and only then will the lids be opened and the cells then scrapped from the culture vessel surface using disposable scrapers. Dislodged cells and media will then be decanted into sealable centrifuge containers and the cells pelleted by centrifugation. The containers will be returned to the class 2 cabinet. The media will be decanted directly into 1%w/v Vircon. Cell pellets will then be transferred to a -80 degrees C freezer. This process of freezing effectively kills the cells. After this stage, there is no more potential hazard from viable COS-7 cells. Subsequent work will then be carried using good microbial practices. All waste generated (irrespective of required containment level), will be autoclaving at 103Kpa for 30 minutes prior to disposal. All disposables (ie tips, pipettes) used during the process will be soaked in a 1% w/v solution of Vircon prior to collection and subsequent autoclaving 103KPA for 30 minutes, prior to disposal via incineration. Any spillages will be treated with solid Vircon, and material then soaked up onto paper towels, and subsequently autoclaved at 103Kpa for 30 minutes via to disposal.
This project was presented to members of the Celltech R&D Ltd GMSC on 13/1/2005, at a meeting convened at the request of the site HS&E Manager and BSO. It was noted that there was a requirement for containment level 2 for work involving COS-7 cell lines. Alternative expression systems were considered, however the principal scientist for the work noted that previous experiences of the expression of these proteins in the USA has shown that COS-7 cells were the most successful. Therefore, although all other aspects of the project would require class 1 containment, the use of COS-7 cells necessitate a containment level 2 and thus the project needs to be documented and treated accordingly.

- **Consent Granted**: Not Applicable
- **Project notified under transitional arrangements**: No
- **Tick if notifying a connected programme of work**: Yes

**Historical Significant Changes**

**Historical Date of Additional Info**
Project Additional Information

**Purposes of the contained use**

To produce stable and high level expression of transgenes in mammalian cell lines and primary cells for use in the study of disease mechanisms in the areas of cancer, autoimmune diseases, inflammation and CNS. The transduced cells will be used directly in vitro for biological assays or to produce recombinant proteins. Recombinant proteins may be purified and used in procedures like ELISA assays. Stable transduced cell lines or preparations of (e.g. membranes) may be used as antigens for the immunization of laboratory animals.

**Recipient or parental organism**

Well characterised mammalian cell lines e.g. U937, HeLa, which will be transfected with the recombinant virus and used to produce stable cell lines which may then be used to immunise animals.

**Host/vector system**

The Lentiviral system is a third generation retroviral expression system which is commercially available from Invitrogen with enhanced biosafety features. This is achieved by several mechanisms including (1) reduction in the number of genes from HIV-1 (now limited to three; gag, pol and rev) (2) structural genes and other components are separated onto 4 different plasmids (3) no regions of homology between 4 plasmids to prevent recombination (4) replication incompetent virus (5) VSV-G gene used in place of HIV-1 envelope. [continued on page 10]

(6) pLenti expression vector contains deletion in 3'LTR which renders it self-inactivating after transduction of the target cell (7) no HIV structural genes present in the packaged viral genome and hence cannot be expressed in the target cell (8) constitutive promoter place upstream of 5'LTR in pLenti expression hence tat gene no longer required for production of viral RNA. These biosafety features mean that the viruses can infect cells but are unable to replicate once they have done so.

Well characterised packaging cell lines e.g. HEK293 and HEK293T will be used for the for the production of the recombinant virus containing the GOI's. Recombinant virus is liberated into the cell culture medium generating a high titre stock of replication incompetent virus.

**Origin & function**

The genes of interest which will be delivered to target cells using the lentiviral systems are of 3 types. Firstly genes that are involved in infectious disease, autoimmune diseases and CNS diseases. Secondly genes associated with cancer and thirdly genes encoding antibodies or fragments thereof. Apart from the genes above, proteins that are commonly used as reporter genes and genes used for the identification and selection of transfected cells (i.e. fluorescent...
proteins, beta-galactosidase, Luciferase or antibiotic resistance genes) will be used in this system. Genes that will be excluded from this expression system are genes encoding (a) proteins of retroviral origin and (b) toxins.

**Evaluation of foreseeable effects**

During the virus production steps using the packaging cell lines (HEK293 and HEK293FT) there is a potential for exposure of operators to virus. This could only occur through inoculation with sharps, contact with skin which is cut or scratched or by aerosol formation. Sharps will not be required for these procedures and standard biosafety guidelines followed i.e. all cuts will be covered with a waterproof dressing and gloves worn at all times. To prevent exposure by aerosol formation or splashing a class II MHC will be used for all procedures where this could arise.

The VSVg coated particles will be used to stably transduce mammalian cells. Transduction leads to integration of the transgene into the host cell DNA. It is not expected that the inserted sequences will alter the inherent properties of the host cells such that there will be an increase in the hazards associated with the host.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**Not applicable**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Not applicable**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Plastic disposable pipettes and pipette tips are soaked in a 1% w/v Virkon solution for at least 12 hours prior to autoclaving as described for other solid waste described below.

Solid Waste is collected in biohazard bins double-lined with autoclave bags. After completion of work the double-lined bags are removed and loosely taped with autolcave tape. These are placed into metal containers and then transported to the waste autoclave facility using a trolley. The waste is autoclaved using the plastic discard cycle which is 103Kpa for 30 mins. The autoclave used for waste disposal is serviced, calibrated and validated every 6 months by thermocouple. At the end of the autoclave cycle the paperwork is checked to ensure that the cycle has "passed" and the parameters have been met. The processed waste is then disposed of as non-hazardous waste.

Liquid waste is decontaminated in culture vessels or robust plastic sealed containers by the addition of Virkon to give 1% w/v solution and left for 12 hours. Once decontaminated the liquid waste is disposed of down the drains with copious amounts of cold water.

Please enter comments on the GM safety committee on the risk assessment

---

02/03/2022
Although the lentiviral system is well characterised and has a number of safety features the committee felt that the ability to test for replication competent virus should be evaluated. The p24 ELISA will be used to test periodically for replication competent particles.

The committee agreed that although containment level 1 would be sufficient for most of the work with the lentiviral vectors, containment level 2 was required for the expression of tumour associated genes.

All the lentiviral work will be carried out in a designated containment level 2 or animal containment level 2 laboratory.

Purposes of the contained use

To enable transient expression of transgenes in mammalian cell lines and primary cells for use in the study of disease mechanisms in the areas of cancer, autoimmune diseases, inflammation and CNS. These transgenes include gene cassettes that code for siRNA/shRNA or for overexpression of wild-type or mutated forms of proteins, or for introducing genetic components that facilitate genome editing (eg. CRISPR/Cas9). Premade viral particles will be purchased from Contract Research Organisations (CROs) such as Sirion Biotech / Sigma / Horizon Discovery.

The nature of these studies is to conduct biological research experiments into the genetic functions associated with our drug targets. The benefit of using viral based vectors is that genes can be delivered into more primary cell/tissue cultures that are often very difficult to transfect via standard means. The transduced cells will be used directly in vitro for biological assays or to produce recombinant proteins. Recombinant proteins may be purified and used in procedures like ELISA assays. Transduced cells or preparations of (e.g. membranes) may be used as antigens for the immunization of laboratory animals.

Recipient or parental organism

Well characterised mammalian cell lines e.g. U937, HeLa, or primary cells ego monocytes, T cells, which will be transduced with the recombinant virus in order to overexpress transgenes of interest, which will then be used in downstream standard biological assays ego mechanism based studies on signal transduction pathways.

Host/vector system

The AAV system can be used as a vector to transduce cells resulting in transient, quantitative gene expression or knockdown, and are very efficient for infecting non-dividing terminally differentiated cells ego macrophages. Current vectors contain enhanced biosafety features: they have low immunogenicity, low integration events - episomal dsDNA genome, AAV belong to family Parvoviridae, no known link to any human illness AAV are defective, require co-infection with helper virus (eg. Herpes simplex virus) Most AAV-based vector systems to date are typically ‘gutless’ AAV-2 systems consisting of a plasmid containing the foreign DNA to be transduced into the cell flanked by AAV ITR sequences

Origin & function

The genes of interest which will be delivered to target cells using AAV vectors will include the following types:

1. genes that are involved in infectious disease, autoimmune / inflammatory diseases, CNS diseases and cancer.
2. genes encoding antibodies or fragments thereof.
3. commonly used reporter genes and genes used for the identification and selection of transfected cells (i.e. fluorescent proteins, beta-galactosidase, Luciferase or antibiotic resistance genes) will be used in this system.
4. Commonly used genes used for genome editing ego Cas9 and its variants.
5. Small gene cassettes designed to express RNA ego siRNA, shRNA and guide RNA (used in conjunction with Cas9 for genome editing).

Genes that will be excluded from this expression system are genes encoding (a) proteins of retroviral origin and (b) toxins.

Evaluation of foreseeable effects

AAV belong to family Parvoviridae, no known link to any human illness, and they are essentially defective, requiring co-infection with helper virus (eg. Herpes simplex virus). 80% of individuals are already seropositive for AAV serotype
2, with no symptoms and long lasting immunity. Wildtype AAV's are not categorised by ACDP and therefore containment level 1 is usually sufficient. The main hazards arising from AAV vectors are due to properties of any inserted genetic material and therefore necessitate additional containment measures. All work will be conducted in containment level 2 laboratories following Standard Operating Procedures. We will not be generating AAVs in house (they will be purchased from external CROs) due to the requirement for helper viruses (Herpes). There is a potential for exposure of operators to virus. This could only occur through inoculation with sharps, contact with skin which is cut or scratched or by aerosol formation. Sharps will not be required for these procedures and standard biosafety guidelines followed i.e. all cuts will be covered with a waterproof dressing and gloves worn at all times. Aerosol formation can occur during techniques such as pipetting, vortexing, centrifugation. To prevent exposure by aerosol formation or splashing a class II MHC will be used for all procedures where this could arise. Vortexing or centrifugation will be conducted in sealed and capped tubes / rotors. Spills will be dealt with according to standard procedures as detailed in the accompanying Risk Assessment. Cells will be fixed using formaldehyde before removal of material from designated room, eg Flow cytometry, FACs. For live material that is to be removed from the designated virus room, the material will be assessed for the presence of infectious AAV (using rtPCR or ELISA). People who are pregnant or immunocompromised may be more susceptible to AAV infection and associated complications. High risk individuals will be advised not to work with AAV. Ongoing training of Staff and maximised use of PPE will be conducted. Only personnel with a professional qualification, and/or experience working with viruses along with company training may work in this room. Personnel will be overseen by the lab supervisor until deemed competent.

Purposes of the contained use

To enable transient expression of transgenes in mammalian cell lines and primary cells for use in the study of disease mechanisms in the areas of cancer, autoimmune diseases, inflammation and CNS. These transgenes include gene cassettes that code for siRNA/shRNA or for overexpression of wild-type or mutated forms of proteins, or for introducing genetic components that facilitate genome editing (e.g., CRISPR/Cas9). Premade viral particles will be purchased from CROs such as Sirion Biotech, Sigma, Horizon Discovery.

The nature of these studies is to conduct biological research experiments into the genetic functions associated with our drug targets. The benefit of using viral based vectors is that genes can be delivered into more primary cell/tissue cultures that are often very difficult to transfect via standard means. The transduced cells will be used directly in vitro for biological assays or to produce recombinant proteins. Recombinant proteins may be purified and used in procedures like ELISA assays. Transduced cells or preparations of (e.g. membranes) may be used as antigens for the immunization of laboratory animals.

Recipient or parental organism

Well characterised mammalian cell lines e.g. U937, HeLa, or primary cells e.g. monocytes, T cells, which will be transduced with the recombinant virus in order to overexpress transgenes of interest, which will then be used in downstream standard biological assays e.g. mechanism based studies on signal transduction pathways.

Host/vector system

The Adenoviral system can be used as a vector to transduce cells resulting in transient, quantitative gene expression or knockdown, and are very efficient for infecting non-dividing terminally differentiated cells e.g. macrophages. Current vectors contain enhanced biosafety features: they are replication deficient, disabled vectors (in cells that do not express viral E1/E3 proteins) - and are referred to as third generation 'gutless' vectors. Adenovirus serotype Ad5 based vectors (7.5kb capacity) will be purchased from external CROs e.g. Sirion Biotech.

Origin & function

The genes of interest which will be delivered to target cells using Adenoviral vectors will include the following types:
1. genes that are involved in infectious disease, autoimmune / inflammatory diseases, CNS diseases and cancer.
2. genes encoding antibodies or fragments thereof will also be delivered to target cells.
3. commonly used reporter genes and genes used for the identification and selection of transfected cells (e.g. fluorescent proteins, beta-galactosidase, Luciferase or antibiotic resistance genes) will be used in this system.
4. Commonly used genes used for genome editing e.g. Cas9 and its variants.
5. Small gene cassettes designed to express RNA e.g. siRNA, shRNA and guide RNA (used in conjunction with Cas9 for genome editing).

Genes that will be excluded from this expression system are genes encoding (a) proteins of retroviral origin and (b) toxins.

Evaluation of foreseeable effects

Wildtype Adenovirus is transmitted by inhalation, contact with mucus membranes (eyes, nose and mouth), fecal-oral
Transmission and waterborne transmission. However commercially available Adenovirus vectors are not wildtype, and have been engineered to contain multiple safety features (as discussed in section 7). People who are pregnant or immunocompromised are susceptible to adenovirus infection and associated complications. High risk individuals will be advised not to work with Adenovirus. There is a potential for exposure of operators to virus. This could only occur through inoculation with sharps, contact with skin which is cut or scratched or by aerosol formation. Sharps will not be required for these procedures and standard biosafety guidelines followed i.e. all cuts will be covered with a waterproof dressing and gloves worn at all times. To prevent exposure by aerosol formation or splashing a class II MHC will be used for all procedures where this could arise. Vortexing or centrifugation will be conducted in sealed and capped tubes / rotors. Spills will be dealt with according to standard procedures as detailed in the accompanying Risk Assessment. Although adenovirus is low risk GM activity (class 1), and technically could be handled at Containment level 1, due to risk associated with inserts used all work will be conducted in containment level 2 laboratories following SOPs. Cells will be fixed using formaldehyde before removal of material from designated room, e.g. Flow cytometry, FACs. For live material that is to be removed from the designated virus room, replication competency can be first assessed by infecting a permissive non-complementing cell line (e.g. HeLa) and look for signs of productive replication (cytopathic effect, plaque formation). Or PCR for E1 sequences in cell culture samples to confirm lack of replication competence. Ongoing training of Staff and maximised use of PPE will be conducted. Only personal with a professional qualification, and/or experience working with viruses along with company training may work in this room. Personal will be overseen by the lab supervisor until deemed competent.

## Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

Y
Composition:
- Chairperson
- Biological Safety Officer (BSO) acting as vice-chair in the absence of the chair
- Secretary
- The heads of school/department that undertake GM work
- One member of technical staff with GM experience by nomination of the faculty manager.
- Manager of the bio-resources unit
- One senior researcher with GM experience from each school that undertakes GM work, nominated by the respective Head of School
- Representatives from organisations affected by the GM activities conducted within the GM Centre
- The Principal Investigator or a representative from the project group intending to carry out a particular GM activity can be invited
- Representative with relevant experience by invitation
- University Health & Safety Manager

Operation:
- The committee will receive for scrutiny and review all risk assessments for GM projects.
- The committee will advise on laboratory procedures and safe systems of work.
- Safety inspections of laboratory facilities will be used to monitor the performance of the ‘The Genetically Modified Organisms (Contained Use) Regulations’.

Outcomes of the inspections will be reviewed.
- The committee will meet termly. There will be at least 3 meetings per year.

The Chair is co-opted onto the University Health and Safety committee. Minutes from the GMSC meetings are forwarded to this committee.

2002/03/2022
Volumes of GM bacterial (E. coli) culture range from 1 ml up to a maximum volume of 8 litre (as 12x 500ml flasks) in shaking orbital incubators. Primary and secondary cell cultures are grown in culture flasks, orbital shakers or roller bottles (normally no more than 250ml cultures). Cells are killed using virkon tablets. Plastics and reusable glassware are soaked in virkon for 24 hours and then autoclaved. Waste from all liquid cultures are either autoclaved with a cycle at 121 degC for 30 min. prior to disposal as conventional liquid waste, or treated with disinfectant powder (virkon) and then poured down a sink with dilution. Solid waste is autoclaved and then mixed with conventional waste on normal skip disposal using our contractors, Biffa. Each run is logged. Liquid spills are treated with disinfectant powder (Virkon or Haz-tab granules) or solution (Virkon or BioCleanse) according to standard procedures and contaminated waste then disposed as above. Leaks within centrifuges are decontaminated with 70% ethanol.

All autoclaves are checked for performance (including temp calibration) and safety on an annual basis. The autoclaves are also pressure checked, annually under the Pressure Regulations (and for insurance purposes). Maintenance logs are present. Continuous monitoring of temperature is possible during a cycle. The autoclaves are checked periodically (monthly) for temperature maintenance. There are plans for an in-load temperature probe to monitor the temperature, in addition to the chamber probe. Routinely, waste is checked through the use of autoclave tape to confirm the contents have indeed been autoclaved.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment
All class 1 GM work will be conducted in category 1 laboratories in accordance with the general COSHH measures to control exposure to biological agents:

1) Display suitable and sufficient warning signs, including the biohazard sign.
2) Put in place appropriate decontamination and disinfection procedures.
3) Put in place the means for the safe collection, storage and disposal of contaminated waste. This includes the use of secure and identifiable containers after treatment if appropriate.
4) Test, where it is necessary and technically possible, for the presence of biological agents outside primary physical containment.
5) Set out the procedures for working with (and on-site transport of) biological agents or material that could contain them.
6) Where appropriate, make effective vaccines available to employees who are not already immune.
7) Put in place good occupational hygiene measures including the provision of appropriate and adequate washing and toilet facilities. Where appropriate, eating, drinking or smoking is prohibited in any workplace where there is a risk of contamination with biological agents.

and in accordance with GMM Level 1:

8) Surfaces will be impervious to water and resistant to acid, alkalis, solvent, disinfectants, decontamination agents and easy to clean. Hand washing facilities with taps that can be operated without being touched by hand and a supply of disinfectant soap (required for bench).
9) An autoclave will be on site.
10) Suitable protective clothing including eye protection will be required.
11) Efficient control of vectors that could disseminate disease or GMMs, e.g. rodents and insects is required where and to extent the risk assessment shows it is required.
12) Specified disinfection procedures will be in place. Effective disinfectants should be available for immediate use in the event of a spillage, required where and to extent the risk assessment shows it is required.
13) Inactivation of GMMs in contaminated material is required by validated means.
14) An observation window, or alternative, is to be present so that occupants can be seen is required where and to extent the risk assessment shows it is required.
15) Safe storage of biological agents and GMMs. Must be clearly labelled and have compliant biohazard sign is required where and to extent the risk assessment shows it is required.
GM Centre Number: 85

This project is an investigation into the molecular basis for Bordetella infection and immunity. It attempts to elucidate the processes by which these bacteria colonise the host tissues, multiply within these tissues, cause pathology, transmit to other hosts and how the host immune response reacts to the bacteria. In particular, it studies the genetic and cellular basis for these processes. Data arising from this project will obviously expand understanding of the infection biology of these bacteria. However the Bordetella are models for numerous processes that are of general interest to the infection and immunity field, including control of gene expression, interactions with ciliated respiratory epithelia, mucosal immunity in the respiratory tract, host-adaptation and the evolution of virulence.

This project involves studies at the cellular level using whole bacteria and at the molecular level using purified bacterial components (proteins, nucleic acids, carbohydrates, lipids and glycolipids).

<td>Laboratory strains of Escherichia coli. These strains are used for plasmid maintenance and plasmid amplification and recombinant protein expression. They are non-infectious due to stable mutations. These strains are well characterised, and used extensively world wide for these purposes.</td>
</tr>
<tr>
<td>Species of Bordetella B.pertussis and B.parapertussis are pathogens of the human respiratory tract and the causative agents of whooping cough. Infants who have yet to receive the full schedule of pertussis vaccinations are susceptible to whooping cough. Adolescents and adults for whom vaccine or infection induced immunity has waned are susceptible to chronic cough and are sources of infection of susceptible infants. Pertussis is naturally endemic in the human population. Little is known about the contribution of B.parapertussis to the burden of whooping cough disease. Thus, laboratory workers are at risk from infection but the morbidity from such infection is very low. Appropriate control measures to prevent exposure should be used (see below). B.bronchiseptica infects a very wide range of mammals but is described as a pathogen of just a few (cats, dogs, pigs), causing a relatively mild respiratory tract infection. Human infections are rare and almost always associated with immuno-compromised people or close contact with infected animals. It is not considered a risk to healthy humans. It is a DEFRA controlled organism. B.avium infects mainly turkeys and wild fowl to cause rhinotracheitis. There are no reports of avium infection in humans or mammals. The other bordetellae cause sporadic disease in humans including respiratory disease and septicaemia. Risk factors for infection by these organisms are unknown, as is their true pathogenic potential. Although infections by these bacteria are rare, appropriate control measures are sensible. Workers may spread the bacteria, particularly B.avium and B.bronchiseptica, to other susceptible animals if they are carried out of the lab on clothing or person. All workers will be made explicitly aware of the need to maintain rigorous standards of occupational hygiene to minimize the risk of this. All workers will be required to sign that they understand this risk and the control measures required to prevent it on personal safety training/risk assessment records. Importantly, horizontal gene transfer among the bordetellae is rare. Infact, B.pertussis and B.parapertussis evolved through genome reduction. Thus, they are low risk in terms of transfer of genetic material to other bacteria.</td>

</tbody>
</table>
move the mutate loci back into Bordetella to generate allelic replacement mutants. Mostly, mutations will be constructed by inserting an antibiotic resistance cassette into the Bordetella locus.

The creation of defined bacterial mutants via allelic exchange mutagenesis is a powerful technique for elucidating gene function, is a standard technique in my laboratory and forms the majority of genetic manipulation in this project. The phenotype of the wild type parental strain is compared to that of the isogenic mutants. Changes in phenotype are correlated to the genotype. This approach is a powerful technique for ascribing gene function, for elucidating the role of that gene in the biology of the host organism and is used in studies of bacterial pathogenicity.

Some Bordetella mutants will be used to infect mice to test their phenotype in an in vivo model of infection and immunity. The mouse model of Bordetella infection is well characterised and has been instrumental in understanding the infection biology of these bacteria.

In other cases, Bordetella genes will be cloned in order to express them from the recombinant plasmids ans is also used to study gene function. Complementation of mutations is used to confirm that a mutant phenotype is due to the experimentally constructed mutation and not a secondary effect or artifact. Expression of genes in heterologous hosts is used to identify possible functions of the gene by analysing the phenotypes of the recombinant, purifiable protein for in vitro studies of protein function.

Evaluation of foreseeable effects

It is considered very unlikely that using lab strains of E.coli in this way will result in a pathogenic phenotype. A vast majority of DNA constructs used will not encode functional proteins. Bordetella promoters are not well recognised in E.coli. In the very rare instances where a Bordetella encoded protein is expressed in these E.coli hosts, it is highly unlikely to convert them to an infectious phenotype. Deliberately expressed recombinant proteins will be metabolic enzymes involved in polysaccharide synthesis and not virulence factors.

There are no foreseeable adverse effects from performing in vivo work with Bordetella mutants. The bacteria will be handled in containment level two facilities and infected animals housed in isolator facilities that will not permit release of bacteria in to the environment or to other animals.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid and liquid waste and contaminated glassware will be inactivated by autoclaving. Autoclaves are validated by temperature probe. Contaminated surfaces will be disinfected using 70% ethanol. 70% ethanol validated by

Date of Significant Change

Project Additional Information
**Purposes of the contained use**

The aim of the investigation is to express the prion protein (mouse, chicken, tuttle, Zenopus sequences) in E.coli and extract the protein for function studies and to express the protein in mammalian cell cultures to assess the consequences of that expression for cell survival. Non-pathological mutants of the prion protein (mouse) will also be expressed in both systems to assess their effect on prion protein function.

**Recipient or parental organism**

| E.coli (JM109, AD494, XL1 Blue, XL2 Blue, DH5a) |
| mammalian cell lines, neuroblastoma, PC12, neuroblastoma/cerebellar cell fusion cell lines. |
| Primary neuronal cultures from mouse brain. |

**Host/vector system**

d

**Origin & function**

The genes are from mouse, chicken, turtle and toad. The genes will express the prion protein (prnp) or doppel protein (prnd).

**Evaluation of foreseeable effects**

The normal protein product of the prion protein gene. The level of expression will be high in E.coli and moderate to high in mammalian cells. The mutants that will be used are the following:

1. The mouse prion protein has two known alleles. Most mice express the a allele. The b allele differs at only two amino residues (being aa 108 and 189). Mutants will be made with either the b form of codon 108, the b form of codon 189 or both. These mutations are not associated with disease. Mice expressing the b allele are less susceptible to disease.

2. Deletion of codons 51-90 of mouse prion protein. This deletion removes the copper binding domain. This mutation is not associated with disease. There is no correlation with the scrapie isoform. PrP-Sc does not contain this region of the prion protein.

3. Deletion of codons 114-120. Removal of this region abolishes the ability of the prion protein to be converted to PrP-Sc. This form of the prion protein would be safer than wild type (see Holscher et al, J. Virol. 72, 1153-1159, 1998).

4. Production of a fusion protein with the green fluorescent protein expressed before codon 23 of the prion protein. The sequence of GFP would be cloned into the prion protein gene after the signal peptide coding region. This is unlikely to have harmful effects and has been done before (Lorenz et al. 1999; P161, Conference on Prion Disease held in Tubingen).

5. Deletion of codons 235-254. This part of the protein is the signal to form a GP1 anchor. As such the protein produced would not be anchored to the cell membrane. As GP1 anchoring is believed essential for conversion of the protein to the abnormal isoform then this mutant would also be "safe".

For the following reasons it is unlikely that an infectious activity would be associated with the protein expressed:

1. Despite many attempts no researcher has managed to convert recombinant prion protein into an infectious form.
2. Conversion to the abnormal isoform (PrPSc) seems to require GP1anchoring to a cell as well as contact with the abnormal isoform. Therefore recombinant material is probably far less dangerous than prion protein expressed by mammalian cells (present ubiquitously in the environment).
3. Overexpression of the prion protein does not lead to disease in mice or production of the disease specific from (PrP-Sc).
4. The mutants to be generated are all non-disease associated mutations and in some cases actually prevent the possibility of conversion.
5. The proteins to be generated will be based on the mouse and the lower vertebrate sequences. The chicken sequence has no association with disease. There is no
naturally occurring mouse transmissible spongiform encephalopathy. Scrapie is transmitted experimentally to mice from sheep brain extracts.

6. No abnormal isoform of the prion protein will be introduced into the experimental system. Therefore conversion will either be very improbable or impossible.

7. The abnormal isoform (PrP-Sc) requires the presence of prion protein expressing cells to form. The spontaneous production of PrP-Sc known to arise in diseases such as scrapie of CJD in humans takes years to be generated. The cultures to be used will only be maintained for two weeks.

8. There exists in conversion of cellular prion protein to the abnormal isoform by PrP-Sc a species barrier. This barrier implies that there is a very low probability of human cellular prion protein being converted to the abnormal isoform by mouse PrPSc.

However it is unknown under what conditions the altered isoform of the prion protein may be generated.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

**Prokaryotic Work**

Decontamination: All non-disposable glass and plasticware is to be rinsed with 2M NaOH (sodium hydroxide) for 15 minutes after use.

1. Liquid waste: all solutions are to be collected in Schott (borosilicate) bottles and autoclaved at a minimum of 126 degrees C for 30 minutes. After autoclaving this waste is to be mixed with Virkon (to a final concentration of 50%) and left to stand overnight. This treatment will give an effective 100% kill of viable GMMs. After this time the liquid is safe to tip down the sink.

2. Solid waste: to be collected in a doubled biohazard bag. At the end of each round of protein purification, or when it is full, it is to be autoclaved at a minimum of 126 degrees C for 30 minutes. The waste is then treated as non-hazardous industrial controlled waste and sent for landfill.

Wastes from those parts of the procedure involving 8M Urea need not be collected or treated in this manner as 8M Urea will fully denature the protein.

**Eukaryotic Work:**

Decontamination: All non-disposable glass and plasticware is to be rinsed with 2M NaOH (Sodium hydroxide) for 15 minutes after use.

1. Liquid waste: all solutions are to be mixed with Virkon (to a final concentration of 50%) and left to stand overnight. This treatment will give an effective 100% kill of viable GMMs. After this time the solutions are safe to tip down the sink.

Solid Solid waste: to be collected in a doubled biohazard bag. At the end of each round of protein purification, or when it is full, it is to be autoclaved at a minimum of 126 degrees C for 30 minutes. The waste is then treated as non-hazardous industrial controlled waste and sent for landfill.

**FOR VALIDATION OF WASTE INACTIVATION**

After bacterial cultures are treated with Virkon, samples will be taken and streaked onto bacteriological plates to determine if there are any viable bacteria. If a positive culture is found the waste material will be autoclaved at minimum of 126 degrees C for 30 minutes.

Inactivation of theoretically infectious prion protein cannot be validated as at the present time there is no evidence of any kind that recombinant prion protein can be infectious.
All researchers involved in the work and those in the vicinity are to be made aware of the control methods required. Every three months discussion of the control methods with researchers involved is carried out to ensure that the control methods are indeed carried out. The problem with this work is that the requirement for waste treatment is applied to prevent a potential threat for which there is currently no evidence.

This project examines the contribution of environmental events leading to cessation of growth on the expression of Pseudomonas aeruginosa genes associated with survival and persistence in stationary phase. The work involves the use of some plasmid-borne lux and gfp reporter constructs (isolated in other laboratories).

The host strains are well-characterised laboratory strains of P. aeruginosa, PAO, PAK and PA103. These strains were clinical isolates dating back to the 1950s, and characterised by workers such as Bruce Holloway. P aeruginosa is an opportunistic pathogen, notably causing infection in immunocompromised and burns patients and those with cystic fibrosis. Infections are rare in otherwise healthy individuals, with eyes, middle ear and the urinary tract being most likely involved. The vectors are derivatives of pUC18 able to replicate within P. aeruginosa.

Incomplete transcriptional and translational fusions used to drive expression of gfp. Level of expression and biological activity likely to be low. Complementing sequences for rpoS, lasR/l, rhlR/I, exsA, exoS, exoT, pilU, pilT and pilA.

RpoS is a sigma factor that controls expression of genes on entry into stationary phase (J. Bacteriol 181, 3890-3897).

LasrR/I are the regulatory and synthetic components of the one of the two quorum sensing systems in P. aeruginosa. RhlR/I control the second system (Infect Immun 68,4839-4849).

ExsA controls expression of the type III secretion system (Nature Medicine 5,392-398). ExoS is and ExoT are Ras GTPase activating proteins delivered by the type III secretion system (Infect Immun 66,2607-2613; Infect Immun 68,6066-6068).

PilA is the pilus structural subunit which is secreted by the type IV secretion apparatus including the PilU and PilT components (Infect Immun 67,3625-3630).

The proteins RpoS exists in many Gram-negative organisms, so acquisition of the Pa gene would not be expected to have additional effects. Expression of components of the two quorum sensing systems would not be expected to have biological activity in other organisms. The promoter sequences to which the LasR and RhlR transcriptional
Regulators bind appear specific to the host organism. ExsA regulates expression of a type III secretion system found only in Pa. Similarly, ExoS and ExoT require the Pa type III system for secretion and this heterologous expression in another organism is unlikely to occur. Heterologous expression of PilA, PilT and PilU components could confer additional adhesive properties, however closely homologous structures are expressed by related organisms anyway.

Overall, unlikely to cause harm to healthy subjects, but P. aeruginosa is an opportunistic pathogen in immunocompromised patients. These infections are susceptible to antibiotic treatment. The plasmids are selected on the basis of resistance to carbenicillin, which is not in current clinical use, or gentamicin. Gentamicin is in clinical use.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The GMM is handled in an ACDP containment level 2 laboratory. All material leaving the laboratory is decontaminated by autoclaving at 126 degrees C for 30 min. The cycle is under dual process control. Spills within the laboratory are treated with alcoholic cetrimide or chlorine-based agents (>2500 ppm available chlorine). Surfaces are swabbed to monitor for contamination control. Disinfection procedures follow EN1276.

Project Ref 85/03.2
We are studying the genetic mechanisms controlling the symbiotic interaction between Photorhabdus and its nematode host, Heterorhabditis. These studies will involve the generation of mutant strains of Photorhabdus and assaying these mutants for their ability to support nematode growth and development (symbiosis).

Recipient or parental organism

The recipient organism is Photorhabdus, a gram negative bacterium that is a member of the family Enterobacteriaceae. This bacterium is highly pathogenic to a wide variety of insect larvae whilst also maintaining a symbiotic relationship with nematodes of the family Heterorhabditidae. The bacteria-nematode complex exists naturally in most countries surveyed (including the UK) and is commercially available as a natural biocontrol agent. Photorhabdus are considered to be non-pathogenic to humans. However one species, P.asymbiotica (interestingly this species does not have a nematode partner), has been found associated with non-lethal, easily treatable infections in the US and Australia (a total of 10 cases have been reported in the last 13 years). It is difficult to see how Photorhabdus could establish systemic infections in humans as the bacteria cannot grow well at 37°C.

Host/vector system

The host/vector system used will be based on E.coli K-12 strains and pBR and pGP704-derived vectors. E.coli S17-1 will be used to deliver a kanamycin-containing cassette to Photorhabdus. The E.coli strains used are nutritionally disabled (thi mutation) and would not survive outside of the laboratory. Furthermore pGP704-derived vectors will only replicate in S17-1 as it has been engineered to contain the lambda pir protein. Therefore once this plasmid is introduced into Photorhabdus it can no longer replicate and must recombine into the chromosome. Therefore the risk to the environment is low and there is no risk to horizontal transfer of the plasmid from Photorhabdus to other organisms.

Origin & function

We will be using several transposon-based delivery systems to generate mutants. These systems have been designed to result in stable mutants. Therefore there is no risk of the antibiotic marker spreading horizontally.
The recipient/parental organisms have all been isolated from the wild. We are currently using bacteria-nematode complexes that were originally isolated in Ireland, the UK, the US and Trinidad. The bacteria from these complexes will be mutated to determine what genes are important for the maintenance of the symbiosis. This will involve combining mutant bacteria with wild-type nematodes.

**Evaluation of foreseeable effects**

Insertion mutations generated by transposons are normally associated with the loss of gene function. Therefore I expect that the vast majority of mutants generated in these studies will result in the loss of symbiosis between the bacteria and the nematode implying that these mutants will not pose any threat to the environment as they will not be able to form active complexes with the nematodes.

Some mutants will probably increase the efficiency of symbiosis (e.g. mutants in a gene encoding a repressor protein). Although these mutants would be extremely useful in our studies we have evidence that suggests that these bacteria are not able to compete with wild-type bacteria during infections of insect larvae (Joyce and Clarke (2002), Mol Microbiol in press). However it is possible that we could generate a mutant with increased symbiosis potential and such a mutant would have important applications in the commercial production of these nematode-bacteria complexes. However it is difficult to see how this mutant might have any adverse effect on the environment.

Our mutant screens will also produce strains of Photorhabdus that are attenuated or avirulent and clearly these bacteria will not be able to survive in the wild. Moreover the LD50 of Photorhabdus against our model insect, Galleria mellonella, is normally <5 bacteria/insect suggesting that it would be difficult to isolate a mutant with increased virulence. In addition the host range of the bacteria is determined by the nematode i.e. host seeking and penetration and the presence of mutated bacteria in the nematode will not affect the normal host range of the nematode.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For laboratory manipulations the use of good microbiological practice will be sufficient to limit contact with humans and the environment. All bacterial waste i.e. agar plates, contaminated plasticware, liquid cultures will be inactivated by autoclaving before disposal. The routine regime in the Department of Biology and Biochemistry at the University of Bath is 126C for 30 minutes (as specified by DEFRA). The degree of kill is expected to be 100%.

Nematodes grown with mutated bacteria are not stored and they are inactivated by heating to 60C for several hours before autoclaving. Viability can be monitored by microscopic observation. Living nematodes have a characteristic sinusoidal "swimming" motion and they are "S-shaped". Dead nematodes do not move and they are straight.

Infected insect cadavers (and uninfected insect larvae) are placed at -70C for several days before autoclaving.

Project Additional Information

Purposes of the contained use

To deliver transcription factors involved in the development of endodermal organs to the liver, other tissues and organs cultures, studying the ability of such transcription factors to transdifferentiate (ie convert) other cell types into pancreatic B-cells capable of controlled expression and secretion of insulin. This could prove to be a viable treatment for patients with diabetes mellitus.

Adenovirus vectors were chosen because of their ability to efficiently deliver exogenous genetic material to the adult liver and other tissues.
Recipients or parental organism

Adenovirus (Ad) was first isolated from the adenoids of latently infected individuals (humans) in the 1950s and since that time at least 47 human adenovirus serotypes have been categorised. Symptoms associated with adenovirus infection vary widely. Ad5, the serotype used to construct first-generation, replication-defective adenovirus vectors, is usually associated with mild respiratory infections in children (Shenk, Adenoviridae. Fundamental Virology. Fields et al. Philadelphia, Raven Publishers: 980-1016, 1996).

Host/vector system

First-generation, replication-defective adenovirus vectors are derived from the wild type adenovirus type 5 serotype.

The adenovirus vector has a deletion within an early region of its genome known as E1. This region is essential for virus replication in vivo and infectious virus particles are only produced when the vector infects a complementing cell line such as HEK 293. These cell lines provide the E1 functions in trans allowing the production of infectious virus particles. Without this region, no infectious virus particles are produced. Both the parental and vector genomes reside within the cell as an extrachromosomal element and do not integrate into the host genome. The injection of adenovirus vectors into athymic mice results in transgene expression for over six months with minimal decrease in expression. This suggests that the adenovirus vector genome is very stable.

First-generation adenovirus vectors are contaminated with replication-competent adenovirus (RCA), arising through the homologous recombination between the vector and the producer cell DNA sequences. (Mountain, Trends Biotechnology 18: 119-128, 2000).

Origin & function

The vectors will be utilised as delivery vehicles of exogenous genetic material to the liver of adult rodents, to embryonic organ cultures and other primary cultures eg bone marrow cells.

In the first instance, the transcription factor to be utilised is a homeobox gene called Pdx1 (or its Xenopus homologue Xihbox8), which has a fundamental role in pancreas development (MacKinnon et al. Diabetologia 44, 120301214, 2001). Expression of an activated form of Pdx1 (formed by the addition to the C-terminal of a herpes simplex virus transactivation domain, VP16) has been shown to convert larval Xenopus liver cells into pancreatic cells (Horb et al. Current Biology 13: 105-115, 2003). I will continue these studies within the mature liver of adult rodents.

Other transcription factors involved in endodermal development may be used in the future.

GFP was originally isolated from the jellyfish A. victoria. The inclusion of a reporter gene will allow the easy identification of transdifferentiated cells.

Evaluation of foreseeable effects

The mammalian homeobox gene Pdx1 encodes a transcription factor involved in the early development of the pancreas and also in the functioning of the mature endocrine B-cell. (Chakrabarti and Mirmira, Trends in Endocrinology and Metabolism 14(2):78-84). A number of studies indicate that expression of this gene within ectopic sites does not invoke transdifferentiation into pancreatic cells (Grapin-Botton et al Genes and Development 15: 444-454, 2001; Heller et al. Gastroenterology 115(2): 381-387, 1998). However, studies by Horb et al. (Current Biology 13, 105-115, 2003) suggest that the addition of a C-terminal transactivation domain enables Pdx1 to succeed in this conversion. The adenovirus vector is intended to deliver and express an activated Pdx1 construct to the liver of adult rodents in an attempt to transdifferentiate mature liver cells. Other transcription factors that may be used will have a similar risk profile to Pdx1.

The vectors will also express GFP under the control of a mammalian pancreatic-specific promoter allowing transdifferentiated cells to be viewed under fluorescence. This reporter is widely used.

All human adenoviruses that have been tested are able to oncogenically transform cultured rodent cells. However, adenovirus type 5 shows no tumourigenic potential in humans or rodents. There is currently no data suggesting that Pdx1, Xihbox8, or their fusion derivatives are oncogenic. An adenovirus expressing the transgene Pdx1 has been constructed and injected into mice. There were no reports that this vector was oncogenic (Taniguchi et al. Gene Therapy 10: 15-23, 2003). VP16 fused to lymphoid enhancing factor 1 generates transcriptional regulators that induce oncogenic transformation in chicken embryo fibroblasts (Aoki et al. Proc. Natl. Acad. Sci. USA 96: 2023/2022
Adenovirus tissue tropism is very well characterised. There is no suggestion in the literature that a developmental transcription factor, such as Pdx1, will alter the vector tropism. The expression of a transcription factor will in no way alter the vector capsid (a protein coat that encapsulates the viral DNA), which is the major factor determining which cells the virus particle can infect. Numerous transcription factors have been expressed using an adenovirus with no evidence that such factors alter the tropism of the parent vector or virus.

Care must be taken to avoid spread of infectious material by aerosol, direct contact or accidental injection. If the adenovirus vector entered the bloodstream, for example via an open wound, it is likely the vector would be delivered to a tissue where it is biologically active. The liver takes up adenovirus vectors injected systemically into rodents almost exclusively (Smith et al. Nature Genetics 5:397-402, 1993). The vectors we intend to construct may contain a tissue-specific promoter driving a transcription factor. This has demonstrated the potential to transdifferentiate liver cells into pancreatic cells. Entry gained via an aerosol would infect the respiratory epithelium but it is unlikely that the transgene would be expressed unless a lung promoter is used.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Good Laboratory Practice will be maintained, with gloves and lab coats worn at all times. The GMM will be handled in an ACDP containment level 2 laboratory. The work will be performed within the confines of a BioMat Class 2 Microbiological Safety Cabinet (Medical Air Technology). Air entering the cabinet is filtered through two HEPA filters before leaving the cabinet. Twice a year contractors (Bioquell Service) organised by the university Microbiological Protection Officer visit and check the unit. Fumigation will be carried out prior to inspection and containment tests will be performed once a year. All cell lines will be grown in a CO2 incubator positioned closed to the safety cabinet.

Notices will be placed on the safety cabinet and the incubator instructing users in the event of accidents and spillages. The virus is inactivated using 1% sodium hypochlorite.

All solid waste (flasks, pipettes etc.) will be placed in a red "Biohazard" bag situated next to the safety cabinet. The bag will itself be contained within a solid container (with lid) so if virus contaminated pipettes etc. pierce the bag they will remain contained. This container can then be carried to the autoclave room. The waste is decontaminated by autoclaving at 126 degrees C for 30 minutes completely destroying all adenovirus (adenovirus is inactivated at 56 degrees C).

Is an emergency plan required according to regulation 20?

### Purposes of the contained use

The project will involve the construction of recombinant retroviral vectors and packaging them into retroviral particles using packaging cell lines. The retroviral particles (virions) will be used for high efficiency infection of cells in culture for the purpose of expressing recombinant proteins in mammalian/mouse/rat cells. The purpose of the proposed work is to study the effect of the expressed proteins on membrane trafficking pathways and membrane transport. The methods that will be employed when cultivating virions are described in the Retroviral Gene Transfer and Expression Manual (BD Biosciences, Clontech).

### Recipient or parental organism

The vectors that will be used to produce virions are derived from MMLV (see below). The retroviral vectors we will use can only replicate and produce virions in special
packaging cell lines (see below). The recipients of the GM virions will be cultured cell lines. Genetically modified virions that can only infect mouse/rat cell lines will be produced in Ectotropic packaging cell lines. MMLV does not naturally infect human cells. However, when it is necessary to infect cell lines such as Hela (human), Cos (monkey), the virions will be packaged in Pantropic or Amphotropic packaging cell lines (BD biosciences Clontech). Virions packaged in these cell lines have an extended host range, including human cells.

Retroviruses require close contact for transmission and their survival in the general environment is poor. Although certain scenarios can be envisaged (such as needle stick) that virions packaged in amphotropic or pantropic cell lines may infect human cells it is unlikely that the GM virions we propose to make will cause harm to human health, due to the nature of the proteins to be expressed and the replication deficient nature of the virions.

Host/vector system

The packaging cell lines are all modified HEK-293 (human embryonic kidney) packaging cell lines.
BD EcoPack2-293 cell line.
BD Amphopack-293 Cell Line
GP2-293 cell line
All are available from BD Clontech.

pLRCX retroviral vectors and related retroviral vectors (BD Biosciences, Clontech).

Origin & function

The genetic material will be cDNA encoding proteins from a variety of eukaryotic sources. For example cDNA coding for human/rat proteins involved in multivesicular body sorting, glucose transporter trafficking and for ion channels. The purpose of the project is to study the cellular function of the proteins encoded by the genetic material.

Evaluation of foreseeable effects

Once packaged by the packaging cell line the virus is replication incompetent as the structural genes are absent in the virions. The virus is derived from MMLV. The mechanism of viral attenuation is deletion of the gag pol and env genes. The separate introduction and integration of the structural genes into the packaging cell lines minimizes chances of producing a replication competent virus due to recombination events.

The inserted genes encode for proteins that are involved in membrane trafficking and/or membrane transport. There is a possibility that the expressed proteins may alter cell physiology. The project will involve studying protein function by looking for differences between cells expressing the recombinant protein (infected cells) and control cells. Viruses expressing known oncogenes will not be constructed.

Virions will be in a contained laboratory environment and will not have access to organisms other than authorised laboratory personnel.

Retroviruses require close contact for their transmission and their survival in the general environment is poor. Although certain scenarios can be envisaged (such as needle stick) that virions packaged in amphotropic or pantropic cell lines may infect human cells it is unlikely that the GM virions we propose to make will cause harm to human (or animal) health, due to the nature of the proteins to be expressed and the replication deficient nature of the virions.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

### Project Additional Information

#### Purposes of the contained use

University bench research to examine the cellular role of intracellular signalling molecules in the regulation of T cell function.

#### Recipient or parental organism

Recipient cells will be T cells and T cell lines including Jurkat, Hut 78 and CEM cells.

#### Host/vector system

- **Lentivirus derived from HIV-1.** The virus has been stripped down to its minimum essential components, which have been encoded on four separate plasmids. To inactivate the virus in the unlikely event of recombination of the four plasmids, the vector itself in inactivating (SIN). This is achieved by the deletion of the genetic sequence from the 3’ long terminal repeat (LTR) encoding enhancer and promoter functions, resulting in the transcriptional inactivation of the provirus in the infected cell.

  The virus is similar to those available commercially such as Virapower vector sold by Invitrogen.

#### Origin & function

- The Lentiviral vectors will deliver modified versions of intracellular signalling molecules including the SH2 domain containing inositol phosphatasease (SHIP). Endogenous human SHIP has been modified by fusing its catalytic region to the extracellular and transmembrane regions of rat CD2 protein. This creates a constitutively active lipid phosphatase predicted to result in depletion in cellular levels of the secondary messenger PtdIns(3,4,5)P3. (See Freeburn RW et al (2002) Journal of Immunology 169 (10):5441-5450).

  Lentiviral vectors will also be assembled to deliver short interfering RNA sequences designed to oppose expression of intracellular signalling molecules including endogenous SHIP.

#### Evaluation of foreseeable effects

The rCD2:SHIP protein will metabolise the intracellular signalling molecule PtdIns(3,4,5)P3 leading to the formation of PtdIns(3,4)P2. In T cells this may modulate cellular...
responses to receptor stimulation including growth, cytokine production and chemotactic responses.

Conversely, opposing SHIP expression with short interfering RNAs would be predicted to make T cells more responsive to receptor stimulation.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Cell used for assembling viral particles and infected target cells will be maintained (seeded, transfected and fed) in a dedicated biosafety level 2 cell culture cabinet. This will be supplemented by placing a 5L beaker containing 1% solution of Virkon for immediate use treatment of wastes and contaminated items.

The cabinet will be sprayed before and after use with 1% solution of Virkon followed by 70% ethanol.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid wastes including cell suspensions, will be soaked in a 1% solution of Virkon overnight before disposal to the drain. Overnight treatment with virkon would be predicted to result in 100% killing of viral particles.

Dry waste will be placed in autoclave bags and sent for autoclave treatment.

Dear GM advisors, I have completed the attached form as best I can, but I will need guidance on a number of points.

Page 2: ACDP Hazard category?
Page 4: Provisional containment level?
Page 5: Provisional final activity class?

Sent 07 February 2007 08:36
To:
Subject: RE: Viral Safety

We will provide guidance to your questions soon.

In the meantime, you answered yes to these questions. Please could you just add a sentence describing which tissues could be affected and by what route of transmission?

Are all potential routes of transmission of the virus known, e.g. those that may occur during a laboratory accident? ("Yes").
If yes, will the routes of transmission deliver the virus or its products to tissues where it may be biologically active? ("Yes").

Page 5, section 2B. Level of risk has not been identified in the first block. Please could you estimate that? You say that there is a potential for harmful effects of gene expression on other organisms. Could you briefly say what that could be?

Sent 07 February 2007 10:08
Subject: RE: Viral Safety

Having spent some time looking at this today, I suggest that this work be assigned to category 2. Although the lentivirus system is not strictly listed in an ACDP category, notes I have found from ACDP meetings suggest that it should be placed in hazard category 2. Also, regardless of the modification to the virus, its final containment level etc. is level 2.

**Project Additional Information**

**Purposes of the contained use**

University bench research to explore cellular function, differentiation, and development.

**Recipient or parental organism**

For example, HEK-293 or HEK-293T will be used to package the retrovirus and HEK-293FT cells will be used to package the virus. The virions produced will be used to transduce various tissue culture cell lines and also tissue in vitro or in vivo.

**Host/vector system**

Various vector systems may be used as the technology improves in transduction and safety but will almost exclusively be purchased from a scientific company. Initially, the retroviral vector system to be used will be Stratagene’s Viraport system and the lentiviral vector system Invitrogen’s ViralPower Lentiviral Gateway Expression system.

**Origin & function**

The genetic material will be cDNA thought to be involved in development or altering the phenotype of cells or tissue (e.g., transdifferentiation) or cDNA libraries (e.g., prepared from tissue like liver or pancreas). Promoters will be used to confer constitutive expression or cell/tissue specific expression. Marker proteins (e.g., GFP, lacZ) will be used either co-expressed or as fusion proteins to follow expression. Genes may be used so that some sort of selective pressure can be applied to isolate only cells that are transduced (e.g., antibiotic resistance). Also, vectors to deliver shRNA designed to specifically knock down a protein's expression may also be constructed.

**Evaluation of foreseeable effects**

To our knowledge, there is no suggestion in literature that any of the sequences that we would hope to look at will alter the vector tropism compared to if the vector was made without it present. Numerous proteins have been expressed in systems like this or similar with no evidence of the factors altering the tropism of the parent vector or virus.

The cells transduced by the virus may be altered by the genetic information we choose to include. The aim will be to study the effects of the information we include. For example, the cells/tissue may have altered phenotype/function and express selectable traits so that we can study the effects of the factors and also identify new factors.

**Containment and control measures for GMOs that are not microorganisms (e.g., GM animals & plants)**

The control measures for the virus to enable it to be safe and easy to use are described in detail on the proposal and risk assessment form and also in company literature.
of systems we hope to use such as Stratagene's Viraport system or Invitrogen's ViralPower Lentiviral Gateway Expression system. In brief the virions are replication
defective and or self inactivating. Important genes involved in the assembly of the virions are encoded on many different plasmids which do not require the use of stable
cell lines expressing these factors.
Good laboratory practice will be maintained. Laboratory coat and gloves will be worn at all times. Good hygiene will be maintained and surfaces will be disinfected
following manipulations using virions.
All procedures with recombinant virus will be performed in an ACDP containment 2 laboratory. A class 2 microbiological safety cabinet will be used when handling virions.
Twice a year contractors organised by the University Microbiological Protection Officer visit and check safety cabinets. Fumigation will be carried out prior to inspection and
containment tests will be performed once a year. Access to the laboratory where retroviruses are used will be restricted to authorised personnel only and the laboratory door
will be kept closed at all times except for access.

All cell lines will be grown in a CO2 incubator positioned close to the safety cabinet.
Notices will be placed on the laboratory door, the safety cabinet and the incubator instructing users in the event of accidents and spillages.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The virus is inactivated using 1% sodium hypochlorite. Solid waste (pipettes, flasks etc.) will be placed in red Biohazard bag prior to removeal from the laminar flow hood,
enclosed in a second bag outside the hood and carried to the autoclave room. The autoclave facility is situated in the building for the sterilisation of waste. Waste will be
autoclaved at 126C for 30 minutes completely destroying virions. Contaminated liquid waste will be disinfected with an appropriate disinfectant (eg 10% bleach or 1%
Virkon) for at least 30 minutes.

02/03/2022
Tests of gene function in vertebrate development. We will contribute to this by focussing on vertebrate embryonic development particularly that of the limb. We will test gene function in the development of chick and fish embryos because these are good models for vertebrate development and the eggs develop outside the mother. We will overexpress genes that encode for secreted factors by implanting cells transfected with the gene into chick embryos using RCAS (Replication Competent Avian Sarcoma Virus) or attenuated AdV (Adenoviral Vector) systems. We will inhibit expression of genes in fish embryos using morpholinos and in chick embryos using antisense strategies based on viral delivery. Some of these approaches have already been used to gain insights into fundamental aspects of embryonic development. In addition, in some cases these experiments could provide direct links to clinical medicine, thus it is possible to study in these model vertebrate embryos, the roles of genes known to be responsible for human congenital defects, such as Holt-Oram syndrome. Furthermore many genes expressed in embryos were first identified in tumours and embryos provide an efficient way of exploring gene function that does not require killing adult animals.

1. COS (African Green Monkey) cell lines- these cells will be transfected with genes that and then used as grafts to deliver factors to embryos (see below). In addition to transiently transfected cell lines will be produced and grafted.
2. QT6 cell lines- used for same purposes as above.

These cells will be transfected with RCAS vectors containing genes of interest (these genes may be chicken sequences or sequences from other vertebrates including mouse, human and fish) and used to produce genetically manipulated virus stocks that can then be used to infect susceptible chicken embryos.
4. HEK1293 cells for adenovirus production- these well-characterised and authenticated tissue culture cell lines will be used for propagation of the disabled adenovirus vector. We will also use HEK1293 and other well-characterised mammalian cells to express proteins for cell localisation and biochemical studies.

5. Chick embryos- we will test gene function with RACS using eggs from SPAFAS (Pathogen Free) chickens in addition to commercially available eggs because such embryos are more susceptible to viral infection and we have been importing SPAFAS eggs from Germany. We will infect chick embryos at different stages in development in 3 ways: injection of high titre virus suspensions, grafting fibroblasts producing virus, electroporating RCAS constructs directly chick embryos and then letting the infection spread. For experiments with adenovirus vectors, we will use eggs from normal supplier and the same three strategies to infect embryos. We will also carry out transient transfections in both normal and mutant chick embryos by electroporating gene constructs driven by promoters such as CMV.

6. Fish embryos and fry- we will test gene function in early development by injecting morpholinos designed to block function of specific genes into single cells at cleavage stages. We will graft cells expressing secreted factors into embryos and young fry and also introduce constructs using electroporation.

3. Chicken embryonic fibroblasts and chicken DF1 fibroblast cell lines for RCAS production.

**Host/vector system**

1. Mammalian expression vectors will be used to introduce DNA into COS cells by employing special conditions such as electroporation, use of calcium phosphate crystals, lipofectamine etc.

2. RCAS vectors will be used to transfect QT6, primary chick fibroblasts, DFI cells and chicken embryos. The [retrovirus is replication competent but infects avian species and not mammals. Very high viral titres are required to infect significant amounts of tissue in chick embryos and pathogen free embryos are most susceptible. The src gene that makes this virus oncogenic in chickens has been removed and replaced with a restriction site so that transgene can be easily inserted here. Any potentially harmful effects will depend on the gene or antisense construct inserted into RCAS. Infected embryos will not usually be allowed to develop beyond 10 days of incubation and never be allowed to hatch.

3. The adenoviral vectors to be used, such as the Ad5-SVR4 system, are attenuated through deletions in both E1 and regions of the genome. The net result is that the virus is rendered replication incompetent, the potential for viral transformation is eliminated and the ability to evade the host immune system is abrogated. Furthermore these viruses do not integrate into the genome and thus cannot cause insertional mutagenesis. The site of insertion of the gene sequence to be used is the same site as the site of disablement. The types of insert will be known or unknown vertebrate gene sequences mostly chicken sequences. None of the genes expressed will complement E1 function because as far as is known only viral sequences can do this. There is also no evidence that vertebrate sequences could interfere with capsid proteins and thus alter the immune response to the virus. The genetically modified chickens will be handled as in 2. above. The worst case scenario would involve infection of a human being with a disabled adenovirus containing an oncogenic sequence despite precautionary measures to reduce aerosols etc. Normally the human being would be immune to infection but if the individual was immuno-compromised the virus might survive. However in this case the virus would only infect single cells and not be propagated to daughter cells, therefore not producing lasting oncogenic changes. Another scenario would be that the human being was already infected with normal adenovirus. In this case, even if recombination occurred to generate replicative virus, the inserted sequence would be lost and again no oncogenic thages would be produced in the host. The wildtype Adenovirus serotype 5 causes sub-clinical infections and is categorized by the ACDP as Hazard Group 2. Most human adults are immune to these serotype 5 viruses. Based on the information given above, the attenuated adenoviral (Ad5-SVR4) vector can be classified as ACDP Hazard Group 1.

4. Morpholinos act in a cell autonomous way and must be injected into indivual cells. The effect wears off after about 3 days - genetic modification is transitory- and genetically manipulated fish embryos or fry will not be allowed to reach maturity.

**Origin & function**

We will obtain sequence information about genes that have already been described or from EST databases that have been assembled from different organisms. We will also design antisense sequences to interfere with the function of specific genes. We will test the function of genes in embryonic development by either over-expressing genes or trying to inhibit their function as described above. We will assess the phenotype morphologically and also use in situ hybridisation and immunohistochemistry where appropriate to monitor any molecular changes at either mRNA or protein level.
protein level. The chick system allows localised genetic modification and this will enable us to test the functions of genes at different stages and in different regions of developing embryos. We will use this system to examine, in particular, how limb formation is initiated and limb bud outgrowth and patterning is controlled. The fish experiments should allow rapid screening for the effects of lack of gene function in a vertebrate model system and we will focus our attention on development of paired fins. The vertebrate genes that will be investigated include genes encoding growth factors, transcription factors, phosphatases, enzymes, receptors and other genes of so far unknown function.

Evaluation of foreseeable effects

We will be over-expressing products of a range of different genes including both transcription factors and secreted factors. Many of the molecules involved in embryonic development are also found in tumours. However in embryos, the production of these molecules is normally tightly regulated and tumours are not produced. Avian specific retroviruses cannot infect humans and strains of chickens differ in their susceptibility to viruses with different envelope subgroups. Most chicken strains purchased from commercial vendors are typically CIE strains and resistant to viruses with E envelope subgroup, while the viruses we will be using most often have envelope subtypes A and B (Morgan & Fekete, 1996, Methods in Cell Biology 51, 185-214). In the very unlikely release of virus from level 2 containment facility, it could potentially infect susceptible avian species if they entered the laboratory. However we have found that very high viral titres are required to infect experimental embryos even when injected and it would be impossible for avian species from outside to get into the laboratory which is secured by a series of doors.

Adenoviral vectors and host cells transfected with these vectors are considered to be equivalent to ACDP Hazard Group 2 and require Level 2 Containment because these viruses can infect humans. These adenoviral systems have been used in many laboratories to over-express, for example, both normal and dominant-negative cell adhesion molecules in chicken embryos (Nakagawa & Takeichi, 1998, Development 125, 2963-2971; see also Leber et al, 1996, in Methods in Cell Biology 51, 161-181) without any reported harmful effects on researchers. In the very unlikely event of the release of virus from the Level 2 containment facility, manipulated virus could survive for a similar length of time to wild-type virus, If the virus infected a susceptible host then expression of the recombinant genes would occur in the infected cell. Since the virus cannot replicate under normal circumstances, expression would be limited to the infected cell and, once this cell divides, to one of its daughter cells. The virus never integrates in the host genome and the episomal DNA is eventually lost through natural degradation.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The chick embryos and embryos infected with genetically modified organisms will be kept in incubators in a room with a closed door off a main laboratory, which is accessed from a corridor in the research area of the building. The door to the main laboratory is locked when there is no-one working there. The fish will be kept in aquaria behind a locked door system.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste disposal
Solid waste is collected in a lined biohazard labelled bin. After work, the liner is sealed and transported directly to the autoclave facility in a dedicated container for immediate autoclaving. After autoclaving, solid waste is disposed of as normal refuse.

Liquid waste is collected in a plastic autoclavable flask. After work the sealed flask is transported in a plastic tub or bucket directly to the autoclave facility for immediate autoclaving. After autoclaving liquid waste is disposed to drains with copious amounts of cold water.

Monitoring
Disinfection: the disinfectant of choice (Virkon) is used in strict accordance with the manufacturer’s (Antec’s) guidelines.

Autoclaving: to ensure 100% efficacy, testing of the autoclave is carried out annually to monitor temperature and pressure.

Inspections: These are carried out to ensure that local rules are adhered to and that risk assessments and training is in order.
Microbiological safety cabinets: serviced and tested annually and records displayed on each cabinet.

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID
### Date of Significant Change

**Project Additional Information**

#### Purposes of the contained use

- University bench research to investigate the role of genes for protein translocation in *E. faecalis* and *E. faecium*

#### Recipient or parental organism

- *Enterococcus faecalis* and *Enterococcus faecium*. *Escherichia coli* will be used as an intermediate host for the construction of plasmids

#### Host/vector system

- Two systems will be used. The first is to use *E. coli* vectors that do not replicate in Gram-positive bacteria (pBR322 derivatives), clone an internal fragment of a gene of interest in that vector, and then use that to transform *E. faecalis* or *E. faecium*. The plasmid can only be maintained if it integrates into the chromosome. The second system makes use of plasmid pCJK47, which can (i) only replicate in strain that provide repA gene in trans (plasmid lacks repA gene), and (ii) is only mobilised in the presence of a helper plasmid. See Kristich et al.(2007) Plasmid 57, 131-144

#### Origin & function

- Both donor and recipient strains are *E. faecalis* and *E. faecium*. *E. coli* is used as a host for construction of vectors.

- The genes that will be disrupted or deleted are involved in the targeting and secretion of proteins. These genes include those for components of the translocase (*SecY, SecE, SecG*), signal peptidases (which remove N-terminal signal peptides of secretory proteins), foldases, and cell wall components.

#### Evaluation of foreseeable effects

- *E. faecalis* and *E. faecium* are normally part of the intestinal flora of humans. In humans, typical concentrations of enterococci in stools are up to 108 CFU per gram. They do not cause disease in healthy humans, but they are opportunistic pathogens. Enterococci have been associated with a number of infections, including urinary tract infections, bacteraemia, wound infections, and endocarditis. Most of these infections occur in hospitals. The genes that are targeted for disruption are involved in protein transport. Protein transport is an important cellular process, and disruption of these genes could affect e.g. export of cell surface proteins, which could for instance affect biofilm formation. The mutations could, therefore, have an effect on pathogenicity, although it seems most likely that it would be reduced.

- Strains resistant to antibiotics (mainly erythromycin or kanamycin) will be created. However, these resistance markers will be present on the chromosome, and not on plasmids. The probability of resistance markers being transferred to related strains is therefore low. Any plasmids used can only replicate in *E. coli* or, in the case of pCJK47, only in a specific *E. faecalis* strain that provides the repA gene in trans. That plasmid is also not mobilisable, unless mob functions are provided in trans.

- After integration, plasmid pCJK47 is removed again through a counter-selection procedure, resulting in strains that are either wild-type or have the desired mutation. These strains do not contain any antibiotic resistance gene anymore.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

02/03/2022
All solid waste will be placed in autoclave bags and sent for autoclave treatment. Autoclaves in the department are checked regularly. Liquid waste will be soaked in a 1% solution of Virkon overnight before disposal. This treatment is predicted to result 100% killing.

### Project Additional Information

**Purposes of the contained use**

Staphylococcus aureus is a major human pathogen and the purpose of our contained use will be to study the role specific genes play in diseases caused by the bacterium.

**Recipient or parental organism**

Wild type Staphylococcus aureus (ACDP category 2) will be used (e.g., strain 8325-4). E. coli strain DH5α (ACDP category 1) will be used (genotype: F-cp8O(dZAMi5 A(lacZYA-argF)U169 deoR, recA1 endA1 hsdR17(rk- mk+ phoA supE44 A- thi-1 gyrA96 relA)). Wild type Lactococcus lactis strain MG1363 (ACDP category 1) will be used.

**Host/vector system**

pUC based plasmids e.g., the pLL plasmids (Luong et al. 2007. J. Micro. Methods. 70:186-190) and the p5K plasmids (Grkovic et al. 2003. Microbiology. 149:785-794) will be used to manipulate S. aureus. For expression in L. lactis the pKS8O plasmids will be used (Massey et al. 2001. Cell. Micro. 3:839-851). For purification the pQE vectors provided by Qiagen will be used. These plasmid contain a multiple cloning site into which the gene in question can be cloned. It results in the fusion of this gene to a poly-histidine tag which facilitates easy purification of the gene product.

**Origin & function**

This project will involve functional studies of genes believed to contribute to S. aureus’ pathogenicity. Specifically it will involve the cloning of pieces of DNA amplified from the chromosome of S. aureus by PCR into plasmid vectors in E. coli. In E. coli the genes may be further manipulated for example by performing site-directed mutagenesis (Strategene kit) to identify important amino acids. Proteins may be purified at the stage using a His-tag system. Where we need to inactivate genes in S. aureus a shuttle vector will be used. These are typically pUC based plasmid into which a S. aureus origin of replication has been cloned, which allows the plasmid to replicate in both host organisms. Gene inactivation will be performed as follow: an antibiotic resistance cassette will be cloned into the middle of the gene in . coli. The resulting plasmid will be electroporated into the restriction minus, modification plus S. aureus lab strains RN4220. Here the temperature sensitive plasmid will be forced to jump into the chromosome by shifting between temperatures. From here the inactivated gene can be transduced using Phage 11 into the final recipient wild type S. aureus strain. S. aureus genes may also be cloned and expressed in the bacterium Lactococcus lactis. This bacterium is used as a heterologous expression system to study bacterial proteins in a non-invasive or non-pathogenic bacterium. Here the virulence genes will be cloned into the pKS8O plasmid.

The types of genes to be studied will be those involved in host-pathogen interactions. For example the fibronectin binding proteins, the Eap proteins. These are both involved in adherence of the bacterium to human tissues.
**Evaluation of foreseeable effects**

With good microbiological practice the host organisms pose minimal risk to human health. Expression of individual S. aureus proteins in either E. coli or L. lactis may make them behave more like this ACDP cat 2 organism but is unlikely to make them more pathogenic than S. aureus itself. There are no foreseeable hazards associated with inactivating these genes in S. aureus above what is already associated with working with wild-type S. aureus. If anything we will be making them less pathogenic. With good waste kill management and microbiological practice environmental contamination with these organisms is unlikely, however should a breach in procedure occur the genetic manipulations will make them less fit than wild type environmental organisms and they will therefore not be competitive.

The plasmid vectors used in this study are not naturally mobilisable. They contain origins of replication specific to the host strains and antibiotic resistance cassettes, but not ability to form conjugative pili. Under laboratory conditions (e.g. electroporation of high concentrations of purified plasmid into a strain) they can be made to move between E. coli and S. aureus. But as neither of these organisms (nor L. lactis) are naturally transformable and neither have the ability to form conjugative pili, the plasmids are considered non-mobilisable from this point.

<th>Howie style laboratory coats and disposable glove will be used when handling the GMM5. Gloves will be autoclaved (131 oC, 30psi for 30 minutes) following use, and coats autoclaved and washed monthly. All disposable plastic (eg Petri dishes, pipettes, tubes etc) will be autoclaved after use. All glassware will be decontaminated by soaking in a 1% Virkon solution overnight before either disposal or washing for re-use. Liquid cultures of GMM5 will be killed by the addition of virkon powder to a 1% solution, and these will be poured down the sink after 24hours. This has been shown to be fully effective at killing all the bacteria. The GMMs will only ever be grown as pure cultures, and killed after use, minimising the risk of transfer of DNA to other organisms. Regular testing of the efficacy of our Virkon treatments will be performed using viability assays on material believed to be decontaminated. The departmental autoclave is regularly tested and serviced for efficacy.</th>

comments on first draft of risk assessment:
Further detail on the following issues is needed as requested by the HSE advisors:
1. mobilisation of the vector
2. decontamination procedures
3. genetic characteristics of strains used (i.e., DH5a genotype)
These suggested amendments were all incorporated into this application and to the attached risk assessment. The final draft was then reassessed and considered to meet local requirements.

Date of Significant Change

Project Additional Information
To identify novel Burkholderia pseudomallei proteins involved with interactions with invertebrate hosts. This will help us understand its persistence in the environment and also inform on the evolution of virulence factors it uses in human infections. We will also sub-clone parts of cosmid inserts into plasmids such as the pUC, pET or pBAD series.

The parental organism from which the genomic DNA library is made is Burkholderia pseudomallei strain K96243. This is a class III containment Gram-negative bacterium which is a pathogen of humans. At no point will we handle the parent bacterium, only an E.coli cosmid library previously constructed by the Sanger Centre (Hinxton, UK). The library clones are not expected to have any disease causing attributes, only toxicity to invertebrates at high dose.

The vector system is the (non-conjugating) pCC1FOS Fosmid in E.coli EPI-3000-Ti (Epicentre). The library us a set of 37 plates containing ~40kb inserts and with~10X coverage of the Burkholderia pseudomallei strain K96243 genome.

The Sanger Institute recently published the 7.2 Mb genome of Burkholderia pseudomallei in collaboration with Dr. Rick Titball of the Defence Science and Technology Laboratory, Porton Down, and Dr Ty Pitt of the Health Protection Agency. The sequenced strain K96243, is a clinical isolate from Thailand, supplied by Dr S Songsivilai of Mahidol University. The genome is 7247,547 bp in size with a G+C content of 68.06% consisting of two chromosomes of genome sequence for toxicity against Lepodopteran insects, amoeba (Acanthamoeba and/or Dictyostelium) and nematodes (C.elegans) in accordance with the protocols outlined in the following publication: (Waterfield,Sanchez-Contreras, Elefherianos, Dowling, Wilkinson, et al.2008. Rapid Virulence Annotation (RVA): identification of virulence factors using a bacterial genome library and multiple invertebrate hosts. Proc Natl Acad Sci USA. 105 (41): p 15967-72). It is also possible we will sub-clone regions of certain Fosmid clones into expression plasmids in order to test the specific anti-invertebrate activities of candidate toxins.

Burkholderia can infect humans and insects and it expresses proteins used in this infection process. We will clone genes and regions of their chromosomes into normal E.coli hosts which are harmless and test the activity of recombinant expressed proteins on invertebrate hosts. Toxins and virulence factors may be active against insect or human hosts however expression levels will be low and the vectors are not sustainable away from the host. Our screening method relies upon exposure of invertebrate hosts to high doses (for them) of the GMO E.coli which present any toxic proteins expressed (rather than as a disease process per se). The only danger to a human would be through accidental injection of recombinant E.coli. Procedures for injection of GMO into insects are closely monitored using a well-tested technique in which the needlestick injury. Needles and sharps exposed to GMOs are immediately consigned to a sharps bin provided which is later incinerated. Broken glassware containing GMOs could also potentially introduce GMOs to the blood. Full care is taken when dealing with GMO bacterial cultures to avoid this, and disposable plastic vessels are used whenever possible to minimise this risk. All work involving GM material will be performed in the class II containment microbiological hood. In brief we foresee no strong risk from handling this genome library using standard class II containment microbiological techniques.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All standard microbiological procedures for recombinant E.coli are in place in our lab. Including the use of disposable gloves and lab-coats (which do not leave the lab). Any work done with these GM bacteria would be done in the Class II containment hood. We also ensure careful monitoring of what equipment and materials will be
sterilized by 70% ethanol swab or autoclaving at 126°C for 30 mins in biohazard bin/bags provided. Most importantly all recombinant R. coli will either be stored at -80 as a freezer stock in a lockable unit or autoclaved (126°C for 30 mins) in a loosely tied autoclave bag the department autoclave under the standard sterilization conditions in daily use. Bacterial cultures or any disposable materials exposed to recombinant E. coli (such as spreaders etc) will all be sterilized for disposal by autoclaving (126°C for 30 mins) in the same manner. Under certain circumstances equipment (such as plate replicators) exposed to GMMs will be sterilised by 70% ethanol. Any solutions that cannot be autoclaved will be soaked overnight in diluted commercial bleach (>20%) to kill any surviving GMMs. All work will be conducted in a class II containment microbiological hood. Material for autoclaving will be sealed bags.

Project Additional Information

Purposes of the contained use

Each vector will express a protein (or a modified version of the protein) or a construct designed to inhibit protein function, for example by generating short inhibitory (sh) RNA. These proteins may be involved in cellular processes such as polarity, cell proliferation or be a marker gene such as Green Fluorescent Protein (GFP). They may be under the control of ubiquitous promoters (e.g. the cytomegalovirus promoter), tissue-specific promoters or inducible promoters (e.g. tetracycline regulated systems).

These replication-defective adenovirus vectors will be used to infect mammalian cells in tissue culture, and will lead to a better understanding of how normal and transformed cancer cells establish and maintain their polarity and undergo changes in regulation of cell proliferation. This builds on similar previous work in which adenoviral vectors were extensively used safely and successfully to define mammalian cell function (see Dukes et al. Mol Bio Cell. In Press Caunt et al. J Cell Sci. 123: 4310-20, Mol. Endo. 23: 510-9, J. Biol. Chem. 283: 6241-52 and J. Biol . Chem. 281; 2701-10).

Recipient or parental organism

Host/vector system

Origin & function

First generation adenovirus vectors originate from serotype 5 adenovirus (Shenk, Adenovindae, Fundamental Virology. Fields et al. Philadelphia, Raven Publishers: 979-1016, 1996). The vectors will be used as delivery vehicles of exogenous genetic material to mammalian epithelial cells cultured in vitro either as cell monolayers or in organotypic cultures and explant tissue.

In the examination of cell polarity in isolation, we will express GFP-Vps4EQ and CHMP3-GFP fusion proteins (Dukes et al. Biochem. J. 411: 233-9). The latter two of these proteins have been shown to perturb membrane trafficking to lysosomes when expressed in a variety of mammalian cell lines. We intend to investigate whether protein trafficking defects interfere with cell polarity and proliferation. We also intend to express other mammalian proteins implicated in cell polarity and proliferation. These include Protein Kinase C iota and lethal gian larvae (Chalmers et al. Development 312: 977-86) as well as wild-type and mutated alleles of extracellular signal regulated kinase (ERK) and ERK phosphatases from the DUSP (dual-specificity phosphatases) family (namely, wild-type, catalytically inactive and non-MAPK binding variants of SUSPs, see Caunt et al. J Cell Sci. 123: 4310-20, Mol Endo. 23: 519, J. Biol. Chem. 283: 26612-23, J. Biol. Chem 283: 2701-10). We also intend to express wild-type and oncogenic variants of Ras and Raf with the oestrogen receptor ligand binding domain (Dajee et al. Oncogene 21: 1527-38 and Samuels et al. Mol. Cell Biol. 13: 6241-52) and perform targeted knock down of proteins implicated
Vps4, CHMP3 and ERK cDNAs originate from rat, but the encoded proteins have highly conserved human homologues. All DUSP, Ras and Raf cDNAs are from human origin and new cDNA clones are likely to originate from human, mouse or rat.

Either epitope tags, GFP, ZsGreen or DsRed Express fluorescent proteins will be used as fusions to track protein localisation. Destablished variants of these proteins cloned downstream of responsive promoter elements (such as Egr-1, see Caunt et al. J Cell Sci. 123: 4310-20, Mol. Endo. 23: 510-9, J. Biol. Chem. 283: 26612-23 and J. Biol. Chem. 283: 6241-52) may also be used as transcriptional reporters in combination with the vectors described above.

Evaluation of foreseeable effects

All vector systems use viral genomes which, as a minimum, the E1 region has been deleted. This prevents expression of E1a and E1b genes, which are essential for viral replication and the production of infectious virus particles (Jones and Shenk, Cell 13: 181-88).

Adenovirus (Ad) was first isolated from the adenoids of latently infected humans in the 1950s and since that time at least 47 human adenovirus serotypes have been categorised. Symptoms associated with adenovirus infection vary widely. Ad5, the serotype used to construct first generation, replication-defective adenovirus vectors, is usually associated with mild respiratory infections in children (Shenk, Adenoviridae. Fundamental Viriology. Fields et al. Philadelphia, Raven Publishers: 979-1016, 1996). The vectors are deleted for most of the E1 region and are unable to replicate and produce infectious virus particles, except when introduced to complementing cell lines, such as HEK293. Both the parental and vector genomes reside within the cell as an extra chromosomal element and do not integrate into the host genome. The injection of adenovirus vectors into athymic mice results in transgene expression for over six months with minimal decrease in expression. This suggests the adenovirus vector genome is very stable.

First generation adenovirus vectors are contaminated with replication-competent adenovirus (RCA), arising from homologous recombination between the vector and producer cell DNA (Mountain, Trends in Biotechnology 18: 119-28). Fallaux et al. (Human Gene Therapy 9: 1909-17) tested batches of adenovirus vector for their RCA content at a sensitivity of 1 RCA in 2.5x109 infectious units. Five out of nine batches tested positive.

The design of the vector systems we are using, such as the AdEasyTM XL Adenoviral Vector System (stratagene) and the improved "RapAd" system from the University of Iowa ensures that transgenes can only be inserted into the E1 region of the adenovirus backbone. The RapAd system backbone lacks the left hand inverted terminal repeat (ITR), the packaging signal and the E1 sequence. Sensitive PCR based assays detected negligible amounts of wild type viral genomes in purified recombinant preps (three E1a genomes per 109 adenovirus genomes). Further, wild-type virus remained equally low after 15 serial amplifications of virus preparation, indicating a substantial improvement compared to previous methods where low levels of wild-type virus can be amplified in serial rounds of purification, see Anderson et al. (Gene Therapy 7: 1034-38).

Care must be taken to avoid spread of infectious material by aerosol, direct contact or accidental injection. If the adenovirus entered the bloodstream (for example via an open wound), it is likely the vector would be delivered to a tissue where it is biologically active. The liver takes up adenovirus vectors injected systemically into rodents almost exclusively (Smith et al. Nature Genetics 5: 397-402). If viruses were inhaled they might infect the lungs. The inserted genes encode for proteins that are involved in cell polarity and proliferation. The outcome of infection is uncertain. However, a worst-case scenario might predict that these cell may hyper/hypo proliferate or lose their epithelial morphology. These cells would probably die by apoptosis and if they did not, would be rapidly removed by the host immune system. This is normally very rapid, but if individuals were for some reason unable to raise antibodies to Ad5, this process could take two to three weeks. However, virally expressed proteins that are presented as foreign antigens will lead to the generation of cytotoxic T lymphocytes that will eliminate virally transduced cells from the host. For individuals previously exposed to Ad5 vectors, clearance will be significantly shorter than two weeks. In fact, neutralising antibodies are most likely to prevent significant transduction of host cells.

Assuming good laboratory practice is maintained, there is no potential for the transmission of naked nucleic acid. Transfection of host cells by naked nucleic acid is very inefficient and such sequences are rapidly degraded by endonucleases should they enter the bloodstream (Kawabata et al. Pharm. Res. 12: 825-30). Ad vectors infect a wide variety of human cell lines and primary cell cultures. Ad vectors have also been injected into humans via the protal vein where they subsequently infect the liver (Raper et al. Human Gene Therapy 13: 163-75).
Wild-type serotype 5 adenoviruses show no tumorigenic potential in humans or rodents. PKCi is a suspected oncogene (Zhang et al. Cancer Research 66: 4627-35). However, expressing it at high levels in the mouse colon did not cause increased proliferation or changes in differentiation (Murray et al. J. Cell Biol. 164: 797-802). Increased tumorigenesis was only seen after induction of tumours by azoxymethane. ERK is often deregulated in cancer, and this is overwhelmingly caused by upstream mutation of Ras or Raf, rather than mutation or overexpression of ERK (Roberts and Der, Oncogene. 26: 3291-310). The constitutively active mutants of these proteins are known to cause cell transformation in vitro and cause cancer when they occur as somatic mutations in patients, but the ER fusions of these proteins do not show high levels of activity in the absence of high levels of oestrogen. In addition, one mutant of ERK2 we intend to use (D319N mutation) confers resistance to phosphatases and has been shown to cause hyperproliferation of cells in Drosophila (Brunner et al. Cell 76: 875-88) and an increase in epithelial to mesenchymal transition of cells in vitro (Shin et al. Mol Cell. 38: 114-27). The other mutants of ERK we intend to use are inhibitory to ERK signalling in our assays (Caunt et al. J. Cell Sci. 123: 4310-20). There is currently no data to suggest other constructs we will make shall be oncogenic and it appears unlikely that short-term infection with any of our vectors would cause oncogenesis because of the rapid viral clearance even if directly injected at high concentration. In addition, the proteins we intend to express are unlikely to alter the antigenicity and cytotoxicity of the vector, which is defined primarily by the capsid.

Homologous recombination between the vector and the HEK293 genome or the vector and a wild-type adenovirus might lead to the production of a replicating, infectious virus capable of expressing transgenes. Co-replication of a vector and a wild-type virus might occur due to trans-complementation within a co-infected cell. Some cell lines and viruses also have the ability to complement E1 functions allowing the vector to replicate. Packaging constraints (a limit on the amount of DNA that can be encapsulated in the viral capsid) would most likely ensure that the non-essential transgenes can only be inserted into the E1 region of the adenovirus backbone. In the case of both systems, the transgene is placed adjacent to the adenovirus encapsidation signal and the left Ad5 inverted terminal repeat. Therefore, homologous recombination eith E1 from the HEK293 cells is likely to result in loss of the transgene.

In summary, the Ad vector is highly antigenic and would be cleared rapidly from the host by the immune system. A massive dose of virus would be required to cause harm to a human and the delivery of such a dose within a lab environment seems impossible given that we are not carrying out any large scale cultures.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Good laboratory practice will be maintained with gloves and lab coats worn at all times. The GMM will be handled in an ACDP containment level 2 laboratory. The work will be performed within the confines of a Biomat Class 2 Microbiological Safety Cabinet (Medical Air Technology). Air entering the cabinet is filtered through two HEPA filters before leaving the cabinet. Twice a year contractors (Bioquell service) organised by the University Microbiological Protection Officer visit and heck the units. Fumigation will be carried out prior to inspection and contamination tests will be performed once a year.

All cell lines will be grown in a CO2 incubator positioned close to the safety cabinet.

Instruction notices of how to deal with accidents or spillages will be placed on the safety cabinet, incubator and laboratory COSHH handbook. The virus is inactivated using a 1% aqueous solution of hypochlorite, and emergency "spill kits" consisting of decontaminant, gloves and absorbent disposbale towels will be kept to hand in all areas where viruses are prepared and used.

All solid waste (flasks, pipettes etc.) generated in virus preparation will be placed in a "biohazard" bag next to the safety cabinet. The bag will itself be placed within a solid container (with lid) so if virus contaminated material pierces the bag it will remain contaminated by autoclaving at 126°C for 30 minutes completely destroying all adenovirus (which is inactivated at 56°C).

Project Additional Information

Purposes of the contained use
The study of fungal virulence factors

Recipient or parental organism
Class 2 fungal species: Candida albicans, Candida spec., Sporotrich schenkii, and Cryptococcus neoformans var. neoformans C. neoformans var gattii.

Host/vector system
Vectors used to transfer fungal DNA onclude pBluescript derivatives, pSP72 derivatives, pUC19 and pUC derivatives

Origin & function
Genetic material involved originated from fungi, including the class 1 species Saccharomyces cerevisiae and Ashbya gossypii

Evaluation of foreseeable effects
We will delete or replace genes that are involved in diverse aspects of fungal virulence. Thus, we assume, that most strains created here will be less virulent due to reduced gene function

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid cultures will be treated with Dettol for 5 minutes. This is expected to kill >99% of microbes. Validation could be achieved by test plating of a de-contaminated culture prior to disposal. Solid cultures and contaminated solid waste will be collected in appropriate bins and autoclaved (126C, 30 minutes). Color-changing autoclave tape is used as the standard for a successful autoclave run. Autoclaving should eradicate all fungi completely.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The Genetic Safety Committee approved the risk assessment without further comments.

Project Containment

02/03/2022
Factors involved in the infection process of Trichophyton rubrum and other dermatophytes

Recipient or parental organism
Trichophyton rubrum (and related fungi) and Escherichia coli

Host/vector system
pUC18/19 or similar cloning vectors for E. coli will be used, and genes of interest will be cloned in E. coli. A hygromycin resistance cassette will then be inserted into these genes, and the resulting constructs will be used to transform T. rubrum. These vectors cannot replicate in E. coli, and will integrate into the genome via homologous
recombination, resulting in disruption of genes.

Origin & function

Donor organisms are T. rubrum and related organisms, and the genes of interest are those involved in the infection process. Initially we will work on putative keratin-binding proteins as well as keratinases, which are involved in early steps such as adherence. Other related genes may also be targeted.

E. coli JM109 or similar is used as a host for construction of vectors, and a hygromycin B resistance cassette (originating from E. coli) will be used as selection marker.

Evaluation of foreseeable effects

T. rubrum and other dermatophytes are the causative agents of fungal skin, hair or nail infections. Symptoms are usually mild. Genes that will be targeted for disruption include keratinases (which degrade keratin in skin, hair or nails), keratin-binding proteins, and other genes encoding components in the membrane or cell wall of the fungi. We do not seek to express the gene products in E. coli or T. rubrum - constructs are only made to create knock-out strains.

Risk of transfer of genetic material of T. rubrum mutants is very low, as only the hygromycin resistance gene is integrated into the chromosome. The plasmid itself (including e.g. the b-lactamase gene on pUC vectors) is lost during recombination of the vector with the chromosome (via a double-crossover). Presence of the hygromycin gene and absence of the remainder of the vector will be verified by PCR and/or Southern blotting. Vectors in E. coli are unlikely to transfer to other organisms, as the vectors used are non-mobilisable and risk of transfer to other organisms is low.

We aim to disrupt genes involved in the infection process, and any mutants constructed are thus less likely to cause disease. Nevertheless, the GMM could potentially cause an infection of skin, nail or hair. However, symptoms of dermatophytosis are mild. The disease is very common and is easily managed with antifungals. T. rubrum mutants will be resistant to hygromycin B, but this antibiotic is not used in humans (it is only used in veterinary medicine as an antihelminthic).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Good microbiological practice techniques will be used for this project (as it is for all projects in the laboratory), and all work with fungi will be done in a class 2 biosafety cabinet. Culturing of fungi and E. coli will only be on plates or in small-scale liquid cultures. Maximum volumes will be -1 L, but in most cases only a 5-10 ml scale is required. Fungi are normally cultured statically on agar plates. All waste will be sterilised by autoclaving, using 30 min at 1260°C. Autoclaves in the department are checked regularly.

Work surfaces are regularly cleaned with "Distel", a laboratory disinfectant suitable for fungi (and fungal spores). This disinfectant contains a mixture of quaternary ammonium and biguanide compounds, all of which have proven activity against fungi. We will also conduct our own experiments to validate the activity of this disinfectant against T. rubrum spores. We will test this using a suspension test (following pharmaceutical standards). In addition, we will spot a known number of fungal spores (10^6-10^8) on a work surface, followed by drying for 1 hour and then treatment with diluted concentrations of the disinfectant for 30 sec-1 min. Swabbing and plating on Sabouraud agar plates will then be used to check for any surviving organisms.
Comments on draft:
It all looks fine. The one thing I would add is some method of verification that sterilisation/disinfection procedures work.
DB
You might want to add a sentence saying you'll confirm that each T.rubrum targeting construct doesn't have any bla sequences
TP
Will that be done so that there is a homology region to the left and right of the hygromycin cassette? Will the gene be merely interrupted or completely deleted? Not even the vectors will be integrated, just the hygromycin cassette. The vector backbone will be lost through the double cross-over.
SG
Comments on final version:
Looks fine to me now.SG

**Project Additional Information**

**Purposes of the contained use**
Exploring the role of specific cellular proteins in regulating epithelial cell functions (mammalian cell lines) and their potential involvement in cellular processes in health and disease.

**Recipient or parental organism**
Mammalian cell lines used in laboratory research (Caco-2, HT-29, MDCK and T84).

**Host/vector system**
Replication incompetent lentivirus (commercially-available).

**Origin & function**
Lentivirus is originally derived from human immunodeficiency virus (HIV). Viral particles will be used to transduce cell lines.

**Evaluation of foreseeable effects**
We can anticipate that the possibility of transmission by direct injection is minimized as no hypodermic needles are used in any step using this vector. Aerosolizing the virus, and thus pulmonary exposure, is minimized as all studies will be performed in a bio-safety cabinet. Skin exposure will be minimized through the use of appropriate personal protective equipment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
Not applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
Work including viral particles handling and transduction of target cells will be carried out in a dedicated bio-safety...
culture hood. A beaker containing a 1 % of virkon solution for inactivation of virus samples and infected target cells will be placed inside the hood. Contaminated samples will sit for 24 hours in this solution before disposal to the drain.
All dry waste generated will be sent for autoclaving before disposal (127 °C for 30 min).

---

Comment from GMSC on a draft copy of the risk assessment:
Please include some information on the types of genes that will be over expressed or knocked down. It's good to make description fairly broad, but at the moment there is no information at all so it is difficult to make any judgement on what the risk to health or the environment is.
This was addressed to the satisfaction of the GMSC members and the risk assessment approved.

Investigation of the biological properties (including photoprotective and antioxidant/therapeutic) of novel molecules including iron chelators on cell cultures.

We are interested in the role of iron in cellular oxidative stress occurring in environmental conditions, cancer, pathologies notably. We plan to investigate the biological effects on cells in culture, of novel bespoke compounds aiming at protecting cells against the deleterious effects of oxidative stress.

The cell lines we plan to use in this project are all within category RG2. Examples of GM cell models systems (and relevant references) we plan to use:

1) The Friedreich's Ataxia (FRDA) model systems: FRDA is a neurodegenerative and cardiodegenerative disease caused by a mutation within intron 1 of the frataxin (FXN) gene, in the form of a GAA triplet repeat expansion (up to 1700 repeats). This mutation results in the reduction of the levels of frataxin protein, a nucleus-encoded protein which migrates to the mitochondrial compartment where it is critical for the biogenesis and delivery of iron (Fe)-sulfur clusters. Recent studies provide evidence of its role in heme biosynthesis and mitochondrial iron storage (Reviewed in Burk K. 2017 Apr 7;4:4. Cerebellum Ataxias; Chiang S et al. 2017 Aug 4. Neurochem Int). Consequently, reduction in frataxin expression leads to oxidative stress, mitochondrial iron accumulation and cell death.

We plan to use mouse kidney fibroblast cell lines derived from a transgenic mouse model (called "GAA-repeatexpansion-based human frataxin transgenic model") of this disease: Y47R cells (derived from control mice) express normal level of FXN and YG8sR cells (derived from "FA-like" mice) express significantly reduced level of FXN (from Pock's laboratory, see Anjomani Virmouni S et al., 2015 Mar;8(3). Dis Model Mech).

We also plan to use EBV-immortalized human B lymphocytes (LCLs) obtained from repositories, from healthy individuals (e.g. AG15799, GM14406, GM05398, GM03798), unaffected carriers (e.g. GM15849, GM16200, AG15799, GM14406, GM05398, GM03798),
2) The N27 rat neuronal cell line is used as a Parkinson's disease (PD) model system. The N27 cells are neurons which have been harvested from E12 rat mesencephalic tissue and immortalized with SV40, so they can conveniently be studied in vitro. N27 cell line has been extensively characterized in studies on dopamine biosynthesis, neurotoxicity and used as a dopaminergic neuron model for in vitro and in vivo studies (from Dexter's laboratory, see Di Fruscia et al. 2015 Jan;10(1). ChemMedChem).

Characteristics of the host and/or host/vector system and any associated hazards to human health:
The level of risk to human health is low.

1) FRDA model systems:
Mouse Y47R and YG8sR cell lines: The vector is a Yeast Artificial Chromosome (YAC) containing the gene encoding the human frataxin protein (FXN) with respectively a short and a long stretch of GAA-repeats. The YAC is stably integrated in the mouse cell line genome and expresses the protein frataxin, at physiological (i.e. normal) level in Y47R cell line and at much lower level (i.e. similar to what is found in FA) in YG8sR cell line. No foreseeable associated hazards.

Human EBV-immortalized human lymphoblasts cells from healthy, unaffected carriers and FRDA patients: The vector is the whole EBV genome. It can persist as episome (multiple copies of circular DNA) or can be integrated into the host's genome (Hurley EA et al. 1991;65. J. Virol.).

2) Rat N27 cell line:
The vector is pSV3-neo, an expression vector derived from pBR322 and containing the large T antigen (TAg) gene of the SV40 virus under the control of SV40 regulatory sequences, SV40 origin of replication and Amp and Neomycin resistance genes for clone selection in bacteria and mammalian cells respectively (Prasad KN et al. 1994 Sep;30A(9). In Vitro Cell Dev Biol Anim). pSV3-neo is stably integrated in the genome of the host cells (therefore not episomal). It is not able to self-replicate in mammalian cells. No complete virus can be produced from such vector within the host cell. Therefore as such represents a low danger for the worker. Host (neurons from rat mesencephalic tissue) is incapable as such to grow outside of very specific optimal conditions of nutrients, temperature, pH etc which are provided in vitro by the culture medium. An SV40 immortalized line such as N27 would not be able to colonize a worker, unless possibly if the person would be strongly immunocompromised already.

Origin & function
Source, characteristics and intended functions of the inserted gene product and hazards arising directly from its use (including an estimation of the level of expression and biological activity of the recombinant gene product):
The level of risk to human health is low.

1) FRDA cell models:
Mouse Y47R and YG8sR cell lines:
Genetic material involved: the human frataxin (with low or high GAA repeat) gene sequence cloned into a YAC.
Function: stable expression of human mitochondrial protein frataxin which is involved in heme and iron-sulfur cluster biosynthesis and mitochondrial iron storage. There is no known hazard associated with these biological functions. In Y47R and YG8sR cell lines, the human frataxin is expressed at respectively physiological and FA disease level.
Reduced level of frataxin leads to high sensitivity to oxidative stress but this only occurs under very specific and rare pathologies such as FA. In transgenic mice, artificial overexpression of frataxin by up to tenfolds has been shown to have no deleterious effects. Natural situations of overexpression of frataxin are not known.

EBV-immortalized human lymphoblasts:
Genetic material involved: the whole EBV virus. Function: cell immortalization. In vitro generated LCLs, the virus expresses all of its proteins from its ca 172kbp genome (i.e. latency III). While individual infection with the virus is possible, it is highly unlikely to be an issue, notably because the vast majority of the population are infected asymptomatically at a young age or have had infectious mononucleosis. Seronegativity amongst laboratory workers is a very unlikely event. Nevertheless, cautions in handling is required as EBV combined with various factors (e.g. immunodeficiency, environment etc) has been linked with the development of various cancers.

2) N27 cell line:
Genetic material involved: elements of SV40 virus. Function: immortalization of the rat neurons by inactivation of tumour suppressor genes. The inserted gene product SV40 TAg drives immortalization of the rat cells and is a suspected oncogene. Nevertheless, grafting of N27 cells in mice did not lead to their proliferation nor induce tumour (Adams FS et al., 1996). In vitro immortalization of primary human cells via expression of TAg is a rare event, although TAg can efficiently delay cell senescence (Fields BN and Knipe DM. 1990. Virology, 1, 2. Raven Press, New York). Therefore overall the hazard for the user can be considered low.

Evaluation of foreseeable effects

As per the characteristics and the origin of the host and host/vector systems, there is n%r low foreseeable hazard to human health associated with the handling of the GMOs described in this form. The risk for human health could come from accidental inoculation during handling. However, this is unlikely to happen as appropriate RG2 handling protocols will be followed. Also, the possibility of transmission of the GMO to the worker by direct injection is minimized as no hypodermic needles are used in any steps of the techniques employed in our laboratory. Even if accidental inoculation should happen, an infection of the worker would be unlikely unless he/she would be strongly immunocompromised already.
Risk of aerosolizing any cells (e.g. virus-immortalised), and thus pulmonary exposure, as well as spillage are minimized as all studies will be performed in a class 2 bio-safety cabinet. Skin exposure is also minimized via the use of appropriate personal protective equipment (lab coat, gloves, safety glasses).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All handling of the cells lines described will take place within a containment class 2 laboratory (building 5W, 2.20 outer and inner), within a designated tissue culture area, under Class 2 safety cabinet, and using established code of practice (SOP) for work at containment level 2 which will be sufficient to keep contact with humans and the environment to negligibly low levels.
Contaminated sharps (e.g. Pasteur Pipettes) will be disposed of in designated yellow biohazard bins for "sharps" destined for incineration. If contamination of centrifugation equipment (e.g. buckets, seals and lids) should occur, these items will be submersed in Virkon ® (as per manufacturer's recommendations of use), then thoroughly rinsed with water prior to reuse.
Any non-sharp contaminated material (e.g. disposable gloves, plastic tips and pipettes, and vessels) will be disposed of in biohazard bags destined for autoclaving. The routine regime in the Department of Pharmacy & Pharmacology at the University of Bath is 126 degC for 30m in.
Dedicated pipettes (e.g. Gilson) will be used for the class 2 work and parts potentially exposed to contamination will be regularly soaked in Virkon®.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

A number of the lines have already been described in publications by our collaborators/providers were supported by a citation or two (which is a general point) and it's not really very clearly written: the Frataxin gene (FXN) is the one in which the triplet expansion occurs in Friedrich's Ataxia but this isn't stated, its function isn't really known and it's a little misleading to say it's a mitochondrial protein - yes, it's in mitochondria, but it's encoded by the nucleus.

Amend the document in line with the above comment.

02/03/2022
FUNCTIONAL GENOMICS: GM fungal strains will be generated to 1) remove a native gene, 2) re-insert the same native gene (complementation), or 3) insert the native gene fused to a reporter protein such as GFP, or alternative promoter sequence. This will enable the study of gene function and localisation. The comparative analyses of the parental and GM fungal strains described below (section 7) will identify differences in the ability of GM fungal strains lacking individual fungal genes to complete different aspects of their biology. This will assist in the discovery of the function of the respective fungal gene and its contribution to fungal disease. The identification of fungal genes important to disease and mycotoxin production, plus increased knowledge of their function, will advance the development of novel strategies to control fungal borne diseases and mycotoxin contamination.

RECIPIENTS: The application of fungal functional genomics and the assessment of genes/biological processes involved in pathogenicity and mycotoxin production will include fungi from Fusaria and Aspergilli. The characteristics of each genus is described below, followed by the potential risks of the resulting GMOs.

FUSARIA: Fusarium graminearum and F. culmorum are fungal ascomycete pathogens of small grain cereals, and while other members of the genus Fusaria have been associated with infections of immunocompromised humans i.e. F. solani and F. oxysporum, this is not the case for F. graminearum and F. culmorum. However, F. graminearum and F. culmorum can produce the DON (deoxynivalenol) and ZEA (zearalenone) mycotoxins, which are harmful to humans if ingested. DON and ZEA are produced specifically during plant infection, and under specialised in vitro growth conditions. Therefore, do not present a direct risk to human health during the handling of these fungi. Fusarium species do produces conidia, and also ascospores under specific conditions. These spores can cause allergic and respiratory issues in humans, similar to those caused by constituent high level exposure to pollen and dust. F. graminearum and F. culmorum are pathogens of small grain cereals including wheat, barley and maize, reducing grain yield, quality and safety due to the contamination with the DON and ZEA mycotoxins. Some academic studies have reported the ability of F. graminearum to infect other non-host plants, namely Arabidopsis and Soybean, under laboratory settings which do not naturally occur. Due to the predicted debilitated nature of the GM F. graminearum and F. culmorum strains, it would be predicted that the native UK Fusarium populations would outcompete the laboratory derived strains. The F. graminearum PH-1 strain originates from the USA and is therefore classified as a non-native pathogen. As a result of the genomic and genetic resources available for this strain, it used by all the prominent research groups in the UK and worldwide.
APSERGILLI: Aspergillus species are ubiquitous in the environment. They have been associated with infections of immunocompromised humans or those with chronic granulomatous disease, i.e., pulmonary aspergillosis. Aspergillus species are also food spoilage microbes and can produce mycotoxins (A. nidulans- Sterigmatocystin; A. fumigatus-Gliotoxin), which are harmful to humans if ingested. Aspergillus species airborne conidia, and also ascospores under specific conditions. These spores can cause allergenic and respiratory issues in humans, similar to those caused by constituent high level exposure to pollen and dust. Aspergillus nidulans and A. fumigatus are not pathogen of plants and present no risk.

RISK OF GMO TO HUMANS: The likelihood of non-GM or GM Fusarium strains causing harm to human health after direct exposure to the fungus is very low, as it is not a human pathogen. The likelihood of non-GM or GM Aspergillus strains causing harm to human health after direct exposure to the fungus is very low, as long as they are not immunocompromised. The ingestion of plant/food material infected with Fusarium or Aspergillus strains could be harmful to human health, through the impacts of the mycotoxins. But the likelihood of this occurring is very low. The chance of inhaling allergenic fungal spores during the preparation of suspension (the starting point for most experiments) is very low, as these suspensions will be prepared under sterile conditions within a CAT2 microbiological safety cabinet.

RISK OF GMO TO ENVIRONMENT: F. graminearum, F. culmorum, A. nidulans and A. fumigatus are not reported to be a pathogen and harmful to other organisms beyond the previously discussed animals and plants. The exception being the feeding of humans/animals with grain or plant produce contaminated with fungal mycotoxin. The GM Fusarium or Aspergillus strains would have the capacity to survive and propagate in the environment, on small grain cereals and dead plant biomass within the soil or food produce. However, due to the predicted debilitated nature of the GM strains, it would be predicted that the native UK fungal populations of these pathogens would outcompete the laboratory derived strains.

RISK OF GMO WITH INCREASED VIRULENCE: None of the genetic modifications to the CAT2 fungal pathogens are envisaged to increase fungal virulence. In fact, of the 1250 F. graminearum GM strains documented within www.PHI-base.org, only 8 have increased virulence, demonstrating that it is difficult and very rare to increase fungal virulence, and therefore the risk to human health. If the loss of gene function does cause increased disease, or mycotoxin production, experimentation will cease and the GMSC committee at the University of Bath and HSE will be notified.

Host/vector system

HOST: Whole plants or excised plant tissues (such as wheat, Maize and Arabidopsis) will be used as experimental hosts to compare the disease-causing, and mycotoxin-producing, abilities of parental and GM fungal strains. These studies will occur in the CAT2 controlled environment chamber or laboratory. The containment procedure and disposal of plant material is described in sections 8 and 12.

VECTOR: The DNA transformation cassettes will be constructed within E.coli via the Gibson protocol and the pGEMT vector, which is not mobilisable. DNA transformations cassettes will be PCR amplified from the vector carrying this cassette and purified prior to Fusarium / Aspergillus protoplast transformation. The vector will not be transformed into the fungal GM strains.

Origin & function

ORIGIN: The fungal DNA sequences will originate for the host Fusarium or Aspergillus strain, and will target the transformation cassette to a specific locus of the fungal genome by homologous recombination. The selectable markers encoding resistance to Hygromycin and Geneticin are of bacterial origin, while the auxotrophic marker are from Aspergillus species. These markers will permit the selection of positive fungal transformants on selective growth media. Fluorescent reporter proteins, such as GFP, come from the jellyfish Aequorea victoria. The fungal genes under
Investigation are conserved in closely related fungi and therefore their transfer to these fungal relatives is not believed

to present a potential hazard. The Hygromycin and Geneticin resistance genes are not present in related non-GM
fungi. However, these drugs are not used to treat fungal infections in the agricultural or clinical settings. The
auxotrophic marker are already present in environmental Aspergillus strains.

Intended Function: GM fungal strains will be generated by targeted transformation, inserting a fragment of DNA
plus a selectable marker into a specific locus of the fungal genome. This will either 1) remove a native gene, 2) reinsert
the same native gene (complementation), or 3) insert the native gene fused to a reporter protein such as GFP,
or an alternative promoter sequence. This will enable the study of gene function and localisation. Additionally, sexual
crosses between different GM or native strains may be used to incorporate the GM loci into different genetic
backgrounds within the same fungal species.

Evaluation of foreseeable effects

Evaluation of GMO: The comparative experiments between the parental and GM fungal strains described below
will enable the identification of differences in the ability of GM fungal strains lacking individual fungal genes to
complete different aspects of their biology. This will assist in the discovery of the function of the respective fungal
gene and its contribution to fungal disease.

Quantification of fungal growth in vitro on solid agar plates or liquid cultures.

Quantification of sexual and asexual sporulation in vitro.

Assessment of fungal colonisation of plants (host or non-host species) / plant derived biomass and quantification
of fungal biomass within plants.

Observation of fungal infection within plant material via microscopy, including 1) stereomicroscopy to visualise
macroscopic appearance, 2) scanning electron microscopy to visualise fungal colonisation on the surface or within
plant tissues, and 3) histology of ultrathin sections of plastic embedded materials via light or transmission electron
microscopy.

Observation of the localisation of the fungal reporter proteins or immune-labelled proteins during in vitro culture or
plant colonisation via fluorescence microscopy.

Biochemical analyses (western blots) to determine protein localisation.

Quantification of fungal toxins within infected plant materials or during in vitro culture under specific conditions, via
a specific ELISA based assay.

Extraction of fungal and/or plant RNAs, proteins and metabolites for transcriptomic, proteomic and metabolomic
analyses.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

CAT2 Laboratory: Only fully trained persons or trainees under the supervision of fully trained project group
members will be permitted to use the facility. Access to the CAT2 facilities will be controlled by Drs N. Brown and V.
Cervik. The handling and storage of all CAT2 fungal pathogens will only occur within the CAT2 laboratory and the
CAT2 control environment chamber, where users will wear a dedicated lab coat and disposable gloves to avoid
transfer beyond the CA T2 environment. A sticky matt will be placed at the entrance to the facility to reduce the risk of
fungal spores being transferred on shoes beyond the laboratory. Although the CAT2 fungal pathogens are usually
contained within the CAT2 microbiological safety cabinet or the CAT2 control environment chamber, if contamination
of the main laboratory occurs, then the appropriate decontamination procedure will be performed. Following
contamination of a local area, debris must be swept up and autoclaved and the area disinfected (Microsol 3 at 1 :50
dilution). If the contamination is general then all surfaces should be thoroughly vacuumed and washed down with a
disinfectant. (Microsol 3 at 1 :50 dilution). If there is considered to be any risk from spores or insect vectors, which is
unlikely to occur, then a full decontamination with Formaldehyde should be considered.
CAT2 STORAGE: Fungal pathogens can be stored doubly contained on sealed agar plates or in sealed vials, contained within boxes or within the refrigerator/freezer provided within the CAT2 laboratory. For long term storage, fungal spore suspensions be stored within a dedicated CAT2 -80°C freezer.

CAT2 MICROBIOLOGICAL SAFETY CABINET: The preparation of all CAT2 fungal pathogen spore suspension will be performed in a CAT2 microbiological safety cabinet, and all CAT2 waste will be autoclaved, protecting the user and the environment for the pathogen. After use the surfaces will be decontaminated with 70% ethanol. After changing the filters of the CAT2 microbiological safety cabinet, the used filters will be autoclaved upon removal. Annually or after a contamination event, the CAT2 microbiological safety cabinet will be decontaminated via washing the surfaces with a disinfectant (Microsol 3 at 1 :50 dilution), and a full decontamination with Formaldehyde.

CAT2 CONTROL ENVIRONMENT CHAMBER: Access to the CAT2 facility will be controlled by Dr N. Brown. Users will wear dedicated lab coats and disposable gloves, which will stay within the CAT2 facility, to avoid transfer beyond the CAT2 environment. A sticky matt will be placed at the entrance to the facility to reduce the risk of fungal spores/plant pollen being transferred on shoes beyond the laboratory. Infected plant material and any other waste from the CAT2 control environment chamber will be transferred in an autoclave bag within a sealed metal bin, which will be autoclaved directly, without opening. The CAT2 control environment chamber may be required to be decontaminated following the arrival of unwanted pests or pathogens that could increase the risk of either the licensed organisms being distributed to unintended locations within the facility, or licensed organisms being released or escaped into the general environment. Following any contamination the room should be thoroughly vacuume, all surfaces washed down with a disinfectant. (Microsol 3 at 1 :50 dilution). The room should be run at 40°C for 48 hours minimum. If there is considered to be any risk from spores or insect vectors then a full decontamination with Formaldehyde will be considered.

TRANSFER OF CAT2 MATERIALS: The transfer of conidial suspensions of any of the CAT2 fungal pathogens to the CAT2 control environment chamber, where plants are grown, will occur in a double sealed container to prevent the risk of escape. Similarly, the transfer of any fungal or plant material to the CAT2 laboratory for downstream processing or the microscopy suite will occur in double sealed container to prevent the risk of escape. All waste will be returned using the same approach to the CAT2 laboratory for inactivation and disposal.

MONITORING CAT2 USAGE: A log of authorised users of the CAT2 facilities and the CAT2 organisms being used will be kept by Drs N. Brown and V. Cervik. Users will have to read and sign the SOPs for the use of the CAT2 facilities prior to starting their independent work. Signed SOPs will be kept by Drs N. Brown and V. Cervik. Within the CAT2 facilities, log books will record the efficacy of the pathogen inactivation procedure (double kill procedure) and any incidence that require decontamination. Additionally, the dates when routine decontamination procedures were performed. An electronic record will be kept of all fungal plant experiments performed in the CAT2 growth chamber including the experimenter, project code, plus the start and end date, noting any alteration in fungal virulence.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

CAT2 WASTE DISPOSAL: Solid and liquid waste produced in category 2 facilities must be decontaminated using steam sterilisation for 30 min at 121 C. For this reason no packaging material (i.e. cardboard boxes) should be brought into the facility to keep waste to be autoclaved at a minimum. The facility will be equipped with one or more pedal bins or autoclavable aluminium bins fitted with autoclavable bags, which can be used to dispose of smaller waste items. Lab coats which need to go to the laundry, should be deposited in a sealed autoclave bag. Liquid waste should be deposited in autoclavable glass bottles to allow chemical inactivation (Microsol 3 at 1 :50 dilution) followed by steam sterilisation, i.e. a double kill microbiological procedure. The validation of the degree of kill will be confirmed.
annually via performing the double kill procedure on a spore solution and then counting colony forming units.

The University Genetic Modification Safety Committee (GMSC) asked for more information to be provided on the mobilisation of vectors within the risk assessment. The risk assessment was amended to the satisfaction of the GMSC.

Project Ref 85/18.2

Investigation of the biological processes of self-renewal and terminal differentiation in cultures of normal and neoplastic human epithelial cells

Date Ackn'd 26/10/2018

Date Project Ceased

Class 2 Culture VolClass2 < 1 Litre

Consent Granted

Project notified under transitional arrangements
Stratified epithelia (e.g. skin epidermis, oral and tongue epithelia, esophagus epithelium) are essential for our survival as terrestrial beings. They provide protection from harmful microbes and other assaults from the external environment, and retain body fluids. To withstand normal wear and tear, these epithelia constantly self-renew. This ability resides in tissue-resident stem cells, which self-renew, preserve, and repair their tissue during homeostasis and following injury. Studying the normal process of tissue homeostasis is providing us a foundation to understand how these processes go awry in human diseases, including chronic wound-healing, hyper-inflammatory disorders and epithelial cancers.

The purpose of this work is to understand the biological mechanisms which regulate the processes of stratified epithelial stem cell self-renewal, differentiation, dysplasia and neoplastic progression. We have already identified several important components of the intracellular signalling pathways (Mishra et al., 2017; Walko et al., 2017) and we now propose to manipulate these proteins using recombinant molecular biology technology to deliver selected genes to cultured normal and dysplastic/neoplastic human epidermal cells and further dissect their roles in cell fate determination.

Commonly used customised or commercially available retroviral and lentiviral vector systems will be employed to deliver gene constructs to human epithelial cells. The genes may be those directly associated with proliferation such as proto-oncogenes or genes which produce protein components of mitotic signalling pathways. Other intracellular signalling pathways are more important for initiating cell differentiation, such as the Wnt and Hippo pathways and we will analyse the proteins which contribute to them.

Stem cell fate decisions are also made in response to their “niche” or local micro-environment and cell surface protein receptors transduce this information to the nuclear transcription machinery. Integrins, Cadherins, Delta and Notch proteins are all directly involved in cell-cell or cell-niche interactions.

Over-expression of selected relevant proteins in undifferentiated epidermal cells using cDNA constructs can yield useful information about their function. However, it can also be highly informative to suppress expression of certain genes, also resulting in modified cell phenotypes and we can employ specifically designed shRNAs to target these genes.

screen identifies YAPIWBP2 interplay conferring growth advantage on human epidermal stem cells. Nature communications. 8:14744.

Recipient or parental organism

HaCaT is a spontaneously transformed aneuploid immortal epidermal cell line from adult human skin (Boukamp et al., 1988). We will also use a panel of cutaneous squamous cell carcinoma progression cell lines derived from the parental HaCaT cells. These include the benign tumorigenic HaCaT-RAS AS cells, the malignant HaCaT-RAS 11-4 cells and the metastatic HaCaT -RAS AS-RT3 cells (Boukamp et al., 1990; Mueller et al., 2001). PM1-4 are clonal epidermal cell lines derived from adult dysplastic human forehead skin (Proby et al., 2000).

Human squamous cell carcinoma lines (e.g. SCC4, SCC12, SCC13, SCC-NR, MET1-4, SCL-1, SCL-II) have been derived from tumour tissue (Boukamp et al., 1985; Proby et al., 2000; Rheinwald and Beckett, 1981; Tilgen et al., 1983). They are capable of unlimited proliferation due to spontaneous genetic mutations present in carcinoma tissue. Human oral squamous cell carcinoma lines (e.g. SJG-003, SJG-006, etc) have been derived from tumour tissue (Benaich et al., 2014; Hayes et al., 2016). They are capable of unlimited proliferation due to spontaneous genetic mutations present in carcinoma tissue.

Primary human epithelial cell cultures have been derived from normal skin biopsies (neonatal foreskin; strains Km, Kp, etc.) (Estrach et al, 2007; Mulder et al., 2012; Walko et al., 2017). They have been banked at passage 2 and are capable of limited propagation up to 10 passages.

Additional stocks of primary human epithelial cell cultures will also be established for the proposed work from surgical waste from healthy donors and tissue biopsies from patients with cancer for the proposed work once ethical approval has been obtained from the NHS.

3T3 mouse fibroblasts will be used as a feeder layer to allow human epithelial cells to be grown at clonal seeding density under conditions that preserve the stem cell state for a several passages (Rheinwald and Green, 1975).

For certain biochemical/cell biological studies we might also use well characterised human simple epithelial cell lines. These could include: HEK293T (ATCC CRL-3216), MCF7 (ATCC, HTB-22), BT474 (ATCC-HTB-20), T-47D (ATCC, HTB-33), MCF10A (ATCC, CRL-10317), MCF10F (ATCC, CRL-10318), MDA-MB-453 (ATCC, HTB-131), MDA-MB-231 (ATCC, HTB-26), MDA-MB-436 (ATCC, HTB-26), MDA-MB-361 (ATCC, HTB-27), MDA-MB-468, ATCC, HTB-132), BT549 (ATCC, HTB-122), ZR-75-1 (ATCC, CRL-1500), SK-BR-3 (ATCC, HTB-30), Caco-2 (ATCC, HTB-37).

The level of risk to human health is medium.
Phoenix ECO cells are a second-generation gamma-retrovirus producer line for the generation of helper free ecotropic retroviruses (ATCC CRL-3214)(Swift et al., 2001). This line is based on the 293T cell line (a human embryonic kidney line transformed with adenovirus E1 a and carrying a temperature sensitive T antigen co-selected with neomycin). The Phoenix ECO line stably expresses Gag-Pol proteins and an ecotropic Env protein (for infection of mouse and rat cells), eliminating the need to deliver these genes in trans by specific plasmids. Gag-Pol and Env proteins are driven by different promoters, minimizing their inter-recombination potential.

Health and Safety

Executive

AM12 cells (ATCC CRL-9641) are an amphotropic gamma-retrovirus packaging cell line derived from 3T3 mouse fibroblasts in which the gag, pol, and env genes of the helper virus are separated on two different plasmids and in which the packaging signals and 3’ long terminal repeats are removed (Markowitz et al., 1988). The HEK293T (ATCC CRL-3216) and HEK293FT (https://www.thermofisher.com/order/catalog/product/R70007) cell lines are highly transfectable derivatives of human embryonic kidney 293 cells, and contain the SV40 T-antigen (Pear et al., 1993). They will be used for packaging of lentiviruses.

The replication-incompetent gamma-retroviral vectors are designed to greatly reduce the probability of the production of replication-competent retrovirus by homologous recombination. The transfer vectors to be used (e.g. pBABE-puro, https://www.addgene.org/1764/) are derived from Moloney Murine Leukemia Virus. These widely used vectors provide the viral packaging signal, transcription and processing elements, and a target gene, but the gag, pol and env genes are not present (Morgenstern and Land, 1990). Packaging requires the use of helper-free packaging cell lines that provide the genes required for retroviral packaging and transduction in trans (Markowitz et al., 1988; Swift et al., 2001). This means that none of the structural genes are actually present in the packaged viral genome. Moreover, in the packaging cell lines Gag-Pol and Env proteins are driven by different promoters, minimizing their interrecombination potential (Markowitz et al., 1988; Swift et al., 2001). Consequently, the recombinant gammaretroviruses can transduce target cells, but the transduced target cell does not produce additional virus.

All lentiviral transfer vectors are second or third generation vectors. Lentiviral transfer vectors will include the pLenti vectors (third generation) in the ViraPower™ expression system (ThermoFisher), the SMARTvector lentiviral shRNA vectors (second generation) in the constitutivelinducible SMARTvector lentiviral shRNA expression system (Dharmacon), and pLKO.1 and TRC-pLKO lentiviral shRNA vectors (second generation) in the MISSION lentiviral shRNA expression system (Sigma)). Lentiviral packaging vectors will include the pLP1, pLP2, and pLPNSV-G vectors in the third generation ViraPower™ expression system (ThermoFisher), and the psPAX2 (Addgene, 12260, https://www.addgene.org/122601) and pMD2.G (Addgene, 12259, https://www.addgene.org/12259/) vectors for packaging of second generation lentiviral expression vectors. These vectors include a significant number of safety features:

All lentiviral transfer vectors contain a deletion in the 3’ LTR (t.U3) that does not affect generation of the viral genome in...
the producer cell line, but results in "self-inactivation" of the lentivirus after transduction of the target cell (Yee et al., 1987; Yu et al., 1986; Zufferey et al., 1998). Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing packageable viral genome.

I- The number of genes from HIV-1 that are used in the systems has been reduced to four (Le. gag, pol, rev and tat in psPAX2, second generation system) or three (Le. gag and pol in pLP1 and rev in pLP2, third generation system).

- The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 envelope (Burns et al., 1993; Emi et al., 1991; Yee et al., 1994).

I- Genes encoding the structural and other components required for packaging the viral genome are separated onto three (second generation systems) of four (third generation) vectors. All vectors have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus (Dull et al., 1998).

- Although the packaging vectors allow expression in trans of proteins required to produce viral progeny (Le. Gal, Pol, Rev, Tat, Env) in the HEK293T and HEK293FT producer cell lines, none of them contain LTRs or the 4J packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced.

- The lentiviral particles produced are replication-incompetent and only carry the gene of interest. No other viral species are produced.

I- Expression of the gag and pol genes from pLP1 has been rendered Rev-dependent by virtue of the HIV-1 RRE in the gag/pol mRNA transcript. Addition of the RRE prevents gag and pol expression in the absence of Rev (Dull et al., 1998).

- A constitutive promoter (RSV promoter) has been placed upstream of the 5'L TR in the pLenti expression vector to offset the requirement for Tat in the efficient production of viral RNA (Dull et al., 1998).

Origin & function

The inserted genetic material will be varied. These genes may be those directly associated with proliferation such as proto-oncogenes (e.g. YAP and TAZ, WBP2, beta-Catenin, Lef/TCF) or genes which produce protein components of mitotic signalling pathways (e.g. Erk1/2, Mek1/2, Ras, Raf), or those that are more important for initiating terminal cell differentiation (e.g. TP63, Jun/Fos, Lats1/2) or controlling cytoskeletal dynamics (e.g. RhoA, RhoE, Rock1/2, Rac, Cdc42). We might also examine cell surface-associated cell-cell and cell-matrix signalling receptors including integrins, cadherins, and Notch ligand- and receptor proteins that are all directly involved in stem cell-niche interactions. In addition, we will investigate genes/proteins which yet unknown function (previously identified in genome-wide screens; Walko et al. 2017) in the normal and neoplastic epidermal (stem) cell context.
These various genes will be under the control of constitutive or cell/tissue-specific promoters. Other genes used will be reporter genes such as GFP to track pattern of expression of a protein or as a guide of the activity of a promoter. Antibiotic resistance genes will be used so that selective pressure can be applied to isolate only cells that have been transduced. We will also use vectors expressing (either constitutively or inducibly) shRNA molecules to selectively silence the expression of endogenous genes.

**Evaluation of foreseeable effects**

Human epithelial cells are derived using skin biopsies. The likelihood of adventitious pathogens will be increased if cells are sourced from populations known to have an elevated prevalence of HepB, HepC, HIV, HPV or other pathogens. Therefore, low risk patients are selected by interview prior to surgery at the time consent is given and iv drug users, those who have received blood transfusions or have a lifestyle likely to suggest a high risk of infection with blood borne viruses, are excluded. Alternatively, patient material may be screened for HIV, HepB or C prior to use in cell culture and positive samples excluded from further analysis. Prophylactic Hepatitis B vaccination will be offered to staff in contact with human cells by the Occupational Health Department.

There is a possibility that the expressed proteins may alter cell physiology and pharmacological response, as some of them may functions as proto-oncogenes or tumour suppressors. Consequently, the expression of an oncogene in the host cell will increase proliferation and survival and could induce oncogenic cell transformation. Likewise, the shRNA-mediated down-regulation of a tumour suppressor protein could cause similar effects on cell physiology. However, it is unlikely that expression of a single oncogene would cause tumours, as multiple genetic alterations (between 4 and 6) are required for inducing tumours, and safeguard mechanisms exist impeding the accumulation of these alterations in the organisms. No infected cells will be propagated indefinitely.

The viral production systems are widely used and generally considered safe. The replication-incompetent gammaretroviral- and lentiviral vectors are designed to greatly reduce the probability of the production of replicationcompetent retro- and lentivirus by homologous recombination. The potential for generation of replication-competent retro- or lentivirus is specifically addressed by the design of the vectors and by Good Laboratory Practice. The VSV-G enveloped pseudotype virus particles produced have a wide host range, which includes humans and can infect many tissues. However, each particle can only infect one cell and not give rise to further virus production. Also, expression of the VSV glycoprotein on the plasma membrane of any infected host cell would immediately present a target for the immune system. Retro- and lentiviruses are very unstable due to their fragile envelope protein hence VSV-G is used to increase stability of the recombinant viral particles. Wild type VSV-G can survive for 3-4 days in the natural environment (in saliva etc). It is therefore reasonable to assume that any escape of virus in untreated waste may be active for a few days. However, the viral particles outside of the closed controlled conditions of cell culture are rapidly inactivated by dehydration or other environmental insult, and so scope for spread via the environment is severely limited.

In the case of a laboratory accident there is a possibility the virus may infect a member of laboratory personnel. Care must be taken to avoid the spread of infectious material by aerosol (e.g. in the event of accidental release of bacterial cultures in a shaking incubator), direct contact (e.g. through contact with mucous membranes via splashes or spills) or accidental needle stick injection. If the virus vector entered the blood stream it is likely the vector would be delivered to a tissue where it is biologically active. Entry gained by an aerosol may infect the respiratory epithelium but in this and the latter case expression of the gene would depend on the promotor used.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
All procedures involving culture of human cells and handling of recombinant virus (virus particle production and infection of cells) will be performed in ADCP containment level 2 laboratories (University of Bath, Department of Biology and Biochemistry, 4 South Building, Rooms 1.38 (dedicated virus production laboratory) and 0.7 (cell culture laboratory)). Class 2 microbiological safety cabinets equipped with double HEPA filters will be used when handling virus and for culturing cells post-infection for downstream analysis. This will greatly reduce the risk of spread of infectious material by aerosol or direct contact. No hypodermic needles will be used in any steps of the techniques employed in our laboratories. Access to the virus laboratory (Room 1.38) will be restricted to authorised personnel only and the laboratory door will be kept closed at all times except for access.

Good Laboratory Practice will be maintained at all times. Skin and eye exposure will be minimised via the use of appropriate personal protective equipment (lab coat, gloves, safety goggles). Good hygiene will be maintained, and work surfaces will be regularly disinfected (ChemGene HLD4H, 1:20 dilution), but especially following manipulations using viruses.

Solid contaminated waste (plastic pipettes, flasks, etc) will be placed in a Biohazard bag prior to removal from the Class 2 microbiological safety cabinet, enclosed into a second bag outside the cabinet and carried to the autoclave room. Contaminated solid waste will be autoclaved at 126°C for 30 min, completely destroying all biological material including the viral particles.

Contaminated sharps (e.g. plastic Pasteur pipettes) will be disposed of in designated yellow Biohazard 'sharps' bins destined for incineration.

Contaminated liquid waste will be disinfected with an appropriate disinfectant (e.g. 10% bleach) for at least 30 minutes.

Spillages will be inactivated with 5% ChemGene HLD4H spray, collected with absorbent material and disposed of via autoclaving.

If contamination of centrifugation or other laboratory equipment (e.g. buckets, seals, lids, pipettes) should occur, these items will be submerged in 5% ChemGene HLD4H, then thoroughly rinsed with water prior to reuse.

Is an emergency plan required according to regulation 20? N

No comments were made by the committee.
### Project Additional Information

#### Purposes of the contained use

The aim of the project is to utilise molecular genetic approaches to investigate the genetic basis of virulence, biofilm formation and antimicrobial resistance in a range of opportunistic bacterial pathogens (both Gram negative and Gram positive species). All species to be studied are ACDP Hazard Group 2 pathogens. A greater understanding of the genetic basis of these processes and the underlying gene regulation, will lead to novel strategies for the prophylaxis and treatment of diseases associated with these organisms. The interaction of these organisms with bacteriophage (viruses which infect and kill host bacteria) will also be studied on a genetic level, with the view to generating novel bacteriophage based antimicrobials. Because all organisms to be studied will be subjected to the same molecular genetic techniques (described in detail in the attached RA: mutagenesis, construction of gene libraries, DNA cloning, and Genetic complementation), the same attributes investigated in all organisms (virulence, biofilm formation, antimicrobial resistance, interaction with
bacteriophage), and the same hazard group assigned to all organisms, they are included within the same genetic modification risk assessment.

Recipient or parental organism

Parental organisms (all ACDP Hazard Group 2):
Proteus mirabilis,
Pseudomonas aeruginosa,
Klebsiella pneumonia,
Moraxella catarrhalis,
Acinetobacter baumannii,
Staphylococcus aureus,
Staphylococcus epidermidis,
Streptococcus pyogenes,
Streptococcus pneumoniae,
Streptococcus agalactiae,
Streptococcus bovis,
Enterococcus faecalis
Enterococcus faecium.

Recipient organisms:
Standard attenuated Eschericia coli strains, e.g. disabled K12 type cloning strains. These have a long history of safe use with no reported harmful effects. Unlikely to survive outside the laboratory or initiate infection. Hazard group 1.
Lactococcus lactis. This is also extensively used as a cloning host, and for peptide surface display. This organism is non-hazardous, non-colon ising and non-pathogenic. Unlikely to survive outside laboratory. Hazard group 1.
Bacterial species listed as arental organisms will function as recipients ONLY for self-cloning experiments (e.g. complementation - as covered in detail in the attached RA). Hazard Group 2
No activities will increase the Hazard Group of resulting GMMs above that of the original parental organisms - Hazard Group 2

Host/vector system

A range of vector systems will be used to study the organisms listed, but all share key features relevant to containment of GMMs. No vectors capable of self-transfer between bacterial species will be used. All vectors to be used require introduction through laboratory manipulation (Electroporation, transformation of chemically competent cells, conjugal transfer from specialised hosts). The vector systems to be used include narrow host range vectors, broad host range vectors, and expression vectors. All selectable markers present are naturally occurring, and already present in the wider environment. The majority of vectors to be used are commercially available and all have a history of safe use. Small insert peptide display library vectors: such as pVESS47, pHIE11, pACL 1, pUvBBAC. Vectors contain open reading frames for cell wall anchored proteins. Cloning of DNA fragments into this region results in display of peptides on bacterial cell surface. As cloned DNA is expressed from the promoter associated with the surface anchored protein, for risk assessment purposes these vectors will be treated as expression vector systems. Standard cloning vectors: Narrow host range vectors such as pUC18, pUC19, pTOP040and pGEM-T will be used. For construction of genetic libraries in standard E. coli cloning strains, narrow host range, large insert vectors such as pCC1 FOS, pCC1 BAC, pBleoBAC will also be used. Reporter gene constructs: Reporter gene vectors such as, pPL2lux, pTCV-lac, or derivatives of pUC18 and pUC19 such as p18GFP, will be utilised to construct small insert reporter gene libraries. Mini-TnS based transposons will also be developed which incorporate reporter genes such as gfp, lacZ, luxAB, or phoA during this study. Broad host range vectors: Broad host range vectors, such as pC1372 capable of replication in E. coli and L. lactis will
be used to transfer DNA between these species only. Broad host range vectors such as pUCP, and derivatives such as pSCOSBC1 (and derivatives such as pSCOSPA1), pAT28 (derivative of pUC with a broad host range Grampositive origin of replication), pRMC2 (shuttle vector permitting expression of genes from a TetR-controlled promoter), pCN34 (broad range Gram-positive expression vector), pB4 (derivative of plasmid pOT182 lacking the TnS-OT182 transposable element), or plasmids with temperature-sensitive origins of replication such as pL T06 and pKOR1 will be used to construct genetic libraries, deliver constructs for site-directed mutagenesis and undertake self-cloning based genetic complementation studies in species to be studied.

Transposons: For random transposon mutagenesis transposable elements will be maintained on narrow host range vectors in disabled E.coli or L. lactis cloning hosts, and TnS based elements will primarily be used. These will also be used in in vitro transposon experiments in which they are not maintained in any vectors. TnS based elements have been extensively used for mutation based analysis of bacterial gene function and integrate stably into target DNA molecules. Narrow host range suicide delivery vectors, such as pUTKm, and pRL27, which cannot replicate outside of specialised disabled E. coli K12 based cloning strains, such as S17.1 lambda pir and SM10 lambda pir will be used to introduce TnS transposons into P. mirabilis, Ps. aeruginosa, K. pneumoniae or S. aureus. Introduction of the pUTKm or pRL27 is accomplished by conjugation between specialised E. coli cloning stains (e.g S17.1 lambda pir and SM10 lambda pir) and recipient organisms, however the pUTKm and pRL27 plasmids do not encode the necessary genes for self-transmission, and these are encoded only on the chromosome of the disabled E. coli donor strains. Furthermore, the pUTKm and pRL27 plasmids are unlikely to replicate outside the specialised E. coli host strains.

Genetic material involved in this work will encode a wide range of functions, related to virulence, biofilm formation and antimicrobial resistance. Some genetic material may be naturally expressed in standard E. coli or L. Lactis disabled cloning strains, but this will not increase the overall hazard above that originally assigned to bacterial species to be studied (Hazard Group 2).

**Origin & function**

**Evaluation of foreseeable effects**

Four main approaches will be applied to the genetic manipulation of the organisms to be studied, and used to identify the genetic basis of virulence, biofilm formation, antimicrobial resistance, and bacteriophage interaction with host bacteria. Bacteriophage capable of infecting and killing the above organisms will also be studied using the same molecular genetic approaches:

1) Mutagenesis
2) Construction of reporter gene libraries and surface display libraries
3) DNA cloning and sequence analysis
4) Genetic complementation

For mutagenesis based strategies (1), transposon DNA carrying selectable markers or reporter genes will be inserted into the chromosomal DNA of species to be studied, or genes of interest inactivated/removed by deletion through site directed mutagenesis based on homologous recombination. Such strategies result in the generation of attenuated mutants, with a reduced fitness in respect to the wild type organisms.

For strategies based on sub-cloning DNA from the organisms to be studied (2,3), cloned DNA will be transferred to standard E. coli or L. lactis disabled cloning hosts. As the cloned DNA may contain virulence genes that are expressed in the E. coli or L. lactis hosts, there is potential to increase the pathogenicity of these organisms.

However, as these inserts will be cloned in disabled level 1 recipient organisms (E. coli and L. lactis standard cloning strains) the overall risk is low and would not result in an increase in associated hazard group above that originally assigned to donor organisms (Hazard Group 2).
Complementation studies (4) involve the transfer of DNA between wild type organisms and derived mutants. As this is a self-cloning procedure (e.g., P. mirabilis donor DNA cloned in P. mirabilis host only) there is no additional risk above that originally assigned to donor organisms, and the overall risk is negligible. Genetic complementation is employed for restoration of a known wild-type phenotype lost in mutants and will not constitute a hazard above that of the original wild-type parent.

Overall inserted and donated genetic material is highly unlikely to increase the pathogenicity of recipient organisms, when using the proposed molecular genetic approaches and host species, and the overall risk associated with the proposed work is low.

Risk to Humans: All organisms to be studied are opportunistic pathogens and do not cause infection in normal healthy individuals. These organisms are already ubiquitous in the natural environment and/or as part of the normal human microbiome. The molecular genetic approaches to be employed will focus on generation of attenuated derivatives which are reduced in fitness compared to wild type organisms.

Risk to Animals: Species to be used do not normally constitute a risk to healthy animals. Infection in animals may also be treated as for humans. Transfer of DNA to E. coli or L. lactis cloning strains may introduce virulence genes to these organisms, but they are unlikely to survive outside the laboratory or pose a significant risk to animals, and the associated hazard will not be greater than that originally assigned to the donor species (Hazard Group 2).

Risk to Plants: Ps. aeruginosa and K. pneumoniae may cause opportunistic infections in plants, but are not typically considered to be plant pathogens. Other organisms have no known ability to cause infection in plants. However, all organisms and derived GMMs will be studied in the context of human infection, and will be handled exclusively in containment level 2 laboratories. All waste will be sterilised before disposal. Therefore, it is highly unlikely that the work undertaken will pose any risk to plants.

Risk to Environment: All GMMs and donor organisms will be handled according to ACDP containment level 2 procedures and as such are highly unlikely to disseminate from the laboratory. As all GMMs created will be the result of mutagenesis procedures, self-cloning, or transfer of DNA from hazard group 2 pathogens (into hazard group 1 disabled cloning strains (E. coli and L. lactis), the resulting GMMs will not possess an ability to displace environmental strains or survive in the environment above that of the original parental species.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be collected in robust, sealed vessels in leak proof secondary containers, and all other waste collected in robust leak proof autoclavable boxes or containers with lids. Waste will be sterilised by autoclaving (121 degrees C for 15 min). Autoclaving will be monitored using standard chemical indicators and the integral diagnostic output of autoclave units, which monitor parameters of each cycle. All autoclaves are regularly serviced and performance validated. Sterilised liquid waste will be disposed of as for standard wastewater. Sterilised solid waste will be disposed of through a specialist laboratory waste contractor.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
The University of Bath GMSC has reviewed the risk assessment for this work and approved the proposed procedures. No issues were identified by the GMSC.

### Project Additional Information

#### Purposes of the contained use

The purpose of using AAV viral particles containing GFP-tagged tau is to develop a more robust neuronal model of tau pathology. Tau is thought to be a key protein involved in the disease mechanisms of Alzheimer's Disease. By creating a neuronal model of tauopathy in vitro we can investigate these pathological mechanisms as well as the ability of dietary flavonoids to reduce this pathology.

#### Recipient or parental organism

Primary cortical neurons derived from embryonic CD1 mice or human neuroblastoma-derived SH-SYSY cells are the recipient organisms.

#### Host/vector system

- **pAAV-hSyn1-GFP plasmid (Addgene #50465)** is used as the vector.
- The AAV viruses are replication incompetent as the vector lacks the genes needed for AAV replication.
- The generation of AAV particles will be outsourced and the host will most likely be HEK293T cells.
- The WPRE element has been removed from the vector plasmid and as such there is no foreseeable risk of oncogenic effects.

#### Origin & function

- The genes of interest code for: GFP, GFP-TauWT or GFP-TauP301 L. GFP, GFP-TauWT and GFP-TauP301 L have been previously inserted in pRK5-CMV or pSF-hSyn1 vector backbones, and these constructs have been validated and characterised in primary cortical neurons. Both tau genes encode for human 4RON isoforms. These genes of interest have been subcloned into the pAAV-hSyn-EGFP plasmid. The hSyn promoter is neuronal specific and confers constitutive expression.
- Tau is a microtubule associated protein which is known to be associated with Alzheimer's disease pathology. The P301 L missense mutation is known to facilitate tau pathology and is sufficient to cause the disease Frontal Temporal Dementia with Parkinsonism on chromosome 17 (FTDP-17). The purpose of transducing cells with these genes is to investigate the pathological mechanisms of tau and whether dietary flavonoids can ameliorate these effects.

#### Evaluation of foreseeable effects

Although certain scenarios can be envisaged that the recombinant viruses may infect human cells, it is very unlikely that the recombinant viruses we intend to generate will cause harm to human health, due to the containment, neuronal-specific expression and replication-deficient nature of the recombinant viruses.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Notices will be placed on the laboratory door, the safety cabinet and the incubator instructing users in the event of...
accidents and spillages. The virus is inactivated using sodium hypochlorite (bleach) at a final concentration of 10%.
Solid waste (pipettes, flasks, etc.) will be placed in a Biohazard bag prior to removal from the microbiological safety

cabinet, enclosed into a second bag outside the cabinet and carried to the autoclave room.
Waste will be autoclaved at 126°C for 30 min completely destroying the viral particles. Contaminated liquid waste will
be disinfected with an appropriate disinfectant (e.g. 10% bleach or 2% Virkon) for at least 30 minutes.
Spillages will be inactivated with 5% ChemGene HLD4H spray, collected with absorbent material and disposed of via
autoclaving.

The University of Bath GMSC has reviewed the risk assessment for this work and approved the proposed procedures.

Maximum culture volume used is one litre.

Waste is deactivated in one of two LTE Scientific Kestrel 150 autoclaves which are operated by trained users according to a Plant Operating Procedure. Validation of deactivation is by temperature monitoring in a timed cycle, viewed on a control panel display and chart read-out. Both autoclaves are checked and serviced once each year by qualified LTE Scientific operatives.

### Project Additional Information

#### Purposes of the contained use
- To improve the concentration of the heterologous protein lysozyme in a novel fermentation system coupled with optimisation of environmental and nutrient conditions.

#### Recipient or parental organism
- Aspergillus niger is classified by ACDP as Group 1. However, as it has been known to cause aspergillosis and otomycosis it is treated here as Group 2.

#### Host/vector system
- The vector is pIGR, a non-selectable G498 fusion vector, which is integrated into the fungal genome and has no transposon-like activities.

#### Origin & function
- The genetic material is the hen egg white lysozyme gene. The intention is to produce lysozyme under fermentation conditions.

#### Evaluation of foreseeable effects
- There is no known hazards associated with lysozyme and it is classified as Generally Regarded as Safe (GRAS). It is unlikely to increase the pathogenicity of the cloned host and there are no foreseeable hazards to the environment.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

</tr>
<tr>
<td>3) Paecilomyces Lilacinus: A well characterised wild type fungus with a history of safe use, but some isolates are reported to infect humans, but isolate used in this proposal does not grow at 37 degrees C.</td>
</tr>
</tbody>
</table>

### Host/vector system

Escherichia coli bacterium carrying well defined and characterised plasmids.
Plasmids are described in detail on attached forms.

### Origin & function

cDNAs

### Evaluation of foreseeable effects

Gene sequences where any biological effect is considered highly unlikely because of the known properties of the proteins.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Work with V. chlamydosporium and P. cucumerina is anticipated to be level 1 (see risk assessment). These fungi are not pathogenic to man, nor do they produce dry spores so containment is thought to be appropriate.

For P. lilacinus work in a CL2 cabinet is appropriate for all GM material. All manipulations and sub-culturing is to be performed in a CL2 cabinet. All material to be sealed and placed in a secure secondary container for storage and transport to prevent escape.

Growth room equivalent to plant growth facility level 2. Material in growth rooms to be contained in clearly labelled sealed containers to prevent accidental escape.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All material, equipment and waste to be autoclaves.

Is an emergency plan required according to regulation 20? [N]
If yes, tick to confirm that it is attached to this form [N]
Tick to confirm that you have attached a risk assessment to this form [Y]
After much discussion amongst committee members, it was agreed that certain parts of this proposal would probably require C2 containment. The proposal was returned to the proposing Scientist asking him to arrange this before final approval could be given.

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change
### Purposes of the contained use
Design and develop a model vector system for wheat transformation, and evaluate its transformation efficiency against conventional bombardment vectors and conditions.

### Recipient or parental organism
- E. coli BL21(DE3)pLysS
- E. coli JM109 for cloning
- Wheat

### Host/vector system
- **Expression vector:** pET11A. This vector is designed for high level protein expression under the control of T7 promoter and is operating only in E. coli strains carrying gene for T7 RNA polymerase.
- **Cloning Vectors:** pGEM-7Zf(-) and pGEM-7Zf(+). These are standard commercial DNA cloning vectors. They contain an Amp resistance marker as well as origin of replication for producing ssDNA. The T7 and SP6 promoters that flank the polylinker, are useful in in vitro transcription experiments but are generally not designed for protein expression. These vectors will be used in E. coli JM109 which do not carry genes for T7 or SP6 RNA polymerases thus avoiding any unwanted transcription or translation from these promoters.

### Origin & function
DNA sequences will be cloned into a pET11a bacterial expression vector, having ampicillin resistance and expression driven by the T7 promoter. Expression will be achieved in E. coli carrying the T7 RNA polymerase gene, inducible by IPTG. The intended function of the gene will be studied in relation to transformation.

### Evaluation of foreseeable effects
Expression host: E. coli BL21(1DE3) PlysS. Part of these mutations are useful for successful protein expression. This strain is incapable of colonising human gut. The expressed T7 lysosome destabilises bacterial cell walls making the E. coli susceptible to mechanical or chemical damage. The strain has an attenuated ability to colonise bird guts but is not able to grow and propagate. The E. coli strain is a standard cloning vector host. The mutations make it non-viable outside favourable laboratory conditions.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Bombarded wheat tissue will be destroyed by autoclaving at 121 degrees C and disposed in deep land field.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
The cloning steps involving pGEM vectors, and culturing in DH10B will be done at CL1, as this does not warrant CL2.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
- Glassware will be autoclaved in the presence of detergent (Savlon) before washing. A special glassware set will be devoted to this work.
- Liquid media will be autoclaved in the presence of detergent (Savlon).
- Centrifuge bottles and tubes will be autoclaved in the presence of detergent (Savlon) before washing.
- Plasticware will be autoclaved in autoclavable polyethylene bags and then will be disposed in deep land field.

**Project Additional Information**
### Purposes of the contained use

Isolates of the oilseed rape fungal pathogen, *Leptosphaeria maculans*, will be transformed with the colour variants of the green fluorescent protein (GFP). The project will compare the efficiencies of two transformation methods commonly used for fungi, PEG-mediated transformation and transformation using *Agrobacterium tumefaciens*. Transformed fungal isolates will be used to infect oilseed rape plants. Using fluorescent confocal microscopy, the progress of infection from the leaves (initial inoculation site) down the petiole and into the stem will be monitored. The response of two genotypes of the fungus (A- and B-type) to fungicide treatments will be monitored to determine whether the genotypes differ in their response to fungicides commonly used to control the disease.

### Recipient or parental organism

The recipient organism (*Leptosphaeria maculans*) is a phytopathogenic fungus which causes stem canker or blackleg disease of brassicas including oilseed rape (*Brassica napus*). Populations of the fungus consist of two main genotypes, designated A- and B-type. A-type isolates are generally considered to be more damaging to host plants than B-type although both genotypes are capable of infecting most brassica species and are common throughout the UK and continental Europe. The asexual spores (conidial) of the fungus are splash dispersed and are known to be highly infective to the host plants. Successful infection by candidia requires the host to be wounded prior to inoculation. The sexual spores (ascospores) of the fungus are considered to be the infectious stage and are airborne. *L. maculans* is not capable of crossing with other fungal species. The fungus is unable to infect humans and is not capable of growth at 37 degrees C. The fungus does not cause known allergies in humans.

### Host/vector system

For propagation of plasmids and nucleic acid sequences, to be used for the transformation of *L. maculans*, a well characterised disabled *E. coli* strain (NovaBlue) commonly used in cloning manipulations will be used. This bacterial strain is not capable of survival in the environment or in humans and consequently does not pose a risk.

The plasmid pGpd-GFP will be used for PEG-mediated transformation of *L. maculans* protoplasts. This vector has a background of pBluescript, a well characterised standard cloning vector. The vector also contains sequences coding for the *Aspergillus nidulans* glyceraldehyde-3-phosphate dehydrogenase (gpdA) promoter, enhanced GFP (eGFP; F64L and S65T mutated form) and the hygromycin B resistance cassette. Colour variants of the GFP gene will be cloned in place of the eGFP gene to enable production of transgenic *L. maculans* expressing these markers.

*Agrobacteium tumefaciens* strain LBA 4404 will be used to transform *L. maculans*. This strain could survive if released into the environment. A tumefaciens is capable of transferring genetic material to plants and fungi but is not pathogenic to, or capable of surviving in humans.

For *Agrobacterium*-mediated transformation of *L. maculans*, the vectors pcJ102 or pSJ34 will be used. These vectors are based on the Glucuronidase Plant Transformation Vector pGPTV-KAN and contain a selectable marker for kanamycin resistance in addition to the uidA (GUS) marker (which will be removed as it is not necessary for this project and the left and right border sequences of the *A. tumefaciens* T-DNA. The gpdA-eGFP-hph cassette from pGpd-GFP will be cloned between the T-DNA border sequences of these plasmids for transformation of *L. maculans*. Colour variants of the GFP gene will be cloned in place of the eGFP gene to enable production of transgenic *L. maculans* expressing these markers.

### Origin & function

**gpdA** - glyceraldehyde-3-phosphate dehydrogenase promoter from *Aspergillus nidulans* used to drive expression of eGFP in transgenic *L. maculans*.

**PtrpC-hph-TrpC** - cassette containing hygromycin B resistance gene from *E. coli* flanked by trpC promoter and terminator sequences from *Aspergillus nidulans* used as a selectable marker to enable identification of successfully transformed *L. maculans*.

**eGFP** - enhanced green fluorescent protein from *Aequoria victoria* jellyfish (and modified colour variants such as cyan and yellow forms) used to enable visualisation of transgenic *L. maculans* in infected oilseed rape plants.
### Evaluation of foreseeable effects

The genes used in this project are purely for marker purposes and none of the inserts used will increase the pathogenicity or host range of the transgenic L. maculans isolates. None of the inserts are known to cause harm to humans, none are toxic or are known human allergens. As a precaution, however, inoculation of oilseed rape plants with transgenic L. maculans spores will be done by applying droplets of spore suspensions to wounded leaves. No spraying will be necessary and this will reduce exposure to researchers.

Transgenic L. maculans isolates will be resistant to the antibiotic hygromycin. However, hygromycin is not used for control of the fungus in diseased crops and hence this characteristic will not impose any selective advantage should escape occur.

The consequences of escape of transgenic L. maculans is considered as low - the pathogen is present normally in oilseed rape crops and is routinely controlled using fungicide sprays. Only asexual conidia will be used in this project and these spores are known not to be highly infective, even to the host species. To reduce the risk of escape, however, leaves will be removed from infected plants before the fungus sporulates. The disease is mainly initiated by airborne ascospores which are only produced if the fungus is allowed to undergo sexual reproduction with a compatible isolate of opposite mating type. Isolates of only one mating type will be used in this project so as to remove the risk of sexual reproduction occurring.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid and solid media cultures used for growth of E. coli and A. tumefaciens and solid media cultures and spore suspensions of transgenic L. maculans will be autoclaved at 127 degrees C for 50 minutes in an autoclave registered for the disposal of genetically modified organisms. 100% kill is achieved using this method and temperatures are monitored using an internal probe. Autoclave equipment is inspected annually to ensure that it reaches the correct temperature and pressure.

Oilseed rape material (leaves, whole plants, soil and material used for microscopy) infected with transgenic L. maculans will be autoclaved at 127 degrees C for 50 minutes in an autoclave registered for the disposal of genetically modified plant material. 100% kill is achieved using temperatures are monitored and recorded using an internal probe. Autoclave equipment is inspected annually to ensure that it reaches the correct temperature and pressure.

All autoclaved material is deposited into a skip, which is emptied into landfill sites by a contractor.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

Comments by GMSC: Part of this project comes under a C2 classification, as such HSE will have to be notified.

### Project Additional Information

**Purposes of the contained use**

**Specific Project Purpose**

- To generate various transgenic strains of the fungus F. graminearum and F. culmorum to
  
a) Quantitate fungal biomass in plants
  b) Determine the fungal hyphal infection route in susceptible and resistant wheat cultivars and other host and non-host plant species
  c) Ascribe a function to specific fungal genes discovered through genomics.
Overall description of the work

Five types of experiments will be performed:

1. Over-expression experiments.

Normally pathogenic strains of F. graminearum and F. graminearum will be used to generate reporter strains. These reporter strains will constitutively co-express the uidA gene from E. coli, that codes for glucuronidase (GUS) enzyme activity and the GFP gene from the jellyfish Aequorea victoria that codes for the green fluorescent protein. Transgenic isolates expressing both GUS and GFP will be selected that have an equivalent growth habit and disease causing ability as the original strains. Details of the exact constructs are given in the next section, and involve either pUC or Bluescript based vectors. The selectable marker initially used for Fusarium transformation will be hygromycin antibiotic resistance. Other markers that may be used include kanamycin or benomyl resistance. Fusarium transformation is achieved using asexual spores and/or hyphal fragments and either protoplast transformation or Agrobacterium tumefaciens mediated transformation methodology (de Grott et al., 1998) Nature Biotechnology 16:839-842).

2. Gene disruption experiments by homologous gene replacement or insertions.

Homologous gene replacement will be used to substitute a gene of interest, identified through genomics/bioinformatics experimentation, with a "null" allele for this gene. At the null allele, will be placed a gene sequence coding for either a bleomycin/phleomycin or hygromycin antibiotic resistance. This will result in a complete loss of function in the gene of interest. Alternatively gene disruptions will be generated by A. tumefaciens mediated transformation of a gene cassette encoding for hygromycin resistance or by in vitro transposition of the EZ-TN transposon (source E. coli) into F. graminearum cosmids and subsequent fungal protoplast transformation.

These novel transgenic fungal isolates will be tested for their ability to (a) infect and cause disease on wheat ear, stem and root tissue, and on various tissues and organs of other host cereal plant species and non-host plant species, (b) produce trichothecene toxins in vitro and in vivo, and (c) to produce asexual conidia and sexual ascospores in vitro.

Where the loss of a specific gene's functions result in an inability or highly reduced capacity to cause disease, produce toxins or generate spores, these isolates will be used in follow up biological and genomics experiments.

Where the reverse is observed, i.e., loss of gene function causes increased disease, toxin production or spore production further experimentation will cease. The isolates will be placed in long term storage and on an annual basis DEFRA will be informed of the frequency of occurrence of this experimental outcome.

3. Transgenic Fusarium strains harbouring fungal promoter:reporter gene fusions

The experiments described in (2) above will lead to the discovery of various Fusarium genes required to invade and cause disease on wheat, to regulate toxin production and to control sexual and asexual spore formation. Follow up transformation experiments will be required to ascertain the exact spatial and temporal patterns of each gene. PUC-based and/or binary plasmid vectors will be made containing the promoter and 3' end sequence of each Fusarium gene of interest fused to a GUS, GFP or GUS:GFP fusion reporter cassette in association with an antibiotic resistance marker cassette required for fungal transformation. The plasmids will be transformed into both wild-type strains and gene knock-out strains. Transformants for further characterisation will be selected where the reporter fusion cassette resides at an ectopic location in the Fusarium genome.

4. Sexual crosses between different transgenic fungal strains.

These experiments will only be performed with F. graminearum because the species F. culmorum lacks a sexual stage. To determine the exact gene hierarchy controlling the various biological processes, it is necessary to make both double knock-out gene mutants (from 2 above), and to combine each single-gene knock out mutant with various promoter: reporter gene fusions (from 3 above) or the constitutive reporter gene construct (from 1 above). Sexual crosses in the laboratory will only involve previously well characterised transgenic strains. It is anticipated that when combining the loss of 2 functionally important genes this will result in the double mutant strain acquiring a phenotype equivalent to one of the original mutant phenotypes.
Where the reverse is observed, i.e., the loss of 2 functional Fusarium genes causes increased disease on plants, greater toxin production and/or greater spore production, further experimentation will cease. The isolate will be placed in long-term storage and on an annual basis DEFRA will be informed of the frequency of this experimental outcome.

5. Mixed fungal strain inoculations on the same plant.
It is currently unclear if each successfully penetrating Fusarium spore establishes a separate mycelial colony within plant tissue, or if a mixed infection develops in the tissue colonised. It is also unknown whether the different Fusarium species colonise to produce a mixed infection, or whether the ear becomes a mosaic of different fungal species colonies. By generating transgenic Fusarium isolates carrying different reporter gene constructs, for example the blue and red variants of GFP, it will be possible to answer these basic biological questions by conducting dual inoculation experiments. We also wish to determine if different gene-knock-out strains, can complement each other in vivo to cause wild-type disease levels. Note: perithecia containing the sexual ascospores are never produced on inoculated ears.

Work involved.
In general the work involves obtaining relevant genes (either through direct cloning from a source organism, or indirectly from third parties), production of ‘gene constructs’ suitable for fungal transformation (via sub-cloning using plasmid vectors and micro-organism hosts), transfer of ‘gene constructs’ into plasmid vectors and host strains suitable for fungal transformation, and fungal transformation. The fungal transformants once produced are then tested for various biological characteristics through laboratory, growth room and glasshouse experimentation.

### Recipient or parental organism

<table>
<thead>
<tr>
<th><strong>Fungal hosts:</strong></th>

<tr>
<td>2) <em>F. culmorum</em> strains 97/7, 98/11, 99w.5Fc</td>
</tr>
</tbody>
</table>

*F. graminearum* and *F. culmorum* both cause ear blight disease of wheat and other cereal species. *F. graminearum* produces both rain splash dispersed asexual conidia and air dispersed ascospores which form within block perithecial structures (approximately 1 mm in diameter) on exposed cereal crop debris. *F. culmorum* only produces rain splash dispersed asexual conidia. The three *F. culmorum* strains to be used in these studies are of UK origin and produce water soluble trichothecene toxins. Two strains, 97/7 and 98/11, are well characterised by our group through extensive laboratory, growth room, glasshouse and field experimentation over the past 4 years. The third *F. culmorum* strain, 99w.5Fc has been used extensively at Rothamsted Research over the last 3 years by the group of Dr Bateman. The two *F. graminearum* strains, PH-1, 16A, selected for study belong to the genetic lineage group 7. This genotype is pandemic throughout the Northern Hemisphere (O’Donnell et al., PNAS (2000) 97:7905-7910). The strains PH-1 and 16A are both of USA origin and also produce water soluble trichothecene toxins. The strain PH-1 has been selected by the world’s academic community for full genomic sequencing in 2002/2003 because of the pandemic distribution of lineage group 7. Both *F. graminearum* strains have been used by our group for the past 3 years under containment facilities and are no more pathogenic to plants than the two selected *F. culmorum* strains or other natural UK isolates of *F. graminearum* and *F. culmorum*. A third *F. graminearum* strain, 10Fg131. of UK origin will also be used. This strain has been used at Rothamsted Research for the past 3 years in the group of Dr Bateman.

*F. graminearum*/*F. culmorum*: Both fungal species are exclusively pathogens of plants and cannot infect humans. Both fungal species produce water soluble trichothecene toxins when they invade plant tissue and also when grown under specific conditions in the laboratory. The trichothecene toxins produced by *F. graminearum* and *F. culmorum* species include 4-acetyl-nivalenol, nivalenol, deoxynivalenol (DON) and other acetylated derivatives. Only if infected plant parts or grain were eaten could cause illness. The target site for the DON toxin is the peptidyl transferase protein in the ribosome, which is required for protein translation. The target sites for other trichothecenes is unproven, although suspected to be in the ribosome.

*F. graminearum* and *F. culmorum* are not included in the list of fungi known to infect and colonise immuno-compromised (AIDS) human patients are are not capable of growth at 37°C. Both fungal species are present in the UK and are routinely imported in slightly infected cereal grain samples destined for human consumption. These grain samples originate from the USA, Canada and other EU countries. The two USA *F. graminearum* strains to be used in our studies belong to genetic lineage group 7. This lineage is pandemic in Europe and North America. (O’Donnell et al. (2000), PNAS 97:7905-7910). Some humans are known to have allergies to fungal spores.
**Host/vector system**

F. graminearum/F. culmorum will be used. The transformation system will be E. coli K12 derivatives and non-mobilisable vectors pUC and Bluescript. The bacterial strains are not capable of survival in the environment or in humans and consequently do not pose a risk.

For A. tumefaciens-mediated transformation of F. graminearum/F. culmorum only the disarmed A. tumefaciens strains GV3101, GV3101:VirG++, LBA 1100, LBA 4404 will be used. As binary vectors pBin19, pSLJ vector series (The Sainsbury Laboratory, Norwich, UK), pGREEN II and derivatives will be used. A tumefaciens is capable of transferring genetic material to plants and fungi but is not pathogenic to, or capable of surviving in humans.

**Origin & function**

1. Specific vectors for fungal transformation

   a) Sources for hygromycin resistance:
      pCB 1003 and pCB1004:
      Both vectors confer resistance to hygromycin B as a dominant selectable marker. The vector backbone of pCB 1003 and pCB 1004 is pUC 19 and pBCSK respectively.
      pHAI1.3 and pUCH2-8

   b) Source of benzimidazole resistance
      pBT3:

   c) Source for phleomycin/bleomycin resistance
      pMON5161

   d) Cloning vector for genomic library preparation
      pMOCosX (M. Orbach, Gene 150:159-162, 1994)
      The vector confers resistance to hygromycin and was used for genomic library preparation of F. graminarum DNA. Individual cosmids carrying 20 kb fragments can be introduced into the fungus by transformation and selection for the hygromycin resistance marker.

   e) Vectors for A. tumefaciens mediated F. graminearum/culmorum transformation
      The pGreenII/pSoup dual plasmid system (see www.pgreen.ac.uk) is used. pSoup contains the Rep A gene function for replication in A. tumefaciens and a tetracycline resistance cassette for selection in A. tumefaciens. pGreenII contains the kanamycin resistance gene for selection in A. tumefaciens, the pSA region for replication in A. tumefaciens and a polycloning site flanked by Left and Right Border sequences essential for T-DNA transfer.

**II. cDNAs and genes**

1. F. graminearum map1 deletion allele (defective protein kinase gene) for construction of non-pathogenic F. graminearum strain.
2. E. coli GUS (uidA); GFP (Aequorea victoria). various colour types avalable commercially for reporter gene constructs
3. Chloramphenicol and Ampicillin resistance (E. coli selectable markers)
4. E. coli lacZ (plasmid backbone)
5. E. coli Byg B Phosphotransferase resistance (hph) gene as fungal resistance marker

III. Gene regulatory sequences
1. Aspergillus nidulans promoters PptrpC and Pgpd and A. nidulans 3' noncoding region TrpC for expression of GUS.GFP reporter genes and for antibiotic gene expression.
2. F. graminearum TR15 and TR17 promoter sequences linked to GUS/GFP reporter genes will be used to monitor TR15/TR17 expression.

IV. E. coli and A tumefaciens cloning vectors, plasmids and transposon for in vitro transposition:
pUC19 - derivatives (pUC18, pUC8, pUC119, pPAN7), pBluescript, pCRII-TOPO, pSPORT, pGEM Teasy, commercially available EZ::TN transposon (www.epicentre.com) carrying an E. coli KAN resistance marker to generate insertions into cosmid pMOcozX.

Evaluation of foreseeable effects

E. coli/Agrobacterium: None. The product of the inserted genes and promoters are unlikely to have biological properties (activities) which may give rise to harm. None of the sequences we intend to use have homology to known toxic proteins.

F. graminearum/F. culmorum: The inserted genes include the reporter genes GUS and GFP. These two proteins are not known to be inherently harmful to humans. Similarly the fungicide (benomyl) resistance gene/protein is not known to present any direct hazard to humans. The preferred antibiotic resistance gene to be used confers hygromycin resistance. This antibiotic is sometimes used in human health care in the UK.

Gene replacement experiments are likely to produce Fusarium strains that are less fit than the wild type but there is a possibility that strains of greater pathogenicity to plants for ability to produce toxin will be generated.

The gene silencing experiments involving Agrobacterium tumefaciens mediated fungal transformation and fungal gene replacement experiments will cause random and targeted disruption/insertions of endogenous Fusarium genes. These gene knockout experiments are again likely to produce Fusarium strains that are less fit than the wild type but there is a possibility that strains of greater pathogenicity to plants or strains able to produce toxins or metabolic bi-products in greater quantities will be generated. Only isolates found to be reduced in pathogenicity, toxin production and/or spore producing ability will be selected for follow up experiments. It is extremely unlikely that these types of experiments will alter the allergenic properties associated with the fungal spores.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid and solid media cultures used for growth of E. coli and A. tumefaciens and solid media cultures and spore suspensions of transgenic F. graminearum/F. culmorum will be autoclaved at 127 degrees C for 30 minutes in an autoclave registered for the disposal of genetically modified organisms. 100% kill is achieved using this method and temperatures are monitored using an internal probe. Autoclave equipment is inspected annually to ensure that it reaches the correct temperature and pressure.

Plant material (leaves, whole plants, soil and material used for microscopy) infected with transgenic F. graminearum/F. culmorum will be autoclaved at 127 degrees C for 30 minutes in an autoclave registered for the disposal of genetically modified plant material. Autoclave equipment is inspected annually to ensure that it reaches the correct temperature and pressure. All autoclaved material is deposited into a skip, which is emptied into landfill sites.
For the F. graminearum strains PH-1, 16A, held under a UK DEFRA import licence liquid cultures will be treated using a double kill procedure, i.e. chemical treatment prior to autoclaving because disposal to a landfill site is not an option.

This was approved subject to the availability of Class 2 containment facilities for the plant/fungal pathogen work. (Taken from the minutes of the GMSC 15 October 2002).

All of these require level 2 plant and laboratory containment. A second category 2 laboratory has been secured in the new building. There is also a possibility of a further room becoming available in the Bawden Building. Class 2 glasshouse facilities are available at Rothamsted. However, growth room containment facilities at class 2 are not yet available at Rothamsted. There is a facility at Long Ashton that can be moved to Rothamsted.

Project Additional Information

Purposes of the contained use

Specific Project Purpose

- To generate various transgenic strains of the fungus *T. yallundae* and *T. acuformis* to

  a. Quantitate fungal biomass in planta

  b. Determine the fungal hyphal infection route in susceptible and resistant wheat cultivars and other host and non-host plant species.

  c. Ascribe a function to specific fungal genes discovered through genomics.

Overall description of the work

Five types of experiments will be performed:

1. Over-expression experiments.

   Normally pathogenic strains of *T. yallundae* and *T. acuformis* will be used to generate reporter strains. These reporter strains will constitutively express the GFP gene from the jellyfish *Aequorea victoria* that codes for the green fluorescent protein. Transgenic isolates expressing GFP will be selected that have an equivalent growth habit and disease causing ability as the original strains. Details of the exact constructs are given in the next section, and involve either pUC or Bluescript based vectors. The selectable marker originally used for *Tapesia* transformation will be hygromycin antibiotic resistance. Other markers that may be used include phleomycin or benomyl resistance. *Tapesia* transformation is achieved using asexual spores and/or hyphal fragments and either PEG precipitation or Agrobacterium tumefaciens mediated transformation methodology (de Grott et al., (1998) Nature Biotechnology 16: 839-842).

2. Gene disruption experiments by homologous gene replacement or insertions.

   Homologous gene replacement will be used to substitute a gene of interest, identified through genomics/bioinformatics experimentation, with a 'null' allele for this gene. At the null allele, will be placed a gene sequence coding for either a bleomycin/phleomycin or hygromycin antibiotic resistance. This will result in a complete loss of function in the gene of interest. Alternatively gene disruptions will be generated by *A. tumefaciens* mediated transformation of a gene cassette encoding for hygromycin resistance or by an in vitro transposition of the EZ:TN transposon (source E. coli) into *Tapesia* cosmids and subsequent fungal protoplast transformation.

   These novel transgenic fungal isolates will be tested for their ability to (a) infect and cause disease on wheat stem and leaf tissue, and on various tissues and organs of other host cereal plant species and non-host plant species, (b) to produce asexual conidia and sexual ascospores in vitro.

   Where the loss of a specific gene's function results in an ability or highly reduced capacity to cause disease, or generate spores, these isolates will be used in follow up biological and genomics experiments.

   Where the reverse is observed, ie, loss of gene function causes increased disease, or spore production further experimentation will cease. The isolates will be placed in long term liquid nitrogen storage and on an annual basis DEFRA will be informed of the frequency of occurrence of this experimental outcome.

   The experiments described in (2) above will lead to the discovery of various *Tapesia* genes required to invade and cause disease on wheat and to control sexual and...
asexual spore formation. Follow up transformation experiments will be required to ascertain the exact spatial and temporal patterns of each gene. PUC-based and/or binary plasmid vectors will be made containing the promoter and 3' end sequence of each Tapesia gene of interest fused to a GUS, GFP or GUS:GFP or GUS:GFP fusion reporter cassette in association with an antibiotic resistance marker cassette required for fungal transformation. The plasmids will be transformed into both wild-type strains and gene knock-out strains. Transformants for further characterisation will be selected where the reporter fusion cassette resides at an ectopic location in the Tapesia genome.

4. Sexual crosses between different transgenic fungal strains.

These experiments will only be performed with T.yallundae. To determine the exact gene hierarchy controlling the various biological processes, it is necessary to make both double knock-out gene mutants (from 2 above), and to combine each single-gene knock out mutant with various promoter: reporter gene fusions (from 3 above) or the constitutive reporter gene construct (from 1 above). Sexual crosses in the laboratory will only involve previously well characterised transgenic strains. It is anticipated that when combining the loss of 2 functionally important genes this will result in the double mutant strain acquiring a phenotype equivalent to one of the original mutant phenotypes.

Where the reverse is observed, ie the loss of 2 functional Tapesia genes causes increased disease on plants and/or greater spore production, further experimentation will cease. The isolate will be placed in long term liquid nitrogen storage and on an annual basis DEFRA will be information of the frequency of this experimental outcome.

5. Mixed fungal strain inoculations on the same plant

It is currently unclear if each successfully penetrating Tapesia spore establishes a separate mycelial colony within plant tissue, or if a mixed infection develops in the tissue colonised. It is also unknown whether the different Tapesia species colonise to produce a mixed infection, or whether the stem base becomes a mosaic of different fungal species colonies. By generating transgenic Tapesia isolates carrying different reporter gene constructs, for example the blue and red variants of GFP, it will be possible to answer these basic biological questions by conducting dual inoculation experiments. We also wish to determine if different gene-knock out strains, can complement each other in vivo to cause wild-type disease levels. Note: perithecia containing the sexual ascospores are never produced within the time scale of pathogenicity experiments.

Work involved

In general the work involves obtaining relevant genes (either through direct cloning from a source organisms, or indirectly from third parties), production of 'gene constructs' suitable for fungal transformation (via sub-cloning using plasmid vectors and micro-organism hosts), transfer of 'gene constructs' into plasmid vectors and host strains suitable for fungal transformation, and fungal transformation. The fungal transformants once produced are then tested for various biological characteristics through laboratory, growth room and glasshouse experimentation.
T. yallundae and T. acuformis are not included in the list of fungi known to infect and colonise immuno-compromised (AIDS) human patients and are not capable of growth at 37°C.

Both fungal species are present in the UK.

The two strains have previously been studied in the UK under our existing DEFRA licence (PHL 184/4031(01/2002) and currently reside in long term storage at Long Ashton research Station, Bristol. The other Tapesia strains to be used are of UK origin.

Some humans are known to have allergies to fungal spores.

### Host/vector system

T. yallundae/T. acuformis will be used. The transformation system will be E. coli K12 derivatives and non-mobilisable vectors pUC and Bluescript. The bacterial strains are not capable of survival in the environment or in humans and consequently do not pose a risk.

For A. tumefaciens-mediated transformation of T. yallundae/T. acuformis only the disarmed A. tumefaciens strains GV3101, GV3101: VirG++, LBA 1100, LBA 4404 will be used. As binary vectors pBin19, pSLJ vector series (The Sainsbury Laboratory, Norwich, UK), pGREEN II and derivatives will be used. A tumefaciens is capable of transferring genetic material to plants and fungi but is not pathogenic to, or capable of surviving in humans.

### Origin & function

1. Specific vectors for gungal transformation
   a) Sources for hygromycin resistance:
      pCB 1003 and pCB1004:

      pAN7-1
      This plasmid confers resistance to hygromycin B. It contains a 2.2kb fragment of the Aspergillus nidulans gpdA promoter upstream of the hygromucycin resistance gene and an 0.8kb fragment of the A. nifulans trpC terminator region downstream of the gene in a pUC 19 backbone. This plasmid has been extensively used for fungal transformation over the last 10 years.

      pHA1.3 and pUCH2-8

   b) Source for phleomycin/bleomycin resistance
      pBT3:
      c) Source for phleomycin/bleomycin resistance

d) Cloning vector for genomic library preparation

pMOcosX (M. Orbach, Gene 150:159-162, 1994)
The vector confers resistance to hygromycin and was used for genomic library preparation of F. graminarium DNA. Individual cosmids carrying 20 kb fragments can be introduced into the fungus by transformation and selection for the hygromycin resistance marker.

e) Vectors for A. tumefaciens mediated F. graminearum/Culmorum transformation.

The pGreenII/pSoup dual plasmid system is used. pSoup contains the Rep A gene function for replication in A. tumefaciens and a tetracycline resistance cassette for selection in A. tumefaciens. pGreenII contains the kanamycin resistance gene for selection in A. tumefaciens, the pSA region for replication in A. tumefaciens and a polycloning site flanked by left and right border sequences essential for T-DNA transfer.

II cDNAs and genes

1. T. yallundae TYG1, TYG2 (G-proteins), PKA (protein kinase A) TYSACH (stretch activated calcium channel) and adenylate cyclase alleles for construction of signal transduction deficient strains.

2. E. coli GUS (uidA); GFP (Aequorea victoria), various colour types available commercially for reporter gene constructs.

3. Chloramphenicol, kanamycin and Ampicillin resistance (E. coli selectable markers)

4. E. coli lacZ (plasmid backbone)

5. E. coli Hyg B phosphotransferase resistance (hph) gene as fungal resistance marker

III Gene regulatory sequences

1. Aspergillus nidulans promoters (PtrpC and Pgpd and A. nidulans 3’ noncoding region TtrpC for expression of GUS/GFP reporter genes and for antibiotic gene expression.

2. T. yallundae actin (TYAC) promoter sequences linked to GUS/GFP reporter genes.

IV E. coli and A. tumefaciens cloning vectors, plasmids and transposon for in vitro transposition:

pUC19 - derivatives (pUC18, pUC8, pUC119, pPAN7), pBluescript, pCR II-TOPO, pSPORT, pGEM Teasy, commercially available EZ:TN transposon carrying an E. coli KAN resistance marker to generate insertions into cosmid pMOcosX.

Evaluation of foreseeable effects

E. coli/Agrobacterium: None. The product of the inserted genes and promoters are unlikely to have biological properties (activities) which may give risk to harm. None of
the sequences we intend to use have homology to known toxic proteins.

T.yallundae/T.acuformis: The inserted genes include the reporter genes GUS and GFP. These two proteins are not known to be inherently harmful to humans. Similarly the fungicide (benomyl) resistance gene/protein is not known to present any direct hazard to humans. The preferred antibiotic resistance gene to be used confers hygromycin resistance. This antibiotic is sometimes used in human anti-cancer therapies in the UK.

Gene replacement experiments are likely to produce Tapesia strains that are less fit than the wild type but there is a possibility that strains of greater pathogenicity to plants or ability to produce toxin will be generated.

The gene silencing experiments involving Agrobacterium tumefaciens mediated fungal transformation and fungal gene replacement experiments will cause random and targeted disruption/insertions of endogenous Tapesia genes. These gene knockout experiments are again likely to produce Tapesia strains that are less fit than the wild type but there is a possibility that strains of greater pathogenicity to plants will be generated. Only isolates found to be reduced in pathogenicity and/or spore producing ability will be selected for follow up experiments. It is extremely unlikely that these types of experiments will alter the allergenic properties associated with the fungal spores.

### Purposes of the contained use

To express genes for enzymes (e.g., protease, chitinase) from Pochonia chlamydosporia and other non-pathogenic fungi, and proteins involved in cell-cycle regulation from free-living or plant parasitic nematodes (Caenorhabditis elegans, potato cyst nematodes), in suitable plant host roots, to examine any nematicidal effects. Transgenic roots will be produced using *A. rhizogenes* containing pBin-type binary vectors with the fungal or nematode genes in the T-DNA.

### Recipient or parental organism

The recipient will be non-disarmed Agrobacterium rhizogenes (containing a functional Ri plasmid). This will be transformed, using electroporation, with pBin 19-type vectors constructed in *E. coli*, containing fungal or nematode genes with plant promoters (constitutive or induced in the root cells where nematodes are feeding). The *A. rhizogenes* will be used to induce hairy roots on suitable host plants including some species of the Solanaceae group (tomato, potato, tobacco) and others, such as Lotus japonicus and Arabidopsis thaliana. The class 2 activity concerns the use of *A. rhizogenes* which is classified as a plant pathogen. The presence of fungal or nematode genes, unlikely to be expressed in this bacterium, is not expected to increase the pathogenicity or host range of *A. rhizogenes*.

### Host/vector system

* A. rhizogenes strains LBA9402 and 8196/pBin 19-type binary vectors.

### Origin & function

The origin of the genes (proteases, chitinases, cell cycle regulators) will be non-pathogenic nematophagous or entomopathogenic fungi, or free-living (*C. elegans*) or plant parasitic nematodes. The origin of the promoters to drive expression of the genes in plants will be constitutive and inducible plant promoters. The pBin19-type vectors are well characterised. The function of the genetic material is to be co-transformed into plants during hairy root induction by *A. rhizogenes*, to express fungal enzymes in these roots that can then be assayed for resistance to infection by plant pathogenic nematodes in enclosed assays. Whole plants may be regenerated from transformed material - these will be checked to ensure they are free from *A. rhizogenes* before any nematode infection assays on a larger scale are undertaken - this will no longer be a Class 2 activity.

The agrobacteria are held at Rothamsted under Plant Health Licence PHL 174/4099(02/2002) which will also cover the use of the genetically modified derivatives. Plant parasitic nematodes are held at Rothamsted under licence PHL 174A/4485(04/2003).

### Evaluation of foreseeable effects

It is highly unlikely that the fungal or nematode genes will express in *A. rhizogenes*, as they will be inserted in the T-DNA of the binary vector pBin19, with a plant promoter. There is not normally any significant expression of genes within the T-DNA in bacteria. In the unlikely event that they are expressed, it is not anticipated that they will increase. *A. rhizogenes* plant pathogenicity or host range.

The intention is to examine the effect of these genes on transfer to plants and it is anticipated that they may have some effect in preventing infection by plant parasitic nematodes.

### Confinement and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Plants will be transformed by co-culture with the *A. rhizogenes* at level 2 containment. Transformed plants will be treated with appropriate antibiotics or sterilants to kill the live agrobacteria before subsequent experiments. However, some nematode infection assays may be carried out on hairy roots on the host plants in sealed containers in a locked growth cabinet before removal of the agrobacteria has been verified.

If plants are regenerated from hairy roots they will be checked for the absence of *A. rhizogenes* before moving to the appropriate level of containment. Experiments with regenerated transgenic plants and their progeny will be performed in the GM glasshouse facilities to avoid pollen dispersal.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste material (bacterial cultures, plants, nematodes, growth media and disposable plasticware) from this project will be subjected to autoclaving, using a validated autoclave, prior to disposal with other laboratory waste. Glassware will likewise be autoclaved before washing and reusing. This autoclave, No. 1 in Room 238 (building 60) is checked annually. It is set on a waste sterilisation and kill cycle of 1 h at 121 °C, 15 psi, each cycle logged and if these prescribed conditions are not met, the load will be re-autoclaved.

Non-GMM Consent Granted  

Consent Granted: not applicable

Project notified under transitional arrangements  

N
Project Additional Information

Purposes of the contained use

To construct gene libraries from bacterial genomic DNA obtained directly from environmental populations and with no prior culturing, the libraries to be screened in different, non-pathogenic, bacterial hosts for any clones that contain genes that determine phenotypes of importance in the nitrogen cycle and in certain biotechnological applications.

Recipient or parental organism

The hosts will be Escherichia coli K12 and derivatives thereof; and a wide range of bacteria including rhizobia, Paracoccus, Streptomyces spp, Bacillus subtilis, Azotobacter vinelandii, Rhodobacter spp., non-pathogenic Pseudomonas, Burholderia, Alkaligens and related "pseudomonad" spp., and Nitrosomonas spp. E coli K12 is unable to colonise the human gut and the other genera will be chosen on the basis that, as far as is known, they are unable to cause any damage to animals, plants or the environment. These strains will be hosts for Metagenomic libraries containing DNA fragments obtained directly from bacteria isolated from the environment and cloned in cosmid vectors. By their nature, such libraries and the individual recombinant plasmids within them will be very varied in their identities. Therefore, the characteristics of any given GMO are impossible to predict.

Host/vector system

DNA will be obtained, en masse, from bacterial cells in natural populations from a range of environments. The functions to be tested initially will be the ability to confer individual steps in the Nitrogen cycle - nitrogen fixation, nitrification and denitrification. However, the libraries will also be screened for genes involved in other, known bacterial transformations including the synthesis of enzymes (eg protease and lipase) of biotechnological value and for the presence of genes (eg for polyketide synthesis) involved in the synthesis of novel antibiotics. Other genes may be sought but in no case will these include functions (eg toxin production) that are immediately deemed to be hazardous. The process of cloning DNA extracted from the soil community means the frequency which particular genes are represented in the library will reflect their abundance in soil. Relatively uncommon pathogenic bacteria are very unlikely to be represented in the library and the processes will reflect their abundance in soil. Relatively uncommon pathogenic bacteria are very unlikely to be represented whereas abundant bacteria (and genes) will be well represented. This can be justified by the observation that soil is not a potent source of virulent human pathogens nevertheless common sense dictates that the soil metagenomic libraries should be treated with caution at C2. Similarly, until the frequency of different types of genes in the library is investigated, we cannot be sure that it is dominated by innocuous housekeeping genes.

Evaluation of foreseeable effects

As stated above, exact foreseeable effects are hard to determine, just as would be the case when plating out samples of soil, mud, deep ocean water etc on appropriate microbial growth media. However, the hosts to be used for the libraries are compromised, non-colonising, and will be grown in small volumes. Therefore it is extremely

unlikely that any large-scale escape will occur and that even in the unlikely event of a single clone having a vast selective advantage, compared to the parental strain, the numbers involved would be so low as to compare with the natural exchange of genetic material between different bacteria in the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid and solid media cultures used for the growth of E.coli will be autoclaved at 121 degrees 15 psi for 60 minutes in an autoclave registered for disposal of genetically modified organisms; 100% kill achieved using this method and temperatures monitored using and internal probe. Autoclave equipment is inspected annually to ensure it reaches correct temperature and pressure. The autoclave run is recorded so it can be repeated in case the required temperature and pressure are not achieved for the prescribed period.

All contaminated glassware and plastics will be treated either by autoclaving or with a broad-spectrum disinfectant. Liquid waste, once treated, will be disposed to drains; solid disinfected waste (plastics, agar) will be double bagged and disposed of in the general waste skip.

### Project Additional Information

#### Purposes of the contained use

Screening of candidate nematode genes on suitable host plants in a search for necrosis phenotypes.

---

#### Recipient or parental organism

Agrobacterium tumefaciens strain C58C1 containing the helper plasmid pCH32. The pCH32 plasmid carries two vir genes (vir E and vir G) and resistance to tetracyclin. This plasmid is under kanamycin selection.

---

#### Host/vector system

Expression vector pSfinx (described in full detail in Takken et al. 2000 J.24(2):275-283). This is binary, potato virus X (PVX)-based expression vector. It contains the left and right border of the T-DNA sequences. The expression of the PVX sequence, consisting of replicase, triple block and protein genes, is driven by the 35S promotor. Two SfiI sites are used for cloning of the cDNAs. The vector also contains a neomycin-phosphotransferase II sequence. Viral-encoded suppressor vector of gene silencing 35S:p19 (described in full detail in Voinnet et al. 2003 Plant J. 33:949-956). This vector contains the p19 and the HcPro sequences of the tomato bushy stunt virus inserted into the binary vector pBin61.

---

#### Origin & function

The expression library will be constructed with cDNAs from the potato cyst nematode Globodera rostochiensis, which is endemic in the UK. This library will contain the transcriptome complement of the nematode at the moment of genetic material extraction (parasitic stage J2-J3), which may include paratism-pathogenicity-factors.

We aim at selecting nematode cDNAs from the library, out of a screen on suitable plant genotypes, that elicit a cell death phenotype (hypersensitive response). Vector 35S:p19 will be co-inoculated to avoid possible gene silencing of nematode cDNAs in planta.

The putative functions of the selected cDNAs might be related to the initiation and/or signal transduction leading to cell death. Some of these cDNAs could also be recognised specifically resistant host genotypes.

---

#### Evaluation of foreseeable effects

The expression library of parasitic nematode cDNAs will be expressed by the PVX-based binary vector pSfinx. The library will then be introduced in the A. tumefaciens strain C58C1 for sorting and expression of individual clones on suitable plant genotypes in a search of nematode cDNAs eliciting visible phenotypes. The bacteria transfer the expression vector to the plant cells, and the CaMV 35C promotor drives the synthesis of infectious recombinant PVX transcripts. These transcripts subsequently initiate the formation of virus particles that infect the tissue surrounding the inoculation site.

The modified PVX-expression vector, into which the nematode cDNAs will be inserted, is not thought to cause harm to humans or animals. PVX is a plant virus with restricted range of hosts (some Solanaceae crops such as tomato and potato). Potato virus X could be virulent to other non-target host plants. The nematode genes integrated into the PVX vector are thought not to add any more risk than the vector alone.

It is extremely unlikely that the products of the G. rostochiensis genes inserted into the PVX-based expression vector have biological properties or activities which may give rise to human or animal harm. However, it is unknown if the plant cyst nematode G. rostochiensis genome encodes for any toxin that can have a deleterious effect on human health. Some of the cyst nematode genes inserted into the PVX may be pathogenicity determinants for their natural hosts, but it is very unlikely that these factors (or any other non-pathogenicity factors) would work synergistically with PVX to alter or affect this virus features.

The experiments will use modified viruses that are as virulent or less virulent than the wild type constructs. The most virulent constructs would allow the ability to survive, establish and disseminate in the environment. However, given the use of the GM containment facilities and the known fact that PVX is not transmitted by invertebrate vectors or true seed, there is only a low likelihood of hazard from these experiments.

The most severe consequence of survival, establishment and dissemination would be the mild disease caused by PVX in potato and tomato used in other experiments.
PVX infection is already widespread but does not cause serious agronomic problems even in the susceptible cultivars. Thus the worst case scenario is that there would be a low consequence of hazard. The risk of harm is therefore low. The risk will be managed by ensuring strict compliance with the containment procedures in the nematode glasshouse GH40 at Rothamsted Research.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A.

However, since the screening of the nematode expression library will be carried out in plants, GM containment glasshouse space for nematode work (GH40) will be used for this purpose. After plants are inoculated, transient expression of individual clones on plants will be carried out. Visible phenotypes will be expected to appear in the plants 2-3 weeks after inoculation of clones. Inoculated plants used for screening will be autoclaved after use following the standard operating procedures put in place for this glasshouse space and material (procedure BB_QA_Doc/0589/002 enclosed) for work with the transformed/genetically modified plants in the nematode glasshouse.

Entry to these glasshouses is restricted to users. Doors are kept locked at all times, with entry by coded entry blocks.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

PVX-based expression library. All materials (solid or liquid cultures) not used for the construction and/or screening of the library will be treated and disposed by heat treatment (autoclaved in autoclave bags).

Plants used for screening. After inoculation and selection of individual nematode clones on plants in the containment glasshouse, plants will be destroyed by autoclaving and disposed.

All selected, post-screening Agrobacterium colonies (on solid or liquid cultures) that are not for further studies will be disposed of after autoclaving.

Autoclaving conditions for disposal of all materials are 121 C, 15psi, 60 minutes. Temperature of autoclaving is monitored using an internal probe. Autoclave runs are recorded and checked. Autoclave equipment is inspected annually.

The GMSC was satisfied that the work could be conducted at CL2.

### Project Containment

**Laboratory Activities**

**Glass Houses**

**Growth Rooms**
Rhynchosporium secalis is a phytopathogenic fungus causing leaf scald, an economically damaging disease in barley. This project's aims are:

1) To investigate asymptomatic infection in susceptible and 'resistant' host cultivars, using strains transformed with fluorescent marker genes;
2) To investigate sensitivity to chemical control, by silencing genes that may be associated with reduced fungicide sensitivity.

Two types of experiment will be performed:

1) Isolates of the phytopathogenic fungus Rhynchosporium secalis will be transformed with visible marker genes encoding colour variants of the green fluorescent protein (GFP) and red fluorescent protein (DsRed) under the control of either constitutive fungal promoters or endogenous inducible promoters isolated from virulence factors. Transformation using Agrobacterium tumefaciens will be compared with transformation using traditional PEG-mediated procedures. Host plants and seeds will be infected with transformed isolates by application of a spore suspension and the progress of infection will be monitored by confocal microscopy under UV light.

2) Homologous gene replacement will be used to substitute a gene with a "null" allele for this gene. At the null allele, will be placed a gene sequence coding for hygromycin antibiotic resistance. This will result in a complete loss of function in the gene of interest. Alternatively gene disruptions will be generated by A. tumefaciens mediated transformation of a gene cassette encoding for hygromycin resistance or by in vitro transposition of the EZ: TN transposon (source E. coli) into cosmids and subsequent fungal protoplast transformation.
Recipient or parental organism

The recipient organism (Rhynchosporium secalis) is a phytopathogenic fungus which causes leaf blotch of barley (Hordeum vulgare L.) The fungus is unable to infect humans and is not capable of growth at 37°C. The fungus does not cause known allergies in humans. None of the micro-organisms used are capable of infecting domestic or wild animals. None of the micro-organisms used are listed in ACDP hazard groups 2, 3 or 4. The pathogen is not controlled by Defra and no licence is required. Populations of the fungus consist of two mating types (I and II). The infection is often asymptomatic in early infection and it is unknown as to how seed-borne infection plays a role in the proliferation of the fungus. The asexual spores (conidia) of the fungus are splash dispersed. The putative sexual spores (ascospores) of the fungus have yet to be identified.

Host/vector system

For cloning purposes, E.coli K12 derivatives will be used. These disabled bacterial strains are not capable of survival in the environment or in humans and consequently do not pose a risk.

For transformation, the disabled A. tumefaciens strains AGL1 and/or LBA4404 will be used. These strains could survive if released into the environment. A. tumefaciens is capable of transferring genetic material to plants and fungi, but it is not pathogenic to, or capable of surviving in humans.

Origin & function

gpdA - glyceraldehyde-3-phosphate dehydrogenase promoter from Aspergillus nidulans used to drive expression of eGFP in transgenic R. secalis - non-harmful.
PtpC- hph- TrpC - cassette containing hygromycin B resistance gene from E. coli flanked by trpC promoter and terminator sequences from Aspergillus nidulans used as a selectable marker to enable identification of successfully transformed R. secalis - non-harmful.
eGFP - enhanced green fluorescent protein from Aequoria victoria jellyfish (and modified colour variants such as cyan and yellow forms) used to enable visualisation of transgenic R. secalis in infected barley plants - non-harmful DsRed - red fluorescent protein from Discosoma (sea anemone) - non-harmful.

None of the inserts are known to cause harm to humans, none are toxic or are known human allergens. As a precaution, inoculation of barley plants with transgenic R. secalis spores will be done by applying droplets of spore suspensions to barley leaves and seeds. No spraying will be necessary and this will reduce exposure to researchers.

Evaluation of foreseeable effects

The genes used in this project are purely for marker purposes and none of the inserts used will increase the pathogenicity, host range or fungicide resistance of the transgenic R. secalis isolates. The inserted DNA does not have any potentially harmful biological activity and is not a toxin, oncogenic protein, allergen or hormone. The inserted DNA does not encode a pathogenicity determinant. The inserted DNA will not alter the host range of the pathogen. The inserted DNA encodes resistance to the antibiotics kanamycin and hygromycin - these antibiotics are not used for the treatment of laboratory-acquired infections, nor for the agricultural control of R. secalis.

The gene silencing experiment is expected to give unaltered or increased sensitivity to fungicides, since naturally-occurring R. secalis isolates lacking a functional Cyp51A gene have higher triazole sensitivity, and previous studies in Aspergillus fumigatus (Antimicrobial Agents and Chemotherapy 49 (6): 2536-2538) and Fusarium species (Phytopathology 99(5): 487-497) have found Cyp51 disruptants to have increased or unaltered sensitivity to DMI fungicides. Only cases of increased fungicide sensitivity of transformants would be tested in planta.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A: GM micro-organism only
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid and solid media cultures used for growth of E. coli and A.tumefaciens and solid media cultures and spore suspensions of transgenic R. secalis will be autoclaved at 127°C for 30 minutes in an autoclave registered for the disposal of genetically modified organisms. 100% kill is achieved using this method and temperatures are monitored using an internal probe. Autoclave equipment is inspected annually to ensure that it reaches the correct temperature and pressure. All autoclaved material is deposited into a skip, which is emptied into landfill sites.

All R. secalis liquid cultures will be treated using a double kill procedure, i.e chemical treatment prior to autoclaving.

Plant materials (leaves, whole plants soil and material used for microscopy infected with transgenic R. secalis will be autoclaved at 127°C for 30 minutes in an autoclave registered for the disposal of genetically modified plant material. Autoclave equipment is inspected annually to

Project Ref 92/10.3

Date Ackn’d CU2 Project Title Class Culture Vol Class 2 Culture Vol Class 3-4

02/03/2022
Analysis of Gaeumannomyces graminis var. tritici and Magnaporthe oryzae infection of cereal roots and visualisation of green fluorescent protein (GFP)-transformedMagnaporthe oryzae during infection of cereal roots

Purposes of the contained use

(a) To intercompare the infection biology of these two root infecting species.
(b) To use the reporter strain of the Magnaporthe oryzae fungus as a surrogate for Gaeumannomyces graminis var. tritici when investigating the genetic basis of resistance identified in various cereal species.
(c) To explore in depth the cellular and molecular basis of resistance to Magnaporthe oryzae and Gaeumannomyces graminis var tritici.

Recipient or parental organism

G. graminis var. tritici (Ggt) causes take-all disease of cereals and grasses, and M. oryzae causes rice blast disease. Both are economically damaging fungal diseases. No GM strain of Ggt will be used in experiments, only wild type isolates collected from the field. The Ggt cultures will be used to compare infection of wheat roots with wild type M. oryzae strain Guy-11 and a GFP-transformed M. oryzae strain.

Magnaporthe oryzae (previously called M. grisea) is an economically damaging fungal pathogen causing Rice Blast (Baker et al., 1997). The process of infection of rice plants by M. oryzae is typical of foliar pathogens (Xu et al., 1997). The air-borne asexual spores, conidia, attach to leaf surfaces upon contact. Under moist conditions the conidia germinate producing germ tubes that can form specialised infection structures, appresorium, that penetrate through the leaf surface. Bulbous infection hyphae colonise the initially infected cells, from these develop filamentous hyphae which then spread rapidly between plant cells causing visible lesions on the plant surface. Under high humidity mycelia within the lesion sporulate producing conidia to start the infection cycle again.

M. oryzae strains can infect a range of temperate cereals and grasses but individual strains have limited host ranges (Valent & Chumley, 1991). M. oryzae strain Guy11 (the strain stored at Rothamstead Research and to be used in experiments; Leung et al., 1988; Chao and Ellingboe, 1991) can cause disease on the leaves of rice as well as barley and the model grass species Brachypodium distachyon (Parker et al., 2009). Under the experimental conditions M. oryzae can also be inoculated onto barley and wheat roots and causes visible disease symptoms (Dufresne and Osbourn, 2001). In rice, root infections can spread to the aerial parts of the plant and so may contribute to epidemic development in the field under natural conditions (Sesma & Osbourn, 2004).

Natural infections of M. oryzae on barley have previously not been recorded (Sweigard et al., 1998) but in 2007 field infections of M. oryzae on barley were reported for the first time in Brazil (Lima et al., 2007). Under experimental conditions high relative humidity and temperature (greater than 24°C) are required for infections on barley and...
Brachypodium. Conditions in the UK are unfavourable for rice blast development so it is unlikely to pose a significant threat. *M. oryzae* is also distributed throughout the rice growing regions of Europe (including Southern France, Italy, Portugal, Spain and Hungary; (Roumen et al., 1997)) so if it was to be a threat in the UK it is likely that it would already be a problem.

References

Host/vector system
*M. oryzae* cultures will be inoculated in plant pathogenicity assays onto the roots of cultivars of hexaploid, tetraploid and diploid wheat species to compare the infection process with that of the root attacking fungus *Gaemannomyces garminis* var. *tritici*. Various other cereal species will be included as additional controls in some experiments. These will be oats, barley, rye, triticale and rice. In the field *M. oryzae* causes leaf blast disease on a range of temperate cereals but under experimental conditions it has been shown to be able to infect rice, barley and wheat roots.

Origin & function
The genetic material involved is a GFP-transformed strain of *M. oryzae*. No transformation of *M. oryzae* will be carried out as part of this project. The GFP transformed strain to be used in plant infection studies is already stored at Rothamstead. The H3:eGFP strain (Veneault-Fourrey et al., 2006) carries the eGFP gene fused to the C-terminus of the histone E11-encoding gene hH1 from *Neurospora crassa* under control of the CCG1 constitutive promoter. The strain displays fluorescent nuclei and is hygromycin resistant. The expression of enhanced green fluorescent protein (eGFP) will be used to visualise transgenic *M. oryzae* in infected wheat plants and compare the infection process in resistant and susceptible wheat cultivars.

Reference

Evaluation of foreseeable effects
There are no foreseeable harmful consequences of the release of these fungi, either for human health or the environment.

The inserted DNA in the H3:eGFP *M. oryzae* strain does not have any potentially harmful biological activity and is not a toxin, oncogenic protein, allergen or hormone. The inserted DNA also does not encode a pathogenicity determinant and will not alter the host range of the pathogen. The inserted DNA encodes resistance to the antibiotic
Hormycin - this antibiotic is not used for the treatment of laboratory-acquired infections. Finally, the inserted DNA does not encode resistance to any disease control measures such as fungicides. The genes used to transform the GFP M. oryzae strain are purely for marker purposes and none of the inserts have been shown to increase the pathogenicity or host range of the transgenic GFP M. oryzae strain. eGFP is also not harmful to humans.

Conditions in the UK are unfavourable for rice blast development so it is unlikely to pose a significant threat. M. oryzae is also distributed throughout the rice growing regions of Europe (including Southern France, Italy, Portugal, Spain and Hungary; (Roumen et al., 1997)) so if it was to be a threat in the UK it is likely that it would already be a problem. None of the micro-organisms used are capable of infecting domestic or wild animals.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable to this application.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste: To discard plants at the end of each inoculation experiment in a Containment Level 2 growth room/glasshouse, a microbiological lab coat and gloves will be worn. All the aerial plant parts will be cut and placed in large plastic bags for autoclave disposal. Any soil, vermiculite, pots, capillary matting and labels will be collected into autoclave bags in the large stainless steel bins. Bags weights should not exceed 5kg. Bins should only be half full before they are sealed and taken directly to the autoclave. The solid trays will be wiped down with Microsol 3 (Anachem) disinfectant as a 1 in 10 dilution in water before a new experiment is initiated. The autoclave cycle will be 121°C for 30 mins for soil or large volumes of plant material. The autoclave will be monitored to determine that sterilisation cycle has been successfully completed. Bins must be taken directly from the growth room component to the autoclave and autoclaved immediately. Waste material should be bagged for disposal within the growth room/glasshouse in which it was generated. Transport of GM and/or licensed materials for disposal must always be in double contained bags and transported in a metal box with a lid. Once the box has been placed inside the autoclave the lid is carefully removed and placed by the side of the box within the autoclave. Ensure that bags are left open to allow steam to get into the bag. If the autoclave is in use the full bags will be sealed and left in the growth room until the first opportunity to undertake the autoclaving becomes available. This entire procedure will be undertaken only by members of the research team.

Liquid waste: To discard any liquid waste a microbiological lab coat and gloves will be worn. Any waste water or Hoaglands solution (plant growth solution for hydroponics) will be poured into 1 litre flasks as 750 ml batches, situated in the deep trays, in the growth rooms/glasshouse compartments. To each flask Microsol 3 will be added to give a final dilution of 1 in 50, i.e. 15 ml per 750 of waste water. The flasks will be wiped down with Microsol 3 (1 in 50 dilution) and transferred to a cleaned tray. They will then be transported in theses clean deep trays to the autoclave for disposal with an autoclave cycle of 121°C for 30 mins. This double kill procedure should ensure no live organisms enter the drainage system.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The Rothamstead Genetic Manipulation Safety Committee has carefully considered the attached Risk assessment and the appropriateness of the containment measures proposed and has given approval for the work to proceed at Containment level 2 once ratified by the HSE.

### Project Additional Information

**Purposes of the contained use**

This is a connected programme of work, comprising of the following activities (from the highest perceived risk to the lowest):

A.1 (RRes GM project 158). Use of Barley stripe mosaic virus (BSMV) vector for transient overexpression of Fusarium graminearum predicted secreted proteins (i.e. putative effectors) in the leaves and ears of cereal plant species.

A.2 (RRes GM project 157). Identification and characterisation of genes in cereal plant species required for disease and/or resistance against floral tissue invading fungal phytopathogens using BSMV-mediated Virus-induced gene silencing (VIGS)
A.3 (RRes GM project 156). Functional characterisation of genes expressed in floral tissues and/or grain and controlling yield and various other sustainability traits in cereal plant species using BSMV-VIGS (non-pathology projects).

B.1 (Rres GM project 154). Transient BSMV or Agrobacterium tumefaciens mediated overexpression of Mycosphaerella graminicola predicted secreted proteins (ie putative effectors) in the leaves of cereal plant species.

C (RRes Gmproject 155). Functional characterisation of genes in cereal plant species required for growth and development , and those involved in resistance or required for disease caused by leaf tissue invading fungal phytopathogens using BSMV-VIGS.

D (RRes GM Projects 152 and 153). Investigating the role of different plant defence signalling pathways against phytopathogenic fungal species using GM non-flowering and flowering plants.

NOTE: Only activities A.1 and A.2 will require the use of the higher level (containment level 3) facilities. All other activities will require the use of containment level 2 facilities.

There are three classes of GMOs involved in the proposed programe of work.

1) Barley stripe mosaic virus (BSMV) engineered to express secreted fungal proteins or carrying short fragments of various cereals genes in antisense orentation (activities A.1, A.2, A.3, and C). BSMV only infects plants and is not known as a hazard to human health, nor is there any reason to suppose that it could be unless specifically modified to express toxic proteins or proteins that repoduce toxic products.

2) Wild type or GM strains of the phytopathogenic fungal species Magnaporthe oryzae and Rhychosporium secalis carrying reporter genes and Mycosphaerella graminicola, Fusarium graminearum and F. culmorum with reporter genes or silenced genes (activities A. 2, C and D). All of theses fungal pathogens are solely pathogens of plants and do not infect humans. None of the pathogens, except for F. graminearum and F. culmorum, have been known to produce toxins that are harmful to humans. F. graminearum and F. culmorum produce water soluble trichothecene toxins when they invade plant tissue which may cause poisoning of humans if the infected grain is eaten.

3) Wild type, induced mutants or GM cereal plant species (all activities) and A. thaliana plants (activity D only).

In most of the projects only wild-type plants will be used as hosts. The host plant species that will be used are hexaploid wheat (Triticum aestivum), einkorn wheat (T. monococcum), barley (Hordeum vulgare), maize (Zea mays), rice (Oryza sativa), Brachypodium species, Nicotiana benthamiana and Arabidopsis thaliana. On some projects we will also use GM plants that constitutively express reporter proteins eg GFP (green fluorescent protein), either constitutively express or have reduced levels of expression due to RNAi of genes implicated in resistance to various plant pathogens (see below).

The pollen of flowering plants can be an allergen. However, it is highly unlikely that the fungal species used or BSMV will increase allergenic effects of pollen from host plants, or cause the production by the experimental plants of other unknown allergens or toxins posing health hazard to humans.

1) The genes to be inserted into BSMV for transient in planta expression are predicted secreted proteins of unknown function which have been identified in the genome sequence of the cereal plant species infecting ascomycetous fungi Fusarium graminearum (activity A.1). A subset of predicted secreted proteins from each fungal species (~200 from F. graminearum, ~200 from M. graminicola, and ~50 from R. secalis) will be selected based on expression profiling experiments and further sequence anlyses.
Limitations are also placed on the number of genes we could test based on a maximum insert size of less than 700-nt which is stable in the BSMV vector. The encoded proteins contain no recognisable homologous or functional domains and it is highly likely that they function specifically in these host-pathogen interactions. None are currently known to be toxins. These projects aim to gain new information on the functions of these fungal putative effector proteins during plant pathogenesis and/or disease resistance.

For transient gene silencing (ie VIGS), short 100-500-nt fragments of various cereals genes will be inserted into the BSMV genome in antisense orientation (activities A.s, A.2, A.3 and C). Plant inoculation with these GM BSMV is expected to induce silencing of endogenous leaf, root, flowering-tissue and/or grain-expressing genes with homology to the 'transgene' sequence carried by BSMV.

2) The reporter genes present in the GM fungal species used (M. graminicola, F. graminearum, F. culmorum, M. oryzae and R. secalis) are green fluorescent protein (GFP) from Aequorea victoria or β-glucuronidase (GUS) from E.coli. They will be used to track the presence and progression of fungal pathogen infection in host plant tissues. In addition, we will use transgenic F. graminearum, F. culmorum, or M. graminearum strains with a single endogenous gene of interest disrupted in each strain, resulting in a 'null' allele for the disrupted gene and a complete loss of gene function. The disrupted fungal genes are those required for pathogenicity or for the synthesis of toxins. Only strains found to be equal or less pathogenic on plants, or cause the accumulation of lower levels of toxins in the host plant compared to wild-type strains will be used.

The use of transgenic M. graminicola, F. graminearum and F. culmorum on non-GM plants is covered by Defra licence PHL174C/6222. In this programme of work, we propose to use these transgenic fungal species on GM plants (activity D) or in conjunction with GM BSMV on wild-type or GM plants (activities A.2, A.3 and C).

3) Most of the gene sequences transformed into the GM cereal plant species and A. thaliana plants that are to be used (activities A.2, A.3, C and D) are from the original or other plant species. These plants will either constitutively activate, or be compromised in the ability to activate, one or more of several signalling pathways involved in plant defence against phytopathogenic microbial or fungal species. Some experiments may also involve the use of GM plants transformed with either GFP or GUS reporter genes.

Evaluation of foreseeable effects

There is no anticipated risk of GM BSMV posing any harm to human or animal health as the virus is exclusively a plant pathogen. Also there are no reasons to believe that the fungal gene or plant gene sequences to be inserted into the BSMV vector may pose any risk to human or animal health. The experiments involving BSMV will pose a potential environmental hazard if BSMV-induced down-regulation of endogenous plant genes in infected plants (1) results in developmental defects severely compromising crop yield, (2) severely compromises a host defence reaction, or (3) dramatically enhances plant susceptibility to BSMV itself or to other pathogens of cereal crops. In the initial VIGS experiments the plant phytoene desaturase (PDS) gene involved in the synthesis of carotenoids will be used as a control measure the efficiency and extent of silencing. Down-regulation of this gene results in macroscopically visible photo-bleaching due to chlorophyll photo-oxidation (Kumagai et al., 1995, Proc. Natl. Acad. Sci. USA 92: 1679-1683). Accidental release of the BSMV:PDS VIGS vector may harm the environment as initially infected wheat and barley plants will have reduced photosynthetic ability, which will have a knock-down effect on crop yield.

It has been previously shown by others that sequences inserted into BSMV RNA-gamma vector are unstable as the virus replicates (Pogue et al., 2002, Annu. Rev. Phytopathol. 40: 45-74; Bruun-Rasmussen et al., 2007, Mol. Plant Microbe Interact. 20: 1323-1331). That is, passing the recombinant virus more than once to another plant usually results in either complete loss of the heterologous sequence or its significant shortening. Short host insert sequences (<120 bp) are known to be significantly less effective in BSMV-VIGS (Schofield et al., 2005, Plant Physiol. 138:2165-2173; Bruun Rasmussen et al., 2007, Mol. Plant Microbe Interact. 20: 1323-1331). Therefore, accidental release of recombinant BSMV may cause disease on the initially infected plants. However, due to instability of the insert the hazard would be eliminated in any secondarily infected plants and the virus would be no more severe than wild type virus. BSMV infection is already widespread but does not cause serious agronomic problems even in susceptible cultivars (Jackson & Lane, 1981, Handbook of Plant Virus Infections and Comparative Diagnosis, ed. E Kurstak, pp. 565-625, Amsterdam: Elsevier).

Despite the instability of the BSMV vector, long-lasting silencing extending into second-generation plants is possible (Bruun-Rasmussen et al., 2007, Mol. Plant Microbe Interact. 20: 1323-1331. This is because of BSMV's known ability to be transmitted through seed. To reduce this potential hazard due to accidental release of recombinant BSMV the main bulk of the experimentation will involve the use of vegetative stage plants only. In those experiments requiring seed production the harvested seed from
experimental plants will be securely stored in double sealed boxes. All stored seed will be recorded in the database on a shared project drive which is automatically backed-up on a daily basis.

The transgenic reporter protein-expressing fungal species are not known to be less or more fit than the corresponding parental stains. During these experiments sexual spore formation will not take place and so the risk of vertical gene transfer between the GM fungi to be used and their wild-type relatives is minimal. These reporter proteins have been expressed in a wide range of experimental systems and do not present a risk to human health. The loss-of-function transgenic mutant M. graminicola and Fusarium spp. Strains have been found to be less virulent than wild-type strains and are also likely to be at a competitive disadvantage compared to wild-type strains. In GM host plants that are compromised in their ability to resist pathogen attack, the GM fungal pathogens may be able to spread more extensively or cause more severe symptoms, cause wild-type levels of disease or cause less disease. These fungal strains are not intrinsically more pathogenic or virulent than wild-type strains in experiments on non-transgenic plants. Indeed all the GM strains are likely to be at a competitive disadvantage compared to wild-type strains, and as such present less risk to the environment than the natural wild-type strains. Co-infection of wild-type or GM fungi with BSMV onto host plants is not though to confer any additional risk, and the potential risk of transfer of BSMV-vector genome or BSMV-expressed transgenes to any of the fungal species is negligible as MSMV has not been reported to infect any plant pathogenic fungal species.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**Activities A.2, A.3, C, and D may involve the use of GM cereal plants.** The greatest risk associated with the use of GM plants in this programme of work is the requirement for flowering plants to be used. Extensive measures have been put in place to ensure that neither pollen nor seed can escape, and particular attention has been paid to ensure that flying insects are absent from the building.

All soil used in the building is kept frozen at -20°C prior to use to kill any insects and other invertebrates. All water waste from the building is treated by UV and chemical treatment before it leaves the building (see section 12).

All plants will be grown, and experiments carried out, in containment growth facilities where the access is restricted to authorised personnel. Flowering- and pathogen-inoculated plants will be handled at all times with gloved hands, all gloves being discarded directly into autoclave bags and changed before handling other plants. Any unwanted cereal plant ears will be cut off and discarded. All plants, soil, labels and waste, including microbiological waste, from these growth rooms will be bagged in the room and autoclaved before disposal. Flowers and seed pods on plants are to be bagged and discarded first before they are put into larger autoclave bags, to reduce the possibility of dispersal around the growth chamber. All unwanted grain will also be autoclaved. Plants will be grown on capillary matting in solid trays with 4-cm sides so that all water, potentially containing pollen, fine seed or pathogens, is contained. Seed from experimental plants will be stored in double sealed boxes and records of seed stored kept in an electronic database.

When experiments do not require flowering plants, they will generally be disposed of before they start to flower. When plants need to be left for longer, they will be monitored to ensure that the heads are cut off before flowers emerge.

Designated laboratory coats are provided for work in each separate containment growth room and are never removed from the facility, unless they have been contaminated, in which case they are bagged and autoclaved. Disposable overshoes are also worn in the growth rooms and disposed of into an autoclave bag when leaving the compartment in order to prevent escape of pollen and seed on footwear. In growth rooms with experiments requiring the highest level of containment (i.e. projects A.2, A.2 and A.3) two pairs of disposable overshoes, one over the other, as an extra control measure. Long hair is always kept tied back securely and a hair net is worn to prevent pollen from attaching to loose hair.

Any plant tissue that is transported to other laboratories for analyses will be transported in double sealed containers. The outside of the transportation vessel will be wiped down with 70% Ethanol or Microsol 3 (1 in 50 dilution) just prior to leaving the containment area.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

We request that only activities A1 and A2 are classed as containment Class 3, and that all other activities (A3 through to D) are derogated to Class 2. The greatest risks in activities A1 and A2 are associated with the requirement for flowering plants to be used for infection with a combination of wild-type or GM BSMV and fungal pathogens, but
activities B1, B2 and C will only utilise non-flowering plants, so there will be no risk of pollen from infected and/or GM plants escaping. Although activity A3 will use flowering plants, they will not be infected by fungal plant pathogens and so the risk associated with working with fungal spores will not be present. Similarly, experiments for activity D will be carried out with flowering plants but there will be no infection with BSMV.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste material (discarded plant material, disposable trays, pots, etc) will be bagged and steam autoclaved at 121°C for 30 minutes. Cinbins with sharps will be sealed, placed in an autoclave bag and steam sterilised.

High level liquid waste (i.e. unused liquid cultures) will be treated with concentrated sodium hypochlorite for 1 hour and then autoclaved at 121°C for 30 minutes in a double-kill procedure.

Any spillage will be wiped up immediately with tissue which is then placed in an autoclave bag and steam sterilised. Contaminated, or potentially contaminated, trays and surfaces will be wiped clean with Microsol-3 disinfectant (1:50 dilution with water) - wetted tissue and the waste tissue disposed of as above.

Low level liquid waste (i.e. water used to wash trays after experiments) from the facility is collected in a sump where it is mixed with a 1:50 dilution of Microsol-3 disinfectant (chemical inactivation before being pumped through an UV irradiation chamber for 24 hours in a double-kill procedure).

All lab coats will be steam sterilised before they are removed from the contained facility laundry.

Each autoclave run in the facility is monitored to ensure that all autoclave steam sterilisation runs proceed to completeness. The effectiveness of the UV irradiation and chemical inactivation two-step kill treatment on microbial species in liquid waste from the facility, have been published in HAMMOND-KOSACK, K.E., URBAN , M., FRANKLIN, J. & TABERER, R. (2009) Construction and establishment of a containment level 3 plant growth facility at Rothamstead Research. Proceedings of the UK Controlled User's Group, 20, 2-6. This document can be accessed online at www.ceug.ac.uk/documents/proceedings-09-acro-1_000.pdf.

Project Additional Information

Purposes of the contained use

This is a connected programme of work, comprising of the following activities (from the highest perceived risk to the lowest):

A.1 Identification and characterisation of chemical compounds secreted from two genetically modified strains of T. hamatum, and their role in the enhanced biocontrol and plant growth promotion of lettuce (Lactuca sativa cv. Webb's Wonderful), relative to wild type T. hamatum strain GD12.

N.B. Lettuce plants used in this project are non-GM.

Recipient or parental organism

Trichoderma species are non-pathogenic, avirulent, beneficial soil fungi of agricultural interest as organisms which can enhance plant biomass under low nutrient conditions and used as biological control agents against crop pathogens. Whilst most reports show Trichoderma strains can elicit either plant growth or biocontrol, T. hamatum is unique due to its ability to elicit both properties simultaneously. Genome sequence comparison of T. atroviride, T. virens and T. reesei showed remarkable gene conservation between the three strains (Studholme et al., 2013), but little similarity when compared with T. hamatum. This indicates the presence of novel genomic regions, comprising approximately 40% of the T. hamatum genome, which could account for its dual PGP and biocontrol capabilities. T. hamatum GD12 is the isolate intended for use in this work, which was isolated from agricultural soil in North Devon. T. hamatum GD12 is the parental strain for this work.
There are two classes of GMOs involved in the proposed programme of work.

1) An N-acetyl-β-d-glucosaminidase-deficient mutant of T. hamatum, generated by insertional mutagenesis (using a hygromycin resistance cassette) of the corresponding gene (Saprotrophic competitiveness and biocontrol fitness of a genetically modified strain of the plant-growth-promoting fungus Trichoderma hamatum GD12, Ryder et al., 2012). Disruption of chitinase enzyme expression potentiates plant growth relative to WT T. hamatum GD12, and unlike the WT, the mutant has impaired sporulation. It has been demonstrated that the mutant is a hypersecretor of a T. hamatum specific extracellular antigen, and this phenotype could also lead to plant growth promoting compound hypersecretion, which warrants chemical identification.

2) T. hamatum with a deletion of heterochromatin remodelling protein 1 (hepA). This protein is involved in the activation and repression of silent secondary metabolite clusters in the genome, and deletion of the protein leads to the subsequent de-repression of cryptic metabolomic clusters, leading to enhanced biocontrol of the strain which could occur as a result of an expanded secretome. However, the compounds responsible for the enhanced biocontrol have yet to be identified.

Host/vector system

The wild-type fungus (Trichoderma hamatum GD12) will be the host fungus for all strains used.

In some projects we will also use GM T. hamatum that constitutively express reporter proteins eg GFP (green fluorescent protein), in order to ascertain the mechanisms by which the fungus associates with plant roots to enhance plant growth.

T. hamatum is a sporulating fungus, which has never been shown to be pathogenic to humans. Moreover, it is highly unlikely that the mutant fungal species used will pose a health hazard to humans.

Origin & function

1) N-acetyl-B-glucosaminidase is a key chitinolytic enzyme secreted by fungi to unleash sequestered chitin in soils, which are significant pools of nitrogen and carbon, enabling sequestration by plants and enhancing growth. Contrary to belief, disruption of the enzyme leads to enhancement of plant growth promotion relative to the WT T. hamatum (GD12). Generation of the enzyme deficient mutant used degenerate primers NagA and NagB to amplify the gene encoding the enzyme, and was inserted into a pGEM-T vector. Insertional mutagenesis was performed using fusion-based PCR with the hygromycin resistance gene from Neurospora crassa under the N. crassa TRPC promoter.

2) Heterochromatin protein Hep1 is a highly conserved heterochromatin remodelling protein involved in the activation and repression of secondary metabolite synthesising gene clusters. Inactivation of the protein would lead to the subsequent derepression of clusters which are silent under standard laboratory conditions, which should expand the secretome of the fungus, potentially leading to enhanced antifungal activity and biological control against cosmopolitan crop pathogens. A split marker methods of homologous recombination was used to replace the hepA gene of T. hamatum with the hygromycin resistance conferring hph gene from E. coli under a Neurospora crassa promoter.

3) The reporter genes present in the GM T. hamatum are green fluorescent protein (GFP) from Aequorea victoria. They will be used to track the presence and progression of fungal interaction of host plant tissue.

Evaluation of foreseeable effects

There is no anticipated risk of GM fungi having foreseeable negative effects on plant growth, given that the T. hamatum is a non-pathogenic, avirulent, beneficial organism when grown in association with plants, and the mutants enhance plant growth moreso than the wild type strain. Also, there are no reasons to believe that the fungal gene disruption and deletion for nag and hepA, respectively, may pose any risk to human or animal health.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Activities may involve the use of GM fungal species, which in the case of the hepA mutant, is a sporulating fungus, although the nag is non-sporulating. The greatest risk associated with the use of GM fungi in this study is the use of strains containing a hygromycin resistance cassette as a selectable marker, the effects of which can be attenuated through soaking material which the fungi has been in contact with in either Virkon or Microsol.

All soil used in the building is kept frozen at -20°C prior to use to kill any insects and other invertebrates. All water waste from the building is treated by UV and chemical treatment before it leaves the building (see section 12).

Fungi will be subcultured in Category 2 laboratories.

All fungi will be grown, and experiments carried out, in containment growth facilities with a HEPA filter:
Controlled growth room R62 for the culturing of fungi on solid Potato Dextrose Agar (PDA) or liquid cultures in Potato Dextrose Broth (PDB),

Environmental growth chamber C52 for the use of peat microcosms, whereby the fungus is incorporated into soil matter containing seseds of plant, where the access is restricted to authorised personnel. Fungal-inoculated plants will be handled at all times with gloved hands, with gloves being discarded directly into autoclave bags and changed before handling other plants. All plants, soil, labels and waste, including microbiological waste, from these growth rooms will be bagged in the room and autoclaved before disposal.

An instrumental part of the project is the incorporation of fungal material into sterilized peat. This involves subculturing the fungi on PDA plates, and the addition of plugs of PDA into sterilized bran inocula. After a growth period of 5 days, 8g of bran inocula is incorporated into 300g of peat, which will take place in Cat 2 facilities. 100g of this peat-bran mix is then added to 120mm x 120mm x 7mm square petri dishes, and 25 seeds of lettuce are sown into the peat. The lids are placed onto the dishes, and they are added into an environmental growth chamber at 80% humidity for a period of 3 weeks. These will be watered with deionised water on a bi-daily basis until the plants are ready for harvesting, where the roots will be rinsed with deionised water and placed in foil packaging, and baked at 70 degrees for 48 hours. Biomass measurements will then be taken. The harvesting process will take place in the HEPA filtered room, and all water and material will have Microsol added to it, and will be autoclaved. For images of plant material, a camera will be used which will be wiped with ethanol after use to get rid of spores which may have been released.

Designated laboratory coats are provided for work in each separate containment growth room and are never removed from the facility, unless they have been contaminated, in which case they are bagged and autoclaved. I would also like to request a separate laboratory coat for handling of material in the environmental chamber.

Any fungal material that is transported to other laboratories for analyses will be transported through triple containment.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste material (discarded fungal material, soil inocula waste, disposable trays, pots, etc) will be disposed in autoclaved waste and autoclaved at 121 °C for 30 minutes.

Any spillage will be wiped up immediately with Ethanol tissue which is then placed in an autoclave bag and steam sterilised. Contaminated, or potentially contaminated, trays and surfaces will be wiped clean with Microsol-3 disinfectant (1:50 dilution with water)-wetted tissue and the waste tissue disposed of as above.

Low level liquid waste (i.e water used to wash trays after experiments, condensate from chilled water units, spillages inside cabinet) from the facility is collected in a sump where it is then pumped to an container that is autoclaved at 121°C for 30 minutes.
All lab coats will be steam sterilised before they are removed for laundry.

The autoclave run in the facility is monitored to ensure that all autoclave steam sterilisation runs proceed to completion.

Project Ref 92/20.1

Date Ackn’d 13/11/2020

CU2 Project Title Construction and evaluation of GM strains of the wheat root pathogen Gaeumannomyces tritici and fungal antagonists with biocontrol potential (Gaeumannomyces hyphopodiodes, ilyonectria crassa and Paraphaeosphaeria sporulosa)

Class 2 CultureVolClass2 < 1 Litre

Consent Granted

Project notified under transitional arrangements

Historical Significant Changes
**Project Additional Information**

**Purposes of the contained use**

In this project we will construct different GM strains of the wheat root pathogen Gaeumannomyces tritici to study the function of candidate genes related to virulence and also GM strains for fungal antagonists with biocontrol potential (Gaeumannomyces hyphopodiodes, Ilyonectria crassa and Paraphaeosphaeria sporulosa).

**Recipient or parental organism**

Fungal species, isolated from Rothamsted Research fields. They are found naturally in wheat roots and the roots of other wild plants. The two Gaeumannomyces species are only soilborne, and do not produce airborne spores. I. crassa and P. sporulosa produce airborne spores, but with low establishment potential outside plant roots.

**Host/vector system**

E. coli / Agrobacterium: For cloning purposes E. coli K12 derivatives will be used. For Agrobacterium mediated transformation only disabled Agrobacterium strains will be used (i.e. AGL1).

**Origin & function**

Gene disruption and gene overexpression experiments will be performed in the four fungal species mentioned above for candidate genes related to fungal pathogenicity (for G. tritici) or biocontrol related functions (for the other three beneficial fungi). Reporter strains will be generated using fluorescent marker proteins e.g. GFP and mCherry, and other protein versions derived from them. Epitope tags like Flag or HA will be also used. The selectable marker initially used will be hygromycin antibiotic resistance. Other markers that may be used include geneticin, carboxin, phleomycin or benomyl resistance.

**Evaluation of foreseeable effects**

None of the microorganisms used as recipient could cause harm to humans, animal health or the environment. All fungal cultures will be grown in the laboratory. All materials and cultures will be autoclaved or killed in bleach after use.

The inserted genes are the marker proteins GFP, mCherry and other versions derived from these ones. The molecular epitope tags are Flag and HA tag sequence. These marker proteins and tag sequences are not known to be inherently harmful to humans. Similarly the fungicide resistance genes to be used as selectable transformation markers are not known to present any direct hazard to humans. These selectable marker genes are the E. coli hph (hygromycin phosphotransferase) conferring resistance to Hygromycin, the Neurospora crassa b-tubulin gene conferring resistance to Benomyl and the Streptoalloteichus hindustanus ble gene conferring resistance to the antibiotics bleomycin/phleomycin. Hygromycin is sometimes used in human healthcare in the UK. In addition, point mutations at the succinate dehydrogenase locus will be used to provide resistan to carboxin.

The fungicides used for selection during transformation (hygromycin and phleomycin/bleomycin) are not in use for disease control purposes in agriculture. The fungicide Benomyl is only in use for specialist horticultural purposes, since resistant b-tubulin alleles occur frequently in UK agriculture. Carboxin has been used in agriculture in the past but its use is been reduced.

The potential of the vector systems to cause harm to humans and the environment is negligible. We will use only the common disabled E. coli K12 and Agrobacterium strains that are unlikely to persist in humans, animals or to survive outside culture medium. All materials and cultures will be autoclaved or killed in bleach after use.

None of the new generated mutants is expected to alter survivability or stability. In principle, based on the functional annotations of the genes to be validated with functions expected to be related to virulence, it is not expected an increase in pathogenicity by the deletion of these genes, rather the opposite, but it may be possible in some exceptional cases to obtain an increase of pathogenicity, (e.g. during the complementation of a deleted gene if this is inserted in multiple copies). All materials and cultures will be autoclaved or killed in bleach after use.
The marker proteins and molecular epitope tags are regularly used and they do not affect the plant defence mechanisms in response to fungal infection. For the new mutants generated by gene deletion, they may affect host plant defences by reducing their capacity to escape recognition by the plant, resulting in activation of plant defence mechanisms. None of the mutants is expected to decrease plant defensces. All materials and cultures will be autoclaved or killed in bleach after use.

The planned modifications are not expected to affect tissue tropism or host range.

The planned modifications are not expected to affect transmissibility of the resulting GMM.

The GMM will be performed in fungal species, which can not transfer DNA fragments between related organisms as it is the case of bacteria. This could only happen between sexually compatible organisms within the same species.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

It doesn't apply.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

It doesn't apply.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All contaminated material will be sterilised by autoclaving or other validated means before disposal. Growth media and cultures, disposable plastic and glass ware, swabs, etc. will be placed in sterilin bags in metal boxes. These will be sealed using appropriate metal lids and transferred to Room 238 for autoclaving when the autoclave is free. A validated sterilisation cycle will be used (1h 121 C 15psi).

Only small volumes of liquid waste, of a few milliliters, will be generated. Liquid waste will be also autoclaved prior to disposal, by placing flasks and bottles containing liquid waste directly in the metal boxes.

For solid waste all material will be double bagged and steam autoclaved. Sharps and broken glass will be discarded in designated Cinbins. When full, the cinbins will be sealed, placed in a double autoclave bag and steam sterilised.

After autoclaving, all the materials will be placed in black plastic sacks and taken to the skip.

## Host/vector system

The vectors to be used - pBluescript, pSPORT (Strategene) and pBAD (Invitrogen) - are considered non-mobilisable and can only be introduced into laboratory recipients after chemical induction of competence or by electroporation. The K-12 recipients are incapable of conjugating DNA to other strains. Strain SM10 is the only laboratory strain capable of conjugation that will be used. Gene transfer is thus a very remote possibility. This strain will only be employed in mating experiments to conjugate plasmid constructs carrying inactivated genes. All waste from the experiments will be autoclaved or incinerated to minimise the unlikely discharge of genetic material into the environment.

The construction of mutants will result in the insertion of an antibiotic resistance gene within the gene to be inactivated. As a double crossover approach will be employed, this gene is not likely to be transmissible to other organisms once the mutant has been constructed. During the construction phases, the antibiotic marker will be carried on a suicide plasmid and therefore strains that received this plasmid are unlikely to survive.

## Origin & function

All the cloned (insert) DNA will come from natural isolates of *E. coli*. They are to be cloned to identify unique loci. Vector DNA will be restricted to the well-studied plasmids pCVD442, pBluescript and pSPORT. These will be used to facilitate sequencing of cloned DNA and to construct mutants in the natural isolates that do not possess the cloned genes of interest. Antibiotic markers will be inserted into genes in the process of constructing mutants to provide a means to select strains that have lost the gene to be inactivated. Where necessary, some genes will be expressed using pBAD. Expressed genes will encode outer-membrane proteins that are not toxins. This will be verified by sequencing before expression is attempted.

## Evaluation of foreseeable effects

(a) Hazards associated with the recipient micro-organism.

### E. coli K-12

- **Hazards associated with the recipient micro-organism.**
- E. coli K-12 derivatives DH5a (Stratagene, USA), MG 1655 (Blattner et al. Science 1997 5:277(5331): 1453-74) and Top10 (Invitrogen, USA) will be used as recipients for any cloned genes. Strains SM327 and SM10 (Mobley HL et al. Mol Microbiol 1993 Oct;10(1):143-55) will be used as recipients and hosts for suicide plasmids. All these strains are recognised as non-colonising and disabled and may be considered to be equivalent to ACDP hazard group 1. They are not considered pathogenic to humans or animals. They are expected to have limited survivability in the environment and have auxotrophic requirements which are unlikely to be satisfied outside of laboratory culture.

(b) Hazard arising directly from the inserted gene product.

- **The strains from which DNA fragments will be cloned are enteropathogenic and enteroaggregative E. coli.** These organisms are human gastrointestinal pathogens (laboratory containment level 2). At suitable doses (above 10 to the power of 6), they can cause diarrhea in a susceptible host. Susceptible hosts include mostly children and the immunocompromised. Diarrhoea caused by these organisms resolves spontaneously or can be managed with antibiotics. Even though it is not the initial object to express cloned toxins, for the purpose of the risk assessment, the recipient should be considered to be at least as pathogenic as the donor and thus will be handled with laboratory containment level 2 precautions.
Hazard arising from the alteration of existing pathogenic traits

Most of the initial cloning experiments will be conducted by a shotgun approach and therefore, the gene(s) to be cloned cannot be listed. Fragments to be cloned are to be limited to a maximum of 15 kb of contiguous wild-type DNA, limiting the possibility of cloning a virulence factor along with its accessory delivery systems. It is expected that the sequences that are cloned through this approach will require class 1 or class 2 containment levels. However, all clones to be involved in further studies will be sequenced before these studies commence and risk assessment will be reviewed should sequence analysis reveal that a toxin or other virulence factor that may pose concern has been cloned. Known virulence genes that will be studied and therefore cloned in-frame include those that encode flagellins, iron utilisation systems and adhesins. These factors enhance the pathogenicity of virulent strains but are unlikely to convert the recipient strains to pathogenic status. Nevertheless, recipients carrying these foreign virulences genes will be handled as class 2 pathogens.

It will be necessary to construct mutants in putative virulence factors. These mutants will be constructed as non-polar double cross over deletions using the suicide vector pCVD442 (Mobley HL et al Mol Microbiol 1993 Oct; 10(1):143-55). This approach provides assurance that only the target gene will be delted and that mutants will be stable. In addition, the use of a suicide plasmid creates a situation whereby strains will either be mutated successfully or fail to survive. The genotype of all candidate mutants will be verified before they are used for subsequent experiments. It is expected that mutants will have an attenuated or similar virulence to wildtype strains and they will be handled as Class 2 pathogens.

The vectors to be used - pBluescript and pSPORT (Stratagene) - are considered non-mobilisable and can only be introduced into laboratory recipients after chemical induction of competence or by electroporation. The K-12 recipients are incapable of conjugating DNA to other strains. Strain SM10 is the only laboratory strain capable of conjugation that will be used. Tene transfer is thus a very remote possibility. This strain will only be employed in mating experiments to conjugate plasmid constructs carrying inactivated genes. All waste from the experiments will be autoclaved or incinerated to minimise the unlikely discharge of genetic material into the environment.

The construction of mutants will result in the insertion of an antibiotic resistance gene within the gene to be inactivated. As a double crossover approach will be employed, this gene is not likely to be transmissible to other organisms once the mutant has been constructed. During the construction phases, the antibiotic marker will be carried on a suicide plasmid and therefore strains that received this plasmid are unlikely to survive. If genes encoding outer membrane proteins that are not toxins are identified, the genes will be cloned into pBAD to facilitate purification of these proteins. Genes cloned into pBAD are expressed only in the presence of sufficient quantities of arabinose and are repressed in the presence of glucose, a far more abundant sugar.

Consideration of the likelihood that, in the event of exposure, the GMM could actually cause harm to human health

It is unlikely that the recipient would survive in a human host, even if virulence genes were cloned in an expressible form. However, since the genetic material is to be obtained from human pathogens, recipients will be handled as pathogens and standard laboratory containment level 2 precautions will be employed throughout. Although the risk is negligible, should infection in humans occur, diarrhoea would be the most likely sequelae and should be treated with antibiotics, other than ampicillin (which is the marker on the vectors).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No GM animals or plants will be employed

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid and liquid waste containing genetically modified organisms will be collected in lidded autoclave buckets and treated in a validated autoclave. Sterile waste from the autoclave will be sent for incineration. Any accidental spillage will be treated with 2% Virkon (see manufacturers data sheets).
The Genetic Modification Safety Committee considered this application at its meeting on 25 January 2002 and made the following observations.

The risk assessment had been carefully prepared.

The work will be carried out in a dedicated research laboratory which has access card entry control and is a containment level 2 facility. There is a designated bench for the work, and all equipment is at hand. Adequate hand washing facilities are available at the end of the laboratory.

The University has a Safety Management System, ratified at the University Safety Committee meeting on Tuesday 12 February 2002.

Please enter comments on the GM safety committee on the risk assessment

Non-GMM Consent Granted

Project notified under transitional arrangements N

Historical Significant Changes

Withdrawn N

Tick if notifying a connected programme of work N
Studies of epigenetic regulation of skin development, regeneration and carcinogenesis using 2D and 3D skin cell culture and replication-deficient lentiviruses expressing selected transcription factors, chromatin remodellers and shRNAs targeting their endogenous gene expression. Particularly, we will over-express or suppress the following factors: Lhx2, Oct4, Sox2, Sox9, Brg1, Brm, Ezh2, Ezh1, Lsd1, Tet1/2/3, Hdac1/2, Satb1/2 and Cbx4. The lentiviral vectors based on third generation HIV derived vectors will be obtained from commercial sources (Sigma Corporation) and from collaborative labs. We will produce lentiviral particles using the lentiviral vectors co-transfected together with packaging plasmids pS Pax2 and pMD2.G (Addgene depository, Cambridge, MA, USA) into HEK293T cells. The viral particles will be used to infect established cell lines, primary cultures of mouse and human keratinocytes, fibroblasts and melanocytes as well as the whole mouse embryonic skin cultures. In some experiments, the infected primary cells will be used to establish 3D skin tissue culture in vitro. The effect of over-expression and inactivation of the epigenetic regulators on morphological, physiological and biochemical parameters in the infected 2D and 3D cell and tissue cultures will be analyzed.

Established cell lines, primary skin cell cultures, whole mouse embryonic skin cultures and 3D reconstituted skin tissue cultures will be used in these studies. They are well characterized and are used in many labs worldwide including ours. They are not hazardous to human health in general. Primary human skin cells will be isolated from ethically obtained human skin samples. Such samples could carry human bacterial or viral pathogens and will be handled by trained staff using gloves, lab coats and biological safety cabinets. The samples are collected from dermatological clinics and any derived from patients known to be carrying infections would be excluded at the point of collection. Primary mouse cells and tissue culture will be prepared from mice kept in individually ventilated cages (IVCs) in the Biological Service Facility at the University of Bradford under strict adherence to the National and University animal care and usage regulations. The animals are specific pathogen free. The hazard associated with the recipient organism is considered to be insignificant.

Expression of the selected transgenes in lentiviruses in this research programme would not change the infectious properties of the viruses that will remain non-replicating and able to infect the cells and tissues only on direct contact with viral samples at high titre. The third generation HIV based lentiviral vectors (Sigma Cat Number SHCLND) used in these studies have their envelope (env), structural (gag), regulatory (vif, rev, nef) and replication (pol) genes deleted (Zuffery et al, 1997, Nat. Biotechnol. 15, 871-885). Additionally, they have a deletion in the 3' LTR region leading to the viral self-inactivation after integration into the host cell genome (Zuffery et al, 1998, J Virol., 73, 9873). The unintended infection of the human cells and tissues with the viruses is extremely unlikely when all the protective measures are applied and would be limited only to researchers directly involved in the experiments. Any infection would not spread further due to the replication deficient nature of the lentiviral strain specifically designed for this purpose as described above. The virus will be replicated in HEK293T cells after co-transfection of the viral vector with the packaging plasmids pS Pax2.
expressing gag, vif, rev, nef and pol genes and pMD2.G expressing vesicular stomatitis virus envelope G-protein VSV-G (Addgene depository, Cambridge, MA, USA). The separation of the genes required for the viral replication and packaging into two plasmids without sequence homology with the viral vector prevents the potential recombination to produce a replication competent virus. The viral particles are not air born and rapidly lose the infecting activity at room temperature.

Origin & function

Lentiviruses expressing cDNAs for selected transcription factors (Lhx2, Oct4, Sox4, Sox9), chromatin remodelers (Brg1, Brrm, Ezh2, Ezh1, Tet1/2/3, Hdac1/2, Satb1/2, Cbx4) and shRNAs targeting their endogenous gene expression will be used in these studies. The viruses will be used to over-express and/or inactivate these factors in 2D and 3D skin cell and tissue cultures to analyze the role of such factors in skin development, regeneration and carcinogenesis.

Evaluation of foreseeable effects

Expression of the selected transgenes in lentiviruses proposed for use in this research programme would not change the infectious properties of the viruses. These will remain non-replicating and able to infect the cells and tissues only on direct contact with viral samples at high titre. The third generation HIV based lentiviruses used in these studies have their envelope (env), structural (gag), regulatory (vif, rev, nef) and replication (pol) genes removed (Zuffery et al, 1997, Nat. Biotechnol. 15, 871-885). Additionally, they have deletion in 3' LTR region leading to the viral self-inactivation after integration into the host cell genome (Zuffery et al, 1998, J Virol., 73, 9873). The unintended infection of human cells and tissues with the viruses is extremely unlikely when all the protective measures are applied and would be limited only to researches in any case. The infected cells and tissue would not spread the viral infection further due to the replication deficient nature of the lentiviral strains specifically designed for this purpose. The infection, however, can lead to pathological conditions in affected cells and tissue that could result in cell death or carcinogenesis. Carcinogenesis is very unlikely however, because the viral particles would not be able to penetrate the skin surface in most cases and reach cells susceptible to transformation. The lentiviral strains used in this programme are not air born, are rapidly loose infectious properties at room temperature and could not be spread in the environment. The probability of recombination between the recombinant lentiviruses and natural related viral strains is essentially zero and the transgene sequence could not be transferred to the related natural viruses.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid and small amount of liquid (no more than 10 ml) materials and reagents that were contacted with viral samples will be be collected in the contained double bagged containers and autoclaved in a validated facility to destroy viruses before disposal. The large volumes (more than 10 ml) of liquid materials and reagents contacted with the viral particles will be treated with validated bleach (Virkon) at the final concentration of 10% for 30 min to completely destroy the viruses before disposal.

Is an emergency plan required according to regulation 20?  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N
The application was considered by the University of Bradford GMM Committee on May 11th 2012. The members of the committee noted that this application was a modified version of a draft application previously considered, and that all points raised had been attended to. Some of the recombinant viruses to be used will be supplied by collaborators at another UK HE Institution, which has CU2 approval for their use, thus reference has been made to the information available on the Public Register to ensure consistency.

The Chair of the GMO committee suggested that a SOP be established for the transfer of waste from the laboratory to the designated autoclave.

- **Significant Change ID**
- **Date of Significant Change**

02/03/2022
Purposes of the contained use

For the purpose of either over-expression or knock-down studies, AAV, Sindbis and Lentivirus particles will be produced in HEK293, BHK and 293FT cells respectively. These particles will then be transduced into different mammalian cell lines. Between 1-6 days, the cells will be lysed and the signalling pathways investigated biochemically.

Recipient or parental organism

Cell lines used: HEK293, HEK293T, COS7, HEK293FT, BHK
These cell lines are well established and in use in many laboratories worldwide for epigenetic and other studies. They are not recognised as posing a hazard to human health.
Primary cells from mouse brain will be prepared from specific pathogen free mice kept in individually ventilated cages (IVCs) in the Biological Service Facility at the University of Bradford under strict adherence to the National and University animal care and usage regulations. All staff involved in animal handling will have undergone appropriate training. The Hazard associated with the recipient organism is considered to be insignificant.

Host/vector system

Several predominantly commercial systems will be used:
- AA virus vectors: pAAV.CMV.NT-3; pAAV2.1-CMV-EGFP; pAdhelper (adenovirus helper plasmid); serotype-specific plasmids pXR2 and 4.
- Lentivirus vectors: pLent6/R4R2/V5-DEST (Life Technologies); pFIV-H1/U6-Puro and pGreenPuro (System Bioscience Inc) pLenti-Easy-His Vector and pLenti-Tri-cistronic (Applied Biological Materials (ABM) Inc)
- Sindbis viral vector pSinRep5 (Life Technologies); DH-BB and DH(26S) helper DNA templates

Origin & function

Adeno-associated virus (AAV) is a non-pathogenic helper dependent parovirus with a genome of single stranded DNA. This is one of the most promising vehicles for gene delivery and can insert genetic material at a specific site on chromosome 19 with near 100% certainty. Recombinant AAV vectors have predominantly episomal gene expression and has long-term expression in terminally differentiated cells. The very low levels of pathogenicity of AAV vectors in humans have allowed them to be classified as a Biosafety Level-1 (human pathogenic hazard group 1) agent by the ACDP.

Sindbis Viruses: The purpose is to produce pseudo-virions that may be used to infect a variety of different cell lines to optimize expression in the cell line of choice or to infect large-scale cultures for production and purification of proteins. Previously many labs used Sindbis virus efficiently to everexpress proteins in primary cortical and hippocampal cells. The low level of pathogenicity of Sindbis virus in humans has allowed it to be classified as a Biosafety Level 2 (human pathogenic hazard group 2) agent by the ACDP

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Tissue culture waste will be disinfected with Trigene, Virkon or treated with powdered Chloros (Presept). Treatment will be for a minimum of 20 minutes, followed by disposal into waste bins. Specifically a fresh 2% solution of Virkon® will be used to deactivate all viruses by disinfectant for 12 to 18 hrs. Autoclaved at 121°C for minimum of 20 minutes in the designated autoclave in the BSU. Autoclaved waste will be removed by the University's Waste Contractors.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The local GMO committee were happy with the first draft of the risk assessment in terms of the procedures for the generation of the recombinant viral particles, but requested further information be included as to the genes being incorporated/cellular targets of the viruses, and a more focused overview as to the aims of the specific project. These points were attended to, and the committee was able to approve the application.

Project Additional Information
### Purposes of the contained use

In the proposed clinical studies, Angiogenic Gene Therapy Product, consisting of a recombinant adenovirus (human serotype 5) containing the human gene for the fibroblast growth factor 4, and referred to as Ad5.1fgf-4, will be investigated as a treatment for patients with peripheral arterial occlusive disease (PAOD). PAOD is characterised by decreased peripheral blood flow, usually in the lower limbs. Angiogene is the formation of new blood vessels.

### Recipient or parental organism

### Host/vector system

### Origin & function

### Evaluation of foreseeable effects

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Inactivation of infectious waste - The infectious waste will be transferred to an autoclave in the medical microbiology unit (Jenner Wing, St. George's Hospital) by firstly double bagging the waste then placing it in specially designed, autoclavable, leakproof, metal transport boxes. Inactivation of Ad5.1FGF-4 is by autoclaving at 134C for 20 minutes, giving effectively 100% kill. Autoclaving at 121C for 15 minutes would also be adequate (again, effectively 100% kill), but 134C for 20 minutes is the standard temperature and time used in the medical microbiology unit. The autoclaves are validated on at least an annual basis (including the placing of independent thermocouples at the centre of the load). For each cycle of Ad5.1FGF-4 waste, autoclave indicator tape and the integral autoclave printer readout will be used to confirm that the waste has been autoclaved.

Project Ref 95/01.7

Date Ackn'd 14/05/2001
CU2 Project Title GENETIC REQUIREMENTS FOR IMMORTILIZATION OF NORMAL HUMAN
Class 2
CultureVolClass2 < 1 litre
CultureVolumeClass3-4
**Project Additional Information**

**Purposes of the contained use**

Overall purpose: (i) a better understanding of malignant melanoma development and (ii) to enable the production of immortal human melanocyte lines for a wide variety of research.

Purpose of containment: Amphotropic retroviruses containing candidate cellular immortalizing genes, including certain oncogenes, will be used to transfer several of these genes into normal human melanocytes, to investigate which combination can overcome senescence in this cell type, and to yield immortal (continuously growing) lines of human melanocytes. The retroviruses, capable of infecting human cells, present a potential oncogenic hazard to the user and to others if not contained.

**Recipient or parental organism**

The recipient 'organisms' are primary strains of normal human melanocytes, derived from skin biopsies in other laboratories in Europe and the USA and provided to us after several passages. These cannot grow in humans other than the skin donor, but all early (recently explanted) human cell cultures are considered potential sources of human pathogenic viruses and are therefore grown under ACGM Level 2 containment conditions even without genetic manipulation. They are from identified persons with no known history of viral disease, so the risk of viruses is low.

The level of hazard from these recipient cells is not altered by the retrovirally-mediated insertion of additional genes. The cells will still not be able to grow in other humans, and the retroviruses used are disabled (see below), so that no infectious virus of this kind will be produced by the recipient cells.

**Host/vector system**

(i) The viral vectors alone are not considered harmful. They are disabled retroviruses of the pBABE family, which produce infectious particles only after transfection into packaging cells (Morgenstern, J.P. and Land, H., Nucleic Acids Res. 18: 3587-3596 (1990)).

(ii) The packaging cell line is Phoenix-AMPHO, a third-generation packaging line that contains the packaging construct (genes missing from the defective virus) in two separated components, making the probability of emergence of replication-competent retroviruses through recombination negligible (Xu, X et al., Nat. Genet. 27, 23-9 (2001), and see: http://www.stanford.edu/group/nolan/retroviral_systems/phx.html).

In other words, infectious viral particles are produced by the Phoenix packaging cells only, not by other infected cells. Phoenix cells are well characterized and free of helper virus or pathogenic viruses. They would be unable to grow in another human and thus are not hazardous unless engineered to produce infectious viruses. The half-life of the infectious viruses outside cells is estimated at about 7 hours (Andreadis, S. et al. J. Virol. 74, 1258-66 (2000)), and they are not resistant to desiccation.
### Origin & function

We will not be handling any naked proviral DNA. Phoenix-AMPHO cells already transfected with viral vectors and producing infectious viruses will be provided as frozen stocks by a collaborating group who constructed the viral vectors. The genes involved will be:

(i) hTERT, the catalytic subunit of human telomerase. This has been reported capable alone of immortalizing some types of human cells, although also expressed normally by other human cells. This sequence was originally provided by Geron Inc.

(ii) Several genes that would disrupt the p16/RB1 pathway. p16 is the product of a tumour suppressor gene, a melanoma susceptibility locus in humans. It is an activator of another important tumour suppressor gene, RB1. Both p16 and RB1 have been implicated in cellular senescence and therefore it is relevant to attempt to disrupt this pathway.

### Evaluation of foreseeable effects

If the infectious form of the retrovirus, with one of the above inserted genes, did enter the human body, it would be capable of infecting cells during its lifetime (half-life around 7 hours, as mentioned). It could not pass through intact skin, but could contact and enter cells if inhaled, or via damaged skin or mucous membranes. This would constitute a small oncogenic risk. None of the individual genes to be used can cause tumours on their own, but each might do so in combination with several other sporadic genetic changes, neoplasia being a multistep process. Infected cells would have reduced by one the number of genetic alterations required to produce neoplasia. (We will not use more than one oncogene simultaneously).

The highest risk is to the operator but, if not contained, on escape to the environment, the retroviruses could infect mice or other humans. However, these viruses have only a short lifetime outside cells, as mentioned, and are not resistant to desiccation. Thus the environmental risk is relatively low.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The following control measures will be used, in accordance with the accompanying risk assessment. The experiments will be on a small scale and for research purposes only. The work here will be initiated by a researcher who has visited the laboratory of the collaborating group who are already using these vectors, to study their established containment procedures, which will be replicated here. The procedures should make the probability of infection of the operator or escape to the environment effectively zero. We will comply with ACGM and St George's recommendations for Level 2 containment. In addition to these will be the following extra measures, for all parts of the work assessed as requiring Level 2.

- To ensure that replication-competent retroviruses (RCRs) carrying oncogenes cannot be produced, the Phoenix packaging cells will be monitored for production of RCRs, according to St George's guidance notes.
- Double gloves to be used.
- No sharps to be used.
- No work to be carried out if operator has any skin damage, eczema, etc.
- Virus particles not to be concentrated; the culture medium of packaging cells to be used unaltered as source of viruses.
- The handling of naked proviral DNA is not proposed.
- No more than one insert sequence to be used at a time. Where combinations of genes are to be tested, infections of different genes will take place at least 2 weeks apart.
- Solid waste to be transported to approved autoclave in Medical Microbiology department for autoclaving, in secure secondary container.
- Any new staff to receive careful training in the precautions to be used and the nature of the hazards involved, and should have previous experience with at least Level 1 containment procedures.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

02/03/2022
Liquids such as culture medium: addition of Chloros or other strong chlorine bleach to at least 10 ppm available chlorine, overnight. Then disposal to drains.
Approximately 100% kill of GMOs (cells, retroviruses).

Solid waste: To be transported to approved autoclave in another department in the same building, for autoclaving, in secure secondary container. 100% kill.

Historical Significant Changes
1. To evaluate the suitability of the Institut Pasteur attenuated live Shigella dysenteriae type 1 icsA- ent-, fep-, stxA-; HgR vaccine SC599 when given as a single oral dose as a tool for human studies of immunity to enteric pathogenic bacteria.
2. Evaluation will be made for safety and immunogenicity by immunological, clinical, microbiological, haematological and biochemical measures, in healthy volunteers aged 18 to 45 years. The immunological data may allow for further use of the vaccine in larger scale clinical studies of immune responses.
3. By using an escalating dose, to obtain data on the optimum dose of bacteria which can effectively prime for an immune response without causing diarrhoea or other significant side reactions.

Shigella are pathogenic as a result of two features:
(a) Ability to invade human gut musosa. This is the principal virulence characteristic, and is controlled by plasmid-encoded proteins.
(b) Production of Shiga toxin. In addition to its invasiveness capability, Sh. dysenteriae type 1 produces an enterotoxin (Shiga toxin). High level toxin production enhances the pathogenesis of Sh. dysenteriae 1, but is not the primary virulence characteristic. Sh. dysenteriae type 1 is classified as ACDP Hazard Group 3 by virtue of toxin production.

Shigella are infectious via the oral route - between 10 and 100 bacteria are capable of inducing infection. Infection results in dysentery (bloody diarrhoea) with toxaemia. However, Shigella do not invade systemically and positive blood culture is uncommon. Mortality from species other than Sh. dysenteriae group 1 is almost non-existent and full recovery without sequelae is the rule, except at the extremes of age or in patients with other medical conditions (hence ACDP group 2). The secretion of Shiga toxin increases the pathogenicity of Sh. dysenteriae type 1, and mortality from Sh. dysenteriae type 1 can be up to 20% if untreated (hence ACDP group 3 on the basis of toxin production). Production of Shiga toxin is also thought to be responsible for the haemolytic-uraemic syndrome which can occasionally complicate Shiga dysentery. Post infectious complications include seronegative reactive arthritis in subjects who have the HLA type B27, thought to be an autoimmune process induced by molecular mimicry of human cellular proteins by bacterial proteins.

No virulence genes have been inserted and several key virulence genes have been deleted so there is no risk of a harmful phenotype being transferred to related micro-organisms. Genetic modification of the parent organisms was targeted homologous recombination with plasmids to delete virulence genes. The risks of transfer of other plasmid-encoded natural virulence genes from Shigella dysenteriae vaccine strain to other gut micro-organisms has not been demonstrated and is therefore very remote.

The risks of transfer of plasmid-encoded natural virulence genes from other bacteria into the vaccine strain to reconstitute its virulent phenotype is very small, as the human host would have to be carrying a wild-type Shigella spp in the gut, and multiple gene deletions have been introduced. If transfer did occur then a phenotype no more severe than the wild-type would be reconstituted as the GMM has no additional genetic sequences over the wild-type strain.

Virulence has been attenuated in SC599 by the deletion of the following genes:
1. stxA-: This completely removes the active A subunit of the Shiga toxin, essentially converting the vaccine strain from Sh dysenteriae type 1 (ACDP Group 3) to Sh dysenteriae non-1 (ACDP Group 2).
2. icsA-: This interferes with the bacterial ability to spread from cell to cell within epithelia, limiting potential to cause mucosal invasion and gastroenteritis.
3. ent-, fep-: These genes are responsible for a receptor on the iron-enterochelin complex and the biosynthesis of enterochelin. They attenuate the ability of bacterial growth and division in vivo.
In previous studies with Shigella, subjects were routinely started on ciprofloxacin treatment on days 5-12 or sooner if symptoms developed. Crucially, ciprofloxacin therapy was found to promptly end faecal shedding of bacteria and resolve conical symptoms.

On the basis that the Shiga toxin functionality has been removed, we propose that the attenuated GMM SC599 be initially classified as a wild-type Sh dysenteriae non-type1: ACDP Group 2 and hence be handled at ACGM.

Containment Level 2
In fact the additional attenuations would be expected to reduce the level of risk to less than wild-type Sh dysenteriae non-type 1 and theoretically the GMM could be classified as Group 1 Level 1, but as this is the first evaluation of the actual level of attenuation in man we would await the results of this study before proposing a reclassification of this GMM.

Host/vector system
n/a

Origin & function

The only gene insertion is the mercury resistance phenotype (HgR) inserted as selection marker. This has no clinical significance, does not enhance pathogenicity, viability or the organisms 'fitness', but allows identification of mutants. No antibiotic resistance phenotype has been inserted.

No other functional DNA is inserted. Clean deletions or in activations have been made.

Evaluation of foreseeable effects

A great deal of experience has been developed with strains of S. flexneri (SC602), including community-based phase 1 studies. Amongst subjects given an attenuated Sh flexneri (icsA- iuc- [aerobactin functionality deletion]) vaccine orally, 2/15 given between 1 (to the power of 2) to 1 (to the power of 7) bacteria developed fever, and 2/3 given 3 (to the power of 8) developed fever and diarrhoea. There were no serious adverse events.

Studies in humans of oral vaccination with Sh dysenteriae type 1 bearing only a the deletion of the toxin A subunit and insertion of mercury resistance (Sh. dysenteriae 1 stxA-: HgR) have been undertaken in the USA. This strain would be recognised as only very modestly attenuated and not a suitable vaccine candidate. However, these studies revealed that none of the volunteers given 3 x 10 (to the power of 10) bacteria had symptoms, 1/4 given 3 x 10 (to the power of 3) had fever and dysentery, 1/6 given 3 x 10 (to the power of 4) had fever and diarrhoea, and 3/6 given 3 x 10 (to the power of 5) had fever or diarrhoea. We would expect the two further attenuating mutations introduced into SC599 to be employed in this study would greatly reduce reactogenicity to the levels of acceptance seen with the Sh. flexneri strains reported above.

In all these studies, subjects were routinely started on ciprofloxacin treatment on days 5-12 or sooner if symptoms developed. Crucially, ciprofloxacin therapy was found to promptly end faecal shedding of bacteria and resolve clinical symptoms.

In a community based safety trial of S. flexneri (SC602) in which subjects were not routinely given antibiotics, 36 volunteers ingested 2.5 x 10 (to the power of 4) bacteria. There were no adverse effects. Subjects were allowed home immediately after vaccination and there were no cases of cross-infection. Daily stool sampling revealed that 20 shed bacteria in stool on day 1, rising to 86% by day 4 and all that did shed had an onset by day 7. Shedding was intermittent and the longest was 33 days. All subjects received ciprofloxacin on day 35 which terminated shedding.

Studies with Sh. flexneri SC602 are underway in children under 1 year old in Bangladesh, with does escalation up to 10 (to the power of 6) bacteria, with no ill effect (P. Sansonetti, personal communications).

Thus there is evidence in the literature that Shigella species with similar or less attenuating mutations can be safety administered to humans at the doses we propose in our escalating-dose study, and at the doses likely to be involved through cross-infection without ill effect. Furthermore ciprofloxacin therapy promptly ends bacterial shedding.
and any clinical symptoms.

The removal of the toxA gene makes haemolytic-uraemic syndrome extremely unlikely, as this virulence factor is thought to be the cause of this complication.

It is possible that if a third party became infected with the vbaccine strain then they could develop Seronegative Reactive Arthritis. However studies reported above have shown that cross-infection does not occur with the vaccine strains. Also the frequency of reactive arthritis after an infectious challenge is only 1-2%, of which 80% of affected subjects are HLA B27 positive, and the frequency of HLA B27 is only about 8% of the population. Therefore the chances of a susceptible person coming into contact with an infectious dose and sustaining a post-reactive arthritis is very remote.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

A derogation from level 2 containment is requested to use an autoclave in an immediately adjacent building in the Department of Microbiology or Department of Cellular Molecular Sciences. The vaccine Institute is designed to provide a safe environment for clinical studies, but does not have an operational autoclave in the building. Double-bagging, sealing and transporting clinical and laboratory waste in rigid containers to the autoclaves in Microbiology or CMS provides a safe disposal of material and the safest environment for study subjects.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

(A) Work proposed in the Vaccine Institute:
* All laboratory waste will be autoclaved prior to disposal by incineration.
* All volunteers will be housed in single rooms. Volunteers will use disposable bedpans which will be placed in double-bagged yellow sacks and autoclaved prior to disposal by incineration. The autoclave in the Department of Microbiology will be used as this is currently used for similar clinical specimens. The discard cycle (138 degrees C/30 mins) is validated every 3 months and is validated for inactivation of infectious agents.
* 'Household' waste from vaccines (disposable plates, cups, cutlery etc.) will be disposed of by incineration in yellow bags, as for standard laboratory waste. Laundry will be processed by the Hospital contractors.

Measures to prevent person-to-person spread:
* Proper hand-washing, especially after defecation and prior to food preparation/consumption.
* Avoidance of communal food preparation during likely periods of stool excretion.
* Avoidance of contact with persons especially susceptible to infection by excluding subjects from the study with such risk factors.
* Active monitoring of vaccinees' stool carriage.
* Repeat ciprofloxacin therapy if carriage persists beyond 4 weeks.

(B) Work in the St George's NHS Trust Microbiology Laboratory
It is proposed that Standard Operating Procedures in operation in this NHS laboratory are employed as appropriate for the isolation of wild-type Shigella dysenteriae type 1.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y
The use of two autoclave bags, one inside the other, may be of value in preventing spillage from ruptured bags after autoclaving. But it should be clear that when ready for transport to the autoclave, the bags should be left open (this is required to ensure steam penetration when in the autoclave). The rigid, sealed container should be the mechanism for preventing any leaks during transport to the autoclave. The autoclave operators will release the lid of the metal container before autoclaving the container and its contents.

Given the use of the Microbiological Safety Cabinet in the laboratory within the institute for preparation of material for various studies, rigorous procedures preventing cross contamination should be included in the standard code of practice to be followed by all users of the facility. This should include effective wipe down of the internal surfaces of the cabinet with an appropriate disinfectant.

Purposes of the contained use

The project aims to define the genes that determine virulence and pathogenicity of the pathogenic mycobacteria: Mycobacterium tuberculosis, M. bovis, (including the attenuated strain M. bovis BCG) and M. leprae. The long-term aim of this project is to understand mycobacterial virulence and define the genes involved in determining the host-pathogen interactions, thereby providing a rational basis on which to develop new control measures for tuberculosis, and to identify novel candidates for better drugs and vaccines for human tuberculosis.

Recipients or parental organism

The Genus Mycobacteria, (gram-positive, rod-shaped bacteria of the Family Actinomycete) consists of more than 40 recognised species, but which can be put into two main groups:

i) fast growing non-pathogenic bacteria such as M. smegmatis (commonly used for genetic studies of mycobacteria);
ii) the slow growing mycobacteria which include the major human pathogenic bacteria: TB (tuberculosis causing) complex (consisting of M. tuberculosis, M. bovis, M. africanum, M. microti), M. leprae (leprosy bacillus) and the M. avium complex which have become apparent as a major opportunistic pathogens in HIV infected people.

Mycobacteria can infect most species of animals including rodents, birds and fish. M. avium sub-species paratuberculosis is also responsible for Johne's disease in cattle and is increasingly thought to be associated with the human inflammatory bowel disease: Crohn's disease. Another slow growing mycobacteria is M. ulcerans, that causes Buruli ulcers in parts of Africa.

Mycobacterium tuberculosis is by far the most important human pathogen in the Genus Mycobacterium in terms of morbidity and mortality and sub-clinically infects a third of the world's population, killing 2 million people each year. Tuberculosis can affect almost any part of the body but is commonly of the pulmonary type, where the bacilli damage the lung function to such an extent that oxygen exchange becomes insufficient for life. TB is spread via the aerosol route, but bovine TB can be intestinally acquired. Clinical TB is still rare and is still treatable with alternative antibiotic regimes.

The genetically modified mycobacteria (recipients) will have had one or more of its genes inactivated, with or without the introduction of harmless vector sequences or selectable marker genes.

Origin & function

The genes studied in this proposal will derive from parental mycobacterial species: M. tuberculosis, M. bovis, M. bovis BCG and other pathogenic and non-pathogenic mycobacteria. The genes may be involved in metabolism, global gene regulation, stress response, intracellular survival, in vivo growth and latency. Many genes in M. tuberculosis are of unknown function (~40%) and this project aims to establish the functions of some of these by observing the effect of gene disruption or introduction.

Evaluation of foreseeable effects

The genetically modified mycobacteria (recipients) will have had one or more of its genes inactivated, with or without the introduction of harmless vector sequences or
selectable marker genes. Since virulence in mycobacteria is regarded as being defined by multiple genes acting in a highly regulated and co-ordinated way, the loss or introduction of a gene will either make the GMO either less virulent or have the same virulence as the parent organism. Thus the GMM will be identical to the parental pathogen, but will have small pieces of genes altered, missing or interrupted. These experiments may therefore be regarded as "self-cloning" and the resulting GMM may well exist naturally, although not easily identified from nature. No enhanced risk is perceived for the GMM recipients over and above the hazards of the parent strains. Introduction of genes from M. tuberculosis into the non-pathogen M. smegmatis will facilitate the function of that gene to be readily determined. The recipient GMM will not have any increased potential for harm compared to the parent, because of the multigenic nature of virulence in mycobacteria. Indeed, this has been experimentally shown by many groups. Thus, GMM M.smegmatis containing one or even many genes from the pathogenic mycobacteria will not have any enhanced hazard associated with it compared to parent M.smegmatis. Reintroduction of a gene or genes known to be missing in M. bovis BCG (the attenuated, non-pathogenic vaccine strain of M.bovis) but present in M.tuberculosis back into M.bovis BCG may restore partial or complete virulence, so the GMM recipient may revert to pathogenic status. Thus, these experiments involving reversion in BCG with deleted genes will be performed as if the recipient were pathogenic: i.e. same category of containment as the donor organism: M.tuberculosis, which is a Class 3 activity and performed under containment level 3.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Derogation is applied for in relation to the use of autoclaves sited outside the CL3 labs but within a group of laboratories which have restricted access, for the disposal of waste from ACDP Group 3 GMM pathogens:- See risk assessment part (iv), paragraph 5. The autoclaves to be used are sited within The Department of Medical Microbiology. The autoclaves meet the correct standards and are validated by annual checks and calibrated and are registered for use by the School's GMSC. The protocol for autoclaving non-GMM Group 3 organism-waste generated within the CL3 labs in the Dept. Medical Microbiology makes use of these autoclaves. Even though the autoclaves are not within the CL3 lab, the CL3 labs are sited on the same corridor as the autoclaves and within a single unit of a series of laboratories (Department of Medical Microbiology) that have restricted access from the rest of the School by security pass-locked doors.

IT IS REQUESTED That for GMM mycobacteria the same procedure for autoclaving waste within the Dept. Medical Microbiology be used. On this specific aspect, derogation from the regulations that require autoclaving within the CL3 lab, is applied for. Waste generated within the CL3 lab will be double bagged inside the Class I MSC, placed into a metal, sealable tin for transport to the autoclaves for immediate autoclaving. All waste post-autoclaving will be placed in yellow clinical waste bags and incinerated. All waste from animal (mouse and guinea pigs) infection with GMMs will be autoclaved within the separate specified building within the School for animal work using the authorised and GMSC registered autoclave in that building. The autoclave is outside the CL3 laboratory, part of a single unit of a series of laboratories that have restricted access from the rest of the School by security pass-locked doors. Autoclaved waste is then incinerated.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMM microbiological waste generated, (liquid and solid), is first treated with Hycolin within the Class I microbiological safety cabinet. This gives a 100% degree of kill. The material is drained and then double bagged in autoclavable plastic bags, removed from the MSC to a robust, sealable tins and transported to the autoclave area for immediate autoclaving. The autoclaves are annually tested, validated and approved by the School's safety committee and GMSC for use with GMM waste. Autoclave tape confirms efficiency for each run. All autoclaved waste is then disposed of by incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The risk assessment has been reviewed and approved by the St. George's Hospital Medical School GMSC and a Project Form has been registered with the GMSC.

**Project Additional Information**

Purposes of the contained use

The purpose of this study is to determine murine immune responses to an outer membrane protein of Neisseria meningitidis expressed in recombinant BCG, as a potential human vaccine candidate. NadA was initially identified by whole genome sequencing of N. meningitidis, and in silico analysis (Science 2000; 287:1816-1819). By homology with other bacterial outer
membrane proteins, the gene has been identified as a novel vaccine candidate for N. meningitidis type b (J. Exp. Med. 2002 1995 (11): 1-11) and designated 'NadA' (Neisserial adhesin A).

There is currently no vaccine available against N. meningitidis type b, which is the cause of about 45-80% of cases of meningococcal meningitis in Europe. Cross reactivity of the polysaccharide capsule of N. meningitidis type b with human antigens has made the development of a classical polysaccharide vaccine problematic. Current strategies involve identifying surface exposed proteins that can be the target for antibody and complement binding, resulting in bactericidal activity. The adhesins are a family of outer membrane proteins which mediate bacterial adherence via non-fimbrial attachment. They also confer a degree of serum resistance by unknown mechanisms. By sequence homology with known adhesins, one gene identified from the genome of N. meningitidis has been selected as a potential vaccine candidate. This antigen has been distributed within an EU-funded collaborative programme, to identify novel mucosal vaccines. The antigen is being expressed in a number of model systems including rBCG. We have experience of expressing antigens in BCG and determining murine models of immune responses. Our collaborators have extensive experience of developing expression systems in rBCG, and have expressed NadA in recombinant BCG which we now wish to evaluate in a murine model of immunogenicity.

Recipient or parental organism

BCG is used as a human vaccine for neonates, children and adults. It has a long track record of safety. It is an ACDP HG2 pathogen. It can cause idenitis, retropharyngeal adenitis when given orally in high doses. If administered parenterally to immunodeficient persons it can cause disseminated BCGosis. All these complications are rare and amenable to antibiotic therapy.

Host/vector system

Two vectors have been constructed:
(a) Replicative: based on pAL5000 a plasmid from mycobacterium fortuitum containing a mini mycobacterium - E. coli shuttle plasmid constructed by using the gene for Kan (Tn903) as a selective marker (J Bacteriol 1990; 172(5):2793-2797). NadA was cloned into pGEMT easy by BamHI/Asp718 digest of a PCR product obtained from a N. meningitidis NadA template.
(b) Integrative: Using a vector derived from M. smegmatis mycobacterial phage Ms6 (Microbiol 1998; 144:3397-3406)., pAV6950 E. coli replicative/mycobacterial integrative shuttle vector, contains the attachment site and the gene coding for integrase of Ms6; contains Kan from Tn5 (Infect immun 2002; 70(1):303-314. The expression vector is transferred from the replicative vector to this vector by restriction digest.

These vectors have been electroporated into BCG and protein expression confirmed by Western blot. The rBCG are being cultured into vaccine preparations, suitable for use in murine models of immunisation at SGHMS.

Origin & function

NadA encodes for a protein of Neisseria meningitidis, that has sequence homology with a range of 'adhesins' such as UspA1 and UspA2 proteins of Moraxella catarrhalis, YadA protein of Yersinia and EibF of E. coli. These proteins are anchored in the outer membrane of host bacteria, and have a structure, as follows (taken from EMBO J 2000; 19(22):5989-5999, see also J. Exp. Med. 2002 195 (11): 1-11):

The head region confers resistance to complement binding and bacterial lysis by antibody and complement. It may also increase bacterial adhesion to epithelial cells. The exact mode of this functionality is unknown. Antibodies raised against these regions are bactericidal and therefore excellent vaccine candidates.

Evaluation of foreseeable effects

It is not expected that virulence will be conferred on recombinant BCG by the expression of NadA for the following reasons:-
1. Serum sensitivity is not relevant to mycobacteria, as bacterial killing is mediated via macrophage uptake and intracellular killing. There is no evidence that antibody and complement play any significant role in mycobacterial killing.
2. The mycobacterial cell wall has a different structure, and it is unlikely that the NadA complex could be exported and insert into the cell wall of rBCG efficiently.
3. The cloned gene contains only the sequence from the first mature codon up to codon 350. This excludes the N terminal leader sequence making export of the protein unlikely. The C terminal anchor component is also completely missing, making the stable insertion into the bacterial membrane impossible.
4. As the cloned protein will be incapable of stable insertion into the bacterial membrane, no increased cell adhesion can occur.
This the NadA protein is incapable of exerting its virulence property in rBCG, but the antigenic head and stalk regions are present to induce an antibody response.

(a) Hazards arising from the alteration of existing pathogenic traits (eg. alteration of host range or tissue tropism): None. The shuttle vectors contain a kanamycin resistance gene, but this antibiotic is not used routinely in the treatment of BCG infection in susceptible hosts. The antibiotic sensitivity of the recipient BCG is known (INAH, rifampicin and ethambutol sensitive).

(b) The potential hazards of sequences within the GMM being transferred to related micro-organisms: Unlikely. Should transfer occur, the resultant protein will still be deficient for insertion into bacterial membrane, and therefore unable to exert its virulence properties which requires stable expression on the bacterial surface.

(c) Consideration of the likelihood that, in the event of exposure, the GMM could actually cause harm to human health. No additional harm to human health is expected above that of the parent BCG.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All the infected waste will be autoclaved and the used pipettes and other materials will be soaked overnight in 5% hycolin before autoclave.

The mice will be kept in standard cages in the BRF. The policy in place for disposing of animal carcasses from the BRF will be followed: Animals will be double-bagged for autoclaving using autoclavable bags (transparent with blue writing). After autoclaving they will be put in yellow bags for disposal via BRF contractor and labelled as 'waste for incineration'.

**Purposes of the contained use**

Pre-clinical testing of modified forms of herpes simplex virus for vaccination purposes

**Recipient or parental organism**

Herpes simplex virus strains with attenuating mutations but in which replication competence is retained. Attenuating mutations remove HSV genes, which usually inhibit immune responses and also render the virus non-pathogenic. These genes are VHS and/or ICP47 and may additionally include further mutations in ICP34.5, UL43, U35 and/or vmw65. The modified HSV strains also have genes encoding non-HSV antigens inserted encoding immune modulatory molecules such as cytokines and non-oncogenic differentiation antigens.

In view of the replication competency of some of the HSV vectors, all experimental work will be conducted under class 2 conditions.

The work aims to induce immune responses to the delivered antigents and no untoward effects are anticipated. The mutations to the virus have previously been shown to render the virus non-pathogenic and the genes to be delivered are not anticipated to be harmful according to previous work published in the literature.

**Host/vector system**

Herpes simplex virus 1 or 2
Insert genetic materials is of either human or rodent origin and has been cloned by PCR or obtained from collaborators in plasmid form. Genes to be inserted include tumour antigens such as MART-1, MAGE-1, tyrosinase, gp100, Muc-1, PS1, CEA for the development of anti-tumour vaccines. Antigens from a variety of infectious agents for vaccine development purposes will also be used as will human or rodent forms of various immunomodulatory molecules e.g. GM-CSF, IL12, CD40L, B7.1, RANTES. The immunomodulatory genes are aimed, eventually, at the enhancement of the immune response to delivered antigens.

### Evaluation of foreseeable effects

None of the genes to be inserted are anticipated to result in harmful effects. No genes with oncogenic activity will be used.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste generated during the activity that has been in contact with the GMM will be treated with a 1% Virkon solution for a minimum of 30 minutes. This broad-spectrum disinfectant is effective against herpes simplex virus at a 0.5% (w/v) concentration giving terminal disinfection after 10 minutes of contact. 1 (ref: Hernández A, Martro E, Matas L, Martín M, Ausina VJ. Assessment of in-vitro efficacy of 1% Virkon against bacteria, fungi, viruses and spores by means of AFNOR guidelines. Hosp Infect 2000 Nov;46(3):203-9). Solid waste will be placed in autoclave bags, autoclaved then incinerated. Liquid waste will be collected in glass bottles, treated with 1% virkon then autoclaved prior to disposal in a sink in running water for maximal dilution.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
A number of replication competent and replication incompetent viruses will be used all based on the laboratory strain of HSV1, strain 17+. An essentially wild type virus contains the marker gene GFP (green fluorescent protein) inserted in the UL43 (non-essential) region of the HSV-1 genome. This virus is to be classified as class 2.

The other viral vectors to be used contain an attenuating mutation by the deletion of ICP4. These are not replication competent and will be classified as class 1 (but all experimental work will be performed under class 2 conditions where all HSV work will be conducted) due to their replication incompetency, a helper cell line is required for virus production.

Some of the replication-incompetent HSV strains also have genes encoding non-HSV tumour-associated antigens. These consist of a number of melanoma-associated genes (gp100, MART-1, MAGE) and/or the gene encoding CD40L. These genes are not oncogenic and do not affect the replication potential of the viral vectors. These viruses will also be classified as class 1.

The GMSC has reviewed the risk assessment and accepts that classification of class 2 for HSV constructs that are able to replicate and class 1 for those that are replication-incompetent.

## Project Additional Information

### Purposes of the contained use

We wish to identify and characterise mechanisms involved in the uptake of DNA by S. aureus. This includes transformation, transduction and conjugation of DNA from other bacterial genera into S. aureus. It also includes investigating S. aureus factors that inhibit or enhance these processes. The DNA to be introduced into S. aureus will contain antibiotic resistance genes, as they are useful as selective markers. Understanding how S. aureus acquire foreign DNA will allow us to make predictions about how S. aureus acquire resistance to antibiotics, how virulence genes move between strains of S. aureus, and will allow us to construct new tools for the genetic manipulation of clinical S. aureus strains.

### Recipient or parental organism

S. aureus is a Hazard Group 2 organism. It is found as a commensal of the human nose in 30% of the population. If introduced into a wound, it is capable of causing disease, particularly if the host is immunocompromised. However, it is not considered a risk for laboratory workers. In hospitals, methicillin resistant strains (MRSA) are widespread and infections caused by these isolates can be more difficult to treat, although vancomycin can be used. Intermediate level vancomycin resistant strains (VISA) pose a new threat, but are rare.

### Host/vector system

n/a

### Origin & function

Firstly, we wish to construct libraries of S. aureus mutants using the transposon Tn917 (erythromycin resistant) which randomly integrates into the S. aureus chromosome. To do this, a plasmid containing the transposon is moved into S. aureus, and forced to insert by temperature and erythromycin selection. The resultant library of strains will each have the Tn917 inserted in a unique locations and have a unique phenotype, although none are likely to be more pathogenic or hazardous than the parent. Tn917 is a naturally occurring transposon isolated from S. aureus.

Secondly, we wish to introduce foreign DNA into S. aureus. Specifically, this will be

1. Plasmids propagated in E. coli and introduced by electroporation (pulsing S. aureus with an electric current). The plasmids used will be standard shuttle vectors composed of E. coli cloning vectors with a S. aureus origin of replication and a selectable antibiotic resistance marker.
2. Plasmids and transposons derived from Enterococci and Streptococci, and introduced by conjugation. The plasmids are naturally occurring and carry antibiotic resistance genes on the plasmid or on transposons integrated into the plasmids. The plasmids also carry genes necessary for conjugation. Similar plasmids and transposons are found naturally in S. aureus.
3. Chromosomal DNA and plasmids from other staphylococci, including other S. aureus isolates. This will be introduced by transduction using naturally occurring generalised transducing bacteriophages.

In all cases, foreign DNA will contain an antibiotic resistance gene that can be used as a selectable marker. They will encode resistance to erythromycin, tetracycline or chloramphenicol. None of these antibiotics are used routinely in the clinical treatment of S. aureus infection. Naturally occurring resistance to these antibiotics is widespread in S. aureus.

### Evaluation of foreseeable effects

The antibiotic resistance genes we plan to move are:

- erythromycin
- tetracycline
- chloramphenicol
All of these resistance genes are found naturally in S. aureus and are widespread. The genetic elements carrying these resistance genes are derived from S. aureus itself or are closely related to elements found in S. aureus. Therefore, mutants or recipients are not predicted to be a greater hazard than naturally occurring strains. None of our new strains will be multiply resistant, that is, they will always be susceptible to antibiotics currently used to treat clinical infection, such as b-lactamases or vancomycin.

Toxin genes and virulence factors genes will be moved between strains of S. aureus. S. aureus produces more than 100 known or putative toxin genes, and different strains have unique combinations and novel variants. These genes are often encoded on mobile genetic elements and move between strains naturally in the environment by transduction. Our experiments are designed to mimic this process, and will not generate new strains with any increased hazard.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Level 2 containment, with waste material to be autoclaved (effectively 100% kill) prior to incineration. Autoclaves are validated for effective waste treatment weekly by internal engineers and quarterly by external engineers. Autoclaved waste is incinerated.

An alternative procedure that has been tested for liquid waste is disinfection with Hycolin. Hycolin is added to a final concentration of 1% and left overnight before washing down the laboratory sink. This method has been validated for use with S. aureus in our laboratory. Cultures of 1 x 10^9 (to the power of 9) bacteria per ml were treated with Hycolin overnight, diluted up to 100-fold, and plated onto agar. No viable bacteria were recoverable. Dilutions of 0.5% and 0.25% Hycolin were equally effective.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Animal Units: Large Scale Activities: Human Clinical Applications
The aim of this project is to utilize a replication incompetent adenoviral vector to express inserted genes to elicit immune responses to the inserted gene products.

The vectors under development will be based on the adenovirus family of respiratory viruses. Serotypes expected to be used include the Ad2, 4 and 5. All will be replication incompetent. Any serotype utilized will be gene E1a, E1b and E3 deleted, thereby preventing the replication of the adenovirus after cell entry. The adenoviral life cycle does not normally involve integration into the host genome, rather they replicate as episomal elements in the nucleus of the host cell and consequently there is no risk of insertional mutagenesis.

Unmodified Ad5 is classified in hazard group 2 under the COSHH regulations but the E1a gene deleted forms are classified as hazard group 1. Although recombination with an unmodified virus in vivo is a possibility the further deletion of the E3 gene renders it extremely unlikely that even in the event of such a rare recombination occurring that the recombinant will be packaged with viral coat proteins and secreted from the cell.

Cells used to propagate the recombinant adenoviruses are 293 cells. These are human embryonic kidney cells that have been transformed with the adenovirus genes E1A and E1B, which are required for adenovirus propagation.
The genetic material to be inserted will be encode HIV proteins or natural murine cytokine proteins. In the case of murine derived genetic material, RNA will be isolated, first strand cDNA prepared and primers specific for the gene in question will be used in a polymerase chain reaction to amplify the target sequence. This material will then be inserted into the E3 region of the gene deleted adenoviruses. The selected genetic material will generally constitute an open reading frame of a particular protein that we expect to be fully transcribed using the host cell transcription machinery. Translation of the resulting RNA transcripts into fully functional murine protein is expected. We intend to use these expression vectors to produce physiologically relevant quantities of the murine proteins in vivo in the mouse. These proteins are expected to have various degrees of immuno-modulatory activity, although it is expected, based on current literature, that most will have no detectable effect.

HIV genetic material will be derived from current plasmid vectors that contain small parts of the HIV genome. This material can be sub-cloned from these plasmid vectors and inserted into the E3 region of the gene deleted replication incompetent adenoviral vector.

All the inserts that will be incorporated into the gene deleted adenoviral vector will not have any known oncogenic potential.

**Evaluation of foreseeable effects**

The adenoviral life cycle does not normally involve integration into the host genome, rather they replicate as episomal elements in the nucleus of the host cell and consequently there is no risk of insertional mutagenesis. Unmodified Ad5 is classified in hazard group 2 under the COSHH regulations but the E1a gene deleted forms are classified as hazard group 1. Although recombination with an unmodified virus in vivo is a possibility the further deletion of the E3 gene renders it extremely unlikely that even in the event of such a rare recombination occurring that the recombinant will be packaged with viral coat proteins and secreted from the cell. When injected into mice it is possible that the gene-deleted adenoviruses may come into contact in vivo with endogenous murine viruses. While it is extremely unlikely that these replication-deficient gene-deleted viruses will be transcomplemented by any known murine virus, we will utilise specific-pathogen free mice that do not harbour murine viruses of the papovaviridae genus that contain both murine polyomaviruses as well as human papillomaviruses.

The adenovirus vaccine vector itself will consist of E1a and E3 gene deleted adenovirus and an insert consisting of a DNA sequence encoding for small parts of the HIV genome. Typically, the vaccine vector contains a DNA sequence that encodes individual viral proteins such as the env (structural envelope glycoprotein), gag (matrix and capsid structural protein), rev (regulator of viral protein expression) or tat (regulator of HIV genome transcription) molecules. These small parts of the virus are expressed in such a manner that the essential minimal components of an infectious retroviral particle will not be present, particularly the intact HIV/SIV viral genome, thus preventing any possibility of inadvertently generating an infectious viral particle. There is no conceivable risk inherent in these proteins.

Other inserted cDNA, that will encode for natural, non-modified, mouse proteins will belong to the murine cytokine/chemokine family of secreted proteins. Other insertions may include proteins that have been shown to stimulate the innate immune system, including those that act at the cell surface as well as internal cytoplasmic proteins. These proteins have not been described to have oncogenic attributes in the published literature and are indeed non-modified and identical to those proteins expressed by normal murine cells. The proteins expressed from these constructs have between 30 and 70% identity with the corresponding human cytokine. However, most are not active or have only partial activity on human cells (COPE cytokine Database).

It is not expected that any of the insertions detailed will have an effect on the tissue tropism. However, the deletion of E3 has been shown to increase the immune response due to less down-regulation of the host cell MHC Class 1. The addition of cytokine insertions may also increase the immune response. As these effects are the precise criteria under investigation in our studies, it is impossible to predict the effects of augmentation of the immune response. It is possible that the resulting inflammatory response will be harmful. However, none of the insertions will be human genes, although murine cytokine/chemokine products may have some activity upon human cells. (COPE Cytokine Database).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

We do not intend to use any GM animals or plants.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A
In view of the fact that all adenoviruses used will be replication incompetent but may have undetermined pathogenicity by virtue of the gene insert, it is appropriate for all manipulations involving this virus to be undertaken within a microbiological safety cabinet. It is expected that all large scale work with these GMOs will be done in a dedicated Category 3 facility, that has an autoclave within the lab. Small scale work (less than 100ml) may also be done within a microbiological safety cabinet in a category 2 laboratory. Liquid culture waste in both circumstances will initially be aspirated within the microbiological safety cabinet into a leak-proof container with Virkon S solution. The concentration of Virkon S will be maintained at greater than 1% - a concentration that has been validated as 100% virucidal for adenoviruses as well as most other viruses. Moreover, all waste materials (solid and Virkon S treated liquid) will be autoclaved in an autoclave maintained and appropriately certified to properly inactivate infectious waste. Autoclaved material is considered to be 100% effective at sterilization. The extra precaution of performing large scale preparative work in a category 3 laboratory with an internal autoclave ensures that large volumes of Virkon S treated culture solutions (which although almost certain to be 100% killed should be treated as potentially infectious material) cannot come into contact with other laboratory staff or any non-laboratory personnel. Any small volumes of culture performed in category will be treated with the Virkon S virucide and then contained within a leak-proof container for transport to the autoclave.

Any new staff would be specifically trained in the safety aspects of this work. Since the gene deleted replication incompetent virus is transmissible by an airborne route an inward microbiological cabinet airflow would be required.

The work involves standard laboratory protocols and there are no unusual procedures that require additional containment measures.

All work with these adenoviruses will be performed within a certified category 2 or 3 laboratory.

Mice injected with the replication-deficient gene-deleted recombinant adenoviruses will be maintained within isolators. All injections and handling of these animals after injection with the recombinant adenoviruses will be carried out entirely within a microbiological class 1 cabinet. Cells, blood and tissues harvested from these animals prior to schedule 1 euthanasia as well as post-mortem will be transported from the microbiological class 1 cabinet within the animal facility to a microbiological class 11 cabinet in our class II laboratory entirely sealed within a biohazard container. The exterior of the biohazard container will be sprayed with liquid Virkon disinfectant prior to removal from the microbiological class II cabinet to ensure no GMOs survive on the exterior of the container. Post-mortem, both the mouse carcass and the cage in which the mice lived will be autoclaved in an autoclave maintained and appropriately certified to properly inactivate infectious waste. Autoclaved material is considered to be 100% effective at sterilisation. The sterilized bedding contents of the cage and the mice carcasses will then be incinerated.

The isolators that contained the cages will be fumigated.

The risk assessment has been reviewed and approved by the St George's Hospital Medical School GMSC.
The study has been set up to assess the safety, biodistribution and biological activity of OncoVEX GM-CSF. The study involves intratumoural injection into cutaneous or subcutaneous nodules.

The oncovex human GM-CSF vector (Oncovex hGM-CSF) is a replication competent herpes simplex type-1 virus which will be tested in a phase 1 clinical trial for its safety, biodistribution and efficacy in a variety of solid tumours. The strain of HSV which Oncovex is based on is JS-1 (ECACC No. 85011433). The Oncovex GM-CSF vector is deleted for the neurovirulence factor, ICP34.5 which is essential for pathogenicity. This deletion allows the vector to selectively replicate in dividing cells. The vector is also deleted for ICP47, which blocks antigen presentation to MHC class I and II molecules by blocking the transporter associated with antigen processing (TAP1 and TAP2). The vector also contains the coding sequence for human GM-CSF, a cytokine involved in the stimulation of T-cells. The deletion of ICP47 and the expression of GM-CSF should enhance the immune response towards tumour cells. GM-CSF expression is under the control of the human cytomegalovirus immediate early promoter (HCMV IE). This is an infectious gene therapy product that can only replicate in rapidly dividing eukaryotic cells.

Reference:

Host/vector system

HSV strain JS1/34.5-/47-/CMMVGM-CSF (OncoVEX GM-CSF)

Origin & function

The hGM-CSF gene was cloned from an IMAGE clone 2340997/5808-K14 (UK HGMP Resource Centre). GM-CSF is a potent cytokine responsible for the differentiation and proliferation of dendritic cell precursors and therefore is a potent immune stimulator. Thus if the vectors were to enter a human it would be anticipated to give an improved immune response against HSV.

Evaluation of foreseeable effects

GM-CSF should enhance the immune response towards tumour cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All waste will be placed in a sharps bin or bag and placed in a second bag and securely tied. These will then be placed in an external container in order to prevent external spillages and will be identified as potentially containing genetically modified organisms. The containers will then be transferred to a designated and approved autoclave in the Medical School premises which is a separate building on the same campus as the Vaccine Institute where the trial will be conducted. Air-Sea Biopack-2 (Biojar) containers will be used (Air Sea Containers LTD, Birkenhead) for transport of solid waste. The waste will be placed in autoclave bags, autoclaved then incinerated. The containers will be decontaminated with the application of 1% Virkon.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste generated during the activity that has been in contact with the viral vector will be treated with a 1% Virkon solution for a minimum of 30 minutes. This broad-spectrum disinfectant is effective against herpes simplex virus at a 0.5% (w/v) concentration giving terminal disinfection after 10 minutes of contact. 1 (ref: Hernndez A, Martro E, Matas L, Martin M, Ausina VJ. Assessment of in-vitro efficacy of 1% Virkon against bacteria, fungi, viruses and spores by means of AFNOR guidelines. Hosp Infect 2000 Nov;46(3):203-9). All waste will be placed in a sharps bin or bag. These will then be placed in an external container in order to prevent external spillages and will be identified as potentially containing genetically modified organisms. The containers will then be transferred to a designated and approved autoclave in the Medical School premises. The containers will be placed in autoclave bags, autoclaved then incinerated. Liquid waste will be collected in glass bottles, treated with 1% Virkon then autoclaved prior to disposal in a sink in running water for maximal dilution.
The risk assessment has been reviewed by the St. George's Hospital Medical School GMSC. The committee accepted the statement concerning preferential replication in tumour cells but raised the possibility of virus production from some normal cells. They requested further information about the timing of the return of test results and the discharge of patients. The committee was satisfied that these issues would be dealt with effectively.

02/03/2022
**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**
The aim of this project is to exchange specific amino acids in *P. falciparum* transporters and to investigate (1) altered drug susceptibilities of parasites to anti-malarials, and (2) to study the basic physiology of transporters in the parasite.

**Recipient or parental organism**
The vectors used are generated on a puc 18-backbone and contain a *P. falciparum* specific selectable marker. After transfection they replicate episomally for about 2 months, until integration as single-site crossover into the parasite genome occurs. Since human red blood cells do not contain a nucleus no integration into human host cells is expected. *P. falciparum* is the protozoon parasite responsible for the most severe forms of human malaria. Following infection via the bite of an Anopheline mosquito the parasite invades hepatic liver cells and red blood cells. This leads to a variety of well-documented clinical symptoms. Treatment with modern antimalarials is highly successful. Natural infection with *P. falciparum* is only through the bite of an infected Anopheline mosquito. Cases of malaria have also been reported as a consequence of transfusion with contaminated whole blood. *P. falciparum* needs human red blood cells to multiply and is considered to have extremely limited survivability in the environment. Transmission of asexual blood-stage parasites requires injection into the blood stream. There is no risk of infection through aerosol. The only significant risk of infection in the laboratory is via needlestick or similar penetrative injury with culture material containing infective blood-borne stages of the parasites.

It is not thought that *P. falciparum* would establish itself in the environment, since its asexual replication is dependent on red blood cells. In any case, it would not in itself, be hazardous to the environment. Spread in the environment would require transmission by the Anopheline mosquito vector. This requires strict laboratory conditions (controlled temperature, humidity and feeding) for 7-10 days. Furthermore, the disease vector is absent from the environment, since our climate doesn't meet its requirements for survival.

**Host/vector system**
Cells used to propagate transfected *Plasmodium falciparum* are human red blood cells. These cells are required for routine *P. falciparum* propagation.

**Vector**: pH22Y, pUC18 backbone.

**Origin & function**
The vector transfected into the parasite will lead to an exchange of specific amino acids in transporters of *P. falciparum*. Cultures will be propagated until recombination occurs. DNA will be extracted and primers specific for the gene sequence used to amplify the target sequence and evaluate recombination. Further evaluation steps include Southern blot, RNA isolation and RT-PCR as well as protein extraction followed by Western blot. Once successful integration has been proven, modified parasite lines will be subjected to drug assays to test for possible altered drug sensitivities. There are no indications that modified parasites have an increased pathogenic potential or are harmful to humans.

**Evaluation of foreseeable effects**
During its asexual blood stage life cycle *P. falciparum* replicates within the human red blood cells. It is categorised as a Hazard Group 3 pathogen. However, it falls under an exemption for class 3 as stated by the Advisory Committee on Dangerous Pathogens (Fourth Edition, 1995). Integration of genetic material in vitro experiments is only expected to occur into the parasite genome. In vivo asexual blood stage parasites only invade nucleus-free human red blood cells, making the event of integration of genetic material into the human host genome highly unlikely. Furthermore, it is not expected that genetic modification of *P. falciparum* will have an effect on the tissue tropism and invasion behaviour of the parasite.

Sharp objects (needles, glass, metal) are banned in a malaria culture lab. In the unlikely event of sharps or needle injuries and incorporation of *P. falciparum* into the
bloodstream, general safety measures have to be taken immediately (see also risk assessment P. falciparum culture). This involves reading of blood films in short term intervals and monitoring of potential development of fever. There are no indications that genetically modified parasites are more virulent or invasive. If suspected infection did occur then diagnosis could be quickly carried out and the necessary drug or drug combination prescribed. Infection would be quickly cleared and would not recur. The species of human malaria parasite that recur cannot be cultured in the laboratory. 

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

We do not intend to use any GM animals or plants.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

P. falciparum is listed as an exempted category 3 by the Advisory Committee on Dangerous Pathogens (Fourth Edition, 1995). It has full derogation by the HSE due to its low risk of laboratory required infection, negligible risk of spread in the community and relative ease and success of drug treatments available. Taken this into account we would like to ask specifically for derogation of the following control measures: a) entry via airlock, B) negative pressure related to pressure of immediate surroundings, c) requirements for HEPA filters, d) autoclave in laboratory suite, e) shower, f) footwear as protective clothing.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid culture waste will initially be aspirated within the microbiological safety cabinet into a leak-proof container with 1% Virkon solution, being adjusted to a final concentration of 1% at the end of work, and left there until the next morning. This is an extended precaution since malarial parasites are extremely sensitive to culture conditions. Even a slight rise in pH of the culture medium will kill them. Minor spillage is treated with 70% Ethanol spray, which kills the organism immediately. Spillages of infective material (ie in the incubator or safety cabinet) shall be contained to prevent their spread, and then covered with Virkon powder. It will be left until the liquid is absorbed. The powder/spillage mixture is scraped into a receptacle for disposal. Afterwards the area will be rinsed and disinfected with 1% Virkon. There must always be a fresh supply of 1% Virkon readily available in case of spillage or accidents. Solid waste is placed directly into leak proof boxes. These are sealed for transport and autoclaved following recommended procedures for ADCP category 3 containment. Autoclave tape indicates that the process has occurred. Autoclaved material is considered to be 100% effective at sterilisation.

Any new staff would be specifically trained in the safety aspects of the work. The vector nor the genetically modified parasites are transmissible by an airborne route.

All work with P. falciparum will be performed under derogated category 3 standards within a certified category 2 laboratory.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Project Containment

02/03/2022
THE GENERATION OF GENE KNOCKOUTS IN MYCOBACTERIUM AVIUM-INTRACELLULARE COMPLEX (MAC)

This project aims to define factors that determine virulence in mycobacteria belonging to the Mycobacterium avium-intracellular Complex Systems studies will include genes involved in metabolism, global gene regulation, stress response, intracellular survival, in vivo growth and latency. The aim is to produce strains of mycobacteria that have had individual genes inactivated either by removal or by interruption with transposon sequences. Mutants will also be complimented with the deleted gene in an attempt to restore parental function/phenotype. The mutants produced will be studied in vitro, and also used in murine infection models. The long-term aim of this work is to understand mycobacterial virulence thereby allowing the development of new control measures for MAC related diseases, including new drugs and better vaccines.

The Mycobacterium avium-intracellulare Complex (MAC) includes Mycobacterium avium subspecies avium (MAA), Mycobacterium avium subspecies paratuberculosis (MAP), Mycobacterium avium subspecies silvaticum (MAS) Mycobacterium avium subspecies hominisuis (MAGH) and Mycobacterium intracellulare (MI). However some human and environmental isolates of MAC do not fall within any of the designations listed above. Such isolates can exhibit genotypic features of two or more different MAC
species, and are usually given designations such as "MACx". The existence of such intermediate types suggest that MAC organisms are a continuum of species and subspecies however the pathogens MAA, MAP and MI are distinct in many significant ways, including environmental niches, host preferences, and clinical manifestations. Available epidemiological evidence indicates that humans are infected by MAC living in the environment, not via person-to-person transmission. Although viable MAC cells can occasionally be cultured from the stool of AIDS patients, there is little evidence to suggest that infective populations of the bacteria commonly make their way back to the environment. Therefore, the populations of MAA and MI cells to which humans are exposed are likely to not have human environments in their recent evolutionary histories. MAP is the cause of chonic enteritis in many animals including primates, whilst MAA and MI infect a variety of mammals and birds in serovar-specific fashion. Although there is little evidence for direct transmission from animals to humans, some serovars and strain types can be recovered from both, consistent with the possibility that virulence mechanisms are maintained in animal reservoirs. It is possible that some strains found in the environment are especially infectious to humans, while others may be relatively harmless. This compromises the predictive value of environmental monitoring efforts that assume uniform levels of infectivity and suggests that all MAC require a similar risk classification. Some MAC are undoubted opportunistic pathogens of humans, often requiring a dysregulation of the normal immune response to illicit pathobiological effects. MAA and MI are associated with cervical adenitis in children and as a complication of other immunological disorders including AIDS. A cell wall deficient form of MAP has been found intracellularly in macrophages associated with the gut wall of up to 92% of patients with Crohn's disease and 26 of controls. MAP is also the cause of orofacial granulomatosis. MAA, and MI are currently officially classified as ACDP as a Hazard Group 3 whilst MAP are classified only as ACDP Hazard Group 2 and MAS and MAH are not listed - but are presumably included in MAA. This laboratory however considers that, in the absence of further evidence, all MAC should be classified as Hazard Group 3 and has assumed this level of risk for this assessment. In a few cases, a rapid growing non-pathogenic host (Mycobacterium smegmatis strain MC2 155) will also be used to study the function of single genes in isolation.

Host/vector system

Knockout mutants will be generated by two methods: 1) Double crossover homologous recombination in host mycobacteria using a suicide shuttle plasmid (eg pNIL) that has no mycobacterial origin of replication but contains selection maintenance genes. The plasmid has a hygromycin resistance gene, which is lost in the final generation of the GMO knock-out as a result of counter selection (single-crossover plasmid DNA containing bacteria get killed) using sacB and sucrose selection. However, the intermediate transformants or single cross-over recombinants will have the plasmid with hygromycin gene. Hygromycin is commonly used as a selective marker in mycobacteria; it is not used as an antibiotic in clinical settings. ii) Transposon mutagenesis using mycobacteriophage (L5) delivery of a transposon (with Hygromycin selectable marker) to induce stable integration into the target genes causing disruption of target gene transcription. Complementation mutants of the knocked out gene will be generated by transformation with a simple non-hazardous plasmid (eg pAGAN, pSODIT, pSMT3) containing the wild-type gene. These constructs contains the mycobacterial origin of replication and can be sustained in the host. They also have hygromycin and/or kanamycin antibiotic resistance marker genes. These complemented mutants with genes from the parent strain will have the same hazards as, or less than the parent wild-type organism.

All MAC mutants will be treated as hazard group 3 organisms, exactly as the donor or wildtype recipient and therefore there is no expected increase in exposure hazard risk and no increased disease risk.

Origin & function

This project will be techniques to knockout the transcription of a variety of existing mycobacterial genes or to replace existing genes with modified 'inactivated' genes and will only be introducing 'new' non-self genes functioning as selective markers for each mutant. These include single genes involved in host metabolism, global gene regulation, stress responses, intracellular survival, in vivo growth and latency. The virulence of mycobacteria not determined by a single gene, thus single gene knockouts are not expected to increase virulence. The introduction of altered "self" genes back into the donor to create modified recipient organisms may be regarded as self-cloning.

Evaluation of foreseeable effects

It is highly unlikely that the deletion of a mycobacterial gene will increase the virulence of mycobacteria. However there are several hypothetical possibilities which may result in the phenotype of the GM MAC being altered in favour of increased pathogenicity by directed knockout of host genes. These include:

Deletion of a repressor gene for virulence determinants resulting in genes normally only expressed during a particular phase of infection to cause damage or immune evasion being switched on permanently. An increased hazard, in these cases is unlikely as the mechanism of pathogenicity in intracellular mycobacteria is based on the ability to switch multiple sets of genes on and off at specific times and in specific locations.
Deletion of a growth repressor.
This is highly unlikely to increase the hazard of these organisms as the slow growth rate of mycobacteria is considered to be controlled by the law of mass action and the number of ribosomes as a ratio of the availability of tRNA species and translation initiation factors. Thus multiple genetic manipulations would be required to influence growth rate.

Deletion of a deominant antigen involved is immune recognition, thereby allowing the bacteria to avoid recognation and cause more disease.
This is again highly uniquely as immune recognition is a multiple-antigen-dependent event and others have shown that deletion mutants of dominant antigens in other mycobacteria (eg Mycobacterium tuberculosis) have reduced or unaltered virulence but not increased.

The pathogenicity of mycobacteria is not fully understood but is widely shown not to be a single gene function; rather mycobacterial virulence is a multi-genec property of the bacteria. Virulence and pathogenicity of mycobacteria is determined by the host-pathogen interaction, with host immunity playing a central role, which is independent itself on human genetica, nutritional status and other factors. Thus disease, or the potential for harm to host, is a complex and multi-factorial process, in which gene sets play synergistic roles with other gene sets.

Accidental exposure to GM MAC is likely to give risk to infection with disease occurring at an incidence not greater than the wild type organism. The GM MAC is treatable in the same way as the wildtype organism with antibiotic treatment. Providing genes are not transferred from drug resistance strains of donor mycobacteria, which we shall not use as recipients, then any recipient GM MAC will be treatable in the same way as the fully drug-sensitive donor strain.

Horizontal (lateral) transfer of genetic material in mycobacterial populations is minimal. Mycobacterial plasmids do occur rarely and conjugal transfer has been observed in M.smegmatis (a fast-growing non-pathogenic mycobacteria). The importance of natural horizontal transfer in mycobacteria has not however been established. Introducing DNA into mycobacteria is a very inefficient process in the laboratory with very low frequencies of recombination. So horizontal transfer would be a very rare event within the Genus Mycobacteria. Transfer of mycobacterial genes from the GM MAC to other micro-organisms would be highly unlikely to occur, and alter the properties of the recipient bacteria so as to increase its hazard. Harbouring of extra genomic material in bacteria is usually associated with decreased fitness thereby producing a counter selection against any transformant.

Recombinant mycobacteria to be generated in this project are thus considered to be no more hazardous, and most knockouts to be much less so, than the donor wild-type parental organism. The knockout strains will not contain mycobacterial genes absent from wild type natural strains of pathogenic mycobacteria.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Animal infection with GM MAC will be performed by tail vein or intraperitoneal inoculation under CL3 conditions within a Class 1 MSC, as for fully virulent wildtype organism. This will take place in a specialised CL3 containment Suite. All waste will be autoclaved within the BRF suite and then incinerated. Any material from GM MAC infected animals that is required for further experiments will be performed in the departmental laboratory. CL3 suite. This will involve transport of GM MAC material from the BRF CL3 to the departmental CL3, where it will be treated. The transport will follow strict transport safety guidelines for ACDP Group 3 pathogens, samples will be double bagged and placed in unbreakable and sealed metal transport containers and carried to the CL3 labs, where it will be unloaded within the Class 1 MSC.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All Containment Level 3 (CL3) work will be performed in the specialised CL3 laboratories under the ACDP guidance for Hazard Group 3 micro-organisms. All work will be performed with live GM MAC within a Class 1 Microbiological Safety Cabinet (MSC) following identical protocols as for wild type MAC. GM MAC for culture will be transferred to incubators within the CL3 suite to another CL3 suite will be followed as for group 3 organisms, following current transport safety guidelines.

Waste from work carried out in the Class 1 MSC will be initially treated with 1% Virkon overnight before autoclaving. All waste will be sterilised by autoclaving followed by
incineration. The autoclaves to be used are sited within the CL3 suite. The autoclaves meet the correct standards and are validated by regular checks and calibration. Restricted access to all CL3 facilities is made by security pass-locked doors and to registered CL3 trained personnel.

Class CultureVolClass2 CultureVolumeClass3-4

Class 2 < 1 Litre

Exploring the RhoA-actin, Dyrk and MAP4K4 signalling pathways using lentiviral vectors.
Lentiviruses have the ability to infect human cells, with the subsequent expression of the inserted foreign genes and shRNAs, given that the HIV-envelope protein has been replaced with VSV-G (virus stomatitis envelope) which can infect many different cell types. All progeny cells also express these genes, but are replication defective (no new lentiviral particles can be produced from the infected cells). The purpose of the contained use is therefore to minimize the risk of exposure to the lentiviral particles.

Lentiviral particles will be produced in 293FT cell line (Invitrogen) by transient transfection of vector DNA. The resulting lentiviruses will then be transduced (infected) into eukaryotic cells in vitro, primarily mouse NIH3T3 fibroblasts, mouse skeletal muscle C2C12 cells, human breast adenocarcinoma MDA-MB-231 cells, and primary human mesenchymal stem cells.

Two different lentiviral vectors will be used. Plasmids pSIN and pHR will be used for the cloning of cDNAs and commercially available pLKO.1-puro plasmid (SIGMA-ALDRICH) for shRNA expression. Both lentiviral vectors are secured by gene removal such that no new particles can be produced from infected cells (replication-deficient). Vector DNA will be transformed and purified from bacterial TOPO1O cells (Invitrogen).

Several cDNAs will be cloned into the lentiviral vectors. These include components of the: A) RhoA-actin signalling pathway (i.e. the small GTPases RhoA, Rac, cdc42, the actin remodeling proteins ROCK, LIMK, cofilin and ERMs, and the downstream transcriptional activators MALIMKL1, MALI 6/MKL2 and the novel transcription factor encoded by 8C039093; b) Dyrk signalling (i.e. wild type and kinase-dead Dyrk) and its substrates (i.e., nuclear matrin MATR3, RNA-binding protein hnRNPU and the regulatory subunit of PKA (PRKAR1A); c) MAP4K4 signalling pathway (i.e. wild type and kinase-dead MAP4K4, the small GTPases Rab2 and GBP3, and MEKK1 kinase). These cDNAs will be either subloned into the lentiviral pH/pSIN vectors by restriction enzyme digestion or PCR from mammalian expression vectors currently available in the lab (pUC1S-derivative pEP plasmids, or pACT2-NIH3T3 library from Clontech)

Commercial pLKO1-puro plasmid (SIGMA-ALDRICH) will not be genetically manipulated as they already contain the shRNA against the above mentioned cDNAs.

The lentiviral vectors are replication defective. There is the theoretical risk of recombination with wild-type HIV-1 or HIV-2, although this has never occurred. The lentiviral vectors will be pseudotyped with the vesicular stomatitis viral envelope (VSV-G) and as a result could infect several human cell types, with the theoretical risk that a laboratory worker could be infected (i.e. through wounds or by spillage to the eye) and the transgene could be expressed. There is a low risk that the expressed proteins/shRNAs could give the infected cells an increased proliferative capacity. Although our proteins of interest have not been reported to behave neither as oncogenes nor tumor suppressors, they can affect cell proliferation.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

not applicable
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste (tissue culture media containing most of the lentiviral particles) will be treated with 1% freshly prepared Virkon (DuPont), according to the manufacturers recommendations within the Class II containment laboratory. Virkon is fully active against lentiviruses and its activity will not be reduced by the conditions of use. Solid waste (i.e. pipettes, tips and tissue culture plastic ware) will be deposited in a Sharpsafe box, the box sealed according to the manufacturers instructions and taken to be autoclaved within the building using a secondary container. Autoclaving will be performed in a validated autoclave cycle (100% kill degree) prior to incineration.

Project Additional Information

Purposes of the contained use

To determine what viral and cellular factors are required for the replication and pathogenesis of human cytomegalovirus.
To determine what existing and novel drugs can be using in preventing human cytomegalovirus replication and pathogenesis.

Recipient or parental organism

Human cytomegalovirus

Host/vector system

Human

Origin & function

A laboratory strain of the herpesvirus human cytomegalovirus, AD169, will be modified. Modifications will be made by either of two methodologies.
Method 1: The AD169 genome has been cloned in to a bacterial artificial chromosome (BAC). This BAC is contained within the E.coli laboratory strain GS1783. Red-two step recombination of PCR products with BACs in GS1783 E. coli will be used to modify the nucleotide sequence of the AD169 genome. BACs will be transfected into human cell cultures to generate genetically modified virus. Genetically modified virus containing the desired mutations will be used to infected human cells in subsequent experiments. Mutations in the human cytomegalovirus genome contained within the BAC will be made so as to;
(i) introduce reporter genes including green fluorescent protein or luciferase
(ii) introduce marker peptides including FLAG, His6 or Myc tags into viral open reading frames
(iii) delete open reading frames from the viral genome
(iv) express HCMV genes from ectopic sites within the HCMV genome
(v) modify viral open reading frames so that the virus becomes resistant to the action of anti-viral drugs.
Method 2: AD169 will be cultured in human cell cultures under the selective pressure of anti-viral drugs to generate drug resistant viruses. Drug resistant mutations should be in viral open reading frames nessesary for a particular drugs mechanism of action. Drugs used to generate drug resistant viruses will include bacteriostatic and anti-proliferative agents, kinase and phosphatase inhibitors, or nucleoside and non-nucleoside inhibitors of viral replication.

Evaluation of foreseeable effects

E.coli bacterial strain GS1783 containing a bacterial artificial chromosome (BAC) encoding HCMV genome AD169 will be used to modify the HCMV virus by red two step recombination. Red two step recombination will not alter the biological properties of either the bacteria or BAC used.

Neither insertion of marker genes or tags nor deletion of viral open reading frames will result in virus with altered traits such as pathogenicity, host range, tissue tropism and mode of transmission. However, mutation of virus so that it is resistant to drug treatment will take place.
No GM plants or animals will be used

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Low levels of any known disinfectant can inactivate human cytomegalovirus. All samples containing virus will be exposed to 1% Virkon for at least 1 hour before disposal.
All tissue culture plastic will be autoclaved before disposal.
All glass ware used will be autoclaved before re-use.

Project Ref 95/14.2

Date Ackn’d 01/04/2014

CU2 Project Title Studying Pseudomonas aeruginosa infections and development of novel treatment options

Date Project Ceased 02/03/2022

Class CultureClassVolClass2 CultureVolumeClassConsent Granted

Class 2 < 1 Litre Non-GMM Consent Granted
Bacterial lung infections are a significant cause of morbidity and mortality. Particularly in individuals with underlying co-morbidities e.g. Cystic fibrosis, COPD, asthma and diabetes are more susceptible to bacterial lung infections. We are interested in two aspects here 1) the interactions between the bacteria and the host, looking at how the host tries to control the bacterial infection and how the bacteria tries to evade this. Using both in vitro and in vivo systems, we wish to define differences between healthy individuals and those with underlying co-morbidities that leads to greater disease susceptibility to bacterial lung infection. The 2) aspect we are interested in is the development of novel antibiotics that can kill P. aeruginosa either planctonic or in a biofilm setting.

P. aeruginosa can be carried as part of the normal nasal/ host bacterial flora. The bacterium is able to infect a wide variety of hosts and tissues and is an excellent model for studying infection by gram-negative bacteria. It is particularly prevalent in cystic fibrosis patients. We will be using in vitro models of infection using airway epithelial cells and differentiated airway epithelia to assess the effect of altering physiological conditions on bacterial growth. We will then assess these conditions and drugs that can alter them using in vivo mouse models. We would like to use gene modified P. aeruginosa in order to better follow and monitor infections with the bacterium. We will use luminescent and fluorescent strains of P. aeruginosa and nutrient transporter KO strains. The strains in use will be lab derived strains and no clinical samples or community acquired strains or toxin producing strains will be used. In addition, for screening for novel antibiotics we would also like to use P. aeruginosa with luminescence, as a reporter gene, to get a fast read out for killing activity.

Recipient or parental organism

Pseudomonas aeruginosa PAO1

Host/vector system

- Tn5-luxCDABE transposon
- GFP
- knock out's

Origin & function

Luminescence Reporter Gene -Tn5-luxCDABE stemming from Photorhabdus luminescens
Fluorescence Reporter Gene GFP and derivates stemming originaly from Aequorea victoria

Nutrient (predominantly carbohydrate) transporter/utilisation KO
e.g. FruA, FruR, oprB, carbohydrate kinase, permease of ABC sugar transporter, binding component of ABC sugar transporter, zwf g-6-phosphate dehydrogenase.
P. aeruginosa is a Gram-negative bacteria in the class of Gamma Proteobacteria and in the order of Pseudomonadales. Pseudomonads are ecologically important, since they are capable of breaking down many different molecules, such as pesticides, toxic chemicals, plant and animal materials in soil and water. Pseudomonas aeruginosa is a versatile bacterium that grows in soil, marshes, and coastal marine habitats, as well as on plant and animal tissues. P. aeruginosa is an aerobic, rod-shaped bacterium (K. J. Ryan, C. G. RAY, Sherris Medical Microbiology 4th ed. (MCGRAW-HILL, New York 2004). P. aeruginosa is not an obligate parasite, it is an opportunist, initiating infections in individuals whose resistance is low, e.g immune suppressed patients or patients with large burn wounds. Especially in patients with cystic fibrosis (CF) P. aeruginosa is hard to treat. The lung environment of these patients appears to provide a unique environment, allowing persistent bacterial colonization. Clinical data indicates that P. aeruginosa is the fourth leading cause of nosocomial infection and the foremost cause of hospital-acquired pneumonia. Into the wildtype strain of P. aeruginosa PAO1 glucose knockout mutants or transposon mutant with a luminescence or fluorescence gene will be introduced. Reporter gene like GFP, YFP, RFP or luminescence are well established and used in the background of many different microorganisms as well as eucaryotic cell lines. To our best knowledge and assessment, introducing a reporter into PAO1 will not increase the hazard towards the environment as well as to animals or humans. In addition, glucose knockout mutants will be of an disadvantage of the GMM compared to the wild type strain and there is no evidence that the knockout will show any improved virulence.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use

Development of vectors (viral and plasmid) and molecules for the study of cellular signalling processes in normal development and disease. This will involve transgene over-expression, gene knockdown, cellular reprogramming and directed differentiation. All gene modifier vectors are disabled and lack essential genes which prevent their autonomous replication. All require specific packaging cell types to produce a viral particle which is replication deficient and cannot multiply or produce progeny. All vectors will have no effect to the environment as they will be maintained and contained under strict laboratory conditions.

Recipient or parental organism

Recipient Cells

Mammalian cell lines (for example 293T, 3T3, CHO, HepG2, Huh7, U2OS, ela, PC3, DU145).
Primary human and mammalian cells (for example fetal and adult fibroblasts, blood cells, and vascular and lymphatic endothelial cells).
Human and mouse embryonic stem cells and adult stem cells either obtained commercially or from collaborators and repositories or from biopsy material (for example; mesenchymal stem cells, cardiac and vascular stem cells, pancreatic/hepatobiliary progenitors).

Human embryonic cells and primary cells or tissues are obtained by donation after pathogen screening (HIV, Hepb/c Human primary cells are donated from unscreened patients and are quarantined pending the pathogen screening as described prior to genetic modification.

Viral Vectors

Retroviral vectors used are derived from Moloney murine leukaemia virus (MMLV), a mouse virus therefore chances of mobilisation by recombination with endogenous
Viruses in a human are practically impossible. Furthermore, the vectors contain no MMLV protein coding sequences and so are completely replication disabled and the chances of recombination are minimised.

Lentiviral vectors derived from HIV1, SIV, EIAV and FIV are based on genome integrating viruses. Like retroviruses the severely deleted genomes contain no endogenous protein coding sequences and the 3' Long Terminal Repeat (LTR) contains a self-inactivating mutation that prevents the replication cycle initiating after reverse transcription of the RNA viral genome.

Adenoviral vectors (serotypes Ad2/5) are disabled by mutations to the E1a and E3 genes that are fundamental to the early stages of viral replication. Although adenoviruses are human pathogens infection does not result in serious illness and as such are a low risk to humans. The viral genome is transient in infected cells (does not naturally integrate into the host genome) and so there is minimal risk of insertional mutagenesis.

Adeno-associated Viral vectors (AAV) are disabled by mutations to the Rep gene which is necessary and fundamental to replication. Furthermore, AAV requires the expression of adenoviral genes to facilitate its replication. Recombinant forms of AAV will integrate into the host cell genome at very low frequency and so the chances of insertional mutagenesis are low.

### Host/vector system

#### Origin & function

Transgenic material - Human and mammalian cDNAs of transcribed genes involved in aspects of cellular transformation, self-renewal, differentiation, proliferation, senescence, apoptosis and metabolism will be expressed from pol ll promoters. These genes would include transcription factors, signalling factors, signalling molecules, enzymes, growth factors and cytokines.

Such genes would include but are not limited to:

- **Transformation:** hTERT, BMI-1, C-MYC
- **Self-renewal:** OCT4, Nanog, SOX2, LIN28, KLF4, STAT3
- **Differentiation:** Wnt, PI3K, Notch, Hedgehog, TGFbeta, BMP, MAPK, ERK, JNK, RAS, NFkB
- **Cell adhesion, migration & communication:** ICAM-1, VCAM-1, Selections, ThoGTPases, Ezrin, PDK1, Cadherins, B-Catenin.
- **Hypoxic Responses:** HIF, ARNT, C-MET
- **Innate Immunity:** TLRs, TBK, NFkB, IRF3, IRF7

The above gene targets will also be subject to gene knockdown with siRNA and miRNA expressed from pol ll/lll promoters.

Bacterial Cre-recombinase for removal of LoxP flanked gene sequences.

Reporter genes will also be expressed from endogenous and viral promoters with or without additional enhancer elements either constitutively or conditionally to mark cells or quantify surrogate gene expression. These will include;

- Fluorescent- e.g GFP, YFP, CFP, dsRed, mCherry.
- Luminescent- e.g.firefly and renilla, guassia, vargula luciferases.
- Biochemical marker genes e.g. CAT, AFP

### Evaluation of foreseeable effects

The recombinant viral vectors are all highly disabled vectors.

Lentivirus/retrovirus: These self-inactivating vectors have had regulatory and accessory genes deleted ensuring that viral particles produced in the packaging cells are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication/infection cycles. Whilst the envelope pseudotyping extends the cellular tropism and confers greater stability the viral vector will always be contained within a class II safety cabinet thus user exposure to liquid aerosol is
The exposure of non-human hosts to pseudotyped vector could result in initial infection but, again seroconversion is highly unlikely.

Adenoviral vectors of non-human hosts to pseudotyped vector could result in initial infection but, again seroconversion is highly unlikely.

Adenoviral vectors are deleted of essential replication/packaging genes that are supplemented by an established packaging cell line (293T).

Adeno-associated Virus is defective by nature and has a replication disabled genome and is incapable of replication without the presence of helper adenovirus proteins. In this instance the vectors used would require the provision of cap and rep genes in trans in order to replicate and disseminate. There is no significant chance of reversion to the animal species therefore it highly unlikely that such a virus, if released into the environment, would represent a significant risk. Furthermore, most AAVs proposed for use constitute AAV5 genomes pseudotyped with other AAV envelopes so would never occur in nature and thus would be incapable of reversion.

The majority of the gene products expressed are expected to affect cellular properties such as proliferation, apoptosis, migration, adhesion and fate. Also, some have known or suspected oncogenic or tumour suppressor properties.

Gene products in plasmid form exist in non-mobilisable constructs and are therefore of minimal threat as expression would most likely be restricted to the infected cell, which in itself would be rejected by the host immune system.

Sharps will not be used in the production or handling of any of the viral vectors described in this project.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All viral production and handling procedures will occur in containment level 2 laboratories.

Non-viral work will occur in Class 1 conditions.

Liquid Waste will be treated with freshly prepared 1% Virkon or 10% hypochlorite solution for at least one hour prior to disposal via the sink. Solid waste will be autoclaved at 134°C on a destruct cycle prior to be placed in Tiger striped bags for disposal. Sharps will be placed in yellow sharps boxes that will be first autoclaved then removed by the waste contractor for incineration. Cryovials containing virus will be stored in specified cryofreezer and opened only in Class II microbiological safety cabinets. Spillages and working surfaces will be cleaned with 2% Distel or 1% Virkon and with 70% ethanol.

Solid waste that has not been autoclaved will be placed in clearly labelled biohazard double bags will be incinerated as clinical waste.

Hazard conditions consist of possible spillages, aerosol spray when opening cryovials.

Work is restricted to determined areas (containment level 2 laboratories), disinfecting solutions will always be available, working guidelines are clearly posted, unauthorised personnel is not permitted. Strict adherence to Category II working practices. Reporting in case of accident is according to College procedures using the online or paper accident incident forms or by contacting the Safety, Health and Environment Office directly on extn. 5365.

Training to work with class II GMM's will include Instruction of the guidelines regarding dressing code, how to treat spillages and disinfection with 2% Distel, 1% Virkon and
70% ethanol. Documented spillage procedures are clearly established. In case of accident with sharps, College procedure with blood borne viruses will be followed. Autoclaves are regularly serviced and checked. Autoclaved material is checked using autoclaving tape and spore strips to assess has reached temperature for disinfection.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N

Project notified under transitional arrangements N

Withdrawn N

Tick if notifying a connected programme of work Y
**Project Additional Information**

**Purposes of the contained use**

Envelope (Env)-pseudotyped HIV-1 will be produced in HEK 293T/17 cells by chemical means. This generates pseudovirus particles that are able to infect cells but are generally unable to produce infectious progeny virions due to the absence of a complete genome. This single round of infection is readily detectable in genetically engineered cell lines (e.g. TZM-bl) that contain a Tat-responsive reporter gene, such as luciferase.

**Recipient or parental organism**

- Human Embryonic Kidney 293T/17 cells [used for transfections]
- TZM-bl cells [Obtained from NIH AIDS Research and Reference Reagents Programme or its UK equivalent the National Institute for Biological Standards and Control (NIBSC)]; Parental HeLa cell line (JC.53) stably expresses large amounts of CD4 and CCR5. They constitutively express CXCR4. The TZM-bl cell line was generated from JC.53 cells by introducing separate integrated copies of the luciferase and β-galactosidase genes under control of the HIV-1 promoter. Cell line is highly sensitive to infection with diverse isolates of HIV-1
- Bacteria DH5a [used for making plasmids]

**Host/vector system**

- an Env expression plasmid (e.g., pcDNA 3.1D/V5-His-TOPO-Env)
- a backbone vector (e.g., pSG3ΔEnv) that expresses the entire HIV-1 genome except Env. pSG3Δenv was derived from pSG3.1 by SpeI partial digestion, Klenow filling of 3' recessed ends and religation. This has introduces four nucleotide insertion mutation (CTAG) in env and a translation stop codon (TAG) after amino acid residue 142 (Wei et al. 2002; Antimicrob Agents Chemother 46: 1896-1905).

Plasmids for pseudovirus will be provided by the NIH AIDS Research and Reference Reagents Programme or its UK equivalent the National Institute for Biological Standards and Control (NIBSC). No genetic manipulation will be required in SGUL.

### Evaluation of foreseeable effects

Human Immunodeficiency Virus (HIV) can cause a currently incurable disease in humans which may be fatal. The virus is categorized as a BioHazard Group 3 pathogen by the Advisory Committee on Dangerous Pathogens (ACDP). However the risk of transmission of the infection in the laboratory work environment is an exceedingly rare event (ACDP/92/P5b). The primary route of infection for lab workers is through contact with open body sites (e.g. cuts, braised mucosal surfaces, eyes, blood to blood contact and through needle stick injuries). Aerosol infection is considered to be a very low risk to lab workers. The risks may be greater when handling purified, concentrated or bulk quantities of virus under laboratory conditions where the virus is present in concentrations far exceeding that found in normal body fluids.

Env-pseudotyped virus has a four nucleotide insertion mutation (CTAG) in the Env gene and a translation stop codon after amino acid residue 142 that renders the Env defunct. However, it is important to note that Env-pseudotyped viruses are handled and treated the same as live HIV-1 cultures since replication competent virus could be present. Sequence analysis indicates that recombination can occur that repairs the defect in the backbone plasmid(s) lacking Env, thus rendering the virus replication-competent. The recombination event occurs at a relatively low frequency and the proportion of the pseudovirus that is replication-competent is low (Abram et al. 2010. Journal of Virology. 84:9864-9787). When recombination occurs that renders the virus replication-competent, the virus generated is predicted to behave identically to wildtype HIV-1.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Sweetie jar for discard of tips, plates, eppendorf tubes and small volumes of liquid inside the safety cabinet (please refer to Appendix A). Sweetie jar will ultimately be autoclaved using a destructive cycle at 134°C.

### Is an emergency plan required according to regulation 20? N

### Tick to confirm that it is attached to this form N

### Tick to confirm that you have attached a risk assessment to this form Y

### Please enter comments on the GM safety committee on the risk assessment

The committee required the preparation and other work with the pSG3Δenv plasmid to be performed under conditions that protect against hazardous naked DNA, under COSHH (wearing of protective gloves, covering of cuts by suitable dressings and avoiding the use of sharps). This was included in procedures and the committee was satisfied with the information provided and agreed that the project could be conducted safely as described.

Project Additional Information

Purposes of the contained use
We wish to understand replication and pathogenesis of Zika virus, with an emphasis on infection of human trophoblast cells.

Recipient or parental organism
A range of cell lines, including human trophoblasts, will be transfected with viral genes. It should be noted that several experiments will entail making replication defective lentiviral particles in order to express Zika virus RNA and proteins upon transduction of human cells.

**List of vectors:**
- pREST
- pcDNA
- pcDNA3.2/V5-DEST
- pcDNA3.2/V5-DEST
- pLenti6.3 - a second generation lentiviral system where the deletion of lentiviral sequences do not allow this vector to be mobilized by other lentivirus or any other virus.

**Origin & function**

We intend to clone and/or create recombinant versions of the following Zika virus genes, whose functions are described:
- **C** - virus capsid
- **prM** - virus maturation factor
- **E** - virus envelope fusion protein
- **NS1** - viral interferon/immunity antagonist
- **NS2A** - viral assembly factor
- **NS2B** - viral assembly factor
- **NS3** - viral protein protease
- **NS4A** - viral genome replication factor
- **NS4B** - viral genome replication factor
- **NS5** - viral RNA polymerase

The recombinant versions will be tagged with fluorescent markers such as Green Fluorescent Protein.

**Evaluation of foreseeable effects**

This activity involves - in the first instance - the infection of cells with a Zika reporter virus that expresses firefly luciferase (Royle et al, Vet J, 2016). Based on the infection experiments we will then perform a range of experiments to study viral RNA and protein function. Initially, this involves modifying the aforementioned viruses to carry other reporter genes, in particular green fluorescent protein. We will also test viral RNA and protein function by introducing mutations that inhibit viral RNA and/or viral protein synthesis or viral protein function.

Ultimately, no GM organism will be produced that is more hazardous than the wild type viruses or any replication defective lentivirus. Only loss of function mutations are to be studied (viral genes replaced by Green Fluorescent Protein (GFP) or other markers or viral genes, or fragments of them, tagged with GFP).

Regardless of which strain is being studied, Zika virus is characterized as a hazard group 2 pathogen. Human infection of the flavivirus Zika virus is typically caused by transmission to humans of virus by infected biting insects, such as certain species of mosquito. Zika virus can be transmitted between humans horizontally via blood-blood contact, sexual intercourse. Also, Zika can be transmitted from mother to foetus across the placenta during pregnancy and, potentially, from mother to child during birth or post partum (via breast milk or salivary exchange). Zika virus infection can be cleared by
immuno-component adults. The greatest risk to human health is in infection of individuals who are pregnant or may become pregnant, where virus infection in the foetus can result in microcephaly and associated developmental disorders, or those who are immunosuppressed, where infection can cause various inflammatory illnesses. There are no vaccines available for Zika. However, infection can be treated with broad spectrum anti-viral agents such as favipiravir, ribavirin, and 5-fluorouracil. Moreover, virus infection can be treated with non-specific agents such as interferon. The laboratory use of Zika virus in the tasks covered by our risk assessment is not part of the viruses normal transmission route and, therefore, viruses are highly unlikely to be laboratory acquired, even if the measures detailed in this assessment are not used. Also, the insect vector for Zika virus is not found in the UK or Northern Europe.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No plant or animal GMO will be created nor will plants or animals be infected with GMMs.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Material will be disposed of in accordance with SGUL guild lines and local rules. These are detailed in COSHH Risk Assessment Number I&l/BLS/004. Low level of any known desinfectant or a 70% ethanol solution can inactivate enveloped viruses, including Zika virus and lentiviruses. Briefly, infected liquid material will be deactivated in 1% bleach or 1% Virkon. Solid material in which infected material was used will be autoclaved on a destrcution cycle (134°C for 20 min) giving and effective 100% kill using the autoclave adjacent to the tissue culture laboratory (J2.125). This autoclaves is validated on an annual basis (including the placing of independant thermocouples at the centre of the load).

Please enter comments on the GM safety committee on the risk assessment

Project Containment
The overarching goal of our research is to generate lentiviral particles pseudotyped with variants of the coronavirus Spike glycoprotein in order to investigate its function and evolution and use a well-established approach (shRNA-mediated knock down) to identify key players in infection.

Pseudotyping with the glycoprotein of interest:

Whilst retroviruses possess the ability to infect and replicate in a range of cell types, tropism and host range is determined by the specificity of the surface glycoproteins encoded by the env gene. To alter or investigate the host cell tropism of a retroviral or lentiviral vector, the env gene may be modified or exchanged with the surface glycoprotein from another virus. This process is known as pseudotyping and envelope proteins such as gibbon ape leukemia virus envelope (GALV-env) or vesicular stomatitis (VSV)-G protein are commonly used to produce pseudotyped viral particles capable of infecting cells from different host species.
In our work, lentiviral vectors will be pseudotyped with envelope proteins such as GALV-env or VSV-G or variants of the coronaviruses Spike glycoprotein. Genetic load: reporter gene or silencing RNA

The lentiviral particles can be loaded with a reporter gene (such as GFP, GST and luciferase) or interfering sequences (i.e. RNA designed to silence specific genes of interest). In addition, the genetic material may contain an epitope tag (such as Myc, His, Strep, V5). Genetic material may also contain a selectable drug marker e.g. the pac gene encoding a puromycin N-acetyl-transferase (PAC) which confers puromycin resistance and enables selection of transduced cells.

Cell lines of mammalian origin (including human, simian, murine origin) will be transduced with recombinant vectors to enable the study of the phenotypic and functional effects of the ectopically expressed glycoprotein(s) or to silence expression of target host genes.

Recipient or parental organism

Mammalian cells (including HeLa, Vero) will be transduced with pseudovirus for transient expression of a reporter gene (GFP, luciferase) in order to investigate the properties of SARS-CoV-2 Spike proteins; in separate experiments, mammalian cells (including HeLa, Vero) will be transduced for transient expression of a silencing hairpin to investigate cascades, including signalling cascades that regulates protein expression (including ACE2 expression).

Host/vector system

List of vectors. (cover names, mobilisation regions, and any disabling mutations.)

- p8.91 packaging plasmid, contains HIV-1 gag-pol, rev (Zufferey et al., 1997). It will be obtained as a gift from Dr Dalan Bailey, The Pirbright Institute, UK.
- pMD.G contains VSV-glycoprotein (Naldini et al., 1996). It will be obtained as a gift from Dr Nigel Temperton, University of Kent.
- pCDNA3.1_Spike and pCAGGS_Spike contain Spike protein from SARS-CoV-2. They will be obtained as a gift from Dr Dalan Bailey, The Pirbright Institute, UK.
- pMD.G.2-WEAU contains the Envelope glycoprotein from HIV-1 isolate WEAU_D15_410 and pMD.G.2-MLV contains the Envelope glycoprotein from MoMLV. Both will be obtained from Dr Laura McCoy, University College London.
- Reporter plasmids (pCSFLW) contain Luciferase or GFP (reporter gene) (Zufferey et al., 1997, 1998) a gift from Dr Dalan Bailey, The Pirbright Institute, UK.
- pCSRQ silencing plasmid (Clontech), contains silencing hairpins.

Example of three-plasmid system with the AIM of investigating Spike function
1. p8.91 packaging plasmid
2. pCSFLW-Luciferase
3. pCDNA3.1_Spike
A Positive Control particle will be generated as:
1. p8.91 packaging plasmid
2. pCSFLW-Luciferase
3. pMD.G (VSV-glycoprotein)

A Negative Control particle ("bald", i.e incapable of cell entry) will be generated as:
1. p8.91 packaging plasmid
2. pCSFLW-Luciferase

Example of three-plasmid system with the AIM of knocking down a host gene
1. p8.91 packaging plasmid
2. pCSRQ silencing plasmid
3. pMD.G (VSV-glycoprotein)

OF NOTE: particles pseudotyped with SARS-CoV-2 Spike will only be used in combination with a reporter gene, GFP or luciferase, and NOT in combination with a silencing hairpin.

Origin & function

Sequences for coronavirus Spike proteins, including SARS-CoV-2, will be obtained from open databases (including the UK COVID-19 Genomics UK Consortium), while silencing hairpins are designed using commercially available software (e.g. GeneArt, Life Technology; Clontech). Sequences will be either custom synthesised commercially (GeneArt, Life Technology) or will be generated using standard molecular biology techniques.

Evaluation of foreseeable effects

Hazards associated with the recipient microorganism:
The generation of pseudoviruses will involve initial amplification of packaging, load and envelope plasmids using competent bacteria and commercially available plasmid purification kits. All bacteria used for such amplification will be standard commercially-available ACGM class 1 strains of Escherichia coli (E.coli) such as JM109, DH5alpha, and TOP10 which do not pose a hazard to human health. Genes encoded by the plasmids are unlikely to be expressed in such strains of E. coli. The bacteria and genetic material will be handled as per COSHH and RAs that mitigate risks to human health to acceptable levels. Briefly, all waste will be discarded after neutralisation (Virkon/Chemgene for liquid and autoclaving for solid waste); staff are required to wear personal protective equipment (including Howie lab coat, gloves) and follow general laboratory code of practice (Local Rules) following appropriate training.
The so generated pseudoparticles will be able to enter mammalian cells, including human cells, and insert their proviral DNA into the genome. This may possibly disrupt the normal pattern of gene expression within a transduced cell. However, the pseudoparticles are replication-defective and would not then proceed to disseminate. Importantly, the cells (including
Transduced ones) and the pseudoparticles will be handled as per Containment Level 2 COSHH and RAs that mitigate risks to human health to acceptable levels. Briefly, all material will be handled in a MSC Class II; centrifugation will be performed with buckets with lids and o-rings; waste discarded after neutralisation (Virkon/Chemgene for liquid and autoclaving for solid waste); staff are required to wear personal protective equipment (including Howie lab coat, gloves) and follow general laboratory code of practice (Local Rules), following appropriate training.

Hazards arising directly from the gene products:
None of the viral genes used or modified in our studies encode a toxin, oncogenic protein, allergen, modulator of growth or differentiation or any other protein which may result in a potentially harmful biological activity. We know of no known harmful biological activity of over expression of any of the viral genes studied here.

Hazards arising from the alteration of existing traits:
The inserted gene product(s) will be reporter genes, including GFP and luciferase, which are not known or suspected to interact with host cellular processes/pathways and/or are virulence factors. The gene product may also be an interfering RNA molecules designed to silence specific genes of interest. These products may interfere with normal cellular pathways if workers get into direct contact with the viral particles. This risk will be minimised by handling the particles at Containment Level 2. In the highly unlikely event of viral particles getting into contact with skin, the skin will be washed with soap and warm water. An incident report will be filed with the Safety, Health, and Environment Office. No sharps will be used in any procedure.

Hazards arising from the transfer of the inserted sequence to other organisms:
Endogenous retroviruses have been described in many animal species. However, recombination with exogenous sequences is only likely to occur when high levels of DNA are present in the same cell and this will not occur during experimental transduction of cell lines (human HEK 293T cells are not known to express endogenous retroviruses).

All cells (including transduced ones) and the pseudoparticles will be handled as per Containment Level 2 COSHH and RAs that mitigate risks to human health and to the environment to acceptable levels. Risks to the environment are minimal as the vectors are replication deficient and very unlikely to remain viable for prolonged periods of time outside ideal culture conditions. The control measures described above to mitigate risks to human health will mitigate any risk to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No larger GMOs will be created

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids that have been into contact GMM is disposed in an autoclave bag and autoclaved using the equipment available in the CL3 suite. The autoclaved waste is no longer hazardous but will be disposed via clinical waste (orange bags) route.
Liquid waste is decontaminated by incubation with Virkon (1% final concentration) or chemgene (1:50) for at least one hour. The decontaminated liquid is then disposed in the CL2/3 laboratory sink.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Please enter comments on the GM safety committee on the risk assessment
Thank you,

I agree with your three comments. The comments add clarity to the risk assessment and should be added to the text. The overall risk of the project remains changed because viral particles will be handled at CL2, which provides sufficient mitigation.

Sent: 26 February 2021 15:59
Subject: Re: New GMM Risk Assessment: GM334 Gaining insight into the function and evolution of the Spike glycoprotein of coronaviruses using a replication-defective pseudovirus system

All -

I have little to add for a virological standpoint. At this junction my only comments are that there is little information about what spike mutants might be used now and in the future. It might be wise include language that covers "the study of mutants with known differences in transmission and pathogenesis compared to wild type" or similar. Plus, a general point that should be made with all lentivirus work; insertional mutagenesis of humans can occur regardless of what lentivector is they are exposed to. That point should be emphasised (I hope I did not miss it!), but should not alter this application in a substantial way.

01/03/2021

Dear All,

I agree with A's assessment and comments made by B. My only small point would be that the question as to whether or not the work can be done by a pregnant worker is not exactly answered - is a definitive answer required prior to notification?

Best wishes,

01/3/2021

Dear all

I also agree with A and B's comments about the categorisation of the work. With regard to immune-compromised people and pregnant individuals, I think it would be best to say that the person should opt of the work unless suitable anti retro viral drugs are available. While the risk assessment says that people will be referred to Occupational Health (OH) for assessment, OH could send the person back to the committee as would say that they are not experts in the work being undertaken.

I know that this may seem draconian given that no infections have been reported due to VSV and that it was used in an Ebola vaccine https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7045819/ but I think it would be best to adopt a precautionary principle.
Regards,

Thank you,
P I think you raised an important point.
I agree with C that immune-compromised people and pregnant women should opt out of work. Not that sure about the anti-retroviral part as it sound too uncertain (to me). To add to the mix, women can become pregnant without knowing it. All this needs to be clarified on the RA before we approve.
I will wait until Thursday, I am hoping to collect more comments, and then request E to deal with the corrections/comments.
Best,
02/03/2021
Dear all,
I agree that this should be a CL2 project. The relevant mitigation for lentivirus production seems to be in place and the biggest unknown is the effect of mutations in the SARS-CoV2 spike protein, but this will be packaged into the replication defective virus and will carry only reporter genes. Although these viruses are likely to be taken up efficiently by relevant cell types, there are no known harmful effects of these reporters.
I wonder whether there’s a need to use shRNA/VSV for gene silencing and whether a CRISPR/Cas9 system using transfection might be a safer approach and potentially more effective?
It’s not clear to me what the increased risks might be for women during pregnancy, but an opportunity to discuss the proposed work with OH on an individual basis might be important to determine if any further mitigation is needed for that person.
Best wishes,

Thank you, You hit the nail in the head with your comment about replacing Lentis with CRISPR; One of the steps in the hierarchy of controls is “to replace the dangerous with the less dangerous”. I will suggest E to consider this. However, in my humble lab experience, lentiviruses are very robust and efficient knocking down genes while CRISPR is far fiddlier. This will have to be weighted depending on the long-term goals of the project and the tools already available to E
I will add your example on the GMO guidance webpage.
Best,

---

02/03/2021
This project aims to study the bacterial fitness of GBS isolates by investigating genes associated with adhesion, invasion, virulence, colonisation and disease using knock in and knock out variants in growth, adherence and invasion assays. To set up the series of functional assays, we would like to ensure the bacteria can be visualised and traced for the different assays we will carry out, such as flow cytometry and microscopy, which requires the bacteria to contain a fluorescent protein marker provided by Prof. Spellerberg at the University of Ulm, Germany.

### Recipient or parental organism
- Clinical Group B Streptococcus isolates
- Group B Streptococcus serotype reference strains (e.g. NCTC 9993) obtained from PHE
- Commercially available ATCC Group B Streptococcus laboratory strains (e.g. COH1(ATCC BAA-1176))

### Host/vector system
- pAT28 with a multiple cloning site to allow cloning of fluorescent proteins
- pBSU409 with a spectinomycin antibiotic resistance gene
- pHY304 temperature sensitive integrating vector with a chloramphenicol resistance gene
- pDCerm shuttle vector for complementation
- and other commercially available plasmids

### Origin & function
- **gfp:** encodes for green fluorescent protein used as a marker protein
yfp: encodes for yellow fluorescent protein used as a marker protein
rfp: encodes for red fluorescent protein used as a marker protein
mcherry: encodes for red fluorescent protein used as a marker protein
and other similar fluorescent proteins

Several genes identified by ourselves and other groups which control the function of protein synthesis, transport, energy metabolism and cell regulation amongst others will be investigated. The genetically modified GBS strains will not be in any way more virulent than wild type strains as we are not over-expressing or introducing gain-of-function mutations. Only mutations hindering fitness will be selected.

Evaluation of foreseeable effects

The genetically modified GBS strains will not be in any way more virulent than the wild type strains for humans or the environment as we are not over-expressing or introducing gain-of-function mutations. Only mutations hindering fitness will be selected.

Hazards associated with the recipient microorganism:
GBS (Group B Streptococcus, Streptococcus agalactiae) is a common commensal bacterium found in 20% of humans, worldwide, and does not tend to cause disease in healthy adults. GBS is also a pathogen found in fish, cows, and various reptiles.
GBS colonises the genitourinary and gastrointestinal tracts of humans. It is spread from mothers to infants during pregnancy during birth or post-partum. Infants under 3 months old are the most at risk. GBS infection can cause meningitis, sepsis, or pneumonia. Disease in infants below 7 days old is called early-onset disease, with the primary risk being maternal colonisation. Disease in infants aged 7-30 days is described as late-onset disease, the risk factors are not well-characterised. Elderly people with co-morbidities also have a higher risk of GBS infections.
GBS is treatable with antibiotics – penicillin is the first line of treatment, or alternatively, clindamycin or erythromycin. Resistance against penicillin is not common and remains the most effective treatment. Pregnant women can be screened for GBS by a risk-based assessment in the UK (or culture based through private clinics) and if deemed at risk of GBS carriage then will be given intrapartum antibiotic prophylaxis (IAP) at 35-37 weeks gestation. IAP has successfully shown that it can prevent early-onset disease.
Genetic modification of the bacterial genome is likely to create a loss-of-function phenotype. There is a possibility of cells being co-infected with the wild type strain during complementation assays to validate the loss-of-function mutations, restoring it to a wild type strain. There will only be restoration of the GMM, there will not be a gain-of-function for it to be more virulent than the wild type.

Hazards arising directly from the gene products:
All vectors used will carry an antibiotic cassette that is not used to treat GBS infections clinically, therefore preventing the risk of untreatable GBS if the pathogen escapes.

Hazards arising from the alteration of existing traits:
Gain of function mutations will not be selected. Only mutations hindering fitness will be selected.

Hazards arising from the transfer of the inserted sequence to other organisms:
Gene transfer or recombination of the GMM with another organism could occur, however, we will take precautions to minimise the risk of this happening. This includes only working with the target organism (GBS) in a microbiological safety cabinet and ensuring surfaces are thoroughly disinfected with 70% ethanol and Virkon 1% before and after. We will also ensure GMM waste is disposed of, separate to non GMM laboratory waste.

Hazards to the environment:
GBS can replicate in humans, cows, fish and reptiles but not in plants. GBS is not regulated under SAPO.
None of the genes manipulated encodes a plant or animal toxin.
We do not anticipate that manipulation of genes to cause loss-of-function will be hazardous to animals or plants.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Material will be disposed of in accordance with SGUL guidelines and local rules. Solid waste will be placed in Bio-Bin Fold Flat and autoclaved at a destruct cycle at 134 degrees C for 30 minutes, liquid waste will be immersed in Virkon 1% for at least one hour, or alternatively autoclaved. 1% v/v virkon (and 70% ethanol) are highly effective at disinfecting GBS (Streptococci) [ref: https://www.fishersci.co.uk/webfiles/uk/web-docs/SLSGD05.PDF]. All samples containing GBS will be disinfected with virkon and surfaces cleaned with 70% ethanol as described.

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Dear GMSC,

My assessment of GM339

I agree that this GM risk assessment for work with Group B Streptococcus should be regarded as a Class 2 activity. All the precautions to mitigate risk, worker exposure and waste disposal are adequate for this organism. Convincing arguments to support the view that any manipulation proposed will not enhance virulence or create more risk to the environment than the wild type. The use of Virkon at 1% for 1 hour is appropriate and a well-established disinfecting conditions for this bacteria. Disposal of waste by autoclaving using the discard cycle should stipulate 134oC for 30 minutes and not as in the document as 132oC. Please can this be changed as in amended RA – attached. Use of PPE and MSC Class II is appropriate and risk to workers has been considered. Pregnant workers are at no greater risk and has been considered in the risk assessment. Immunocompromised workers will not handle live organisms.

A well-considered risk assessment for Class 2 activity with all appropriate measures and risks clearly described.

Dear All,

From the information provided I agree that this should be regarded as a Class 2 activity. My only question would be whether more information should be provided on the actual changes that will be made, other than the fact that they are likely to be loss of function.

Best wishes,

Thank you for contributing to the discussion. Regarding information about the actual changes that will be made, I would argue that the researchers are trying to make the assessment as broad as possible. This was a suggestion that a researcher used to make. They do mention that “For investigation of virulence genes in GBS and the function and significance of mutations of the DNA and at the protein level, we will introduce mutations (knock in and knock out) that inhibit bacterial replication and/or protein synthesis/function”. I agree with the strategy of not mentioning any particular gene or pathway but I could ask what conditions will they use to select these mutations. As requesting “Please state that you will only select mutations that will hinder bacterial fitness” Is this a suitable compromise?

Best,

I agree with approving the risk assessment as a Class 2 activity and have no further comments beyond those mentioned.

Best wishes,

**Project Additional Information**

**Purposes of the contained use**

We aim to define the intracellular signalling events that control differentiation, survival and proliferation of lymphocytes.

**Recipient or parental organism**

We will transfec E.Coli K12 and derivatives with Blusecript containing mouse cDNAs encoding components of lymphocyte signalling pathways. We will introduce these cDNAs into pBabe retroviral vector and transfect into rodent-specific packaging cells, for infection of mouse cells and tissues with these cDNAs in vitro. Although expression of the genes of interest in the retroviral vector may affect mouse lymphocyte development and differentiation in vitro, the retrovirus cannot infect human cells and so would have no effect on human tissues and will not be oncogenic. Nevertheless, as some of the genes of interest have been shown to be oncogenes in the mouse (eg. Smoothened), we will carry out the work under Class II, Containment level II conditions.

**Host/vector system**

- E.Coli K12 type (strains JM101 and derivatives or XL1 and derivatives)
- GP+E retroviral packaging line and derivatives (packaging for infection of rodent cells only: Morgenstern and Land, 1990, Nucl. Acids Res. 18, 3587-3596)
- Bosc retroviral packaging line and derivatives (Packaging for infection of rodent cells only)
- Primary mouse cells and tissue
- Mouse cell lines

**Vectors:**

- Blusescipt and derivatives
- Puc and derivatives
- pBabe and derivatives
- MIGR1 and derivatives

**Origin & function**

- For E.Coli: Commercial (Strategene) or other labs
- For mouse cell lines: other labs
- For primary mouse tissues: mice from CBS, Imperial College
- For retroviral packaging cell lines: other labs
The genetic material will be PCR products from mouse (geneomic or cDNAs, generated by ourselves or from other labs). Vectors will be obtained commercially or from other labs.

The function of these genetic manipulations is to study T cell differentiation in vitro.

Evaluation of foreseeable effects

We hope the genes we introduce into mouse T cell cultures will interfere with or alter T cell differentiation in cell cultures, and thus enable us to study T cell differentiation.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste will be inactivated using Virkon 1% for at least 3 minutes (according to the manufacturer's recommendations). This will give 100% kill. The material will then be autoclaved, reaching 121 degrees C for 15 minutes. The autoclave will be monitored by autoclave printouts of the status of each run and 6 month checks by external contractors to make sure the correct temperature is reached. The waste will then be removed by a College approved contractor for incineration.

Is an emergency plan required according to regulation 20? N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The Committee made the following statements:

1. “We are concerned about the potential oncogenic properties of the insert cloned in the vectors. Therefore we recommend that the production and handling of large quantities of DNA are carried out under Class II conditions to minimise exposure to high amounts of DNA with oncogenic potential. The Committee also requests that the packaging cell line used for generating the infectious pBabe does not generate viruses with residual infection for human cells. Could references be provided please”.

2. “Please state the required contact time required for Virkon to be effective”.

### Project Additional Information

**Purposes of the contained use**

The aim project is to study the mechanism of host cell invasion by the protozoan parasite Toxoplasma gondii by analysing the interactions between three classes of invasion molecules that are expressed in T. gondii. These molecules include molecular motors called myosins, adhesins called microneme proteins and aspartyl proteases. Using stable transfection technique, we propose to disrupt the genes coding for these invasion factors. In parallel, we will express deletion mutant and GFP fusions of these proteins to study their biogenesis. The biochemical analysis of the motor proteins will necessitate the purification of these proteins from toxoplasma gondii.

**Recipient or parental organism**

Toxoplasma gondii tachyzoites from RH and Prugniaud strains as well as the attenuated strains ts-4 mutant derived from RH strain. Toxoplasma gondii is a mild pathogen infecting human and animals. In human, this parasite is pathogen only under two circumstances: infection by immunosurpressed patients and pregnant women. Toxoplasma gondii acute infection can be treated with antifolates drugs combined to antibiotics of the class of macrolides or atovaquone. The genetic modifications proposed in our project are not anticipated to increase the virulence but rather to impair the ability of recombinant parasites to invade host cells.

**Host/vector system**

The vectors to be employed in the proposed experiments are all derived from the commercially available bluescript from Stratagene. Most of the constructs are designed to express modified proteins or to generate knockout by homologous recombination in Toxoplasma gondii. These vectors are all described in the literature and the corresponding publications are listed in the risk assessment protocol.
The selectable marker genes are including chloramphenicol acetyl transferase, hypoxanthine-xanthine-guanosine-phosphoribosyltransferase, bleomycin. The reporter genes include beta-galactosidase, green fluorescent protein and luciferase. Other bacterial genes: tetracycline repressor. Toxoplasma gondii genes and their homologues in other apicomplexa: Myosin heavy chains, myosin light chains, microneme proteins and proteases. The flanking sequences controlling expression of the transgenes are derived from Toxoplasma gondii tubulin, major surface antigens (SAG1, SAG4) genes.

Origin & function

the genetic material originates from Toxoplasma gondii genes or homologues from other Apicomplexa parasites and E.coli. Genes originating from Toxoplasma gondii and apicomplexa:
Adhesins proteins secreted by the micronemes at the time of invasion. MIC1 to MIC9
Molecular motors including myosin light chain and myosin heavy chains and docking proteins: Myosin A to Myosin E, MLC MADP
Aspartyl proteases. AP1 and AP2
Functions: Components of the invasion machinery
Gene originating for other organisms: Beta galactosidase (LacZ), tetracycline repressor (tetR), green fluorescent protein (GFP), chloramphenicol acetyl transferase (CAT)
Functions: Selectable marker to disrupt genes by homologous recombination (CAT), reporter genes (LacZ) and Creation of chimeric fusion to follow the traffic of protein (GFP) and modulation of gene expression (tetR).

Evaluation of foreseeable effects

1. The genes coding for these proteins will be disrupted in Toxoplasma gondii by homologous recombination or by conditional knockout using the inducible tetracycline based gene expression system. We anticipate an alteration of the ability of parasites to infect cells.
2. These genes will be expressed as mutants: site specific point mutations, deletions or GFP fusions of these genes will be used to generate transgenic parasites. No change in virulence is expected.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Toxoplasma gondii is a micro-organism.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No application for derogation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Propagation of Toxoplasma gondii tachyzoites in tissue culture must take place in a containment level 2. All the proposed experiments will take place in a cell culture equipped laboratory located in containment level 3. The room and equipment fulfills all the safety requirements. The room will not be shared with and no containment level 3 activity will take place there. The manipulation of live parasites will be done in a safety cabinet. Wearing gloves and laboratory coats are requested. No material or equipment can leave to zone before decontamination or autoclaving. Both liquids and solids wastes will be autoclaved in the Containment 3 zone. Autoclaving: 30 mins at 121C at 15p.s.i (1.1kg/sq cm. Monitoring: Autoclave performance is monitored continuously by means of the autoclave printout (including a multipoint thermocouple test) annually by an independent company. Work carried out in the Containment level 3 laboratory is autoclaved within the containment room prior to removal to the main autoclave for a second round of autoclaving.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
the safety committee agreed that the project involving Toxoplasma gondii should be conducted in a containment level 2 and that the genetic modifications are not anticipated to change the category of the containment. They agreed that the project will be carried out in a fully equipped cell culture room located in the containment level 3 area since it was the only room available. This room will be exclusively used by the members of the group of D. Soldati. Cell culture will be restricted to Toxoplasma gondii and the host cells to propagate the parasites.

The Committee has suggested to use blunt needles for the rare cases the manipulation of seringes will be necessary. The chemical inactivation of solid wastes before autoclaving has been suggested but since Toxoplasma gondii is not an aerosol borned pathogen, this measure will not be necessary.

Historical Significant Changes trasferred to GM8 13/02/2006

Historical Date of Additional Info 13/02/2006
**Project Additional Information**

**Purposes of the contained use**

In this project we wish to establish the role of metabolic and regulatory genes in the stationary phase survival of Mycobacterium bovis BCG. We propose to make gene knock-outs of metabolic and regulatory genes (for example transporter genes, two-component systems) and investigate the effect of these mutations on stationary phase survival and gene expression. We propose to use a single integrating vector to compliment the knock-out mutants. We plan to use macrophage infection studies to establish the effect of the knock-out mutations on virulence/infectivity.

**Recipient or parental organism**

Mycobacterium bovis BCG is an ACDP class 2 organism. It is widely used as a vaccination strain.

**Host/vector system**

The vectors that will be used in the project use kanamycin or hygromycin as selectable marker and are non-mobilisable. We will use reporter gene vectors containing XyIE or GFP as reporter genes, single integrating vectors and knockout vectors. All vectors contain an origin of replication for E. coli and mycobacteria, except for the knock-out vector, which only has an origin of replication for E. coli.

**Origin & function**

All vectors have been constructed and validated in our laboratories. To create the knock-out and complimenting vectors we have used genomic DNA from M. bovis BCG and M. tuberculosis. The genomic DNA of M. bovis BCG originated from our laboratories, while the M. tuberculosis genomic DNA was from a collaborating department within Imperial College.

**Evaluation of foreseeable effects**

M. bovis BCG is an attenuated vaccination strain, unlikely to survive outside the laboratory. We intend to knock-out genes that are involved in regulatory and metabolic functions. For the genes we propose to knock-out, homologues are described in other organisms and in these organisms the mutation caused the organism to become less virulent. In our laboratories we have made knock-out mutants of genes with metabolic functions in M. smegmatis (a non-pathogenic Mycobacterium species), and it was found that these mutants are less viable than wild-type strains. We expect that we will see a similar effect in M. bovis BCG. Mycobacteria are environmental organisms, and gene transfer between mycobacteria and other organisms has been described. However our vectors are non-mobilisable and need antibiotic selection to be sustained in the organism, it is therefore unlikely that the genetic material will establish itself into another population outside the laboratory.

M. bovis BCG is a difficult strain to maintain in the laboratory, with very specific culture methods. Mycobacteria are also sensitive to UV light. If inadvertently genetically modified M. bovis BCG is introduced to the environment, it is unlikely that the organism will survive. In the unlikely event that the genetically modified M. bovis BCG causes infection, the use of kanamycin and hygromycin as selectable markers, will not affect the treatment since the organism will stay full sensitive to Isoniazid and Rifampicin.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All solid GM waste is autoclaved and this should give a 100% kill, as established by Collins, CH (1993), Laboratory Acquired Infections, 3rd edition, pp 146 et seq.. All liquid GM waste is disinfected with a 2% final concentration of Hycolin for at least 16 hours. This should give a 100% kill, as established by Collins, CH (1993), Laboratory Acquired Infections, 3rd edition, pp 146 et seq..
We will monitor this on an ongoing basis by plating out random samples to establish whether any viable cells are present.

Please enter comments on the GM safety committee on the risk assessment

The GM safety committee approved the project as Class 2, containment level 2. However the committee was concerned about the use of kanamycin as a selectable marker, as this may interfere with susceptibility of the GMO to aminoglycosides such as amikacin. We have submitted evidence, supported by experts in the field of mycobacteria, that amikacin and/or kanamycin are rarely used in the treatment of mycobacterial infection; that M. bovis BCG is fully sensitive to Rifampicin and Isoniazid; and the genetic exchange between mycobacteria is very difficult, therefore making the possibility of transferring resistance from M. bovis BCG to M. tuberculosis very remote. The GM safety committee was very satisfied with our response and granted approval of Class 2, containment level 2.

### Project Additional Information

#### Purposes of the contained use

Study of the RNA polymerases and transcription factors involved in the replication of chrysanthemum chlorotic mottle viroid, potato spindle viroid, barley yellow dwarf virus and cereal yellow dwarf virus.

#### Recipient or parental organism

- Chrysanthemum chlorotic mottle viroid
- Potato spindle tuber viroid
- Barley yellow dwarf virus
- Cereal yellow dwarf

#### Host/vector system

Escherichia coli K12 derivatives, such as DH5 alpha/ pUC-derived vectors, such as pBluescript, and, for the virus studies, expression vectors, such as the pET and PQE series of vectors.

#### Origin & function

- Chrysanthemum chlorotic mottle viroid (infected chrysanthemum plants in Spain, USA)
- Potato spindle tuber viroid (infected potato plants in Germany, USA)
- Both viroids will be used to study interactions with the cellular RNA polymerases which replicate them.

- Barley yellow dwarf virus (Infected barley and other cereal plants in UK, USA)
- Cereal yellow dwarf virus (infected barley and other cereal plants in UK, USA)
- The RNA of both viruses will be used to study interactions with the cognate virus-encoded RNA polymerases which replicate them.

#### Evaluation of foreseeable effects

Sequences alterations in the viroid or virus RNA which interfere with the ability to bind the cognate RNA polymerase will be likely to reduce the infectivity of the viroid or virus RNA to plants or plant cells.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Application for derogation of some containment level 3 measures to containment level 2 for the work involving chrysanthemum chlorotic mottle viroid and potato spindle tuber viroid

Table 1a Measure 2 Laboratory: sealable for fumigation
There is no risk to human health as viroids do not infect humans. Any accidental spillages within rooms 418 and 426 can be adequately contained by the disinfectant measures described in the standard operating procedure (attached)

Table 1a Measure 5 Negative pressure relative to the pressure of the immediate surroundings
Viroid-infected plants will not be allowed to flower. Hence there is no possibility of viroid dispersal via pollen or seed. No other parts of the plants are airborne. Plant residues will not be allowed to dry out, so that there will be no possibility of viroid transmission in dust arising from dried infected plant residues. Immediately after use, all viroid-infected plant residues will be placed in sealed containers prior to disposal by autoclaving and incineration. Precautions are in place to prevent the generation of aerosols. For details please see the standard operating procedure (attached). There will be no susceptible plants in the vicinity of rooms 418 and 426.

Table 1a Measure 6 Extract and input air from the laboratory should be HEPA filtered
Viroid-infected plants will not be allowed to flower. Hence there is no possibility of viroid dispersal via pollen or seed. No other parts of the plants are airborne. Plant residues will not be allowed to dry out, so that there will be no possibility of viroid transmission in dust arising from dried infected plant residues. Immediately after use, all viroid-infected plant residues will be placed in sealed containers prior to disposal by autoclaving and incineration. Precautions are in place to prevent the generation of aerosols. For details please see the standard operating procedure (attached). The air intake into the Sir Alexander Fleming Building is filtered to exclude insects and dust.

Table 1a Measure 7 Microbiological cabinet/enclosure
Viroids are not infectious to humans and do not encode any proteins. Hence a microbiological safety cabinet will not be required. Furthermore precautions are in place to prevent the generation of aerosols (see attached standard operating procedure). There will be no plants in rooms 418 and 426 other than those which it is desired to infect as part of the research project.

Table 1a Measure 8 Autoclave required in the lab suite
There is no possible risk of contaminating the environment in transporting infectious viroid-containing material from rooms 418 and 426 to the autoclave. Liquid waste will be absorbed on a clay-based or wood (cellulose)-based absorbent and treated as for solid waste. Solid waste will be placed in sealed containers. The sealed containers will be placed in autoclave bags, the tops of which will be folded over and taped. The autoclave bags will be placed in autoclavable buckets on which lids will be placed. The buckets will be transported to the autoclave in contained trolleys. On reaching the autoclave, the buckets will be removed from the trolley, their lids removed and the tape removed from the autoclave bags. However the containers containing the infectious viroid material will remain sealed. The white buckets will then be placed in the autoclave. During the autoclave cycle, the specially designed sealed containers will melt allowing access of the steam to the viroid waste material. After autoclaving the waste will be placed in clinical waste sacks prior to incineration.

Table 1a Measure 14 Efficient control of disease vectors which could disseminate the GMM
Viroids are not transmitted by aphid vectors when the aphids feed on plants infected by only viroids. However potato spindle tuber viroid (PSTVd) has been reported to be cotransmitted with potato leafroll virus (PLRV) by aphids feeding on potato plants infected with both PSTVd and PLRV. Several precautions are in place to prevent plants becoming infected adventitiously by aphids which may be carrying PLRV, although it is extremely unlikely that there are aphids carrying PLRV in the vicinity of Imperial College because there are no potato-growing areas in the vicinity of the College. (a) No aphids will be used in the project and there are no other projects involving aphids being carried out in the Sir Alexander Fleming Building. The air exchange system in the level 6 glasshouses, where the healthy uninfected plants are grown, is protected by apid-proof mesh. In the four years that the glasshouse have been in operation, no aphids have been detected. If any aphids were detected, they would be immediately destroyed by application of an aphicide. (b) Plants will be examined for symptoms of virus infection, prior to viroid inoculation. Any putatively virus-infected plants will be destroyed by autoclaving and incineration. (c) Aphids have never been found in rooms 418 and 426 and indeed are unlikely to enter the Sir Alexander Fleming Building because the air
Intake is filtered and there are no windows opening to the outside of the building. However as an additional precaution, sticky insecticidal tape will be placed in rooms 418 and 426.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

<table>
<thead>
<tr>
<th>Solid waste will be autoclaved at 121 degrees C, 15 psi, 30 min, followed by incineration (100% kill)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Liquid waste will be soaked up with a clay, such as bentonite, and then autoclaved at 121 degrees C, 15 psi, 30 min, followed by incineration (100% kill).</td>
</tr>
<tr>
<td>Liquid spillages will be treated with Microsol 3 or Virkon, as recommended by the manufacturer, for 10 min, and then soaked up with paper towels which will then be autoclaved at 121 degrees C, 15 psi, 30 min, followed by incineration (100% kill).</td>
</tr>
<tr>
<td>Full details are described in section (n) of the attached Standard Operating Procedure. A chart print out, giving the temperature and pressure, is provided with every autoclave run. The autoclaves are serviced and the temperature and pressure validated by external contractors every 6 months. Before starting the work, a check that the temperature at the centre of the solid waste reaches the desired value will be carried out by placing a vial of Bacillus stereothermophilus at the centre of a typical solid waste load and carrying out the autoclave procedure. The viability of the B. stereothermophilus will then be tested.</td>

Class 2, Containment level 2 is recommended for Part 3 (Replication of Viruses Causing Yellow Dwarf Disease of Cereals and Part 4 (Expression of Replication Proteins of Cereal Yellow Dwarf and Barley Yellow Viruses).

Class 3, Containment level 3 is recommended for part 1 (RNA polymerase and transcription factors in hammerhead viroid replication) and Part 2 (replication of viruses causing yellow dwarf disease of cereals), subject to application for derogation of measures 2, 5, 6, 7, 8, and 14 as described in section 11. The following CL3 containment measures from Tables 1a and 1b of schedule 8 of the CU2000 Regulations will be in place to prevent dissemination of the viroid GMMs.

Table 1a Measure 1. Laboratory suite isolation.
Growth room 426 and laboratory 418 will be dedicated to work with viroids only. Containment for movement of potentially between rooms will be as follows. Infected plants will be harvested and transferred in sealed bags placed in buckets with lids from room 426 to laboratory 418 where they will be homogenised in a sealed container and processed for isolation of viroid RNA and RNA polymerase-viroid RNA complexes. All subsequent operations with material containing infectious viroid RNA will be carried out in room 418, except for centrifugation. For centrifugation, suspensions containing infectious viroid RNA will be placed in closed centrifuge tubes or bottles in room 418. These will be placed in the rotor which will be closed with the rotor lid and transferred to the centrifuge area of room 433 in a closed trolley. After centrifugation, the rotor will be transferred to room 418 in a closed trolley. The rotor lid will be removed and the tubes will be removed from the rotor. The rotor will be sterilised by treatment with the disinfectant Microsol3 (1:10 dilution) for 10 min (gloves and eye protection must be worn when handling Microsol), followed by washing and deionised water before being returned to the centrifuge area of room 433. The disinfectant and washings will be collected for disposal by autoclaving and incineration, as described for liquid waste in section (n) of the Standard Operating Procedure (attached). Infected sap, infected plant material, purified viroid RNA and recombinant viroid cDNA clones will be stored in a fridge and freezer in room 418. Glycerol stocks of E.coli containing recombinant DNA clones of CChMVd or PSTVd will be kept in racks placed in containers with lids in a -80 degree C freezer in room 444. For propagation, the clones in the containers will be placed in buckets with lids and transported to room 418.

Access to laboratory 418 and growth room 426 will be limited to the authorised workers (see attached risk assessment). Cleaners will not be allowed in these rooms which will be cleaned by the authorised laboratory personnel. If repair work is required to the services in these rooms, all infectious material will be removed from surfaces which will be disinfected by treatment with Microsol or Virkon before access by repair personnel is allowed. All repair work in these rooms will be supervised by one of the authorised laboratory personnel.

Table 1a Measure 2. Laboratory floor.
The floors of rooms 418 and 426 are easy to clean and can be treated with disinfectants, such as Microsol or Virkon, in case of accidental spillages.

Table 1a Measure 12.
Protective overshoes will be worn for all work in laboratory 418 and growth room 426.

Table 1a Measure 18
Laboratory 418 and growth room 426 will where reasonable practicable have their own equipment. When this is not reasonably practical, such as the centrifuges and the -80 degree C freezer for storage of glycerol stocks of E. coli carrying recombinant plasmids, dedicated systems will be in place to safely transfer potentially infective material as described above (see Table 1a Measure1).
Table 1b Measure 5.
Possible transmission of viroids through seed and pollen will be prevented by not allowing infected plants to flower. To prevent airborne dissemination of infected plant residues, viroid-infected plant waste will not be allowed to dry out and will be disposed of immediately after each experiment as solid waste as described in section (n) of the attached Standard Operating Procedure. The additional measures which are not specific to CL3 will also be employed.

Table 1a Measure 13.
Gloves will be worn at all times for work with viroids in laboratory 418 and growth room 426.

Table 1a Measure 21.
Staff have received training on the risks posed by the activity and the containment measures required to prevent the dissemination of the GMM. Written records of the staff training have been kept. Further training will be given as necessary and record kept of it.

Emergency Plan
Consideration has been given to the establishment of an Emergency plan to deal with any reasonably foreseeable accident. Treatment of accidental spillages up to the maximum culture volume of 1 litre are dealt with in the Standard Operating Procedure.

Fire is the only other foreseeable hazard which might arise. A fire emergency plan is attached as Appendix 1 to Standard Operating Procedure.

**Project Ref** 628/01.3

**CU2 Project Title**

IMMORTALISATION OF MURINE CHONDROCYTES USING SV40 LARGE T-ANTIGEN-ENCODING RETROVIRUS.

**Date Ackn’ed**

20/09/2006

**Date Project Ceased**

**Historical Significant Changes**

TRANSFERRED FROM GM 628 - 22/9/06

**Project Additional Information**

**Purposes of the contained use**

A murine chondrocyte cell line would provide a source of joint specific antigens including the model antigen Flu nucleoprotein (NP) that is expressed in the chondrocytes of CIINP14 mice. As reactive arthritis is likely to result from activation of MHC class 1 and class II-restricted T-cell responses (as well as possibly antibody responses), an immunogen that includes multiple relevant antigens may enhance the development of joint-specific disease. Immunisation with NP +ve chondrocytes would provide a known antigen, the response to which could be followed with tetramers etc., as well as uncharacterised antigens that may be more potent targets in the joint.

**Recipient or parental organism**

Murine chondrocytes expressing either wild-type or a temperature sensitive mutant of SV40 Large T-antigen. As chondrocytes will not produce recombinant virus or survive outside tissue culture the foreseeable effect on human health/safety or the environment is negligible.

**Host/vector system**

2 cells to be used in this study are transfected with pZipNeo SV(X) vectors. These contain the sequence required for viral packaging deleted from PMOV- but replace the viral gag, pol and env genes with an inserted transgene (see section C for description of cloning vector). These transfected cells are capable of producing helper-free,
recombinant retrovirus (Cepko et al., 1984. Cell, 37:1053-1062). In this study, pZipNeo SV(X)1 vectors incorporate either Large T-antigen or a temperature-sensitive version of this gene which is derived from Simian Virus (SV)40.

Origin & function

SV40 Large T-antigen (from the DNA tumour virus simian virus 40), tsTAg (temperature sensitive mutant of the SV40 Large T-antigen gene). The SV40 large T-antigen is found in early region of the virus together with the small T-antigen which together are sufficient for transformation of cell lines. Studies have shown that the large T-antigen alone is sufficient for establishment of primary cells but that these cells do not display a transformed phenotype hence the intention in this study to transform chondrocytes.

Evaluation of foreseeable effects

As mentioned immortalised chondrocytes and 2 producer cells will not survive outside tissue culture. They are unlikely to encounter murine hosts other than in experimental conditions in the case of chondrocytes. Recombinant retrovirus will not infect human cells and is helper-free therefore can not replicate in murine hosts. However infection of mice could theoretically result in transformation of cells although this is unlikely as SV40 Large T-antigen transduced cells are non-tumourigenic in murine hosts. The cells will be handled as category 2 agents for all in vitro experiments, limiting the potential of exposure to the environment to a negligible level.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solutions that have been in contact with retrovirus, 2 cells or transformed chondrocytes will be treated with virkon disinfectant. All exposed materials will be autoclaved before disposal.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The committee wish to bring to the proposer's attention paragraph 20 in AnnexIII "Guidance on commonly used viral vectors" to demonstrate the absence of PCRs in vector stocks from the HSE's Compendium of Guidance. Also proposer's attention is requested to observe precautions for handling oncogenic DNA (mandatory wearing of gloves, avoidance of sharps).

02/03/2022 Page 2840 of 15326
In order to aid our studies of the human disease reactive arthritis which may be induced as a result of salmonella infection, we need to study the interaction of salmonella infected cells with antigen specific T cells. Model antigens, to which we have specific T cells for in the laboratory, will be expressed in salmonella. T cell responses to salmonella infected cells can then be assessed.

Recipient or parental organism

Strains of Salmonella typhimurium, some of which are attenuated.

Host/vector system

Non-mobilisable or mobilisation defective plasmid vector systems, using prokaryotic promoter system for expression of recombinant antigens.

Origin & function
In vitro and in vivo experimental use at containment level 2, for induction of immune responses and models of human disease.

**Evaluation of foreseeable effects**

Transformation of Salmonella with recombinant DNA plasmid vectors is not expected to increase virulence or infectivity of Salmonella. The organisms will be handled as category 2 organisms for all in vitro and in vivo experiments, limiting the potential of exposure to the environment to a negligible level.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solutions that have been in contact with Salmonella will be treated with bactericidal disinfectant. All infected materials will be autoclaved before disposal.

Is an emergency plan required according to regulation 20?  
If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

The committee has discussed the possibility of induction of arthritis - however this should be no worse than with wild type Salmonella in non-transgenic mice and humans.

Work has been approved for use at containment level 2.

**Project Ref** 628/03.1
Recombinant adenovirus vectors encoding the S and N genes of the SARS virus under the control of the CMV promoter will be used to study the effect of these proteins in vivo. The recombinant adenovirus vectors will be administered to mice and tissues from treated mice will then be removed to examine the host immune response. In some experiments mice treated with one of these vectors will then be infected with virus or bacteria, for example influenza virus or salmonella. The aim is to be able to examine the effect of the S and N genes from SARS on the host immune response.

The recombinant adenoviruses will be obtained from another investigator Dr Tripp, in the Centres for Disease Control and Prevention in Atlanta, GA. The recombinants were made in his laboratory using the commercial AdEasy vector system from Invitrogen.

The SARS proteins S (spike) and N (nucleocapsid) are from the Urbani strain of SARS isolated by the CDC in Hong Kong. This strain was sequenced by the CDC and the S and N genes were then inserted into the adenovirus vectors in the CDC in Atlanta.

It is presently unknown whether the S or N proteins have any transforming potential or any harmful sequences. None have been reported.

Adenoviruses are associated with a number of mild disorders. The pathology results primarily from inflammation and loss of infected epithelial cells. Serotype 5 which will be used here commonly causes upper respiratory infections in the elderly and in young children. Adenoviruses are Biosafety Level II pathogens.
The Adenovirus vectors do not express any harmful agents. The E3 region which encodes proteins involved in modulating the immune response of infected cells has been deleted. The recombinant adenoviruses are replication deficient due to a large deletion in the E1 gene.

**Origin & function**

The recombinant adenoviruses will be obtained from another investigator Dr Tripp, in the Centres for Disease Control and Prevention in Atlanta, GA. The recombinants were made in his laboratory using the commercial AdEasy vector system from Invitrogen.

The SARS proteins S and N are from the Urbani strain of SARS isolated by the CDC in Hong Kong. This strain was sequenced by the CDC and the S and N genes were then inserted into the adenovirus vectors in the CDC in Atlanta.

These constructs will be used to examine the effects of the S and N proteins of SARS on the host immune response. The vectors will be administered to mice and at certain time-points thereafter the mice will be sacrificed and tissues will be extracted.

**Evaluation of foreseeable effects**

The possibility that replication competence could be restored by rescue of the E1 deletion from the helper cell line or from wild-type adenovirus cannot be excluded. However even if this were the case, it is unlikely that the virus would be more pathogenic than the wild type adenovirus.

The inserted genes would not be expected to render the recombinant viruses able to replicate or to affect the tropism of the virus. Variations of S protein among strains of coronaviruses are responsible for host range and tissue tropism. However, as adenoviruses are not enveloped it is unlikely that the S protein of SARS will affect the tropism of the recombinant adenoviruses. It is unknown how the expression of the N and S genes of SARS will affect the host cells, as no work has been carried out examining this. So far there are no reports that either S or N protein is associated with toxicity or oncogenesis. Also neither is known to be closely homologous to human proteins against which autoimmune responses would be likely to be induced.

The possibility that the inserted sequences may be transferred to other related organisms is remote. The only potential risk may occur if the S or N genes of SARS were transferred to another corona virus. In that case potential problems may occur but the resulting virulence or pathogenicity if such an event occurs is not known.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No application for derogation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All the animal, culture and tissues culture waste will be disposed of by incineration according to the normal rules for Biosafety level II biological waste disposal. Liquid waste will be added to Virkon (final concentration 1%) and left for 24 hours. No microorganisms will be viable afterwards. Solid waste will be put in a metal box, sealed with autoclave tape, autoclaved at 134 degrees C for 30 minutes, before being sent to an on-site clinical waste incinerator. The degree of kill is 100%.

### Project Ref 628/03.2

**Date Ackn’d**: 20/09/2006

**CU2 Project Title**: IN VITRO ANALYSIS OF THE INTERACTION OF HEPATITIS C VIRUS PSEUDOPARTICLES (HCV PP) WITH CELL LINES AND HUMAN PERIPHERAL BLOOD MONOCULAR CELLS (PBMC) SUBSETS.

**Date Project Ceased**: 10/08/2011

**Withdrawn**: N

**Tick if notifying a connected programme of work**: N

**Historical Significant Changes**: TRANSFERRED FROM GM 628 - 22/9/06, Transferred to GM553 10/08/2011

**Historical Date of Additional Info**: 25/07/2007

### Project Additional Information

**Purposes of the contained use**: In order to aid our previous studies of the interaction of the hapatitis C (HCV) E2 glycoprotein with different PBMC subsets and the possible immunomodulatory consequences of this interaction, we would like to carry out studies the HCV pp, which express heterodimers of E1 and E2 on their surface. The proposed work would...
include in vitro analysis of interaction of HCVpp with cell lines and PBMC subsets and investigation of whether HCVpp are able to modulate the activation/functions of different immune system cell types (derived from human peripheral blood), using a variety of in vitro immunological assays.

**Recipient or parental organism**

Murine leukemia virus (MLV), which is a murine retrovirus classified as a category 1 pathogen.

**Host/vector system**

The vector packaged into the pseudotyped MLV particles encodes the marker protein green fluorescent protein (GFP). This is not thought to have any harmful properties. The particles will be pseudotyped with the HCV E1 and E2 proteins. These are not thought to be toxic or oncogenic, but there is some evidence to suggest that the E2 protein may be able to modulate the activation/functions of human lymphocyte subsets. However it is very unlikely that accidental exposure to a small quantity of HCV pp (which are not able to replicate) would have any harmful immunomodulatory effects.

**Origin & function**

The HCVpp will be provided by our collaborators, the Institute Pasteur in Lille, France; they will not be produced here. The method by which the HCVpp are generated is described in Bartosch et al, HJournal of Experimental Medicine, 197:633-642 (2003).

**Evaluation of foreseeable effects**

Pseudotyping of the MLV-based particles with the HCV E1 and E2 proteins results in the particles having a tropism different to that of ecotropic MLV. HCVpp have been shown to bind to and enter human cells expressing what are thought to be HCV receptors (CD81 and other proteins) [Bartosch et al, Journal of Experimental Medicine, 197:633-642, 2003].

This alteration in tropism increases the potential for disease to be induced in humans, although the risk of this still remains very low. Although able to infect human cells, the pseudoparticles would not replicate therein, and expression of GFP within the transduced cells would be unlikely to have deleterious effects. However, it is possible that integration of the MLV vector could lead to modulation of host cell gene expression, and potentially to transformation of the cell.

It is very unlikely that sequences from the GFP-expressing MLV vector within the HCVpp would be transferred to another micro-organism during the course of the planned in vitro experimental work; and even should this occur, it is unlikely to be hazardous, as this vector only encodes GFP.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All equipment and waste that has been in contact with HCVpp will be disinfected using procedures approved for destroying the infectivity of lipid-enveloped viruses.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

02/03/2022
The committee recommended that each batch of HCVpp should be tested for infectivity on a murine cell line, and with this provisionally approved the work to be done at containment level 2.

Purposes of the contained use

A recombinant influenza virus of subtype A/Victoria/3/75 (H3N2) has been generated by reverse genetics at the University of Reading. In addition, a series of derivative
viruses based on A/Victoria/3/75 have been generated in which the open reading frame of the protein PB1-F2 has been deleted, truncated or extended. PB1-F2 is believed to induce apoptosis in immune cells (Chen et al., 2001). We aim to carry out apoptosis studies and mouse model studies to determine whether alterations in PB1-affect virus virulence.

A recombinant influenza virus of subtype B/Beijing/87 has also been generated at the University of Reading, as well as an isogenic virus in which the NB protein has been deleted. The NB protein is believed to function as an ion channel and, although dispensable in vitro, is believed to promote efficient viral growth in mice (Hatta and Kawaoka, 2003). We would like to confirm and extend these observations.

Influenza viruses infect humans and avians and cause a respiratory infection. Transmission is by respiratory infection via aerosols. The recombinant influenza viruses are unlikely to cause harm greater than their parental strains, which are themselves laboratory passaged and thus attenuated versions of naturally occurring influenza viruses, classified as class 2 pathogens. Both A/Victoria/3/75 and B/Beijing/87 have been used extensively in laboratories worldwide with no history of infection of workers or adverse effects as detailed in the following publications and citations therein:

In the event that the A/Victoria/3/75 virus does not produce obvious symptoms in mice, a virus with A/Panama/99 antigens and the same internal genetic backbone will be used. A/Panama/99 surface antigens were used to generate large quantities of vaccines throughout the world in recent years and no adverse affect are associated.

Recipient or parental organism

The NB protein is believed to function as an ion channel and, although dispensable in vitro, is believed to promote efficient viral growth in mice (Hatta and Kawaoka, 2003). We would like to confirm and extend these observations.

Evaluation of foreseeable effects

All mutations in influenza viruses to be used in this study will be attenuating for replication and therefore the hazards will be reduced. This includes the virus strain in which the PB1-F2 gene will be extended by 3 amino acids in order to retain the length of the wild-type gene. There is no expected alteration in host range since neither of these genes is associated with that trait. It is possible that the types of cells affected following infection with the PB1-F2 deletant will be reduced rather than extended.

Since influenza virus has a segmented genome, there is a possibility that reassortant viruses containing genes from the mutants might be generated within a laboratory worker who was coinfected with a wild type strain. We consider this unlikely, but advise all workers to refrain from experiments if influenza infection is suspected.

If reassortment did occur, the PB1-F2 deletion introduced into A/Victoria/75 is not associated with virulence and is likely to be an attenuating mutation. The virus harbouring deletion of NB from B/Beijing/87 is reported to be highly attenuated and cannot replicate efficiently in vivo (Hatta and Kawaoka). Therefore regardless of the genetic background of the virus harbouring these changes, we expect them to be attenuating.

Project Ref 628/04.2

Date Ackn'd 20/09/2006

CU2 Project Title USE OF NOVEL REVERSE GENETICS-GENERATED INFLUENZA VIRUS (RG-X31-SWINE PB1) TO INVESTIGATE THE ROLE OF VIRUS-INDUCED APOPTOSIS

Class 2

CultureVolClass2 < 1 Litre

CultureVolumeClass3-4 Not Applicable

Non-GMM Consent Granted Not Applicable

Date Project Ceased 02/03/2022
Influenza viruses induce apoptosis in cultured cells and in vivo. We have recently shown that influenza virus detrimentally affects early lymphoid progenitor cells by inducing apoptosis mediated by TNFalpha/LTalpha. An alternative reading frame of the PB1 gene called PB1-F2 of the influenza virus has been implicated in inducing apoptosis in vitro. We want to determine whether PB1-F2 is responsible for the apoptosis that occurs in the bone marrow (or other tissues) following infection of mice with influenza virus. We therefore wish to use a novel influenza virus (RG-X31-swine PB1) that has been generated by reverse genetics (RG) to examine these questions. The PB1-F2 open reading frame (ORF) is present in nearly all human influenza A strains but is absent from swine influenza isolates. Therefore by replacing the PB1 of the wild-type x 31 (A/H3N2) virus which contains the PB1-F2 ORF with the PB1 from a swine influenza virus (A/swine/NorthCarolina/44173/00) which does not, we will be able to address these questions. Mice will be infected with the wild type/recombinant virus and sacrificed at certain time-points to assess the degree of cell death in various organs and any other differences in pathogenicity caused by the recombinant virus.

The RG influenza virus RG-x31-swine PB1 will be obtained from St Jude Children's Research Hospital, Memphis TN, USA. The viruses are being made in the laboratory for our use.

Influenza viruses infect humans and avians and cause a respiratory infection. Transmission is by respiratory infection via aerosols. The strain of influenza virus is a reassortant which has the surface proteins of A/Aichi/68 and the internal genes of A/PR/8/34. It is a laboratory strain which is commonly used in immunological studies and is BioSafety Level 2 pathogen. The recombinant influenza virus is unlikely to cause harm greater than the parental strain, which is itself laboratory passaged and thus an attenuated version of a naturally occurring influenza virus.

Recipient or parental organism

Influenza viruses infect humans and avians and cause a respiratory infection. Transmission is by respiratory infection via aerosols. It is a laboratory strain which is commonly used in immunological studies and is BioSafety Level 2 pathogen. The recombinant influenza virus is unlikely to cause harm greater than the parental strain, which is itself laboratory passaged and thus an attenuated version of a naturally occurring influenza virus.

Origin & function

We have recently shown that influenza virus detrimentally affects early lymphoid progenitor cells by inducing apoptosis mediated by TNFalpha/LTalpha. An alternative reading frame of the PB1 gene called PB1-F2 of the influenza virus has been implicated in inducing apoptosis in vitro. We want to determine whether PB1-F2 is responsible for the apoptosis that occurs in the bone marrow (or other tissues) following infection of mice with influenza virus. We therefore wish to use a novel influenza virus (RG-X31-swine PB1) that has been generated by reverse genetics (RG) to examine these questions. The PB1-F2 open reading frame (ORF) is present in nearly all human influenza A strains but is absent from swine influenza isolates. Therefore by replacing the PB1 of the wild-type x 31 (A/H3N2) virus which contains the PB1-F2 ORF with the PB1 from a swine influenza virus (A/swine/NorthCarolina/44173/00) which does not, we will be able to address the degree of cell death in various organs and any other differences in pathogenicity caused by the recombinant virus.
Evaluation of foreseeable effects

No hazards should arise from the alteration of wild-type x 31 to RG-x31-swine PB1. Neither virus growth nor tropism should be affected. The surface proteins HA and NA have not been altered. Reverse genetics enables a recombinant virus to be produced in a much safer way than previously because one has complete control of the genes being transfected to produce the recombinant virus. Therefore there is no possibility that other influenza virus genes can be introduced. It is expected that the inclusion of the swine PB1 gene would either not change the pathogenicity/virulence of x31 or make it less so.

Little is known about the new PB1-F2 protein as it has only recently been identified. It is not essential for viral replication in vitro. The evidence to date suggests its involved in modulating the host immune response to influenza A by caused death of immune cells. A synthetic version of PB1-F2 induces apoptosis in vitro and targeted mutations which interfere with expression of PB1-F2 induce less apoptosis than those that express PB1-F2.

There is no evidence that the PB1-F2 gene causes toxicity or has oncogenic properties.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Influenza viruses induce apoptosis in cultured cells and in vivo. We have recently shown that influenza virus detrimentally affects early lymphoid progenitor cells by inducing apoptosis mediated by TNFalpha/LTalpha. The NS1 gene of influenza virus has been implicated in inducing apoptosis in vitro. We want to determine whether the NS1 gene is responsible for the apoptosis that occurs in the bone marrow (or other tissues) following infection of mice with influenza virus. We therefore wish to use a novel influenza virus that has been generated by reverse genetics (RG) to examine these questions. The NS1 gene in wild-type x31 will be replaced by the NS1 from the H5N1/97 virus, in order to assess whether a greater degree of cell death in bone marrow, thymus and other organs occurs as a result. Mice will be infected with the wild type/recombinant virus and sacrificed at certain time-points to assess the degree of cell death in various organs and any other differences in pathogenicity caused by the viruses.

The strain of influenza virus that will be the recipient of the foreign NS1 gene is x31 (H3N2). This strain of influenza virus is a reassortant which has the surface proteins of A/Aichi/68 and the internal genes of A/PR/8/34. It is a laboratory strain which is commonly used in immunological studies and is a BioSafety Level 2 pathogen. Research to date suggests NS1 is a virulence factor which plays a major role in inhibiting the IFN-mediated antiviral responses of the host. NS1 is a non-structural protein of influenza virus. It is an RNA binding protein which has been implicated in several regulatory functions during the influenza virus replication cycle:
1. It inhibits host mRNA polyadenylation. 2. It inhibits the nuclear export of mRNAs by binding to their poly (A) tail. 3. It inhibits pre-mRNA splicing. 4. It prevents IFN-mediated antiviral responses by binding to ds RNA. 5. It has been suggested to play a role in regulation of viral RNAPolymerase activity. 6. It is able to stimulate the
Translation of specific viral mRNAs.

There is no evidence that the NS1 gene causes toxicity or has oncogenic properties. Recombinant virus will be produced that replaces the NS gene or x31 with the NS gene of H5N1/97.

Background: The H5N1/97 viruses transmitted to humans in 1997 and were highly virulent. Reactive hemophagocytic syndrome with elevated concentrations of proinflammatory cytokines were reported. Lethal H5NI viruses (unlike other human, avian and swine viruses) are resistant to the antiviral effects of IFNs and TNFalpha. This resistance is associated with NS1 and is thought to be the mechanism of the high virulence of H5NI viruses in humans.

RG enables a recombinant influenza virus to be produced in a much safer way than previously (reassortment) because one has complete control of the genes being transfected to produce the recombinant virus. Therefore there is no possibility that the HA or other genes from the H5N1 can be included in the recombinant virus. The tropism or host range of RG-x31-156NS1 should not therefore be different from wild type x31. It would be expected that the inclusion of the H5N1, NS1 gene into x31 would make the resulting RG-x31-156NS1 virus more pathogenic (perhaps greater loss of body weight, more prolonged virus shedding) as a result of increased virus replication due to the resistance of the NS1 to aniviral cytokines.

Host/vector system

Not applicable.

Origin & function

The RG influenza virus will be obtained from Dr Richard Webby, St Jude Children's Research Hospital, Memphis TN, USA. The viruses are being made in his laboratory for our use.

Influenza viruses induce apoptosis in cultured cells and in vivo. We have recently shown that influenza virus detrimentally affects early lymphoid progenitor cells by inducing apoptosis mediated by TNFalpha/LTalpha. The NS1 gene of influenza virus has been implicated in inducing apoptosis in vitro. We want to determine whether the NS1 gene is responsible for the apoptosis that occurs in the bone marrow (or other tissues) following infection of mice with influenza virus. We therefore wish to use a novel influenza virus that has been generated by reverse genetics (RG) to examine these questions. The NS1 gene in wild-type x31 will be replaced by the NS1 from the H5N1/97 virus, in order to assess whether a greater degree of cell death in bone marrow, thymus and other organs occurs as a result. Mice will be infected with the wild type/recombinant virus and sacrificed at certain time-points to assess the degree of cell death in various organs and any other differences in pathogenicity caused by the viruses.

Evaluation of foreseeable effects

The possibility that the inserted sequences may be transferred to other influenza viruses is remote. The only potential risk may occur if the RG-x31-156NS1 virus was grown in eggs or tissue culture at the same time as other influenza viruses so that reassortment occurs. The possibility of this is remote.

In the event of exposure the virus may cause infection in humans. One may expect the infection to be more virulent than wild type x31, due to the expected increase in resistance to anti viral cytokines. In event that any person is exposed to the virus a prearranged protocol will be followed (see attached protocol called The Edward Jenner Institute for Vaccine Research: Protocol for staff working with influenza A viruses shown to have a higher risk of transmission to humans).

All work with the recombinant influenza RG-x31-156S will be carried out in a BioSafety Level 3 facility. (An almost identical virus has recently been made in Dr Webby’s department in St.Jude CRH but on the backbone of A/PR8/34 which is more virulent than x31. The work is carried out in BioSafety Level 3 facilities, Nat.Med. 8:950-954, Sept 2002). Immunosuppressed individuals or those with chronic respiratory problems will not work with these recombinants.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Culture volumes approximately 100ml

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No application for derogation

02/03/2022  Page 2874 of 15326
**Project Additional Information**

**Purposes of the contained use**

An investigation of the interaction in vitro of BCG with Antigen Presenting Cells (APC). Mycobacterium bovis BCG-gfp will be used to investigate uptake of the organism by individual APC and track the bacterium and determine the effect on the function of the eucaryotic cells. HSP genes will be rendered inactive in order that the function of the molecules can be determined in relation to survival of bacteria in the eucaryotic cell. How removal affects how the bacterium affects the biological properties of the antigen presenting cell will also be assessed.

**Recipient or parental organism**

Mycobacterium bovis BCG vaccine strain.

**Host/vector system**

Plasmid pSMT1 carrying the gfp gene of jellyfish, cloned under the control of the BCG heat shock protein-60 (hsp60) promoter on a mycobacterial shuttle vector (pOLYG) BCG that has had HspR gene, or other genes, replaced with a defective copy of the gene using a non-replicating "suicide" vector. Selection of mutants is using the hygromycin gene from Streptomyces hygroscopicus that replaces the HspR gene and allows selection of recombinants in which a double cross over event has resulted in exchange with the wild type gene (Husson et al 1990, J. Bacteriol 172: 519-24; Garbe et al Microbiology 140: 133-8).

**Origin & function**

M. bovis BCG is the vaccine strain that has been used extensively in humans. The gfp will fluoresce under appropriate conditions. The labels are used to detect individual bacteria in cells or tissues. Inclusion into M. bovis-BCG or M. tuberculosis has been shown not to increase their virulence or the effect on antigen presenting cells (Luo et al 1996, Clin Diag Lab Immunol 3: 761-8). Deletion of HSP genes from BCG will enable the function of the gene in the interaction of the organism with antigen presenting cells to be determined in vitro.

**Evaluation of foreseeable effects**

The production of BCG with gfp will be at other establishments. M. tuberculosis or BCG marked in the same way have been produced previously. No changes have been evident when they have been tested for changes in virulence or effects on how they effect cytokine production or surface molecule expression by antigen presenting cells in vitro (Luo et al 1996 Clin Diag Lab Immunol 3: 761-8). BCG as the established vaccine strain for human use is avirulent and no effect on virulence is foreseen. The aim of targeting and removing HSP genes is to determine the properties of the encoded molecules and how they affect pathogenicity in models involving the interaction...
with antigen presenting cells in vitro. The hypothesis is that removal will affect the survival of bacteria in eucaryotic cells and will be detrimental for the bacteria. Deletion of the targeted genes from the vaccine strain of BCG is predicted to cause further attenuation, or be lethal to the bacillus. Hygromycin has no clinical application in the treatment of tuberculosis, or as far as we are aware the treatment of other bacterial infections. The organisms will be handled as ACDP category 2 pathogens for all experiments that are all in vitro thus reducing the potential of environmental exposure to negligible levels.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated or potentially contaminated category 2 laboratory waste is autoclaved or incinerated (100%). Pipettes and similar objects are disinfected, and surfaces wiped, with phenolic disinfectant or ethanol.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form  

Tick to confirm that you have attached a risk assessment to this form  

Tick if you are claiming exemption from disclosure for section of the risk assessment  

Please enter comments on the GM safety committee on the risk assessment

If there is any indication of increased virulence in either of the mutants the work will pause for re-assessment and notification to the HSE. Approval is given on the understanding that no animal work is involved.

Project Ref  97/02.1
Purposes of the contained use

Activation of bovine and human plasminogen is an attribute common to a variety of streptococcal and staphylococcal species and is considered a putative virulence mechanism. We propose identification of domains/residues of bovine and human plasminogens critical to their interactions with subsequent activation by such bacterial plasminogen activators. This will be achieved through the study of the interaction between recombinant mammalian plasminogen derivatives and bacterial plasminogen activators.

Recipient or parental organism

Recipient: proprietary Escherichia coli K12 host strains
Parent/Donor organism: human and bovine.

Host/vector system

Bovine and human nucleic acid encoding plasminogen or plasminogen derivatives will be cloned into inducible expression vectors (for example pET or pCAL) maintained within Escherichia coli K12 bacterial host strains (for example BL21 derivatives).

Origin & function

Cloned bovine and human plasminogen and plasminogen derivatives including chimeric human-bovine molecules will be overexpressed in E. coli hosts from where the protein will be extracted and purified for analysis.

Evaluation of foreseeable effects

The GMOs will be capable of inducible overexpression of cDNA encoding bovine and human plasminogen and derivatives thereof. As such they will produce precursor forms of the mammalian serine protease plasmin. The downstream effects of plasmin production include dissolution of fibrin clots (thrombolysis), cell migration, activation of further metalloproteinase cascades. For this reason under normal physiological conditions, plasminogen activation and the activity of plasmin are tightly regulated in mammals. Specific inhibitors of plasmin (alpha 2-antiplasmin - the primary inhibitor of plasmin-mediated fibrinolysis and alpha 2-macroglobulin) prevent indiscriminate protease activity. In the unlikely event of internalisation and subsequent activation by either mammalian or bacterial plasminogen activators the functional recombinant
moiety plasmin would still be highly likely to be subject to the inhibitory effects of alpha 2-antiplasmin and alpha 2-macroglobulin. The GMOs are unlikely to present any risk to human health. The capacity of the E. coli host strains to survive and/or transfer genetic material to other organisms is low. Release to the environment is thought unlikely to be of significance as human and bovine plasminogen are already present in the environment (mammals) and have no known toxic activity.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste eg plastic ware, gloves and paper waste etc will be placed within autoclave bags prior to removal via a locked storage facility to the site incinerator facility.

Contaminated glass and non disposable plastic ware eg culture vessels, centrifuge pots etc will be housed within metal autoclave tins marked with autoclave tape and autoclaved at 134 degrees C for 30 minutes. Glass pipettes will be decontaminated by overnight immersion in disinfectant (2.5% chloros solution) prior to removal to wash-up facility. Both procedures kill 100% of E. coli.

Liquid waste eg spent culture fluid will be contained in <400 ml amounts within 500 ml glass bottles. The bottles are housed within metal autoclave tins marked with autoclave tape and an additional note to signify the large volumes therein, prior to removal to be autoclaved at 134 degrees C for 30 minutes to accomplish a 100% kill.

Risk assessment passed.

### Project Additional Information

**Purposes of the contained use**

Identification by a genetic screen, of proteins encoded by fowlpox virus, that are able to rescue the replication of vaccinia MVA, deleted for E3L, in primary chick cells and are thus able to modulate the avian type I interferon response.

**Recipient or parental organism**

Vaccinia MVA is a host-restricted derivative of vaccinia virus Ankara. During extensive passage in avian culture it underwent extensive deletion, including the loss of almost all the known vaccinia immunomodulator genes. The MVA genome sequence is known. Originally thought capable of replicating only in avian cells, MVA has been shown to replicate in BHK21 cells and in primary (or finite) fibroblast cells from mammals but not from primates.

The recipient will be further modified to delete its remaining known immunomodulator (equivalent to vaccinia virus E3L) which has been reported to prevent its replication in avian (but not BHK21) cells. MVA is approved for use as a class I virus - the deletion is expected to render it even more reliably attenuated.

**Host/vector system**

Fowlpox virus genes will be inserted, singly or in combination, into the genome of MVAdeltaE3L, at the site of one of the known deletions, by recombination with genomic fragments of fowlpox virus, selecting for recombinants carrying the E. coli Gpt gene with mycophenolic acid.

**Origin & function**

The genes inserted into MVAdeltaE3L will be derived from the attenuated vaccine strain of fowlpox virus, HP1-438 FP9. This plaque purified strain has been completely sequenced. Like all fowlpox viruses, it is unable to replicate in mammalian cells, including those in which MVA can replicate. It is intended that the genes should restore to MVAdeltaE3L the ability, possessed by parental MVA, to replicate on avian cells. As E3L is known to interfere with the mammalian type I interferon response, by binding
dsRNA thus preventing activation of PKR or 2′5′ OAS, it is expected that the rescuing genes will encode the [as yet unidentified] fowlpox proteins responsible for interfering with avian type I interferon.

**Evaluation of foreseeable effects**

Extract from CPW 4a: Modified Virus Ankara (MVA) [is] an attenuated vaccinia strain that has had multiple regions of the genome deleted. This strain has been demonstrated not to replicate in a range of primary human cells, replicates in avian cells and, until recently, was not thought to replicate in mammalian cells. However, recent work has demonstrated replication of MVA in BHK (baby hamster kidney) cells [as well as in other primary mammalian, but not primate, cells]. MVA has been used as a vaccine without adverse reactions in immune compromised individuals. The ACGM has indicated that MVA may be considered for use at ACGM level 1 depending on the nature of the insert. MVAdeltaE3L is likely to be yet further attenuated. Though able to replicate in BHK21 cells, it cannot replicate in CEFs and, like parental vaccinia virus with E3L deletions (Beattie, E. et al (1996) Virus Genes 12: 89-94), is unlikely to be able to replicate in Vero, HeLa, and murine L929 cells.

There are no known hazards arising directly from inserted gene products derived from the completely sequenced FPV genome.

It is extremely unlikely that insertion of FPV genes into MVAdE3L will restore and enhance the virulence of MVA such that it will pose a threat to human health. MVA lacks multiple genes that are believed to be involved in pathogenicity and is extremely attenuated. FPV is unable to replicate at all in any mammalian cells (including those in which MVA can replicate). Moreover, the gene library recombinants will only be made using the attenuated form of FPV (FP9), which appears fully competent for avIFN-resistance, not the virulent form, so that specific virulence genes are likely to be absent. We cannot rule out some increase in virulence but it is unlikely even that this would even be raised even to the level of parental vaccinia viruses. In light of this possibility, we propose to perform the experiments as for parental vaccinia virus (at Cat. 2).

It is extremely unlikely that insertion of a few FPV genes into MVAdE3L will render the recombinants pathogenic for poultry or other birds. This is due to the multiple deletions in MVA and the lack of pathogenicity of even parental vaccinia for poultry. Furthermore the gene donor will be the completely attenuated (Mayr, A. & K. Malicki (1966) Zentralblatt fur Veterinarmedizin B. B13: 1-13) strain of FPV (FP9), which has been completely sequenced and carried 120 mutations relative to virulent FPV.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

- **Liquid waste.** In a contained vessel, Virkon added to give a final concentration of 1%. Left for 24 hours and then disposed of down the drain. Degree of kill 100%.

- **Solid waste.** All contaminated material and solid waste will be placed in a metal autoclave box, sealed with autoclave tape (to indicate sterilisation has been effective) which is then autoclaved at 134 C for 30 minutes, before waste is sent to the on-site clinical waste incinerator for eventual incineration. Degree of kill 100%.

**Tick to confirm that you have attached a risk assessment to this form**

- **Y**
In order to investigate the relative contribution of RSV proteins to the host range phenotype of RS viruses, the replication of recombinant BRSV, in which the surface glycoproteins or the non-structural gens have been replaced either alone or in combination by those from HRSV, will be investigated in different bovine and human primary cell cultures and cell lines. In addition, the replication of these chimeric viruses in cattle and mice will be investigated.
Characterisation of the role of different RSV proteins in determining the host range phenotype of RS viruses may lead to the development of a small animal model of BRSV and/or the development of attenuated RSV vaccines for man and cattle.

Recipient or parental organism

Bovine respiratory syncytial virus.

Host/vector system

Bovine RSV in which the F, G, SH, NS1 and/or NS2 genes have been replaced with those from human RSV.

Origin & function

Bovine RSV in which the F, G, SH, NS1 and/or NS2 genes have been replaced with those from human RSV have been made by collaborators.

The F protein mediates virus attachment and penetration of cells.
The G protein mediates virus attachment and may also have other, as yet unidentified, functions.
The function of the SH protein is not known.
The NS proteins are involved in aspects of virus replication, in resistance to the antiviral effects of type I interferons, in regulating the induction of type I interferons and may also have other, as yet unidentified, functions.

Evaluation of foreseeable effects

HRSV is a major cause of respiratory disease in young children and BRSV causes a similar disease in young calves. Although closely related, with greater than 80% amino acid identity for 8 of the 11 proteins, BRSV and HRSSV display a restricted host range in vivo. However, HRSSV and BRSV have an overlapping host range in cell culture, in vitro. Replacement of BRSV genes by genes from HRSSV may alter the host range phenotype of the virus. Thus the chimeric BRSV may be able to infect humans, chimpanzees, cotton rats and/or mice and may replicate more efficiently in primate cells than the parental BRSV. It is possible that some of the chimeric BRSV may replicate less efficiently than the parental virus in some cells or animals. If replication is poor the chimeric virus may adapt and evolve giving rise to virus with altered pathogenicity.

HRSSV is ubiquitous in the human population, the majority of whom have experienced one or more HRSSV infections and therefore have some pre-existing immunity. HRSSV infection in adults is usually restricted to the upper respiratory tract. However, HRSSV infection in young infants, the elderly or in immunosuppressed individuals can be severe. Similarly infection with BRSV is widespread in the cattle population and reinfection is usually restricted to the upper respiratory tract. If chimeric rBRS viruses were to infect an adult, pre-existing immunity to the F protein of HRSSV, which is the major protective antigen of the virus, is likely to limit the replication of the chimeric virus. Thus there is only 19% amino acid difference between the BRSV and HRSSV F proteins and neutralising monoclonal antibodies specific for the F protein recognise both the HRSSV and the BRSV F proteins. These anti-F mAbs protect against experimental HRSSV infection in mice, HRSSV in children and BRSV infection in calves. Bovine sera will neutralise HRSSV and human convalescent sera neutralise BRSV. However, the neutralisation titres are higher against homologous viruses. Intramuscular injection of cattle with HRSSV will protect against BRSV infection and infection of cotton rats with BRSV will protect against HRSSV infection. Infection of adults with the GMM is therefore unlikely to produce disease any more severe than a cold. In contrast, infants and immunosuppressed individuals are at risk of developing bronchiolitis and pneumonia if they became infected.

The chimeric viruses may be more hazardous to humans than wild-type BRSV, but are unlikely to be as hazardous to humans as wild-type HRSSV.

Since the organisms will be handled as ACDP category 2 pathogens for all experiments, the likelihood of environmental exposure is small. Furthermore, RS viruses do not replicate in the environment outside of the host animal and would not be expected to survive for long in the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
RS viruses are labile viruses and are readily inactivated. All contaminated or potentially contaminated category 2 laboratory waste is autoclaved or incinerated (100% kill).

Pipettes and similar objects are disinfected, and surfaces are wiped, with hypochlorite solution or 70% ethanol (100% kill). Waste animal bedding and small animal boxes will be autoclaved (100% kill). Large animal rooms will be fumigated with formaldehyde (100% kill). Animal carcasses will be incinerated (100% kill).

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

Initially, the proposed genetic modification work was brought to the attention of the Genetic Modification Safety Committee in the form of an amendment to be considered as part of a previously notified CU2 project in 2000 (re-notified under transitional arrangements in 2001) but the Committee felt this was inappropriate and had requested to the project proposer that a new full risk assessment must be carried out and suggested some amendments. This was reviewed by the Committee and is the risk assessment attached here.

Project Ref  97/04.3

Date Ackn’d  28/06/2004

Date Project Ceased  28/06/2004

CU2 Project Title  Characterisation of recombinant bovine respiratory syncytial viruses (BRSV) expressing different forms of the bovine virus diarrhoea virus (BVDV) E2 protein.

Class  Class 2

Cultures Vol Class 2  < 1 Litre

Cultures Volume Class 3-4  Not Applicable

Non-GMM Consent Granted  Not Applicable

02/03/2022  Page 2883 of 15326
Purposes of the contained use

To investigate the ability of a rBRSV expressing the E2 protein of BVDV to protect against BRSV and BVDV infection in calves. The replication of rBRSV expressing different forms of the BVDV E2 protein will be investigated in different bovine primary cell cultures and cell lines. In addition, the replication of these viruses in cattle will be investigated.

Analysis of the virulence of rBRSV expressing BVDV E2 proteins and the immune response and level of protection against subsequent challenge with BRSV &/or BVDV E2 proteins and the immune response and level of protection against subsequent challenge with BRSV &/or BVDV will aid the development of a live attenuated vaccine that will protect against both BRSV and BVDV infection.

Recipient or parental organism

Bovine respiratory syncytial virus (BRSV), strain ATCC A51908Tue. BRSV A51908Tue rescued from cDNA is attenuated in young calves (Valarcher et al., 2003, J. Virol. 77:8426-8439) The virus grows more efficiently in the upper respiratory tract than in the lower respiratory tract of calves, inducing mild pulmonary pathology, but not clinical signs of respiratory disease.

Host/vector system

BRSV expressing various forms of the bovine viral diarrhoea virus (BVDV) E2 protein, which have been constructed in the laboratory, Institut fur Virologie, Tierarztliche Hochschule Hannover, Hannover, Germany:

1. rBRSV expressing the native BVDV E2 protein, which is retained within the endoplasmic reticulum (1)
2. rBRSV expressing a chimeric protein consisting of the BVDV E2 protein with the membrane anchor and cytoplasmic tail of the vesicular stomatitis virus (VSV) G protein to produce expression of the E2 protein on the basolateral side of the plasma membrane (1)
3. rBRSV expressing a chimeric protein consisting of the BVDV E2 protein with the membrane anchor and cytoplasmic tail of the VSV G protein, but with a mutation in the cytoplasmic tail to produce expression of the E2 protein at the apical plasma membrane.
4. rBRSV expressing a transmembrane deleted form of the BVDV E2 protein in an attempt to produce a soluble form of E2. However, the E2 protein cannot be detected in supernatant from cells infected with this virus and appears to be localised in the endoplasmic reticulum.

Origin & function

Bovine RSV expressing BVDV E2 genes have been made by collaborators in Germany. The BVDV E2 glycoprotein mediates virus attachment to cells and is a major protective antigen of BVDV, inducing neutralising antibodies.
Evaluation of foreseeable effects

RS viruses are labile viruses and are readily inactivated. All contaminated or potentially contaminated category 2 laboratory waste is autoclaved or incinerated (100% kill).

Pipettes and similar objects are disinfected, and surfaces are wiped, with hypochlorite solution or 70% ethanol (100% kill).

Waste animal bedding will be incinerated (100% kill). Large animal rooms will be fumigated with formaldehyde (100% kill). Animal carcasses will be incinerated (100% kill).
The GMSC have reviewed and agree with the risk assessment.

### Purposes of the contained use

As part of the current programme on immunity to TB in cattle, we will evaluate immune responses and protective efficacy of recombinant adenovirus expressing antigen (Ag) 85 of Mycobacterium bovis. The objectives of the project are:

1. To evaluate the immune responses elicited in cattle by the recombinant human adenovirus type 5 expressing Ag85A (Ad85A) of M. bovis.
2. To evaluate the use of recombinant the Ad85A for in vitro stimulation of T-cells.

### Recipient or parental organism

No construction of vector will take place at IAH as the GMO will be supplied by our colleagues at Veterinary Laboratory Agency. 
E.coli DH5alpha or equivalent. 
Recombinant, replication deficient human type 5 adenovirus. 
The vector is pACCMV or equivalent, such as pjW24. This is a widely used shuttle vector for producing recombinant adenoviruses.

### Host/vector system

Recombinant DNA will be placed between the cytomegalovirus promoter and the SV40 poly(A) sequence.  
Guest DNA will be placed in frame with the signal peptide of the human tissue plasminogen activator.  

### Origin & function

Mycobacterial DNA encoding Antigen 85A (Ag85A). 
The gene encoding Ag85A will be inserted into the adenovirus vector mentioned above for expression in mammalian hosts for expression and immunization.

### Evaluation of foreseeable effects

Recombinant Ag85A expressed in adenovirus vectors will induce Ag85A specific immune responses in immunised hosts. This construct has been shown to elicit immune responses in cattle (Vordermeier, H.M. Infect Immun 74:1416-1418).

Due to its attenuation, no new virus particles will be produced in the host. Ag85A has no known toxic effects, it is not a known virulence gene and it is not expected to confer replication competency to the adenovirus vector.

The adenovirus to be used in these experiments is human type 5, which is a double-stranded DNA virus. Wild-type, unattenuated adenovirus most commonly causes self-limited infections in the respiratory tract, causing the "common cold" and the gastrointestinal tract, causing diarrhoea.

Wild type adenovirus have been safely used as oral vaccines to prevent adenoviral infections to more than 10 million people and is also being given to military personnel in the USA and Canada (Rubin B.A. and Rorke, L. B. Adenoviral vaccines. In: Plotkin & Mortimer (Eds). Vaccines. (1988) W.B. Saunders. Philadelphia, pp 492).

The vector to be used in these experiments will have deletions in the E1 and E3 regions of the adenoviral genome and has been described by Wang, J. et al. J Immunol 173:6357-6365. In brief, the Ag85 sequence is in frame downstream of human tissue plasminogen activator signal peptide, which in turn is downstream of the murine cytomegalovirus promoter. 3' of the Ag85 sequence will be the SV40 poly (A) signal. The E1 region is essential for replication and propagation and its removal renders the virus replication deficient. Deletion of the E3 region is not essential for viral growth, but its removal allows the insertion of guest genes in this region. (Trapell, B. Adenoviral vectors for gene transfer. Advance Drug Delivery Rev. (1993). 12:185; Bramson, J.L. et al. The use of adenoviral vectors for gene therapy and gene transfer in vivo. Curr.
The recombinant adenoviral vector has been evaluated in a number of clinical trials and found to be safe. The safety and efficacy data from both clinical and pre-clinical studies using recombinant adenoviral gene transfer vectors have widely been reported (Zhang, W. W. Development and application of adenoviral vectors for gene therapy of cancer. Cancer Gene Ther. (1999). 6:113).

The main hazard with adenovirus would be infections of humans and other animals, but no detrimental effects are expected on either. Exposure monitoring by eg. Serological testing of animal carers, etc. is not necessary. These tests would be unable to distinguish between wild type viruses and the attenuated virus used in this study. Wild type adenovirus is a common cause of mild upper respiratory infections worldwide and many of us will already have seroconverted. The hazard is also minimal given the replication deficiency of the construct. We intend to reduce even this minimal risk by working with the construct at ACGM level 2.

Given the replication deficiency and the containment level at which we intend to work, the likelihood of release of the recombinant vector to the environment is effectively zero. There is no production of new viral particles in vaccinated hosts.

All work under this proposal will be carried out at HG 2 containment. No additional hazards over those of wild type adenovirus are foreseen. Cattle inoculated with recombinant adenovirus will be housed in appropriate category 2 containment facilities at all times during the experiment.

Accordingly this proposal seeks approval for a confirmed containment level 2 for work to be carried out under this proposal.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste materials generated by these experiments will be inactivated mainly by autoclaving at 121C for 30 min and/or by incineration. Where necessary, materials will be soaked with 1% solution of Virkon for a minimum of 20 minutes.

Is an emergency plan required according to regulation 20? [N]

Project Additional Information

Purposes of the contained use

To investigate the ability of a rSeV expressing the F and/or G proteins of RSV to protect against RSV infection in mice. The virulence and immunogenic potential of SeV expressing RSV F and/or G proteins will be investigated in mice. Since SeV is being considered as a potential live virus vaccine for use in man to protect against human parainfluenza virus I infection, SeV may also be of value in the development of a live, attenuated viral vaccine against RSV.

Recipient or parental organism

Sendai virus (strains H and Z) rescued from cDNA.

Host/vector system

The RSV F gene has been inserted between the N and P genes of SeV (gene order of wild-type SeV is N-P/C-M-F-HN-L) and has been provided by Queen's University, Belfast. Although the RSV F protein is a major attachment protein and mediates the formation of multinucleated giant cells, it does not contain the amino acid sequence
Since the organisms will be handled as ACDP category 2 for all experiments, the likelihood of environmental exposure is small. SeV does not replicate in the environment

same considerations are likely to apply as for humans.

House will have serious consequences from respiratory infections in experimental animals. There is no information on the susceptibility of other animals to SeV and the genetically manipulated SeV into the environment is unlikely to have a major impact on the wild rodent population. However, accidental exposure of rodents in the Animal show variations in susceptibility to infection, due to both genetic differences and to pre-existing immunity from previous exposure to wild-type virus. Therefore, release of genetically manipulated SeV into the environment is unlikely to have a major impact on the wild rodent population. However, accidental exposure of rodents in the Animal

bronchiolitis and pneumonia requiring hospitalisation in approximately 1-2% infants. Although re-infection with RSV is common throughout life, clinical disease is usually

tropism of rSeV-F are not expected to be different from that of wild-type Sev. In view of the level of pre-existing immunity to SeV (as a result of HPIV-1 infection) and to host-range restriction resulting from virus evolution in mouse versus man, there have been no confirmed cases of SeV human disease. Studies in seronegative African green monkeys inoculated I.n. with SeV showed that virus could replicate in the upper respiratory tract for approximately 4 days without any evidence of disease. There was also evidence of virus replication in the lower respiratory tract, but again without any evidence of disease. Since, in the absence of the correct amino acid sequence in the RSV F protein, it is unlikely that it will be incorporated into the virion, the virulance, host-range or cell tropism of rSeV-F are not expected to be different from that of wild-type Sev. In view of the level of pre-existing immunity to SeV (as a result of HPIV-1 infection) and to RSV, rSeV-F would be unlikely to cause disease in humans. Furthermore, the majority of humans are infected with RSV during their first year of life and causes bronchiolitis and pneumonia requiring hospitalisation in approximately 1-2% infants. Although re-infection with RSV is common throughout life, clinical disease is usually restricted to common cold-like symptoms in adults.

The genetically manipulated Sevs are unlikely to be more pathogenic than wild-type viruses, which are probably present in the rodent population. Virulent strains of the virus can cause pneumonia and death in rodents. Although SeV can persistantly infect neonatal, but not suckling, weaning or adult mouse brains when inoculated intracerebrally, the virus does not infect the CNS following respiratory exposure. Ferrets, rhesus and cynomolgous monkeys and marmosets are susceptible to experimental respiratory infection. Since there is a wide range of variability in susceptibility to infection in different strains of mice, wild, outbred rodents are also likely to show variations in susceptibility to infection, due to both genetic differences and to pre-existing immunity from previous exposure to wild-type virus. Therefore, release of genetically manipulated SeV into the environment is unlikely to have a major impact on the wild rodent population. However, accidental exposure of rodents in the Animal House will have serious consequences from respiratory infections in experimental animals. There is no information on the susceptibility of other animals to SeV and the same considerations are likely to apply as for humans.

Since the organisms will be handled as ACDP category 2 for all experiments, the likelihood of environmental exposure is small. SeV does not replicate in the environment
outside of the host animal and since it is a labile virus, it would not be expected to survive for long in the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Wild-type and recombinant Sendai viruses will be handled at category 2 with additional containment for animals in the Animal House to prevent spread to other animals under experiment, where it may influence the results of others. Therefore the mice will be housed in isolators and all inoculations and post mortems will be carried out in a class II microbiological safety cabinet.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Sendai virus is a labile virus and is readily inactivated. All contaminated or potentially contaminated category 2 laboratory waste is autoclaved or incinerated (100% kill). Pipettes and similar objects are disinfected, and surfaces are wiped, with hypochlorite solution or 70% ethanol (100% kill). Waste animal bedding will be incinerated (100% kill). Large animal rooms and isolators will be fumigated with formaldehyde (100% kill). Animal carcasses will be incinerated (100% kill).

Is an emergency plan required according to regulation 20?  N

**Project Additional Information**

**Purposes of the contained use**

Human immunodeficiency virus type 1 (HIV-1) is a lentivirus that causes a persistent infection in humans associated with the development of an acquired immunodeficiency syndrome (AIDS) which, if untreated, is ultimately fatal. We are studying innate and T cell responses in individuals who have repeatedly been exposed to HIV but have no developed fully-seropositive infection (and unexposed control individuals); and in patients recently infected with HIV who naturally contained viral replication with differing efficiency. Our objective is to identify viral and immune correlates of good control of virus replication, to inform HIV vaccine design. As part of these studies, we propose to compare the relative susceptibility of PDMCs from different individuals to in vitro infection with different HIV isolates, and then go on to dissect mechanisms contributing to differences in in vitro viral replication (focusing particularly on the role of host innate effector mechanisms in inhibiting viral replication).

Some experiments will be carried out with uncloned HIV stocks (including primary virus isolates derived from different infected individuals); but we would also like to work with viral stocks prepared from proviral DNA clones, both for consistency, and to enable identification of viral genetic determinants of differences in in vitro replication capacity.

**Recipient or parental organism**

Plasmids containing infectious molecular clones of HIV will be grown up in disabled host bacteria such as the E.coli K12 derivative DH5α; and then transfected into a eukaryotic cell line such as 293T (a human kidney cell line).

The bacteria to be used are non-pathogenic and unlikely to survive outside culture media or disseminate themselves in the environment. There should be no expression of HIV gene products with these bacteria; but should the plasmid DNA somehow gain entry into dividing eukaryotic cells, there would be potential for HIV production from these cells (HIV RNA production being driven from the LTRs).

293T cells are a highly transfectable derivative of the 293 cell line (an adherent cell line of epithelial morphology derived from human kidney, which contains some adenovirus 5 DNA sequences) into which the temperature sensitive gene for SV40T antigen was inserted. Due to the presence of adenoviral and SV-40 T sequences, which confer the potential to form tumours, this cell line should be handled at containment level 2.

Transfection of these cells with molecular clones of HIV will result in production of HIV.

HIV is a lentivirus that is known to infect humans (via routes including the blood and via mucosal surfaces), and establishes a lifelong persistent infection ultimately...
associated with the development of AIDS. HIV-1 is classified as an ACDP category 3 pathogen.
Many of the infectious molecular HIV clones to be used will be composed of sequences derived from different HIV isolates - ie will result in the generation of genetically modified (chimeric) virus.

Host/vector system

We initially plan to work with plasmid pNL4.3, which contains an infectious molecular clone derived from the NY5 and LAV HIV isolates (Adachi et al. J Virol 59 284-291, 1986) and generates a CXCR4-utilising virus; and a matched clone (pNL4.3BaL,ecto) in which the gp160 ectodomain has been replaced with that of HIV BaL (a CCR5-utilising virus isolate). Details of these HIV molecular clones (both of which are contained in the plasmid pUC18) are provided in the two accompanying pdf files. In future, infectious clones of other HIV isolates and chimeras containing other gp160s or gp 160 fragments may also be used. Some clones may also include marker proteins such as GFP. All the viruses generated from these clones will be of similar or lower pathogenicity to those detailed above. These clones will be obtained from repositories or external collaborators; we do not propose to generate or modify infectious molecular clones of HIV ourselves.

Origin & function

As detailed above, we plan to work with infectious molecular clones derived from CXCR4 and CCR5-utilising HIV isolates. These will include chimeric clones, in which the env gene (or fragments thereof) may be derived from different HIV isolates. Some clones may also contain the marker protein GFP. Infectious HIV will be derived from these clones. Viruses expressing different envelope glycoproteins (the virion surface protein that mediates attachment and entry into host cells) will be generated from different chimeric clones.

Evaluation of foreseeable effects

1. Growth of plasmids containing infectious molecular clones of HIV in E.coli. Bacteria
The plasmids we will work with will contain full-length molecular clones of HIV. Plasmid stocks will be prepared by growth in disabled host bacteria such as the E.coli K12 derivative DH5α.
The pathogenicity of the host bacteria in which the plasmids are to be grown is very unlikely to be affected by the presence of the plasmids. There should not be any expression of HIV genes within the bacteria.
The HIV molecular clones will be contained within the pUC18 plasmid, which is a non-mobilisable vector. Plasmid sequences are thus unlikely to be transferred to other bacteria.
E.coli bacteria containing HIV molecular clones are very unlikely to cause harm to human health. They should not express any HIV gene products, and the presence of the plasmid DNA is not expected to affect their pathogenicity.
It is very unlikely that E.coli bacteria transfected with HIV molecular clones would survive in the environment; and since the plasmid DNA is non-mobilisable, it would also be very unlikely that this would be transferred to other bacteria. These GMOs thus pose an extremely low risk to the environment.

It is unlikely that plasmid DNA contained within the bacteria would be transferred into human cells and initiate HIV production. Nonethe less, this could potentially occur, and is a risk that should be considered. Given the (extremely low) risk that plasmid DNA encoding full-length molecular clones of HIV could conceivably enter replication-competent human cells and initiate production of infectious HIV, it is proposed that plasmid DNA and bacteria containing it should be handled under containment level 2 conditions, to minimise the risk of an infectious exposure incident occurring.
Plasmids containing HIV molecular clones and bacteria containing these plasmids will thus be worked with in category 2 containment laboratories. Gloves and eye protection will be worn at all times when handling these reagents (to minimise the risk of contact with skin or mucosal surfaces). The use of glass and of sharps (eg needles) will be avoided where possible, to minimise the risk of sharps injuries that may result in exposure to plasmid DNA. Equipment and work-surfaces will be decontaminated after use using a suitable a chlorine-containing disinfectant, and all waste will also be treated with disinfectant and/or autoclaved.

2. Transfection of eukaryotic cells with full-length molecular clones of HIV to generate infectious virus
Plasmids containing full-length molecular clones of HIV will be transfected into eukaryotic cells (eg 293T cells), which will then produce infectious HIV particles. Upon transfection of the plasmids into 293T cells, the pathogenicity of the cells themselves is unlikely to change. There is also very little risk of plasmid sequences being transferred from transfected 293T cells to other cell lines.
293T cells transfected with HIV molecular clones would also be very unlikely to survive in the environment.
However 293T cells transfected with HIV molecular clones will produce infectious HIV, which could initiate human HIV infection. These cells and the viruses derived from them thus present a high risk to human health - equal to that of naturally-occurring HIV isolates. Transfection of plasmids into eukaryotic cells and all subsequent work with transfected cells with thus be performed under in category 3 containment laboratories, following the category 3 laboratory code of practice.

3. Use of HIV viruses derived from infectious molecular clones

HIV is a lentivirus that is known to infect humans (via routes including blood and via mucosal surfaces), and establishes a lifelong persistent infection ultimately associated with the development of AIDS. HIV-1 is classified as an ACDP category 3 pathogen.

Some of the HIV clones we propose to work with are chimeric clones containing partial/entire env genes from one HIV isolate in the backbone of another. As gp160 is the virion envelope glycoprotein, its sequence does affect virus interaction with host cell receptors and hence viral tropism and pathogenicity. However it is not expected that any of the chimeric viruses we will generate will exhibit a level of pathogenicity greater than that of the group of primary HIV isolates from which their component sequences were derived.

HIV sequence could potentially be transferred from the chimeric viruses that we generate from molecular clones to other HIV viruses, if replication competent cells were to become co-infected with the chimeric virus and another HIV isolate. However this should not result in the generation of recombinant viruses any more pathogenic than those that could be generated naturally by recombination between the parental virus from which the chimeric virus was derived and the HIV isolate concerned.

The HIV virions we generate would pose a similar risk to the environment as that posed by natural HIV isolates. HIV virions are extremely labile- but if laboratory staff were to become infected, they could potentially transmit virus to other people. To minimise this risk, in the event of any potential HIV exposure incident, the staff involved would be tested for HIV infection, and also receive antiretroviral therapy to try and prevent full-blown infection from occurring.

HIV viruses derived from infectious molecular clones will only be used for in vitro experimental work. All work involving these viruses will be performed in category 3 containment laboratories, following the category 3 laboratory code of practice.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste from bacterial cultures will be treated with 1% bleach for > 30 minutes prior to discarding (100% kill). Solid waste will be disinfected by autoclaving or incinerated (100% kill). Equipment and work-surfaces will be decontaminated after use using a suitable chlorine disinfectant.

Liquid waste from the category 3 containment labs will be treated with a suitable disinfectant (eg.1% Virkon for > 30 minutes) prior to discarding (100% kill). Solid waste will be disinfected by autoclaving (100% kill). Equipment and work surfaces will be decontaminated after using a suitable disinfectant (eg 70% ethanol).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
As part of the current programme on immunity to TB in cattle, we will evaluate immune responses and protective efficacy of the urease deficient recombinant BCG expressing listeriolysin (Hyl) of Listeria Monocytogenes (AueChly+ rBCG). The objectives of the project are:

1. To evaluate the immune responses elicited in cattle by the AureChly+ rBCG.
To evaluate the use of recombinant BCG AureChly+ rBCG for in vitro stimulation of T-cells

Recipient or parental organism

BCG is currently the only vaccine licensed for use against human TB. It is administered to newborn babies and as such it is a safe vaccine (Brewer, T. F. 2000. Preventing tuberculosis with bacillus Calmette-Guerin vaccine: a meta-analysis of the literature. Clin Infect Dis 31 Suppl 3:S64-67). However, BCG could provoke a serious, life-threatening infection in immune compromised individuals.

AureC BCG is a urease negative derivative of BCG which was created by the insertion of an ureC gene disrupted by a kanamycin marker (aph) (aph::UreC) in a suicide vector to replace the native ureC gene (Reyrat, J.M., G. Lopez-Ramirez, C Ofredo, B Gicquel, and N. Winter. 1996).

The cloning of LLO into AureC BCG (AureC hly+ rBCG), which lacks urease, did not result in increased virulence. The construct was shown to be less virulent for immune deficient SCID mice than parental BCG. Cloning and expression of Hyl did not endow BCG with the ability to lyse macrophages (Grode, L. P. Seiler, S. Baumann. J. Hess. Brinkman, A.N Eddine, P. Mann, C. Goosmann, S. Bandermann, D. Smith G, J Bancroft, J.-M.Reyrat, D. van Soolingen, B. Raupach, and S.H.E Kaufmann. 2005 Increased vaccine efficacy against tuberculosis of recombinant Mycobacterium bovis bacilli Calmette-Guerin mutants that secrete listeriolysin. J. Clin. Invest. 115;2472-2479).

The main hazard with AureC hly+ rBCG would be infection of humans and other animals, but no detrimental effects are expected on either. All genetic modifications of BCG to date have attenuated this organism further and have not restored its virulence. However, wild-type BCG can cause disease in immunocompromised hosts. Such opportunistic infection is amenable to drug treatment in humans. The hygromycin resistance marker has been chosen because they are not used in human medicine.

The recombinant AureC hly+ rBCG will be undergoing human clinical trials in Germany in late 2007.

Accordingly, no harmful effects to healthy, immune competent individuals are envisaged.

All work under this proposal will be carried out at containment level 2 by personnel trained to work at this level of containment. No additional hazards over those of BCG are foreseen.

Host/vector system

The attenuated Mycobacterium bovis bacillus Calmette-Guerin (BCG) is currently the only vaccine licensed for use against human tuberculosis. It is administered to newborn babies and as such it is considered a safe vaccine licensed for use against human tuberculosis. It is administered to newborn babies and as such it is considered a safe vaccine (Brewer, T. F 2000. Preventing tuberculosis with bacillus Calmette-Guerin vaccine: a meta-analysis of the literature. Clin Infect Dis 31 Suppl 3:S64-67). AureC BCG is a urease negative derivative of BCG which was created by the insertion of an ureC gene disrupted by a kanamycin marker (aph) (aph::UreC) in a suicide vector to replace the native ureC gene (see figure below) (reyrat, J, F Berthet, and B Gicquel. 1995 The Urease Locus of Mycobacterium bovis Bacillus Calmette-Guerin. PNAS 92:8768-8772.).

Schematic organisation of the ureC disrupted gene used for allelic exchange. Open reading frames are represented by blocks. Relevant restriction sites are indicated (P, Pst I, B, BamHI, S, Sac I). The aph gene on a 1.3-kbp BamHI fragment was inserted into the BamHI site of ureC and is represented as a black rectangle. The solid bar represents the suicide vector pBluescript K S+. Primers used for amplification by PCR of the structure resulting from double crossover are depicted by arrows P3 and P4 (from Reyrat, J. F. Berthet, and B Gicquel. 1995. The Urease Locus of Mycobacterium tuberculosis and its utilization for the Demonstration of Allele Exchange in Mycobacterium bovis Calmette-guerin. PNAS 92:8768-8772).

The hazard associated with the recipient microorganism are not expected to be greater than those expected from the vaccine against TB, BCG, which does not cause harm to immune competent individuals.

**Origin & function**

Listeriolysin O (LLO) is a cholesterol-dependent cytolysin that is an essential virulence factor of Listeria monocytogenes. LLO pore-forming activity is pH-dependent; it is active at acidic pH,(6), but not at neutral pH. LLO’s pore-forming activity is controlled by a rapid and irreversible denaturation of its structure at neutral pH at temperatures > 30 degrees C. Schuerch, D. W. E. M Wilson-Kubalek, and R.K Tweten, 2005. Molecular basis of listeriolysin under normal conditions. LLO induces a number of host cell responses, such as cell proliferation, activation of MAP kinase pathway in epithelial cells, modulation of internalization via calcium signalling and cytokine expression in macrophages (Vazquez-Boland JA, et al.,2001. Listeria pathogenesis and molecular virulence determinants. Clin. Microbiol. Rev. 14(3):584-640.

The cloning of listeriolysin into BCG allows the increased permeabilization of the phagosomal membrane to allow greater leakage of BCG antigens into the cytoplasm and therefore greater processing of Mycobacterial antigens through the cytoplasmic compartment which primes for CD8+ T-cell responses. The cloning of listeriolysin into AureC BCG (AureChly+rBCG), which lacks urease, did not result in increased virulence. The construct was shown to be less virulent for immune deficient SCID mice than parental BCG. Cloning and expression of Hyl did not endow BCG with the ability to lyse macrophages (grode, L Peiser, S Baumann, J. Hess, V. Brinkmann, A.N. Eddine, P. Mann, C. Goossman, S. Bandermann, D. Smith, G.J Bancroft, J. M reyrat, D. van soolingen, B. Rapupach, and S.H.E Kuafmann. 2005. Increased vaccine efficacy against tuberculosis of recombinant Mycobacterium bovis bacilli Calmette-Guerin mutants that secrete listeriolysin. J. Clin. Invest. 115:2472-2479).

**Evaluation of foreseeable effects**

The main hazard with AureChly+rBCG would be infection of humans and other animals, but no detrimental effects are expected on either. The recombinant AureChly+rBCG will be undergoing human clinical trials in Germany in late 2007.

All genetic modifications of BCG to date have attenuated this organism further and have not restored its virulence.

It is not possible to state what effect of this construct would be on immunocompromised people; BCG is contra-indicated for immune-deficient people. However, the cloning of LLO into AureCBCG(AureChly+rBCG), which lacks urease, was shown to be less virulent for immune deficient SCID mice than parental BCG. Cloning and expression of Hyl did not endow BCG with the ability to lyse macrophages(Grodé, L P. Seiler, S Baumann, J. Hess, V. Brinkmann, A.N Eddine, P, Mann, C. Goosmann, S. Bandermann, D Smith, G. J Bancroft, J-M. Reyrat, D. van Soolingen, B. Raupach , and S. H.E Kaufmann. 2005. Increased vaccine efficacy against tuberculosis of recombinant Mycobacterium bovis bacilli Calmette-Guerin mutants that secrete listeriolysin. J Clin Invest, 115:2472-2479).

Nevertheless, should an immune deficient person become infected with the construct and develop clinical signs, such infection would be amenable to antibiotic treatment; the hygromycin resistance gene inserted into the chromosome of BCG during the creation of the AureC BCG poses no additional risk in this respect since the drug resistance marker had been chosen because they are not used in human medicine.

Health screening measures are in place at IAH to prevent immunocompromised individuals working with ACDP class 2 organisms. Accordingly, no harmful effects to healthy, immune competent individuals are envisaged.

The risk to the environment is low. The genetic lesions present in BCG render the organism unable to persist or cause disease in immunocompetent hosts (including humans) so it is unlikely that BCG would be able to establish, diseminate or displace other environmental organisms to a significant extent. The greatest hazard associated with exposure of animals to BCG is that cattle infected with BCG become positive for the tuberculin skin test. Although BCG does not persist in cattle and causes no disease, animals that become tuberculin positive through exposure to BCG would be deemed tuberculosis by the current TB screening measures in the UK and would be slaughtered as a result (please note that cattle held at IAH for experimental purposes are not subject to this routine TB surveilence). The greatest hazard is therefore an economical one for cattle kept on potential farms surrounding IAH Compton. However, there are no commercial cattle holdings in close contact to the CL2 cattle not result in faecal, aerosol or nasal BCG shedding, which is necessary for such an event to occur. The materials and consumables used for the vaccinations will be also incinerated. Cattle will be killed at the end of the experiment and incinerated, thus preventing any exposure of the environment due to BCG persisting in lymph nodes, or other internal organs.

The work to be carried out involves the injection of bacteria into cattle to determine the immune responses induced by this vector. To determine immune responses to the construct we may also use bacterial cultures grown in this laboratory to infect cells in vitro for antigen presentation. For in vitro experiments it is envisaged that the maximum volumes of bacterial culture required will be 100ml. It is extremely unlikely that the mutants of BCG will be released from the laboratory since the bacilli will be stored, analysed and dispensed in a Containment Level 2 (CL2) laboratory by trained workers. The inoculum will then be transported in secure containers to the CL2 cattle accommodation where the vaccinations will take place. Once inoculated (subcutaneously), the vaccinated animals will serve essentially as primary containment; the vaccination route means that the bacteria will be sequestered within the lymphatic system, which makes excretion into the environment highly unlikely. The construct will be stored at -80 degrees C in a secured container and when required, the construct will be transported in a secure container to the CL2 laboratory.

Accordingly this proposal seeks approval to confirm containment level 2 for work to be carried out under this proposal.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Waste materials generated by these experiments will be inactivated mainly by autoclaving at 121 degrees c for 30 min and/or by incineration. Where necessary, materials will be soaked overnight with a 1% solution of Virkon and then disposed by incineration. At the end of the experiment animal carcasses will be incinerated. These inactivation methods achieve 100% kill of BCG.

This request and accompanying assessment has been reviewed extensively by the Institute for Animal Health's genetic modification committee at Compton. We are satisfied with the risk assessment of the proposed work.

Purposes of the contained use

Objective : To transfect Eimeria tenella with constructs designed to express sequences coding for heterologus protozoan, bacterial and viral antigens to facilitate assessment as a vaccine delivery vehicle.

Recipient or parental organism

The Eimeria species, including E. tenella, have been rated by the Advisory Committee On Dangerous Pathogens (ACDP) as requiring a containment level of 1. The Eimeria species are completely host-and, in examples, tissue-specific: E.tenella specifically parasitizes the chicken caecae and poses no risk to human health or safety.

Host/vector system

The commercially available vector pGEM-Teasy (Promega) will be used throughout these studies, together with a series of vectors developed for the purpose of transfecting Eimeria species parasites (Clark et al 2008. mol Biochem Parasitol 162:77-86) The XL1-Blue MRF Laboratory Escherichia coli strain (deficient in all known restriction systems [(mcrA183, (mcrCB-hsdSMR-mrr)173], endonuclease(endA) and recombination (recA) deficient will be used throughout these studies.

Origin & function

DNA templates encoding the Eimeria maxima SAG, Campylobacter jejuni CjaA and Avian influenza hemagglutinin antigens (HA) are already available within the IAH in plasmid stocks (derived by PCR amplification from gDNA or directly synthesised). Thus, there is no requirement to handle either C. Jejuni or the Avian influenza virus. Amplification and manipulation of E. maxima, An ACDP hazard group 1 pathogen, is routine within the IAH. All antigens will be expressed under the control of eimerian stage-specific promoters, limiting antigen production to defined steps of the transfection process which will be controlled as described in section 12.

The primary function of these studies is to generate lines of E. tenella that express heterologous antigens in order to assess the parasite’s potential as a vaccine delivery vehicle. Thus, once created, each line will be assessed for expression of the target antigen (i.e. by RT-PCR and immunolabelling) prior to use to immunise SPF chickens within the IAH experimental facility to monitor correlates of immune protection. Added value will be gained through the phenotypic assessment of all parasite lines generated for divergence from the recipient strain.

Evaluation of foreseeable effects

The Eimeria species are antigenically complex micro-organisms and their interaction with the host is mediated by a complex series of proteins expressed in a sequential manner. All three candidate coding sequences described in this application are considered likely to contribute to host/pathogen interaction in their natural context but whilst the application of such non-self proteins might elevate the potential for novel recipient tropism within the chicken, the addition of a single protein to such a complex process is unlikely to have a significant impact. Once cloned, these sequences will be expressed under the control of one or more stage specific promoters, limiting expression to the sporozoite and/or merozoite lifecycle stages.

I) E.maxima surface antigens (SAGs). Preliminary unpublished data suggest that SAG proteins expressed by E.tennella mediate parasite/host interaction but not invasion. Single parasite RT-PCR has revealed the concurrent expression of seven distinct SAG proteins. Whilst addition of a single novel SAG gene has the potential to modify the recipient parasite’s ability to attach within the host, the possibility of a significant change in tropism is limited.
ii) C. jejuni CjaA antigen. The C. jejuni CjaA antigen has been shown to localise to the inner bacterial membrane where it is thought to function as a component of the ABC transporter system. CjaA acts as a receptor for the amino acids glutamine and cysteine. Thus, whilst CjaA could affect Eimeria/host interaction, expression on the surface of one or more zoite stages of the E. tenella lifecycle via a GPI anchor and not as an internal component of the cell wall will minimise the influence of any possible effects. Expression of the native CjaA under the control of its own promoter in a Salmonella Typhimurium crp-cya-strain previously yielded no increase in virulence or persistence during infection in chickens (Wyszynska et al. 2004. Vaccine 22:1379-89).

iii) Avian influenza HA's have been shown to play an essential role in mediating host cell entry. Pathogenicity among avian influenza isolates has been linked to the presence of a polybasic amino acid sequence at the HA cleavage site. The HA coding sequences to be used will be obtained by PCR amplification from existing artificially synthesised plasmid constructs which lack a polybasic amino acid sequence at the HA cleavage site. HA antigens have previously been delivered to chickens using viral vectors without severe repercussions (eg fowl pox virus, Newcastle disease virus).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Laboratory Eimeria species parasites have never been known to infect humans, thus laboratory handling of all stages of unmodified parasites is appropriately carried out with Hazard Group 1 containment. The transfection process introduces DNA by electroporation into Eimeria sporozoites, a stage of the lifecycle that exhibits severely limited environmental persistence and can only initiate infection following direct cloacal or oral (after bicarbonate gavage) inoculation. Following genetic transformation, the only stage of the parasite that requires additional containment and disposal measures is the oocyst. After recovery, oocysts will be stored in clearly marked, sealed bottles within a designated refrigerator. Bottles of transformed oocysts will be opened only in fumigatable rooms and all manipulations of these oocysts will be carried out in these rooms. Purified sporozoites will be removed to the laboratory for further experiments and these can be safely handled (as outlined above). Doses of oocysts may be removed, double bagged and in sealed containers, and taken to the EAH for infection of animals. All glassware, plasticware, paperware and liquids that contain oocysts, or are potentially contaminated with oocysts, will be fumigated with ammonia before autoclave sterilization.

Experimental Animal House. The passage, handling and disposal of oocysts (the environmentally stable stage of the eimerian lifecycle) will be carefully controlled. Animals are housed in strict isolation and cultured parasites are recovered in rooms which are then sealed for fumigation with ammonia, which destroys oocysts. The EAH facilities used are kept dry throughout all trials to limit oocyst survival and are ammonia fumigated in situ, together with all cages and any waste, at the conclusion of each experiment. All solid waste is removed after fumigation in sealed bags for incineration. Foot baths are removed before each trial commences and water traps are installed. All waste water is removed in sealed containers for autoclaving prior to disposal. Post fumigation all rooms are cleaned and re-fumigated shortly before re-stocking.

### Project Ref 97/09.1

- **Project Title:** GENERATION OF HCVcc FROM INFECTIOUS MOLECULAR CLONES, AND ITS IN VITRO USE
- **Class:** Class 3
- **Culture Volume:** 60ml
- **Date Ackn'd:** 05/03/2009
- **Date Project Ceased:** 10/08/2011
- **Consent Granted:** Yes
- **Historical Significant Changes:** Transferred to GM553 10/08/2011

### Project Additional Information

**Purposes of the contained use**

Hepatitis C Virus (HCV) is a Hepacivirus belonging to the family of the Flavividae that causes a persistent infection in about 80% of infected individuals. The primary site of infection is the liver, where chronic infection can lead to liver cirrhosis and hepatocellular carcinoma (HCC). The virus has also been found in peripheral blood mononuclear cells (PBMCs) and the central nervous system (CNS).

We are studying the modulation of immune functions and infection of different PBMC subsets by the virus, to understand how HCV establishes and maintains a persistent infection.

As HCV isolates cannot be grown in cell culture, these experiments will be carried out with the HCVcc generated from different molecular clones (as detailed below).

**Recipient or parental organism**
The E.coli K12 derivative will be DH5α will be transduced with the plasmids containing the HCV molecular clones and cultured. The isolated plasmid DNA from these bacteria such as the E. coli K12 derivative DH5α will be used to produce plasmids containing infectious molecular clones of HCV; these will then be transfected into a hepatocyte cell line such as Huh-7.5.

The bacteria to be used are non-pathogenic and unlikely to survive outside culture media or disseminate themselves in the environment.

The Huh-7 cell line and its derivatives (Huh-7-L6, Huh-7-L6f) are derived from a hepatocellular carcinoma (HCC). The Huh-7.5 cell line (used for production of HCVcc) is derived from the Huh-7 cell line but contains an inactivating mutation in the RIG-1 gene. RIG-1 is the intracellular sensor for dsRNA and its inactivation makes the Huh-7.5 cell line highly permissive to HCV replication.

When uninfected, this cell line should be handled at containment level 1.

Many of the infectious molecular HCV clones to be used will be composed of sequences derived from different HCV isolates - i.e. will result in the generation of genetically modified (chimeric) virus.

HCV is a Hepacivirus that is known to infect humans, via routes including the blood and via mucosal surfaces. It establishes a lifelong persistent infection in about 80% of infected individuals that is ultimately associated with diseases such as liver cirrhosis and HCC. HCV is classified as an ACDP hazard group 3 pathogen.

Until recently, HCV could not be grown in cell culture, so the use of HCV replicons, HCV proteins or HCV pseudoparticles (HCVpp) was necessary. The discovery of a clone called JFH-1, isolated from a Japanese patient with fulminant hepatitis, revolutionised the field, because it was the first clone that could replicate and produce infectious virus in cell culture and led to the production of what is called HCVcc (cell-culture derived HCV).

Currently, there are only a few HCV clones that can replicate and produce infectious virus. These include H77 (genotype 1a), Con1 and HCV-CG1b (genotype 1b), JFH-1 (genotype 2a) and a few structural chimeras of JFH-1 (H77-JFH-1, Con1-JFH-1, 452-JFH-1 and J6-JFH-1). We initially plan to work with the HCVcc chimera J6-JFH-1, which generates higher infectious titres compared to the JFH-1 clone, but also plan to use the original JFH-1 clone, the chimeras listed above and other structural chimeras (JFH-1 viruses containing glycoproteins from other viruses) in the future. Details of these HCVcc constructs are provided in the attached table.

We do not propose to generate or modify uninfected molecular clones of HCVcc ourselves. However we will grow up bacteria (E. coli derivatives) that harbour plasmids containing HCVcc molecular clones supplied to us by other investigators (Ralf Bartenschlage, Arvind Patel). There should be no expression of HCV gene products within these bacteria; but should the plasmid DNA somehow gain entry into dividing eukaryotic cells, there would be potential for HCV production from these cells. Viral stocks will be generated by transfecting plasmids containing proviral DNA clones into Huh-7.5 cells or other hepatocyte cell lines, collecting the supernatant, and finally concentrating the virus.

These viral stocks will then be used in in vitro assays.
safety cabinet, to minimise the risk of infectious exposure incident occurring. Plasmids containing HCV molecular clones and bacteria containing these plasmids will thus be worked with in category 2 containment laboratories. Gloves and eye protection will be worn at all times when handling these reagents (to minimise the risk of contact with skin or mucosal surfaces). The use of glass and of sharps (e.g. needles) will be avoided where possible, to minimise the risk of sharps injuries that may result in exposure to plasmid DNA. Equipment and work-surfaces will be decontaminated after use using 70% Ethanol and all waste will also be treated with 5% Virkon over night and/or autoclaved (see attached reference for minimal contact times in order to inactivate HCV and general disinfection procedures used in our containment level 3 laboratory).

2. Transfection of liver cells with full-length molecular clones of HCV to generate infectious virus

Plasmids containing full-length molecular clones of HCV will be transfected into liver cell lines (Huh-7.5 cells), which will then produce infectious HCV particles. Upon transfection of the plasmids into Huh-7.5 cells, the pathogenicity of the cells themselves is unlikely to change. There is also very little risk of plasmid sequences being transferred from transfected Huh-7.5 cells to other cell lines. Huh-7.5 cells transfected with HCV molecular clones would also be very unlikely to survive in the environment. However Huh-7.5 cells transfected with HCV molecular clones will produce infectious HCV, which could initiate human HCV infection. These cells and the viruses derived from them thus present a high risk to human health - equal to that of naturally-occurring HCV isolates. Transfection of plasmids into liver cell lines and all subsequent work with transfected cells will thus be performed under in containment level 3 laboratories, following the category 3 laboratory code of practice.

3. Use of HCV viruses derived form infectious molecular clones

Many of the infectious molecular HCV clones to be used will be composed of sequences derived from different HCV isolates-i.e. will result in the generation of genetically modified (chimeric) virus. HCV is a Hepacvirus that is known to infect humans, via routes including the blood and via mucosal surfaces. It establishes a lifelong persistent infection in about 80% of infected individuals that is ultimately associated with diseases such as liver cirrhosis and HCC. HCV is classified as an ACDP hazard group 3 pathogen. Some of the HCV clones we propose to work with are chimeric clones containing structural genes from one HCV isolate in the backbone of another. As E1 and E2 are the virion envelope glycoproteins, their sequences affect virus interaction with host cell receptors and hence viral tropism and pathogenicity. However it is not expected that any of the chimeric viruses we will generate will exhibit a level of pathogenicity greater than that of the group of primary HCV isolates from which their component sequences were derived. The viruses derived from them would pose a similar risk to the environment as that posed by natural HCV isolates. Being enveloped viruses, HCV virions are extremely labile - but if the laboratory staff were to become infected, they could potentially transmit virus to other people. To minimise this risk, in the event of any potential HCV exposure incident, the staff involved would be tested for HCV infection, and also receive antiviral therapy to try and prevent full-blown infection from occurring. HCV viruses derived from infectious molecular clones will only be used for invitro experimental work. All work involving these viruses will be performed in containment level 3 laboratories, following the category 3 laboratory code of practice.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste from bacterial cultures will be treated with 5% Virkon for over night prior to discarding. Solid waste will be disinfected by autoclaving or incinerated. Equipment and work-surfaces will be decontaminated after use using a suitable chlorine-containing disinfectant. Liquid waste from the category 3 containment labs will be treated with a suitable disinfectant (eg. 5% Virkon over night) prior to discarding. Solid waste will be disinfected by autoclaving. Equipment and work-surfaces will be decontaminated after use using a suitable disinfectant (eg. 70% ethanol).

### Project Additional Information

#### Purposes of the contained use

The aim is to assess the potential of new vaccination strategies in protection against bovine TB. Prime-boost strategies utilising MVA expressing mycobacterial antigens have been used in human studies and show enhanced immunogenicity compared to conventional vaccines (McShane et al, Nature Med 2004)

Cattle will be vaccinated with BCG (prime) and boosted at defined intervals with MVA expressing immunodominant antigens from Mycobacteria. Immune responses will be assessed in vaccinated cattle to assess vaccine efficacy. This vaccination strategy is expected to induce broad protective immunity.

#### Recipient or parental organism

Modified vaccinia virus ankara (MVA) expressing M. tuberculosis antigens will be produced by infection of permissive chick embryo fibroblast cell and transfection with a shuttle vector containing the recombinant genes plus a marker gene (green fluorescent protein). The shuttle vector recombines with the viral genome inside cytoplasm of the cell. The MVA viruses will be manufactured at Jenner Institute Vector Core facility at Oxford University.

#### Host/vector system

Modified Virus Ankara (MVA) is an attenuated vaccinia strain that, by extensive passage in chick embryo fibroblasts, has had multiple regions of the genome deleted. This strain has been demonstrated not to replicate in a range of primary human cells and mammalian cells, but has recently been shown to replicate in a baby hamster kidney cells. Genes from M. tuberculosis will be expressed in a shuttle vector under the control of the MVA 7.5 promoter.

#### Origin & function

Mycobacterial DNA encoding Ag85A, TB9.8, TB10.4 and Acr2. The genes have been cloned at the Jenner Institute, Oxford.

The proteins to be expressed (Ag85A, TB9.8, TB10.4 and Acr2) are immunodominant proteins produced by Mycobacteria species during in vivo infection, these are major targets for T cell recognition.

The aim is to test the recombinant MVA expressing these proteins as part of vaccination strategies in cattle: by incorporating immunodominant proteins into the vaccine the protective T cell response should be enhanced leading to immunity from infection.

#### Evaluation of foreseeable effects

MVA is highly attenuated and can only form infectious particles in permissive avian cells.

MVA expressing mycobacterial antigen 85A has been used in phase II human vaccine trials and has an excellent safety record (Hawksridge et al, J Infect Dis 2008).

No infectious particles can be generated in human or animal cells and therefore MVA cannot cause infection or disease.

MVA cannot disseminate in the environment due to its replication deficiency.

None of the expressed genes are oncogenic or toxic and are not expected to increase virulence of MVA.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Laboratory procedures: blood samples from MVA immunised cattle will be handled at containment level 2 within class II microbiological safety cabinets according to IAH vaccinia virus rules. Liquid waste will be treated overnight with 2% Virkon prior to disposal into drains. Solid waste (plasticware) will be autoclaved (121°C, 30 min) prior to incineration. The safety cabinets will be disinfected with 2% Virkon wipe down at the end of any experimental procedure.

Animal housing procedures: animals will be housed at containment level 2 in locked accommodation with restricted access. All personnel handling MVA immunised animals will be required to wear protective accommodation with restricted access. All personnel handling MVA immunised animals will be required to wear protective clothing and gloves, which will be disinfected by wash down with 2% Virkon following contact with animals. Walls and floors within the animal accommodation will be scrubbed with 2% virkon solution (minimum 10 minutes); wash down will be into drains with traps which contain 2% virkon (held for minimum of 10 minutes). Solid waste will be covered with 2% virkon for >30 minutes prior to removal for incineration. All animals will be culled at the end of the experimental period and the carcasses incinerated.

Project Ref 97/10.1

Date Ackn'd 26/07/2010

CU2 Project Title The determinants of replication, transmission and pathogenicity of avian influenza

Class 2

CultureVolClass2 < 1 Litre

CultureVolumeClass3-4

02/03/2022  Page 2907 of 15326
The purpose of these experiments is to increase our understanding of the viral determinants for host adaptation, increased transmissibility and virulence of influenza viruses (AI) of poultry and mammalian species. This may lead to improved vaccines and better control measures against avian influenza infections in poultry and hence reduction of the viral load in the environment. We will use the reverse genetics system to produce recombinant influenza viruses derived from wild-type animal viruses to define which polypeptides, combination of polypeptides or particular amino acid residues are responsible for increases in either virus-host interactions, increased virus attachment and replication of viruses in different avian or mammalian cells and in animal models.

Recipient or parental organism

Recombinant low pathogenicity influenza viruses will be generated by transfecting eukaryotic cells (avian or mammalian) with the plasmids pHW 2000 or pHWSccdB containing PB2, PB1, PA, HA, NP, NA, M and NS genes from low pathogenicity influenza A viruses, specifically;

1. A/chicken/Italy1279/00 (H7N1)
2. A/chicken/Pakistan/UDL-1/08 (H9N2)
3. A/turkey/Turkey/1/05 (H5N1). The HA gene derived from this virus will be modified to delete polybasic amino acids at the cleavage site. The GMP construct will have a mono basic HA cleavage site identical to that present in the low pathogenicity phenotype of H5N1 avian influenza viruses.
4. A/PR/8/34. This virus will be used as recipient of HA, NA and PB2 genes derived from the H7N1 and H9N2 and H5N1 viruses described above (number 1-3).

Host/vector system

cDNA clones will be made in E. coli and plasmid DNA containing influenza virus genes will be transfected into cells of eukaryotic origin (avian or mammalian) to rescue influenza virus

Origin & function

The recombinant viruses produced will be used in tissue culture and animal models to study the effect of specific changes in their replication capacity, pathogenesis and transmission.

Alterations in amino acids will be introduced by site directed mutagenesis in the genes that encode polypeptides of haemagglutinin, neuraminidase and polymerase (PB2) genes. These will mimic strains that have emerged during the adaptation of avian influenza viruses found in waterfowl which act as reservoir for viruses affecting poultry.
As described in the attached risk assessment, the changes in the HA gene will be restricted to those observed in the field isolates. These include the variation in the potential glycosylation sites in the HA and deletion of amino acids in the stalk length of the NA gene.

**Evaluation of foreseeable effects**

The characteristics that we plan to introduce are those observed in viruses isolated from field outbreaks in poultry and are not foreseen to be any more hazardous than parental strains; thus we propose to handle these viruses in the same way as we handle the parental strains.

To minimise the risk of infection to workers, the engineered viruses will be worked on in a Class II Microbiological Safety Cabinet. Furthermore additional procedures will be used to ensure minimal risk to the operator during transfer from the cabinet to incubators, freezers and autoclaves. Individual workers will wear disposable gloves and appropriate protective clothing at all times when handling influenza viruses.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid waste containing infectious virus will be treated with 1% Virkon for a minimum of 30 minutes inside the Class II Microbiological Safety Cabinet (Class II-MSU), then a 50-100 ml maximum volume (in plastic flasks) will be placed into double autoclave bags (double autoclave bags will be made by inserting one autoclave bag inside the other one, this will create two protective plastic layers of the autoclave bags which further reduce the chances of any potential leakage of the contaminating material inside the autoclave bags) and into the designated metal tins, transferred to Microbiological Services (within the same building) and autoclaved at 135° C for 30 minutes prior to disposal by incineration.

Solid waste:

Solid waste contaminated with infectious virus (plastic tips, flasks) will be immersed in 1% virkon for minimum of 30 minutes inside the Class II-MSU, then placed in double autoclave bags, put in a secure metal tin and autoclaved as described above and disposed by incineration.

Other solid waste such as eggs will also be disposed of by bagging in double autoclave bags within the ClassII-MSU, put in a secure metal tin and autoclaved as described above and disposed of by incineration.

The autoclave is serviced quarterly and annually validated; records are kept and examined.

The Class II-MSU are tested and validated every six months during a scheduled maintenance period.

Animal waste in the animal facility (EAH corridor D) will be placed in the autoclave bags and sprayed with 1% virkon before being removed for autoclaving. They will then be autoclaved within EAH corridor D building before disposal by incineration.

The proposal has been extensively reviewed by the local Biological Agents and Genetic Modification Safety Committee and is now considered to be acceptable for notification.

Please enter comments on the GM safety committee on the risk assessment.

The aim of the project is to evaluate immune responses and protective efficacy induced by recombinant Newcastle disease virus (rNDV) expressing either bovine (B) or...
human (H) respiratory syncytial virus (RSV) fusion (F) glycoprotein (rNDV-F) in calves. The rNDV has been produced by Dr*, Mt Sinai School of Medicine, New York, USA. The RSV F gene has been inserted between the P and M genes of the Hitchner B1 strain of NDV. Calves will be inoculated intranasally (i.n.) or i.n. and intratracheally (i.t.) with rNDV-F and analysed at intervals for excretion of NDV, induction of RSV-specific immune responses, and clinical signs of disease. Vaccinated calves will be challenged with BRSV to determine the effect of vaccination on BRSV replication in the nasopharynx and lungs, and the development of pulmonary pathology.

Recipient or parental organism

The Newcastle disease virus (NDV) to be used is the lentogenic, avirulent Hitchner B1 strain, which is a licensed live vaccine virus, available for use in the UK.

Host/vector system

NDV is an avian paramyxovirus serotype 1 (APMV-1), and belongs to the Avulavirus genus within the Paramyxoviridae family. NDV is classified as ACDP CL2 and has been reported to cause short-lived conjunctivitis and 'flu-like symptoms in man. Many of the reported instances of NDV infection in humans have been the result of direct inoculation into the eye, either by laboratory workers or those handling vaccines. Reports of 'flu-like illnesses associated with NDV are rare. Both virulent (mesogenic) and avirulent (lentogenic) strains of NDV appear to be equally able to cause conjunctivitis in humans. However, both mesogenic and lentogenic strains of NDV have been tested in man as oncolytic viruses and cancer vaccines with no adverse effects, signs of evolution towards human pathogenicity, recombination or transmission from human to human. Furthermore, virus could not be recovered from either the nose or tracheal lavage of African green monkeys that had been inoculated intranasally and intratracheally with a lentogenic strain of NDV expressing the HN protein of human parainfluenza virus-3 (HPIV3).

Lentogenic strains of NDV are used as live vaccines in poultry. The Hitchner B1 strain is not classified as a specified animal pathogen by Defra (see page 133 of http://www.hse.gov.uk/biosafety/gmo/acgm/acgmcamp/part2.pdf) and is licensed for use in the U.K. Statutory action to control NDV is taken only for strains which are classified as "virulent" (http://archive.defra.gov.uk/foodfarm/fermanimal/diseases/vetsurveillance/profiles/documents/sp-newcastle disease.pdf). NDV does not appear to infect cattle and vaccine strains of NDV are highly attenuated in experimentally infected calves. Although, NDV has been isolated from pigs with an influenza-like illness, experimental inoculation of piglets with a strain of NDV that resembles the B1 strain did not produce any clinical signs of disease.

Origin & function

The RSV F protein mediates fusion of the virus envelope with the cell membrane and fusion of infected cells with adjacent uninfected cells. The F protein is the major protective antigen of RSV and does not contain any potentially toxic or oncogenic sequences. Inoculation of mice or cattle with eukaryotic expression plasmids expressing the RSV F gene under the control of the HCMV promoter does not result in any harmful effects. There is no evidence that the RSV F protein activates TLR4 and induces the production of pro-inflammatory cytokines. However, no adverse effects have been seen following vaccination of small laboratory animals or cattle with recombinant virus vectors expressing the F protein.

Evaluation of foreseeable effects

RSV and NDV are related iruses of the Paramyovidae family and cause respiratory disease in their respective host. rNDV-F expresses the native NDV F and HN proteins, which are involved in viral attachment and invasion of cells, and does not incorporate the RSV F protein into the virion. Therefore, expression of the HRSV or BRSV F protein will not be expected to alter the host range or tissue tropism of NDV. Furthermore, a lentogenic strain of NDV expressing the HN protein of HPIV3, which is more closely related to NDV than RSV, was highly attenuated in the nose and lungs of African green monkeys that had been inoculated intranasally and intratracheally with high titres of the recombinant virus.

If accidentally released into the environment, rNDV-F could infect susceptible individuals, but is unlikely to cause disease in livestock or poultry. Thus, following i.n. and i.t. inoculation of calves with high doses of a lentogenic strain of NDV expressing the bovine herpesvirus-1 (BHV-1) gD protein, NDV was not isolated from nasal swabs of any of the animals and none of the animals developed clinical signs of disease, even when the gD protein was incorporated into the NDV virion. Furthermore, there is evidence that insertion of a foreign gene between the P and M genes of lentogenic strains of NDV attenuates the virus further for poultry. Thus, rNDV (Hitchner B1 strain) expressing an influenza virus HA gene is attenuated in embryonated chicken eggs, in contrast to the parent wild-type. Similarly following oculonasal inoculation of 1-week-old SPF chickens with 10^6 EID50 of a lentogenic vaccine strain of NDV expressing influenza virus H5 HA gene, replication of rNDV-H5 was attenuated in the lungs and oropharynx compared with the control rNDV, rNDV-H5 was not detected in cloacal swabs, and there were no clinical signs of disease.
Recombination between single-stranded, negative-sense RNA (ssRNA(-)) viruses such as NDV is rare. The ssRNA(-) genome of NDV is found exclusively in a RNAse-resistant nucleocapsid that also contains the viral polymerase. Based on studies with other ssRNA(-) viruses, the potential for intermolecular recombination during mixed infection with closely related parainfluenzaviruses appears to be very rare. However, analysis of the genome of NDV isolates became infected with the GMM and a closely related virus and recombination occurred, transfer of the RSV F gene is unlikely to alter the tropism or virulence of the related micro-organism as virulence of paramyxoviruses is multigenic with the GMM and a related virus, it may be possible that pseudotype viruses could be produced in which the genome of one may be packaged in a virion which includes the surface glycoproteins expressed by the GMM. Such virus particles are unlikely to have an altered cell tropism as they infect similar pulmonary epithelial cells, and their progeny would be that encoded by the viral genome.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Contaminated laboratory plastics will be incinerated and contaminated glassware will be autoclaved. Contamine glass pipettes will be decontaminated with 2% hyperchlorite. Spillages and contaminated surfaces will be decontaminated with 2% Virkon for a minimum of 10 minutes. (http://indianjournals.com/ijor.aspx?target=ijor:ijps&volume=45&issue=1&article-021) (100% kill).

Waste animal beddig will be incinerated (100% kill). Large animal rooms will be fumigated with formaldehyde (100% kill). Animal carcasses will be incinerated (100% kill).

Is an emergency plan required according to regulation 20? [N]

02/03/2022
The purpose of these experiments is to determine if the PB1-F2 protein which is extensively conserved in avian influenza strains is a virulence factor in the infection of poultry by influenza viruses. This will help understand this protein's interactions with the host and elucidate whether the PB1-F2 protein is a valid target for anti-viral strategies. We will use reverse genetics to generate avian influenza strains that express the PB1-F2 protein and isogenic viruses that do not and assess their fitness and probe their interactions in vitro and in vivo using poultry lines.

We will generate recombinant avian influenza viruses which possess:
- The surface proteins (HA & NA) of the attenuated vaccine strain A/PR/8/34 (H1N1) and the internal genes (M, NS, PB2, PA & NP) of either;
  1) A/Turkey/Turkey/01/05 (H5N1)
  2) A/Turkey/England/50-92/91 (H5N1), or
  3) A/Chicken/Pakistan/UDL-1/08 (H9N2).

This will generate 2:6 recombinant influenza viruses safe to use at containment level 2. These viruses will then have various mutations made to them in the PB1 segment to truncate or abolish the expression of the PB1-F2 protein which is in a +1 frame on the PB1 gene. At no time with the HA & NA if H5N1 influenza viruses (either LPAI or HPAl) be rescued in conjunction with these genes. Therefore no complete H5N1 viruses will be generated in this process.

These viruses will be assessed for replication, innate immune response induction, pathogenicity and transmission in vitro in cell lines and ex vivo tissue sections as well as
in vivo in poultry species.

**Host/vector system**

cDNA clones will be generated in E. coli and plasmids containing the above mentioned influenza genes will be transfected into cells of eukaryotic origin (avian or mammalian) to rescue infectious virus.

**Origin & function**

The following cDNA constructs will be provided by Professor W B of Imperial College London, these plasmids have been sequenced; HA & NA from A/PR/8/34, M, NS, PB1, PB2, PA and NP from A/Turkey/Turkey1/05 and A/Turkey/England/50-92/91.

The cDNA constructs M, NS, PB1, PB2, PA and NP for generation of the A/Chicken/Pakistan/UDL-01/2008 will be generated by de novo synthesis by GeneArt (Invitrogen) according to our sequences.

Alterations in the nucleotide sequence of the various PB1 genes will either truncate the expression of PB1-F2 or completely abolish its expression. These alteration will be generated by site directed mutagenesis of the PB1 gene segments. These alterations are not expected to increase the pathogenicity or alter the host range of these viruses.

Once generated these viruses will be used in vitro to assess in avian derived cell lines by measuring replication, innate immune response antagonism and looking at interacting partners and then taken in vivo in poultry species to assess fitness in the whole animal model and whether transmission is effected.

**Evaluation of foreseeable effects**

The hazards directly associated with this class of GM influenza virus are small because they bear the surface antigens of the attenuated vaccine strain PR8 virus and thus are highly unlikely to infect a human or transmit. The main hazard would be from inadvertent co-infection of a cell culture with these viruses and other viruses that bear human or avian influenza surface antigens. This will be minimized by either working with these viruses in a separate MSC and incubator than used for other routine work with influenza viruses or fumigation of the MSC prior to use.

Clear signage on the outside of the hood will be used to indicate the last time the hood was used and which virus was used. We eliminate the possibility that workers are 'mixing vessels' by our OH policy of seasonal influenza vaccination. These viruses remain susceptible to both neuramidase inhibitor used routinely as anti-viral treatment for human influenza infection. Mutation of the PB1 gene segment to remove the expression of PB1-F2 or truncate it should reduce any risk from these viruses as PB1-F2 is thought to be a virulence factor.

The hazards to the environment are small from these GM influenza viruses due to the HA & NA from the vaccine strain PR8. This HA & NA combination should be capable of infecting avian species but the control measures in place in both the CL2 in vitro lab (G1B) and EAH are such that the virus will be contained appropriately. This HA & NA combination will render these viruses low pathogenic in nature in avian species. Manipulation in G1B will be carried out exclusively inside a class II MSC, transportaion will be under double containment, liquid waste will be decontaminated via contact with 1% Virkon for at least 10 minutes and all associated waste directed to autoclave. Poultry infected with these viruses inside the EAH will be done so in containment level 2 rooms and housed inside isolators. Every room in EAH has rodent barriers the input and output air is filterd and all waste and drainage liquid is autoclaved. Poultry to be infected will be screened for pre-infection by Influenza virus by looking for the presence of Influenza antigens or antibodies. Experiments will not be prformed in animals previously infected with Influenza virus preventing the chance of a natural reassortment event in poultry. It is highly unlikely that the animals would be exposed to Influenza prior to the experiment as all poultry are reared on site at IAH under good biosecurity. Mutation of the PB1 gene segment to remove the expression of PB1-F2 or truncate it should reduce any risk from these viruses as PB1-F2 is thought to be a virulence factor.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
**Stewart building lab G1B - in vitro assays**

In vitro assays with live virus will be carried out exclusively in a class II MSC cabinet. Cabinets are routinely serviced and tested on an annual basis by an outside contractor and service records are maintained. The risk to laboratory workers can be virtually eliminated by carrying out all work with potentially infectious samples, virus or infected material, in a class II microbiological safety cabinet (MSCII).

- All workers will wear appropriate protective clothing.
- All work in the MSCII will be carried out in benchcote.
- All items will also be sprayed with 70% Ethanol before removal from the MSCII. Items which cannot be directly sprayed with ethanol before being removed from the MSCII will be placed in plastic storage containers prior to removal, the containers will be sprayed before removing from the MSCII.
- Disposable equipment should be used where possible and filtered tips should be used on pipettes.
- Contaminated waste from the hoods will either be;
  (a) soaked in 1% Virkon for at least 10 minutes and then disposed of through the incineration route for laboratory waste or
  (b) disposed of directly into a double bagged autoclave bag which will be sealed with tape inside the hood and placed directly into an autoclave tin. The autoclave tin will be marked with G18 and INFLUENZA VIRUS before being taken to microbiological services for autoclave.

Infected material will be transported from the MSCII to the destination within a sealed container. e.g. plastic storage containers to incubator, sealed rotors to centrifuges. All items will be sprayed with 70% Ethanol before removal from the MSCII.

Infected tissue culture will be incubated in a designated CO2 incubator. Cells will be transferred to the incubator in a sealed container, once in the incubator the lid will be unsealed and removed to allow circulation of CO2. This will prevent spills and drips whilst inside the incubator also.

Influenza viruses are routinely grown in 10-day old embryonated hen's eggs

- Allantoic fluid will be harvested within the MSCII by cracking the top of the egg shell (placing a disposable pipette tip in the hole made previously by the egg gun) and removing the disc of shell with blunt forceps. The embryo is pushed to one side with disposable equipment (pipetter or wooden spatula), the allantoic fluid is removed using a jumbo pastette or disposable pipette and placed into 50ml falcon tubes.
- Eggs are discarded into a double autoclave bag within the MSCII which is sealed then placed into a metal tin for autoclaving. The tin should then be marked with contents (EMBRYONATED EGG WASTE) and taken immediately to microbiological services for processing.
- Any non-disposable instruments (e.g. metal forceps will be left in 70% Ethanol for 30 minutes and then sent for autoclaving).

All infective material will be autoclaved, incinerated or otherwise rendered sterile, unless being transported to another CL2 facility or being put to storage. Infective material will not be voided through the drain system, but inactivated with either autoclaving or using 1% Virkon. Where possible disposable consumables will be used. Non-disposable items will be soaked in 1% Virkon for the required contact time, any attached labels removed and transferred to the Microbiological Services Department (in the same building) in labelled lidded metal tins for autoclaving and disposal.

The aim of the project is to understand the biology of recombinant Newcastle disease virus (NDV) vaccine strain (LaSota) expressing either fusion 9F) or haemagglutination-neuraminidase (HN) genes, single or jointly, closer to the promoter-proximal region of the genome. Growth kinetics of these constructs will be evaluated in the chicken and duck cell culture systems. Having an improved NDV vaccine candidate in hand, genes of viruses will be introduced into this recombinant La Sota strain. The
V protein, which is a non-structural protein of NDV, will be knocked out from vaccine strain of NDV to investigate the effect on the pathogenesis of the virus. The NDV infectious clone used in this work is tagged with GFP marker and has been produced by Dr Ben Peeter at central veterinary laboratory, The Netherlands. The modified viruses along with vaccine strain of NDV (La Sota) will be used to infect chicken and duck cell-lines to understand the role of these proteins playing in the replication and expression of the surface glycoproteins. The rescued viruses will be inoculated in 9-days old embryonated eggs to propagate and to make a stock. The same stocks will be used for quantification and titration purposes.

Recipient or parental organism

The vaccine strain of NDV to be used in this proposal is the lentogenic, avirulent (non-pathogenic) La Sota strain, which is a licensed live vaccine virus and is being used in Major endemic countries. NDV has extensively been used as vaccine vector for both veterinary and medical viruses with satisfactory results without change in the pathogenicity of the vaccine strain of NDV (Bukreyev, et al. 2005). Moreover, the genomic rearrangement presented in this work has already been made in other paramyxoviruses of medical origin such as vesicular stomatitis Virus and Respiratory Syncytial Virus (Krempl At Al 2002). Such genetic rearrangements did not effect the pathogenicity of these medical viruses (Wertz, Et al 1998). It is therefore plausible to expect that such rearrangement in NDV, a similar virus but of veterinary importance, will not effect its pathogenicity.

Host/vector system

The NDV is an avian paramyxovirus serotype 1 (APMV-1), and belongs to the Avulavirus genus within the Paramyxoviridae family. Vaccine strains of NDV are classified as ACDP CL2 and has been reported to cause short-lived conjunctivitis symptoms in man (Capua and Alexander, 2004). Many of the reported instances of NDV infection in humans have been the result of direct inoculation into the eye, either by laboratory workers or those handling vaccines. However, reports of illnesses associated with NDV are rare. Both virulent (mesogenic) and avirulent (lentogenic) strains of NDV appear to be equally able to cause conjunctivitis in humans. However, both mesogenic and lentogenic strains of NDV have been tested in man as oncolytic viruses and cancer vaccines with no adverse and effects (Zamarin and Palese, 2012). Signs of evolution towards human pathogenicity, and recombination or transmission from human to human. Furthermore, virus could not be recovered from either the nose or tracheal lavage of African green monkeys that had been inoculated intratracheally with a lentogenic strain of NDV expressing the HN protein of human parainfluenza virus-3 (HPIV3) (Bukreyev, et al 2005).

Lentgenic strains of NDV are used as live vaccines in poultry. The hitchner B1 strain, which is very similar to LaSota strain in terms of pathogenicity and genome characteristics, is not classified as a specified animal pathogen by Defra and is licensed for use in the UK. NDV does not appear to naturally infect cattle, and vaccine strains of NDV are highly attenuated in experimentally infected calves. Although, NDV has been isolated from pigs with an influenza-like illness, experimental inoculation of piglets with a strain of NDV did not produce any clinical signs of disease. Genomic rearrangements will likely to attenuate the vaccine strain of NDV as it did in medical viruses such as vesicular stomatitis Virus and Respiratory Syncytial Virus (Krempl et al 2002; Wertz et al 1998).

Origin & function

Three Genes, Presented in this proposal, will be modified. Briefly, (i) the HN protein determines the host tropism by binding to sialic acid receptor of the host. (ii) the F protein mediates fusion of the NDV envelope with the cell membrane and fusion of infected cells with adjacent uninfected cells. Both HN and F protein are the major protective antigens of NDV and do not contain any potentially toxic or oncogenic sequences. (iii) the V protein is a non-structural protein which is known to involve interferon regulations activities.

Evaluation of foreseeable effects

Genomic rearrangement may lead to attenuation of the LaSota vaccine strain of NDV as it has been experienced with viruses of same family. Since the same gene of LaSota vaccine strain will be moved to promoter proximal region, it is unlikely that the resultant virus will change any tropism. Moreover, all the modifications, presented in this protocol, will be made only in the vaccine strains of NDV. Based on the reported studies, it is very less likely that these recombinant NDV vaccine viruses will have increased virulence (Wertz et al 1998; Krempl et al 2002). Examples are available indicating the expression of any foreign gene in NDV can lead to attenuation in the animals that had are available indicating the expression of any foreign gene in the NDV can lead to attenuation in the animals that had been inoculated intranasally and intratracheally with hightitres of the recombinant virus (Bukreyev, A E et al 2005).

Recombination between single-stranded, negative-sense RNA ssRNA(-)) viruses such as NDV is rare. The ss RNA9(-) genome of RDV is found exclusively in a
RNAse-resistant nucleocapsid that also contains the viral polymerase. Based on studies with other ssRNA(-) viruses, the potential for intermolecular recombination during mixed infections appears to be very rare. However, analysis of the genome of NDV isolates from China suggests that homologous recombination of NDV can occur naturally, which is a rare event.

In the unlikely event that this genomic rearrangement will alter the tropism of the NDV since gene of the same vaccine will be moved to promoter region, Virulence is unlikely to increase because pathogenicity in NDV is determined by the cleavage site in the F protein and we are not intended to mutate cleavage site in this proposal. Moreover, such rearrangements in other paramyxoviruses including vesicular stomatitis virus and respiratory syncytia virus have not increased the virulence of the recombinant viruses but has induce the protective immune responses, collectively, indicating least possible hazard associated.

The V protein of NDV is associated with interferon antagonism. Generation of LaSota NDV, Not expressing V Protein, is very much likely to be attenuated due to immune responses produced against NDV in infected cells. Therefore, there appears to be no adverse forseeable effects with this modification.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Contaminated laboratory plastics will be decontaminated by 1% Virkon for 30 minutes prior to disposal by incineration and contaminated glassware will be autoclaved. Any tips, flasks, or there plastic wear that has been exposed to virus will also be decontaminated prior to disposal by incineration. Spillages and contaminated surfaces will be decontaminated with 2% Virkon for a minimum of 30 minutes.

Reviewed by the BAGMSC and Dr M B (a paromyxovirus research group leader) on 26/11/13 and approved at GM2.
The use of recombinant Murine Cytomegaloviruses as vaccine vectors

To develop the use of MCMV as vaccine vectors against human and livestock diseases.

Recipient or parental organism
Mice

Host/vector system
Murine cytomegalovirus

Origin & function
Nucleoprotein (NP) and matrix (M1) proteins of X31 Influenza Virus.
The intended function is to induce a durable immune protective immune response against Influenza viruses.

Evaluation of foreseeable effects
MCMV does not pose any harm to human health. MCMV has been shown to infect human cells in vitro, but infection leads to an abortive replication cycle. Accidental infection could induce immune response to MCMV and inserted transgenes, which would not be harmful.

Release of rMCMV into the environment is very unlikely due to the standard procedures employed in the lab or animal house. However even if such an event occurred,
although rMCMV could infect wild mice (prevalence of wild type MCMV infection in wild mice is 65-90%) this is unlikely to occur because rMCMVs are attenuated and naturally infected wild mice should be cross protected against rMCMV. Furthermore even if infection did occur, attenuated rMCMVs are very unlikely to cause any pathology. The risk of infection of any other species is extremely low.

MCMV is an enveloped virus and therefore has poor survival in the environment. MCMV transmission is thought to require direct contact with contaminated excreta/secretions and cross-contamination between cages has so far not been reported.

The inserted genes are internal proteins from Influenza viruses to which humans are frequently exposed and which are known to induce immune responses. As stated above, because the risk of rMCMV infecting humans is minimal the risk of recombination between the transgene and human Influenza Virus is extremely low. Modified vaccinia Ankara or Adenovirus expressing NPM1 has been administered already to mice, pigs, chicken and humans without ill effects and these genes are present in the influenza vaccines, administered to humans.

In the case of the MCMV infected animals being challenged with Influenza virus there is no increased risk of these animals excreting a virus that could be transmissible to people compared to any other mouse strain. We shall use either A/PR/8/34 or PR8 based viruses. These challenge viruses pose very little risk for humans since PR8 is poorly infectious in people. The animals will be handled in isolators so that the risk is minimal.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Contaminated laboratory plastics will be incinerated and contaminated glassware will be autoclaved. Spillages and contaminated surfaces will be decontaminated with 2% Virkon for a minimum of 10 minutes. All waste will be disposed following MSD-113.

All waste and rubbish from the animal house should be placed in an autoclave bag. This should then be double bagged and sprayed with 1% Distel before it is removed from the room. The waste should then be autoclaved before being placed in yellow clinical waste bags. These yellow bags should then be placed in the yellow bins for incineration. Staff handling the mice will shower out on exit of the unit.

Kid protein is toxic to mammalian cells and Kis protein protects from this effect. When they are expressed together in mammalian cells, death or cell survival depends on the ratio between Kid and Kis that cells are able to sustain. This is potentially a therapeutic or experimental tool. The ratio can be controlled at the level of transcription, mRNA stability and protein stability. We want to exploit the genetic differences between normal cells and cancer cells to regulate, differentially, the Kid-to-Kis ratio in these cells, so that cancer cells are killed and normal cells are protected from toxicity.

Recipient or parental organism

Murine and human cells (primary cells, cancer cell lines and immortalized cell lines)

Host/vector system

1) E. coli, laboratory K12 derivatives/pUC based vectors;

2) Vertebrate tissue culture cells, human and mouse, including as examples 293T cells, murine-embryo-fibroblasts and HeLa and other human cancer cell lines and immortalised normal cells; and primary cultures of human and mouse cells.

3) Adenoviral vectors and Lentiviral vectors (the latter with polytropism through viral pseudo-typing using VSV-G protein)

3.1.) Adenoviral system: The adenoviral system to be used employs a well-characterised vector and packaging cell lines (Refs below). Second generation replication defective human adenovirus serotype 5 derived adenoviral vectors will be used for expression of Kis and/or Kid proteins. Vectors are rendered replication defective by the deletion of the E1 and E3 genes. The E1 gene is essential for the assembly of infectious virus particles and is complemented in vivo by an adenovirus packaging cell. The E3 gene encodes proteins involved in evading host immunity and is dispensable (Luo et al, Nature Prot., 2 (5): 1236 (2007))

3.2.) Lentiviral systems: the two types of viral system to be used employs two well-characterised lentiviral vector and packaging cell lines (Refs below).

3.2.1.) Type A (eg. pLenti6-UbC-V5DEST from Invitrogen):

- The number of genes from HIV-1 that are used in this system has been reduced to three (i.e. gag, pol, and rev).
- Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids. All four plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replicant-competent virus (Dull et al., J Virology 72 8463-8471 1998).
- Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293T derived producer cell lines, none of them contain LTR's or the packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced,
- The lentiviral particles produced are replication-incompetent and only carry the gene of interest. No other viral species are produced.
Expression of the gag and pol genes from pLP1 has been rendered Rev-dependant by virtue of the HIV-1 RRE in the gag/pol mRNA transcript. Addition of the RRE prevents gag and pol expression in the absence of Rev.

A constitutive promoter (RSV promoter) has been placed upstream of the 5 LTR in the lentiviral vector to offset the requirement for Tat in the efficient production of viral RNA. The 3LTR region has a deletion that promotes self-inactivation of the viral genome upon integration in the host genome.

3.2.2. The lentiviral packaging systems mentioned above (type A) is a third generation versions that utilize split-genes to provide the viral packaging elements on individual plasmids that physically separate the viral envelope, env (usually VSV-G), sequence from the gag-pro-pol sequences. These split-gene packaging strategies reduce the risk of generating RCL because multiple recombination events are necessary to create a virus that harbors the sequences required for independent replication.

Type B (Clontech’s Lenti-X HT) Packaging System also uses a split-gene packaging strategy, but adds another level of safety by further uncoupling pol (RT and IN) from gag-pro. The result is that gag, pol and env reside on three physically distinct entities, rather than the standard two. This approach further reduces the possibility of creating RCV to a level below that of standard 3rd generation packaging systems, because extra recombination events are required to create such viruses. In fact, the emergence of RCV is undetectable from systems using this approach (Wu, X., et al. (2000) Mol. Ther. 2 (1):47-55). These improvements significantly increase the safety profile of our Lenti-X HT Packaging System.

Clontech’s Lenti-X Vectors contain less than one-third of the wild-type HIV-1 genome. These wild-type sequences mainly consist of the viral LTRs and packaging signal. All essential replication genes have been completely removed and are instead supplied as separate DNA entities in the Lenti-X HT Packaging Mix (described above).

In brief, the number of genes from HIV-1 that are used in type B system has been reduced to four (i.e. gag, vpr-pol, rev and tat).

- Genes encoding the structural and other components required for packaging the viral genome are separated onto five plasmids. This reduces that incidence of replication competent lentivirus to levels below that of the system A above.
- Although the four packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293T derived producer cell lines, none of them contain HIV-1 LTRs or the packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced.
- The lentiviral particles produced are replication-incompetent and only carry the gene of interest. No other viral species are produced.
- Expression of the gag, tat and rev genes from the packaging plasmids is directed by tetracycline dependent promoters (PrTRE). Therefore their expression requires supplying TetR-VP16 in trans, and it is only active in the absence of doxycycline in the growth medium.
- In this system, expression of tat is required in the packaging cell line, because the lentivirus vector contains an intact HIV-1 5LTR, which allows very high titers in viral preparations.

Origin & function

The overall purpose is to introduce Kis and Kid protein expression into mammalian cells, control that expression and monitor expression. Inserts will encode reporters, such as EGFP, Ds Red; transcriptional regulators such as TetR; prokaryotic genes encoding ribonuclease Kid and its counteracting protein Kis; and transcription and post-transcription-regulating sequences of prokaryotic and mammalian origin.

Genes Kis and Kid will include wildtype, inactive mutants and fusion variants (e.g. fused to unstable protein domains), and they will be expressed under the control of viral and mammalian promoters, both constitutive (e.g. PrCMV, PrUbC, PrEF-Ialpha) and/or repressible (e.g regulated by TetR).

Evaluation of foreseeable effects

Some of the virus vectors will kill infected mammalian cells, so some of the vectors will be toxic to human and mammalian cells. Also because of the presence of the WPRE element in the lentivirus vectors, the lentivirus constructs might transform infected mammalian cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Only micro-organisms (including tissue culture cells) are involved in this work
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 2 waste will be autoclaved (136°C for 10 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

Adenovirus vectors: (Risk assessment H2008-009)

This individual RA H2008-009 is an assessment for adenovectors, and so the main issue is whether, and in what way, the inserts are hazardous to human cells. Oncogenic inserts would be Class 2, most other inserts Class 1. As some of the inserts are toxic, we have chosen precautionary Class 2 containment for the active toxic insert work only. The majority of the work proposed will be concerned with establishing control of expression and this can be done with inactive mutants, in Class 1.

The principal concern here is that, for some of the inserts, the virus generated and the packaging/producer cells are effectively toxins that could kill one human cell per virus particle, though the act of killing the cell would disable the virus. Handling and storing the producer cells and supernatants is therefore similar to handling cholera toxin, ricin, or phalloidin. Those involved must be made aware of this.

A subsidiary concern would be propagation of the virus, but the virus is sufficiently disabled to eliminate this. E1/E3 deleted adenovirus is generally accepted as disabled and, with wild-type adenov being HG2 this allows the mutant to be HG1. Once the virus has infected a target cell those cells pose no particular hazards, since the toxin involved is intra cellular.

Lentivirus (RA H2009-002)

The issues in this work are (i) the expression of the toxin Kid in lentiviral vectors, and (ii) the lentivirus vectors themselves, which, if they carry the complete WPRE, are potentially oncogenic and current guidance is to use them in CL2 regardless of their tropism. Both these have been considered by us before. (i): toxin-expressing human host range virus is toxic to cells in a similar way to a strongly toxic lab reagent and should be treated as such. They are borderline CL1/CL2 but we have previously chosen to recommend CL2. (ii) The lentivirus work does require CL2 when the vectors incorporate the putatively-oncogenic complete WPRE element. The E.coli work raises no particular issues as the vectors do not express in bacteria.

It was noted that appropriate precautions are already given for the naked DNA, to allow for its potentially cytotoxic or oncogenic nature.

The construction work in E. coli is correctly assessed as Class 1.

## Project Additional Information

### Purposes of the contained use

| Preparation of DNA plasmid vectors in prokaryotes for delivery of DNA into mammalian cells in vitro. |
| Expression of cloned DNA in mammalian cells and generation and use of recombinant adenoviral vectors. |

### Recipient or parental organism

| In vitro and in vivo transfection and infection. |

### Host/vector system

| Replication-deficient adenovirus encoding specific genes |

### Origin & function

| Human and/murine promoter/enhancer fragments under the control of which will be placed various human and/or murine genes to be expressed in a tissue-specific manner. |
| B-galactosidase (galactosidase cleavage from substrate) to act as a reporter. |

| These genes/gene fragments will be used to generate plasmids suitable for transfection into mammalian cells in vitro for expression and functional analysis and for subsequent use in adenoviral vectors. |

### Evaluation of foreseeable effects

| Likelihood of microorganism survival outside laboratory environment is negligible. Defective E. coli strains are used throughout. DNA will not survive in the environment. Vectors could not replicate in mammalian cells in the unlikely event of entry. |
| The basic strategy directed towards eventual use in humans utilises adenoviral vectors that have already been extensively tested in human clinical trials with no reported adverse effects. |

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The work proposed is in two categories:
Class 1 activities (preparation of DNA plasmid vectors in prokaryotes for delivery of DNA into mammalian cells in vitro)
Class 2 activities (expression of cloned DNA in mammalian cells and generation and use of recombinant adenoviral vectors).

For Class 1 activities solid waste will be autoclaved to achieve 100% killing (autoclaves undergo annual validation tests); Liquid waste will be treated with 1% Virkon (w/v) for minimum of 12 hours, as per the manufacturer's instructions.
For Class 2 activities solid waste will be autoclaved to achieve 100% killing (assayed periodically by microbiological analysis: autoclaves undergo annual validation tests); liquid waste will be treated with 1% Virkon (w/v) for minimum of 12 hours as per the manufacturer's instructions [Ref: www.anticint.co.uk/main/virkons.htm] to achieve 100% killing, assayed periodically by microbiological analysis.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

The committee were satisfied that the experiments carried out under the conditions proposed present no significant hazard.

Project Ref 98/02.2

Date Ackn'd 02/03/2022
**Project Additional Information**

**Purposes of the contained use**
To discover the signalling mechanisms by which the pathogen responds to the host with the possibility of discovering new antibiotic strategies.

**Recipient or parental organism**
Bacillus cereus, Bacillus thuringiensis, Bacillus subtilis Non pathogen Group 2  
E. coli K-12 or B derivatives (TG1, TG2, JM101, JM109, XL1-Blue) Pathogen derivative Group 2 disabled host.

**Host/vector system**
Host Cells: Bacillus cereus, Bacillus thuringiensis, Bacillus subtilis Non pathogen Group 2.  
E. coli K-12 or B derivatives (TG1, TG2, JM101, JM109, XL1-Blue) Pathogen derivative Group 2 disabled host.  
Vectors various non mobilisable bacterial plasmids (pGEM, pSelect, p Bluescript; pUC series; pC194, pE194, pBR327, pID408).  
Various non-mobilisable vectors. ( GT10, GT11, ZAP; M13 derivatives).

**Origin & function**
This project will study Bacillus cereus and Bacillus thuringiensis virulence factors and their role in pathogenesis. The genetic modification will be limited to endogenous gene inactivation to investigate cellular function, and transposon tagged mutagenesis to identify genes that are essential for infection of the insect or animal host and/or response to stress conditions. Using in vitro cell culture models, in vivo models and an insect model the project will employ a variety of strategies including in vivo selection techniques (eg signature tagged mutagenesis) and RNA arbitrarily primed PCR, to screen for promoters that are selectively activated during the infective phase. The genes controlled by these promoters will then be identified and an attempt made to discover the signalling mechanisms by which the pathogen responds to the host microenvironments and to map the genetic control pathways directing the sequence of events during infection and death of the host. With the exception of certain plasmid cloning vehicles specified above and their associated antibiotic resistance genes (CHLORAMPHENICOL or AMPICILLIN or ERYTHROMYCIN or KANAMYCYIN or LINCOMYCIN) no exogenous gene will be introduced into Bacillus cereus and Bacillus thuringiensis. The procedure may therefore reasonably be categorised as self-cloning.
Evaluation of foreseeable effects

The only genes to be inserted are contained on the plasmid cloning vehicles specified above including their associated antibiotic resistance genes (CHLORAMPHENICOL or AMPICILLIN or ERYTHROMYCIN or KANAMYCYIN or LINCOMYCIN). No other exogenous gene will be introduced into Bacillus cereus and Bacillus thuringiensis. The procedure may therefore reasonably be categorised as self cloning. Therefore it is not considered that any inserted gene has a biological activity which can act directly to cause harmful effects.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste generated is autoclaved using an Astell Scientific Swiftlock Programmable autoclave with a program of 15 minutes pulsed free steaming and 30 minutes at 132 degrees C.

Liquid-based waste materials is treated by soaking in 1% final concentration of Virkon for a minimum of 12 hours before disposal via the drains.

Solid biological material is securely packaged and disposed of by incineration via a registered contractor.

Infected insect waste is disposed off under MAFF (DEFRA) approved guidelines.

Infected solid biological waste will be disposed of by autoclaving with a program of 15 minutes pulsed free steaming and 30 minutes at 132 degrees C followed by incineration via a registered contractor.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  Y

Please enter comments on the GM safety committee on the risk assessment

The committee agreed that the work posed no significant hazard when carried out with the precautions and containment proposed.

### Project Additional Information

#### Purposes of the contained use

The project seeks to exploit this newly acquired wealth of information with the aim of developing new anti-pseudomonal drugs.

#### Recipient or parental organism

**SPECIFIC P. aeruginosa STRAINS TO BE USED**

- PAO-1 (wild-type elastolytic prototroph)
- PAO-R1 (non-elastolytic lasR::TcR, SmR derivative of PAO-1)
- PAO-JP2 (non-elastolytic lasl rhll double mutant derived from PAO-1, HgR, TcR)
- PAO-JP3 (non-elastolytic rhll mutant of PAO-1)
- PDO111 (non-elastolytic rhIR mutant of PAO-1)

#### Host/vector system

P. aeruginosa is an opportunistic human pathogen which is responsible for an increasing number of nosocomial infections. It is resistant to most commonly used antibiotics when applied at conventionally effective therapeutic concentrations. The project seeks to exploit this newly acquired wealth of information with the aim of developing new anti-pseudomonal drugs. Although the project is based in my lab, at various stages it will also involve collaborations with the Biochemistry Dept and Chemistry Dept - drug development. No organisms will leave the secure area during these collaborations. The theme of this proposal is two-fold. First, we want to identify gene products that are elevated in PAO-1 as a result of exposure to antibiotics. This will be tested by inactivating the up-regulated genes and looking for increased susceptibility to antibiotic treatment. We hope to exploit the proteins identified in this way as targets for the development of new antibacterial therapies. Second, we want to continue our investigations into the mechanism(s) that control quorum sensing in pseudomonas. These studies mostly involve introducing pre-evaluated reporter gene constructs into PAO-1 and its derivatives or over-expression/purification of PAO-proteins.

**Origin & function**

Our mutants should be impaired for virulence, and be less able to survive in the field than the wild-type organism. The antibiotic resistance-cassettes being used should not affect the treatment of any infection caused by PAO-1 or its mutant derivatives.

There is always a possibility that the random mutagenesis (or even the targeted one - less likely though) will inactivate a repressor of virulence and therefore give rise to hyper-virulent Pseudomonads. However, this hyper-virulence is unlikely to confer upon the organism better survival characteristics, since by definition, the wild-type carries the optimal complement/expression level of genes to ensure survival in the field/host. Any hypervirulent strains that are identified will be destroyed.

**Evaluation of foreseeable effects**

Not applicable.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste and spent cultures will be autoclaved initially (as per above settings). The contaminated glassware following autoclaving will be soaked for 12 hours (completely immersed) in 1% Virkon before rinsing and sending for washing. Solid waste will be autoclaved as per above. The above HSE-approved SOP is highly effective and was designed for disposal of a comparable level 2 pathogen (Serratia marcesens) which is worked on in an adjoining lab within the level 2 secure area of the department.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

The committee are satisfied that the project posed no significant hazard, when carried out with the starins, precautions, and containment proposed.

**Project Containment**

02/03/2022
### Project Additional Information

**Purposes of the contained use**

The project is concerned with understanding the mechanisms involved in lineage selection upon stem cell differentiation in the epidermis.

**Recipient or parental organism**

The work requires the use of human keratinocytes which are difficult to transfect by standard methods. Recombinant retroviral infection is therefore needed as a means of delivering the appropriate cDNA constructs into the cells. Human keratinocyte cell lines will be derived from a reliable source of normal infant skin which has been surgically removed from screened healthy individuals having a negligible risk of contamination with adventitious human pathogens.

**Host/vector system**

Constructs will be cloned into the non-mobilisable viral plasmid vector pBabe (puro) and derivatives based on Moloney Murine Leukaemia Virus (Morgenstern and Land 1990, Nucleic Acid Research 18 3587-3596).
RNAi constructs will be cloned into pRETRO SUPER and its commercially available derivatives.

Origin & function

All DNA will be propagated in E Coli (e.g DH10B or derivatives).

The plasmid will first be transfected into an ecotropic packaging cell line. Phoenix-eco, and the retrovirus produced will be harvested over 1-2 days.

The helper-free retrovirus producer cell line Phoenix-eco, was developed by Dr. G. Nolan at Stanford University, (http://www.stanford.edu/group/nolan/index.html) and has been used by over 2500 labs. Phoenix-eco cells express the gag-pol and envelope genes using different non-Moloney promoters to minimize both recombination and inter-typic recombination potential. This cell line has a history of safe usage.

This ecotropic retrovirus will then be used to stably infect a second packaging cell line, GP + envAm12, which produces disabled amphotropic retrovirus. The mouse cell line GP +enAm12 has been widely used for the production of amphotropic virus. Tests for the safety of the GP + envAm12 packaging line showed no evidence for the generation of wild type virus and it has a history of safe usage. Markowitz, Goff and Bank. Virology 167, 400-406 (1998). Defective amphotropic virus would then be used for the infection of human keratinocytes. Transduced cell would be selected and maintained in medium containing an appropriate antibiotic before further use in experiments.

All genes will be inserted downstream of the viral LTR with the intention of achieving a moderate level of expression in recipient cells. Infection of keratinocytes will be by transfer of supernatant culture fluids with any concentration of the virus particles. Recipient human keratinocytes expressing the individual genes under study will be created which are likely to have some growth advantage or induce proliferation in an autocrine or paracrine manner.

Evaluation of foreseeable effects

Bacterial strains of Ecoli such as DH10B and its derivatives are not capable of colonising a healthy individual.

The amphotropic retrovirus is able to infect cells from a broad host range, including humans but can not replicate unless it recombines with endogenous retrovirus. Exposure of an individual to amphotropic retrovirus, by possibly a break in the skin, could result in a localised transfer of the pathogenic properties of the particular gene. None of the cell lines would be expected to remain viable outside the controlled culture conditions and we do not anticipate that any of the genetic manipulations we are proposing would alter this.

It is predicted that over-expression of oncogenes and signalling molecules could lead to an increased rate of cell division although tumour progression and disease in the whole organism is unlikely. The major possible source of hazard to the environment would be accidental escape of high titre virus solutions expressing cDNAs, which could then infect rodents. Retroviruses require close contact for their transmission and their survival in the general environment is poor due to their fragile envelope. The vector is non-mobilisable and the successful infection of a cell would include stable integration of the viral genes into host DNA. Although the amphotropic virus would be able to infect humans it could not replicate unless it recombined with endogenous retrovirus. Even then it is unlikely that expression of a single oncogene or inactivation of a tumours, as multiple genetic alterations (between 4 and 6) are required for inducing tumours, and a safeguard mechanisms exist impeding the accumulation of these alterations in the organisms (i.e. single events like Ras or myc expression instead of unrestrained proliferation, induce growth arrest or apoptosis) (Hanahan & Weinberg, Cell 100, 57-70; 2000).

The use of sharps will be strictly controlled and avoided wherever possible. Needles and scalpels will not be permitted. Plastic Pasteur pipettes will be used for aspirating culture medium.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No animals or plants will be used.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste will be sealed in double autoclave bags, and autoclaved with steam at 127°C for 25 minutes. Effectively 100% kill. Autoclaves are routinely monitored and records are kept by the department.

All liquid waste will be inactivated by treatment with Virkon at a final concentration of 1% for 12 hours before disposal via the drains. Effectively 100% kill as determined by the manufacturer.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The committee noted that the consequences are unknown of infection of cells of the worker by the modified virus, and have the potential to lead to cell proliferation. However, the committee felt that the risk is extremely low, because of the method of handling the virus including the avoidance of sharps. Secondly, the rate of infection is likely to be very low as the virus has a low infectivity. This is clear since in vitro infection is increased by optimisation of conditions using eg lipophilic substances. Thirdly, the virus genome will only integrate in proliferating cells, which are relatively rare in the skin.

### Project Additional Information

#### Purposes of the contained use
The project aims to study the function of the apicoplast and mitochondrion of the malaria parasite, *Plasmodium falciparum*.

#### Recipient or parental organism
*Plasmodium falciparum* will be cultured in human blood, obtained from the National Blood Service (screened, and of transfusion grade) or from blood donors at the Department of Biochemistry, University of Cambridge. Dead, fixed *Plasmodium* cells will be observed under light, confocal and electron microscopes.

#### Host/vector system
*Plasmodium* vectors containing *E. Coli* and *Plasmodium* origins of replication, two selectable markers and GFP.

#### Origin & function
In order to determine the localisation of proteins, *Plasmodium* genes/targeting regions upstream of genes will be cloned into *E. coli* vectors immediately upstream of green florescence protein gene (GFP, originally from jellyfish, or similar reporter genes). These vectors will also contain selectable markers and origins of replication for *E. coli*, as well as selectable markers and origins of replication for *Plasmodium*. These vectors will be transfected into *Plasmodium*. This will allow the expression of *Plasmodium* proteins fused with GFP in *Plasmodium* cells.

*P. falciparum* genes manipulated will be for components of the apicoplast or the mitochondrion. They will include nuclear and organellar genes. Genes for housekeeping *Plasmodium* proteins of the cytoplasm or nucleus will be used as controls.

*P. falciparum* will be transformed with antibiotic resistance proteins for selection (geneticin, blasticidin-S from *Aspergillus terrus*, zeocin, nourseothricin, phosphinothricin, puromycin or WR99210 (anti-folate)).

No human genes will be manipulated.

#### Evaluation of foreseeable effects
*Plasmodium falciparum* is the causitive agent for human malaria. There is therefore a risk of catching malaria.
The blood in which the parasite is grown will be of human origin obtained from the National Blood Service or known donors within the department of Biochemistry. Blood from the National Blood Service has been screened for blood-borne disease, such as Plasmodium, hepatitis B and HIV.

The inserted/deleted Plasmodium genes will not be harmful towards humans. The genes affected encode proteins effecting key biochemical processes within the Plasmodium cell. The inserted/deleted genes will not make the P.falciparum parasite more pathogenic. It is extremely unlikely that the host or the infectivity will change. The modifications will most likely cause the organism to be less fit than cells without the genetic modification.

The expression of GFP will not make the P.falciparum parasite more pathogenic, or change infectivity, and will most likely cause the organism to be less fit than cells without the genetic modification.

The antibiotic resistance genes are not toxic. The insertion of antibiotic resistance genes will not affect the selection or efficacy of drugs used for treatment of malaria (genes conferring resistance to geneticin, blasticidin-S, zeocin, nourseothricin, phosphinothricin, puromycin or WR99210 to be inserted). Apart from geneticin, none of these are listed in the British National Formulary as treatments for any human disease, and geneticin is not recommended as an anti-malarial.

containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No animals or plants will be used.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

justification for containment level 2.

P.falciparum is a group 3 pathogen, and as such may require containment level 3. However, the HSE advisory committee on dangerous pathogens, annex 1 lists biological agents that may be used at less than minimum containment conditions required by COSHH. Containment levels can be lowered because of

1. The nature of the work
2. The nature of the biological agent.

P.falciparum is listed as an agent to which this derogation may apply.

Risk assessments would indicate that this it is possible to use containment level 2 for the culturing of P.falciparum in this project for the following reasons:

1. The clonal strain of P.falciparum that has been in continuous blood-stage culture for 20 years. It has known anti-malarial drug sensitivities and a fully sequenced genome. It is not resistant to the major anti-malarial drugs used.
2. Transmission of Plasmodium is by female mosquito. In the wild, the mosquito lands on human skin, pierces the skin and takes up blood. All our blood cultures will be in petri-dishes, so any mosquito that did enter would be unable to feed, so could not acquire parasite. In addition, the strains under study do not regularly form gametocytes. Only the gametocyte form of the parasite life cycle is taken up by the mosquito.
3. The natural mosquito species carrier of P.falciparum is not present in the UK. The nearest population is in the Mediterranean. 
4. Although the UK did have malaria until 1919, this was caused by Plasmodium vivax, which is transmitted by a different mosquito species (Anopheles atroparvus) which is unable to transmit P.falciparum.
5. The laboratory in which we wish to culture P.falciparum is internal within other laboratories, locked, and has no windows.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste (used culture dishes) will be first allowed to soak in 1% Virkon or 10% bleach for 12 hours, followed by autoclaving or incineration. Liquid waste will be treated with 10% bleach or 1% Virkon for 12 hours to kill the parasite, before disposal down the drains.
Please enter comments on the GM safety committee on the risk assessment

CJH01/2007 - Organelle function in Plasmodium. The committee discussed that the organism being used is ACDP group 3.

The committee decided the assessment proposal to reduce aspects of the containment level down to level 2.

1. The organism requires a specific species of mosquito to be transferred to humans. There are none of these insects present.
2. The organism used is a characterised one that has been used for 20 years in culture and is susceptible to standard antimalarial drugs.
3. No sharp implements (needles) would be used in any of the procedures. Glass coverslips will be used only rarely.
4. The proposed culture room is isolated within the building, and is to be kept locked.

The committee agreed that it would be acceptable to derogate the containment to level 2.

Historical Significant Changes
**Project Additional Information**

**Purposes of the contained use**

The project aims to study the role of proteins expressed by the malaria parasite, *Plasmodium falciparum*, in modification of the human erythrocyte cytoskeleton and in clustering of adhesive proteins on the erythrocyte surface.

**Recipient or parental organism**

*Plasmodium falciparum* group 3

*Plasmodium falciparum* will be cultured in human blood, obtained from the National Blood Service (screened and of transfusion grade) or from blood donors at the Department of Biochemistry, University of Cambridge. Dead, fixed *Plasmodium* infected erythrocyted will be observed under light, confocal and electron microscopes.

**Host/vector system**

*Plasmodium* vectors containing *E.coli* and *Plasmodium* origins of replication, ampicillin resistance for selection in *E.coli* and DHFR for selection in *Plasmodium*, as described in:

**Origin & function**

In order to investigate the role of specific protein, and regions of these proteins, mutated parasite lines will be constructed. For protein deletion, the DHRF gene (allowing pyrimethamine or WR99210 resistance) will be cloned in to pGem-based vectors, flanked by sequences either side of the gene of interest. This cloning will be carried out in standard *E.coli* cloning strains. These vectors will be transfected into *Plasmodium falciparum* and selection carried out using pyrimethimine resistance. A similar vector will be used to insert truncated versions of the proteins, allowing investigation of the roles of different regions of the proteins. Dead, fixed cells will be studied by electron, light and confocal microscopy and proteins and nucleic acids will be extracted from modified cells for standard proteomic and molecular biology analysis.
Evaluation of foreseeable effects

The inserted and deleted Plasmodium genes do not code for proteins that are harmful to humans. They will not lead to a selection advantage for the parasite but are likely to lead to reduced pathogenicity.

The DHFR gene is not toxic.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No plants or animals used

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Justification for containment level 2

P. falciparum is a group of 3 pathogen, normally requiring containment level 3. However, the HSE advisory committee on dangerous pathogens, annex 1 lists biological agents which may be used at less than the minimum containment conditions required by COSHH. Containment levels can be lowered because of

1. The nature of the work
2. The nature of the biological agent

P. falciparum is listed as an agent to which the derogation may apply.

Risk Assessments would indicate that it is possible to use containment level 2 for the culturing of P. falciparum in this project for the following reasons:

1. We are culturing a clonal strain of P. falciparum that has been in continuous blood-stage culture for 20 years. It has known anti-malarial drug sensitivities and a fully sequenced genome. It is not resistant to the major anti-malarial drugs on the market.
2. Transmission of Plasmodium is by female mosquito. In the wild, the mosquito lands on human skin, pierces the skin and takes up blood. All our blood cultures will be in petri-dishes, so any mosquito that did enter would be unable to feed, so could not acquire the parasite. In addition, the strains under study do not regularly form gametocytes. Only the gametocyte form of the parasite life-cycle is taken up by the mosquito.
3. The natural mosquito species carrier of P. falciparum is not present in the UK. The nearest population is in the Mediterranean.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste (used culture dishes) will be first allowed to soak in 1% virkon or 10% bleach for 12 hours, followed by autoclaving or incineration. Liquid waste will be treated with 10% bleach or 1% virkon for 12 hours to kill the parasite, before disposal down the drains.

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment
MKH05/2009 - The Committee queried the effect of introducing and deleting genes on the ability of the organism to be more hazardous - however, it is shown that this would not be the case. It was agreed that the work would be carried out in an existing facility which has already been approved by the HSE - "Organelle function in Plasmodium".

1. The organism requires specific species of mosquito to be transferred to humans, of which there are non present
2. The organism used is a characterised one that has been used for 20 years in culture and is susceptible to standard anti-malarial drugs
3. No sharp implements (needles, glass coverslips) would be used in any of the procedures

The committee agreed that providing the work was to be carried out in Room 311 as described with assessment procedures acceptable to both the School Safety Officer and the Department's Biological Safety Officer, it would be acceptable to derogate the work to Class 2. Training would be undertaken according to the procedures already in place.

<tbody>
<tr>
<td>E. coli K12 derivatives</td>
<td>(bacterial host for plasmid are disabled, non-colonising, non pathogenic to humans and unlikely to persist in humans or survive outside lab culture. Examples: DH4a, JM109, SCS110, HB101. ACDP hazard group 1.</td>
<td></td>
</tr>
<tr>
<td>Yeast (Saccharomyces cerevisiae)</td>
<td>- are non-pathogenic, especially disabled and the strains used all have mutations within genes required for amino acid synthesis. They will not survive outside of the laboratory culture. ACDP hazard group 1.</td>
<td></td>
</tr>
<tr>
<td>Gamma retroviruses</td>
<td>- MuLV derived, replication defective. The vectors used are based upon the Moloney murine leukaemia virus (MoMuLV). ACDP HG 1. These vectors while retaining the packaging signal are deleted for the viral gag, pol and env genes rendering them replication defective. Examples: pBabe, pWZL. Infective virus can only be produced following transfection of the retroviral vector into a &quot;Packaging&quot; cell line - one that is engineered to complement the deleted genes (for example, Phoenix, Bosc23). In addition, the packaging cell line contains the gag/pol and env genes on separate DNAs rendering the possibility of generating replication competent virus via recombination very low. While risk of recombination leading to production of retroviral particles competent for replication (RCR) is minimised, viral batches may be tested for the absence of RCR by a variety of techniques such as serial transduction, genomic, Q-PCR, detection of reverse transcriptase (pol) activity. Vectors produced may be ecotropic or amphotropic. The latter are able to infect human cells but they pose an infectious risk via the percutaneous route only. They are considered class 1 GMMs.</td>
<td></td>
</tr>
<tr>
<td>Lentiviruses</td>
<td>- Vectors are derived from HIV-1 ACDP HG 3. However they are replication defective and considered class 1 GMM. In order to minimize the likelihood of recombination events leading to production of viral particles competent for replication (RCR), the native HIV-1 virulence genes. This lentiviral production system incorporates two key safety features. First, HIV-1 virulence genes Vif, Vpr, Vpu and Nef have been deleted from the helper plasmid. Moreover, the vector itself is self-inactivating (SIN vector) i.e deleted of the 3' LTR U3 region encompassing native viral promoter and enhancer. Replication of the 3' LTR in 5' upon reverse transcription leads to a provirus devoid of viral promoter activity. The absence of RCR will be confirmed by transduction into HCT-116 cells (ATCC, #CCL-247) and the presence of the HIV-1 p24 capsid protein determined by ELISA (Perkin Elmer, #NEK050B001KT) after 14 days in culture. Absence of p24 in transduced HCT-116 supernatant will confirm that the lentivirus preparation is free of replication-competent virus. The vectors will be 'pseudotyped' with the VSV G envelope glycoprotein replacing the natural HIV envelope glycoprotein; this will greatly expand the host range and may represent an enhanced risk of infection by contact or aerosol routes.</td>
<td></td>
</tr>
<tr>
<td>Adenoviruses</td>
<td>- Human adenoviruses are associated with mild respiratory or gastro-enteric infections, ACDP HG 2 The Ad5 derived vector is replication defective and considered as a class 1 GMM. The vector is deleted of the E1 and E3 regions and production is dependent on growth in an E1 complementing cell line.</td>
<td></td>
</tr>
<tr>
<td>AAV (Adeno-associated virus)</td>
<td>- AAV is not associated with human disease ACDP HG 1. The AAV vector is replication defective and is produced in the absence of helper virus. Of note, AAV-vectors produced in an identical manner described have been previously used safely in both dogs (Herzog et al, Nat Med 199, 5 56-63) and humans. Insertional mutagenesis is theoretical possibility although this has never been observed when using an AAV vector system. Class 1 GMM.</td>
<td></td>
</tr>
<tr>
<td>Characterised mammalian cell lines</td>
<td>are well described in the literature and are considered especially disabled, non-colonising, non-pathogenic and unlikely to survive outside lab culture. ACDP HG 1.</td>
<td></td>
</tr>
<tr>
<td>Human primary cultures</td>
<td>are considered especially disabled, non-colonising and unlikely to survive outside lab culture, ACDP HG 1. Nevertheless, they originate from primary human tissue that may contain known or unknown adventitious pathogenic agents. Documented clinical serology will, where possible, be associated with clinical primary samples. Primary cultures from human tissue will always be handled inside a class II microbiological safety cabinet by experienced worker(s) and cultivated in dedicated labeled incubators. No culture of human blood-derived cells is anticipated. Nonetheless, cultures from human tissue will be handled at Containment Level 2.</td>
<td></td>
</tr>
</tbody>
</table>
Plasmid vectors - all non-mobilisable pUC derivatives (eg. pTP6, pBSKS, pCDNA3, pLKO, pGEM, pZEG)

Retroviruses - see above. These recombinant viruses derive from the MuLV (Moloney Murine Leukemia Virus) that belongs to the Retrovirus family. They are RNA viruses that stably integrate into the host genome by activity of the viral integrase after reverse transcription resulting in long term expression. Such vectors have been used for more than 20 years and have proved to be a robust and efficient strategy for expression of genes in mammalian cells. Retroviral vectors may include coding sequences for type 1 (cDNA), type 2 (shRNA), type 3 (reporter) or type 4 (antibiotic resistance) inserts. These sequences could be expressed individually by separate vectors or in combination as polycistronic transcripts (cDNA separated by IRES) in the same vector. Gamma-RV particles may be pseudotyped by the VSV-G envelope protein.
Examples: pBabe, pWZL.

Lentiviruses - see above. These recombinant viruses derive from the HIV-1 (Human Immunodeficiency Virus type 1) that belongs to the Retrovirus family. They are RNA viruses that stably integrate into the host genome after reverse transcription and action of the viral integrase resulting in long term expression. Recombinant lentiviral vectors have been widely used for more than 10 years to achieve strong and stable transgene expression in a wide variety of mammalian cells. Compared to gamma-RV, they offer the advantage of being able to efficiently transduce quiescent cells. Moreover, knowledge of the native HIV-1 genome has allowed modifications of recombinant lentiviral vectors to enhance biosafety features (deletion of virulence genes, removal of internal native promoters). Lentiviral vectors may include coding sequences for type 1 (cDNA), type 2 (shRNA), type 3 (reporter) or type 4 (antibiotic resistance) inserts. These sequences could be expressed individually by separate vectors or in combination as polycistronic transcripts (cDNA separated by IRES) in the same vector. Moreover, in order to improve the expression cassette for specific use (lineage specific expression, inhibition of transgene silencing), type 5 (functional non coding sequences) inserts could be used to modify the original lentiviral backbone. These modifications will not involve any modifications of the safety features of the original recombinant lentiviral backbone nor the production method (isolation of complementing activities for viral production on 3 separate plasmids). Vectors with some forms of WPRE have been reported to be associated with tumour development in animal models. Lentiviral particles will be pseudotyped by the VSVG envelope protein.

Adenoviruses - See above Ad5 derived, replication defective. These vectors do not integrate so expression is of a more transient type. The genes of interest are positioned in the site of disablement (E1 deletion).

AAV (Adeno-associated virus) - See above. The AAV vector is replication defective and is produced in the absence of helper virus. The vectors are integrative so can result in long term expression

Expected biological activity of inserted DNA/RNA:

cDNAs (Type 1 inserts) code for wild type and mutant transcription factors, signal transducers, growth factors and receptors (and dominant interfering proteins) of mammalian (including human) origin that are expected to play a role in tumourigenesis. Some of these cDNAs encode oncogenes.

Type 2 inserts are non-coding (miRNA, shRNA), derived from mammalian sequences and designed to interfere with expression of endogenous genes including those represented in type 1 inserts.

Reporter genes (type 3 inserts) of prokaryote origin code for proteins with fluorescent or enzymatic properties allowing detection of genetically modified cells. They are not known to have any deleterious effects when expressed.

Selection genes (type 4 inserts) of prokaryote origin produce enzymes capable of inactivating specific antibiotic families. Expression of these genes will allow selection of genetically modified cells. They are not known to have any deleterious effects.

Functional non-coding sequences (Type 5 inserts) of prokaryote, avian or mammalian origin will act as promoters of transcription (promoters and enhancers), local chromatin structure modifiers (enhancers and insulators), RNA transcript stabilizers (WPRE) or translation regulators (IRES). They will be used (independently or in combination) into viral expression cassettes to achieve best control of transgene expression depending on targeted cells.
Neutral non-coding sequences (Type 6 inserts) of mammalian origin will be used in particular for gene targeting projects to promote homologous recombination at defined genomic loci (intronic/exonic genomic sequences) They should not have biological effect by themselves.

**Evaluation of foreseeable effects**

1. **E.coli containing plasmid vectors** containing a variety of inserts (sometimes more than one type). The plasmid vectors are all non-mobilisable pUC derivatives and E.coli host strains are all disabled, non-colonising, non-pathogenic K12 derivatives. None of the sequences introduced are expected to alter the disabled properties of the host so these GMMs are considered to be Class 1.

2. **Recombinant retroviruses and lentiviruses**. The vectors used are all replication defective “3rd generation” plasmids. Both ecotropic and amphotropic viruses will be generated, some of which encode oncogenic sequences; insertional mutagenesis is a possibility. Consequently, these viruses are regarded as Class 2.

3. **Recombinant adenoviruses**. The vectors used are based upon human type 5 adenovirus, but are deleted within the E1 and E3 regions of the adenoviral genome. This makes the vectors both replication-deficient and with the removal of the E1a and E1b genes (E1 deletion) unable to transform cells since they cannot activate early phase gene expression. Adenoviruses are not integrated into the host cell genome (unlike retroviruses and lentiviruses), provide only transient expression of the encoded sequences, do not replicate and spread to infect neighbouring cells (for example, in an intact tissue) and are usually rapidly eliminated. They are considered to be Class 1.

4. **Viral packaging cell lines** (for example, PA317, Phoenix) are transfected with plasmids to complement (in trans) activities required for generation of infectious virus but absent from the retroviral constructs. These activities (gag, pol and env) are separated on 2 or 3 different plasmids to restrict the possibility of replication competent virus. Transfection or infection with viral vectors results in the production of virions with an ecotropic or amphotropic host range dependent on the tropism endowed by the packaging cell line. Since these cells are used to generate infectious (but replication-defective virus) they will be considered as Class 2. Production of recombinant lentiviral particles will be achieved by transient co-transfection of 3 plasmids into HEK-293 cells by calcium phosphate precipitation.

5. **Established mammalian cell lines** will be transfected or virally infected with GMMs described in 1-3 above. The cell lines generated will have no increased capacity to survive outside of the laboratory environment and can be considered as Class 1. However, where primary human cell cultures are used - all GM derivatives will be handled at Containment Level 2.

6. **Yeast**. The yeast strains used all have mutations within genes required for amino acid synthesis and are therefore disabled. They will not survive outside of laboratory culture. The host yeast will be transformed with pUC-based non-mobilisable plasmids using lithium acetate/PEG/heat shock. None of the sequences used can alter the disabled nature of the hosts so they are considered as Class 1.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Established mammalian cell lines (including those derived from human tissue) are normally regarded as ACDP 1. They pose very little hazard and are unable to survive outside the laboratory. Primary human tissue and cell cultures will also be used in this study. Fresh human tissue from screened and unscreened individuals may therefore contain adventitious biological agents such as HIV, Hep B. Fresh tissue and primary cultures are regarded as ACDP 2 and will be handled under containment level 2 conditions. Although fresh human blood may be used there will be no attempt to culture blood cells.

All fresh human tissue and derived primary cultures will be handled under containment level 2 conditions. Personnel will be specially trained in handling such tissue especially where dissection is required. Personnel involved will be referred to University Occupational health for Hep B vaccination. Culture of human blood cells will not be attempted.

We will also express wild type and mutant alleles of oncogenes in rodents. Some of these oncogenes will be conditional alleles, only having activity when the animals are administered the specific ligand. In addition, we will genetically interfere with the sequence and/or expression of certain tumour suppressors (notably p53) in rodents. While these manipulations may generate tumours in the experimental animals there is a very low risk that the genetically manipulated animals are an increased risk to humans (eg by biting/scratching) and all workers will be specially trained in handling rodents. Due to the tight security of biofacility establishments precluding escape of genetically modified rodents, there is no risk to other animals or the environment.

Recombinant Adenoviral and AAV vectors will be used in animals. Where injections are employed extra care will be taken with the use of needles. Only trained personnel will conduct this procedure. It is anticipated that this procedure will give rise to any increased risk of infection due to bites. In addition, the viral vectors used are...
replication-defective (see above). No shedding in saliva or excreta is anticipated.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste is autoclaved (132°C, 15 mins). Liquid waste is treated with 1% Virkon (final concentration) or 5000ppm Klorsept 87 for at least 12 hours before disposal down the sink. Biological material (eg mouse tissues) is double bagged and incinerated via the Gurdon biofacility. Autoclaving: effective 100% kill, regularly monitored by microbiological testing. Certified testing of autoclave carried out annually. Liquid waste: Virkon gives >10^5 reduction in viable E. coli in 5 minutes and ≥ 4.25 log 10 reduction in lentivirus titre in 10 minutes providing effective bactericidal and virucidal activities when used as per the manufacturer's instructions. (Data supplied by the manufacturers, Dupont). Incineration: Effectively 100% kill.

Routine disinfection
All surfaces wiped with Trigene and 70% IMS. Centrifuge bowl, buckets and inserts wiped with Trigene and/or 70% IMS.

Spillage
Small amounts treated with Virkon wiped with disposable tissue and placed in autoclave bag for autoclaving. Larger spills: carefully add Virkon powder (do not inhale), leave for several hours, absorb onto tissue, bag and autoclave. Spills in orbital shaker are treated in the same way although it may be necessary to remove the orbital platform to access the spillage. Spills in centrifuge buckets should be treated with Trigene or Virkon (depending on the manufacturing material of the bucket) as above. In all cases the spill should be notified to local workers and the appropriate safety adviser. Regular testing for viable microorganisms - for example, colony growth on agar plates.

We use disposable scalpels, needles and glass pipettes. All are disposed of in “Sharps bins” that are collected for disposal by incineration

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form

GIE01/10 - Oncogenes and tumour suppressors in tumour development and maintenance: The Committee discussed this assessment and took into consideration comments made in an email from Dr H (attached). The assessment was passed at Level 2. HSE form to be completed and notified. The assessment was circulated to DR K F (Clinical School Safety Advisor) for any further comments on the project. There were a few minor alterations and a request that training in the CL2 lab would be recorded.

### Project Additional Information

**Purposes of the contained use**

To determine the pathway for potential fuel molecule production in Klebsiella and related species, and to manipulate the productivity of the pathways.

**Recipient or parental organism**

Klebsiella bacteria:
- Klebsiella (local species) - most similar to Klebsiella pneumonia
- ACDP Hazard Group 2 for these species generally, but the isolates 8017 and 418 are not recognized as pathogenic.

E. coli DH5alpha Group 1

**Host/vector system**

Plasmid vectors

pUC19, pKmobsacB, pUC19Km, pUM24, pKO3/pKOV. These vectors can replicate in E. coli DH5alpha. All plasmid constructs will be made in E. coli DH5alpha.
pKmobsacB, pKO3/KOV and pUC19-based vectors will be transformed into Klebsiella species. These are suicide plasmids in these species and therefore cannot replicate in these strains when cultured on media containing sucrose.

### Origin & function

N/A

### Evaluation of foreseeable effects

Final GMMs will be strains with genes in categories indicated disrupted or overexpressed. Genes encoding possible fuel molecule biosynthesis genes will be deleted in Klebsiella (local species) to determine whether they encode enzymes involved. These genes will then be expressed in E. coli to determine whether the fuel molecules can be produced in an industrial microbial strain.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Dr W investigated this assessment which is based on an isolate found in the laboratory and this was identified to be a Klebsiella. The work would be carried out at Containment Level 2 in the W laboratory. It is suggested that the clinical isolates mentioned in the assessment are not used in the project and removed. As the work will involve GM, the HSE will be informed and a CU2 form will need to be completed and approved before work can be started.

Project Additional Information

Purposes of the contained use

The aim of this project is to investigate the role of small G proteins (both wt and activated) and their effector and regulatory proteins in the control of signal transduction.
pathways that are deregulated during cancer progression. The genes encoding these proteins will be cloned into transfer vectors and then recombined into viral vectors. This will include the use of a number of different plasmid and viral vectors (retrovirus and lentivirus) for transduction of mammalian cells. These will be used to establish stable mammalian cell lines.

Recipient or parental organism

Characterised mammalian cell lines are well described in literature and are considered especially disabled, non-colonising, non-pathogenic and unlikely to survive outside lab culture. ACDP HG1. These include: Transformed human cell lines: NIH3T3, HeLa, HEK293T, MCF7, HB4a, MDA-MB-361, MDA-MB-231, HCC1806, MCF71, MCF10a, T47D, DU145, U205, LNCaP, BT474, Cal51 (Class I: extensively documented)

Transformed monkey cell lines: COS 1 and 7

Rodent cell lines: NIH3T3, CHO and Rat-1

Host/vector system

E. coli K12 strains: XL1 Blue MRF', XL10, DH5a, TOP10, TOP10F'. All are disabled, non-colonising, non-pathogenic to humans and unlikely to persist in humans or survive outside lab culture. ACDP hazard group 1.

Gamma retroviruses - MuLV derived, replication defective. The vectors used are based upon the Moloney murine leukaemia virus (MoMuLV). ACDP HG1. These vectors while retaining the packaging signal are deleted for the viral gag, pol and env genes rendering them replication defective. Examples: pBabe, pWZL. Infective virus can only be produced following transfection of the retroviral vector into a "packaging" cell line - one that is engineered to complement the deleted genes (for example, Phoenix, Bosc23). In addition, the packaging cell line contains the gag/pol and env genes on separate DNAs rendering the possibility of generating replication competent virus via recombination very low. While the risk of recombination leading to production of retroiral particles competent for replication (RCR) is minimised, viral batches may be tested for the absence of RCR by a variety of techniques such as serial transduction, genomic, Q-PCR, detection of reverse transcriptase (pol) activity. Vectors produced may be ecotropic or amphotropic. The latter are able to infect human cells but they pose an infectious risk via the percutaneous route only. They are considered class 1 GMMs.

Lentiviruses - Vectors are derived from HIV-1 ACDP HG3. However they are replication defective and considered class 1 GMM. In order to minimize the likelihood of recombination events leading to production of viral particles competent for replication (RCR), the native HIV-1 genome has been isolated onto 3 plasmids; a helper plasmid coding for Gag (matrix and capsid proteins), Pol (enzymes), Tat and Rev genes. This lentiviral production system incorporates two key safety features. First, HIV-1 virulence genes Vif, Vpr, Vpu and Nef have been deleted from the helper plasmid. Moreover, the vector itself is self-inactivating (SIN vector), i.e. deleted of the 3' LTR U3 region encompassing native viral promoter and enhancer. Replication of the 3' LTR in 5' upon reverse transcription leads to a provirus devoid of viral promoter activity. The absence of RCR will be confirmed by transduction into HCT-116 cells (ATCC,#CCL-247) and the presence of the HIV-1 p24 capsid protein determined by ELISA (Perkin Elmer, # NEK0508001KT) after 14 days in culture. Absence of p24 in transduced HCT-116 supernatant will confirm that the lentivirus preparation is free of replication-competent virus. The vectors will be 'pseudotyped' with the VSV envelope glycoprotein replacing the natural HIV envelope glycoprotein; this will greatly expand the host range and may represent an enhanced risk of infection by contact or aerosol routes.

Origin & function

Rho family G proteins (full length, with and without activating and other mutations): Cdc42, Rac1, 2 and 3, RhoA, B, C, D, F and G, Rho 6, 7 and 8, TC 10 and TCL

Ras family G proteins (full length, with and without activating and other mutations): RaIA andB, K-Ras, H-Ras, N-Ras, Rap1A (Human and Simian)

Effector Proteins (full length and domains): ACKs (Human), PAKs (Rat), WASPs (Human), IQGAP (Human), IMP (Human and frog), PRK1, 2 AND 3 (Human), Rhotekin 1 and 2 (Human), Rhosphilin 1 and 2 (Human), Citron (Human), PLC-51 (Human), ZONAB (Human), RLIP-76 (Human), Filamin (Human), Exo84 (Rat), Exo70 (Human), Sec5 (rat), Raf (Human), ROCK (Human), BORGs (Human), SPECs (Human), PI3Kinases (Human), Grb10 (Human), Nck (Human), STATs 1-6 (Human), DLAT (human), COPB (Human), PREPL (Human), DDX49 (Human), BPOZ (Human), Tensin (Human) and TOCA1 (Human).

Regulator Proteins: RhoGAP (Human), p120GAPRas (Human), PIX (Human), RhodGDI-3 (Human), Vav3 (Human), Epsin (mammalian).
### Evaluation of foreseeable effects

Mobilisation defective or non-mobilisable vectors are used in all E. coli work. All E. coli strains use would not survive outside the lab and would not be able to colonise humans.

Recombinant infectious retroviruses and lentiviruses are all replication defective. Such viruses, even if released to the environment, are unable to survive very long. However, since these viruses are capable of infecting animals (including humans) and integrating into the host cell genome (including inserted sequences) there is a possibility that they can persist in an individual. However, viral titres required for infection are extremely unlikely to be achieved outside the laboratory.

The mammalian cell lines used cannot survive outside laboratory conditions. The most significant hazard with cell culture is contamination with pathogenic viruses. No primary cells will be used and all cell lines will be grown under containment level 2 conditions. The genes and vectors that we will utilise have been used extensively by the scientific community with no reported risks.

During the cloning process the DNA fragments are inserted into sites of limited promoter activity or no activity.

Modest expression of inserted DNA will be carried out in mammalian cells using transfection with plasmids containing strong eukaryotic promoters (e.g. retroviral/lentiviral promoter/enhancer sequences). There is no intention to maximize expression in mammalian cells. These GMMs do not express inserted DNA outside a host organism. Although they are capable of infecting animals (including humans) and, in the case of retroviruses and lentiviruses persisting in the host genome, the risk of infection is negligible. All such GMMs will be handled under class 2.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid bacterial waste generated is autoclaved using a Fedagari SPA Programmable autoclave with a program of 15 minutes pulsed free steaming and 30 minutes at 132°C.

Liquid-based waste materials are treated by soaking in 1% final concentration of Virkon for a minimum of 15 min before disposal via the drains.

Solid tissue culture material is securely packaged and disposed of by incineration via a registered contractor. Liquid-based waste materials are treated by soaking in 1% final concentration of Virkon for a minimum of 15 min before disposal via the drains.

---

02/03/2022
2012.30 (vii) DO/HRM04/2012 - Establishment of stable mammalian cell lines expressing small G proteins and their effector proteins. The project involves G proteins and uses mammalian expression systems. It was pointed out that retroviruses and lentivirus must be used in Containment Level 2 laboratories. Work would not use any primary human cell lines, only established cell lines would be used. It is also noted that the work is similar to Professor E's. The assessment required to be revised to reflect this and then would need a CU2 form for HSE. An agreed statement for the work would be required before sending. CF

Withdrawn N

Tick if notifying a connected programme of work N
**Project Additional Information**

**Purposes of the contained use**
To determine the molecular mechanisms of human infectivity of African trypanosomes through the production and analysis of transgenic cell lines expressing modified versions of the genes necessary for human infectivity.

**Recipient or parental organism**
Laboratory adapted isolates of Trypanosoma brucei brucei will be modified through the expression of transgenes that will confer human infectivity. Human infective Trypanosoma brucei rhodesiense (ACDP hazard group 2) and Trypanosoma brucei gambiense (ACDP hazard group 3) will be used as control but will not be genetically modified.

**Host/vector system**
Trypanosome-specific vectors for: (i) the inducible or constitutive expression of transgenes, (ii) inducible RNAi knockdown of gene expression, and (iii) targeted deletion of genes. Introduced genetic material will originate from Trypanosoma brucei rhodesiense or bacterial plasmids including reporter genes.

**Origin & function**
Some of the transgenic Trypanosoma brucei brucei will become infective to humans but will be no more virulent than Trypanosoma brucei rhodesiense. As such, they will be capable of causing human disease if introduced into an open wound, there is no aerosol transmission route. The resulting disease is readily diagnosed and can be successfully treated. A risk assessment, including SOPs, to mitigate the chances of this happening. Accidental escape from the laboratory is extremely unlikely as the trypanosomes cannot survive outside complex tissue culture medium.

**Evaluation of foreseeable effects**
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
I would like to apply for the derogations of some containment level 3 measures to level 2 as detailed on the attached page in the fourth column.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All solid and liquid waste will be autoclaved following a SOP. This results in 100% kill that has been validated experimentally. The Department of Biochemistry has dedicated autoclaves and records of each autoclave run are kept.

Is an emergency plan required according to regulation 20?  
If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment
The committee agreed that this work could be carried out in the laboratories used for Trypanosome work, as they conform to CL3 with derogations justified by the researchers. The committee were satisfied that the standard operating procedures and training instructions for postdoctoral workers involved in the project were satisfactory.

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

Toxoplasma gondii is a single-celled parasite that infects and can cause disease in humans and livestock. Our interests lie in understanding numerous aspects of the basic cell biology of these parasites, with an ultimate view to elucidating treatment options and druggable targets in these parasites. We focus on various aspects of parasite cell biology and metabolism, such as how the parasite invades host cells and how the parasite assembles daughter parasites. An important approach to our study of T. gondii.
biology is to learn about the location and function of proteins in *T. gondii*. We will use gene technology to tag proteins of interest with traceable markers (such as the green fluorescent protein and epitope tags) to study the expression and location of proteins of interest. To study protein function we will use gene technology to control the abundance of proteins of interest either by regulating how much protein is made using inducible promoters, controlling the stability of the protein with destabilising domains, or removing the genes for proteins of interest. Some gene products will be expressed in the host cells and directed to the parasites via attached cell penetrating peptides. All GMOs will be used for in vitro culture studies only, and no GMOs are expected to have increased virulence, pathogenicity or transmissibility of the parasite. None of the proteins to be studied is known to code for a toxin.

*T. gondii* is grown in in vitro cultures of standard mammalian tissue culture lines (such as Human Foreskin Fibroblast (HFF) and Vero cell culture). Shuttle vector cloning will occur in *E. coli*, and genes expressed in both the parasites and host cells.

**Recipient or parental organism**

A. *Escherichia coli* (nonpathogenic strains such as XL-1 Blue, DH5a etc) - Class 1

B. *Toxoplasma gondii* wild type strains, and mutant derivatives: ΔKu80 (lacking the Ku80 gene for non-homologous recombination), TATiΔKu80 additionally containing variants of the *E. coli*-derived tet repressor (TetR) protein (see Meissner et al, Science 298(5594): 837, 2002), Δhxgprt (enabling restoration of mycophenolic acid selection as a selectable marker) - Class 2

C. Mammalian cells: Well characterized mammalian cells in culture, e.g. HFF, vero, NIH/3T3, BHK, 239T, RAW264

**Host/vector system**

Standard *E. coli* cloning vectors such as puC series, pGEM-T-Easy, BACs, cosmids and Lambda ZAPII

*T. gondii* vectors used include:

- pCTG vector and derivatives. pCTG contains a chloramphenicol-resistance marker and a GFP expression cassette. Derivatives include vectors containing resistance cassettes such as those for phleomycin, mycophenolic acid and pyrimethamine resistance as well as fusion proteins such as RFP (DsRed, mCherry and other variants), YFP and other GFP-derived fluorescent protein variants, HA, c-myc, mDHFR, destabilization domain and Ty1 epitope tags. Genes-of-interest may be driven by inducible promoters that include TetR-binding operator sequences (tetO), or by a range of parasite-specific promoter sequences. See van Doore et al, PNAS, 105(36): 13574, 2008 for a description of the base vector.

- pTCY vector and derivatives. pTCY contains chloramphenicol-resistance marker and a YFP expression cassette that is used as a negative selection marker. Derivatives of this vector are used primarily in generating knockouts of genes-of-interest in Toxoplasma or in generating homologous integration events. See van Dooren et al, PNAS 105(36): 13574, 2008 for a description of the base vector.

- pPR2-HA3 vector and derivatives. PPR2-HA3 contains a pyrimethamine-resistance cassette and is used for gene replacements. See Sheiner et al, PLoS Pathog, 7(12): e1002392, 2011) for a description of the pPR base vector that is further modified to include a 3xHA (haemagglutinin) epitope tag and additional restriction endonuclease sites.

- PSB ad TOX cosmids modified by recombineering to introduce resistance cassettes such as those for pyrimethamine, chloramphenicol, phleomycin and mycophenolic acid resistance cassettes and epitope tags. The recombineering procedure and base vectors are described in Brooks et al, Cell Host Microbe, 7(1): 62, 2010.

- loxP flanking sequences will be used to induce Cre recombinase excision, and CRISPR/Cas9 sgRNAs will be used to direct Cas9 excision.

Standard mammalian expression vectors such as the pCAG series will be used for protein expression in the host cell systems.

**Origin & function**
Standard genes used as selectable markers in bacteria (e.g. ampicillin, kanamycin).

The source and functions of some of the commonly used genes responsible for drug-resistance phenotypes in Toxoplasma gondii are as follows:
- mutant Toxoplasms DHFR gene (pyrimethamine resistance): a drug-resistant form of dihydrofolate reductase/thymidylate synthase, which reduces dihydrofolic acid to tetradihydrofolic acid.
- the Streptomyces BLE gene (phleomycin resistance): binds with high affinity to phleomycin drug to prevent it from interfering with an organism's DNA.
- E. coli-derived chloramphenicol acetyltransferase (chloramphenicol resistance): acetylates chloramphenicol drug which prevents the drug from binding to the prokaryotic ribosome (in the case of Toxoplasma, likely the apicoplast ribosome), its site of action.
- Toxoplasma HXGPRT (mycophenolic, xanthine and guanine, providing the parasite with a means of salvaging purines. In the context of Toxoplasma genetic modification, its presence allows the bypass of a second mode of purine salvage that occurs via inosine 5'-monophosphate dehyrogenase, an enzyme sensitive to mycophenolic acid. In the case of negative selection, HXGPRT converts the drug 6-thioxanthine to toxic nucleotides that become incorporated into the parasite's DNA.
- Toxoplasma UPRT (FUDR sensitivity): adds a phosphoribosyl group to the pyrimidine base uracil, thereby functioning in pyrimidine salvage. UPRT catalyses the conversion of FUDR to its toxic nucleotide, which interferes with RNA and DNA synthesis.

Tetracycline-controlled expression utilizes modified T. gondii promoters that contain tet operator sequences derived from E. coli, in cell lines expressing variants of the E. coli-derived tet repressor (TetR) protein (see Meissner et al, Science 298(5594): 837, 2002; van Poppel et al, Int J Parasitol 36(4): 43, 2006). Other promoters used in transgene expression are derived for T. gondii. Cre Recombinase, and Cas9 (of the CRISPR/Cas9 system) will be expressed in both the parasites, and the host cells with cell penetrating peptides attached (e.g. Penetratin, TAT).

Standard reporter proteins will be used including: fluorescent proteins (GFP and derivatives); epitope tags (e.g. HA, cMyc, Ty); enzyme reporters (e.g. BirA* (mutant biotin ligase), APEX (a modified ascorbate peroxidase))

Genes for T. gondii proteins of interest to this research project will be manipulated.

No human genes will be used, and no genes are expected to increase the virulence of the parasites, or produce toxins.

**Evaluation of foreseeable effects**

T. gondii cells will be made with the following final genetic outcomes:
- Knock out of an endogenous gene product
- Endogenous gene product under the control of a regulatable promoter or inducible destabilization domain.
- Reporter protein fusion of an endogenous gene product
- Generate mutant gene replacement products

Mammalian cells expressing proteins able to be directed to the intracellular T. gondii parasites via cell penetrating peptides to mediate gene editing events (e.g. recombination, DNA cutting).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste will be incinerated or autoclaved using a programmable autoclave with a program of 15 minutes pulsed free steaming and 30 minutes at 132°C. Liquid waste will be treated with bleach (1% sodium hypochlorite) or virkon for 12 hours to kill the parasite, before disposal down the drains.
All of these methods have been shown to kill T. gondii parasites.

Microbiological testing has shown that hypochlorite kills T. gondii. This is the standard means of killing the parasite in T. gondii research laboratories. Virkon is also routinely used in T. gondii laboratories.

Autoclaving: Effectively 100% kill at this programme as shown by microbiological testing. Certificated testing of all autoclaves is carried out annually and records are held by the Department. Printed readouts from each run are retained to ensure temperatures within the autoclave were maintained during the cycle.

Incineration: Effectively 100% kill.

Minute 2014.16 from safety committee meeting 12 May 2014
RW01/2014 - The Biology of Toxoplasma gondii parasites.

The organism is not transmissible human to human but is transmissible from a cat to a human, and from culture to human by e.g. needlestick. The Committee requested Dr W to attend the meeting to discuss concerns about methods of disinfection (bleach, 80% ethanol) which will be modified to proprietary chemicals such as trigene, and the use of sharps. The latter will be reduced to a minimum and only blunt needles will be used. The assessment is very comprehensive with an older assessment from Australia included. Dr W would also produce a standard operating procedure document to go with the assessment (now provided). The Committee then agreed it to be Level 2 and the HSE would be notified. Correspondence between Mr E, Dr W and Professor D regarding the importation of the material was available and Dr W will be implementing this as soon as notification has been agreed by HSE.

Project Ref 99/03.1

Date Ackn'd: 08/08/2003

Date Project Ceased: 14/10/2008

CU2 Project Title: TO DELIVER T CELL CO-STIMULATORY GENES AND CYTOKINE GENES OR GENES DESIGNED TO ENHANCE NATURAL KILLER CELL ACTIVITY, TO TUMOUR CELLS FOR BREAST CANCER, OVARIAN CANCER OR LEUKAEMIA

Date of Significant Change: N

Tick if notifying a connected programme of work: N

Historical Significant Changes

Withdrawn: N

Non-GMM Consent Granted: not applicable

Purposes of the contained use

We are developing a number of gene based therapies to try to overcome the lack of recognition by autologous immune effector cells to the patients tumour. We are...
working with breast, ovarian and leukaemic models of disease. We propose to use combinations of the genes encoding CD80, IL-12 and the adenoviral type 5 E1A protein.

Recipient or parental organism

E. coli (including strains TG1, DH5alpha and JM109)
Human cell lines including 293, 293T, HeLa, MCF7, MDA231, BT474, CaOv, OVCAR and SKOv.
Murine cell lines including TS/A, 4T1 and SCK.
Patient derived tissue (material obtained from patients undergoing treatment for their disease, after appropriate consent) including breast, ovarian and leukaemic samples together with peripheral blood.
Transgenic mice eg the Ocomouse (Her2/neu transgenic)
immunocompromised mice (eg SCID)
Normal mice including strain Balb/C and A./J

Host/vector system

Vectors including plasmids based on the mammalian expression plasmid pBK-CMV (Stratagene) encoding human and murine CD80 and IL-12 and Adenoviral E1A, either separately or in combination.
Lentiviral constructs including plasmids pLenti6/V5, pLP-1, pLP-2 and pVSV-G (Invitrogen).
pUC 18/19 general cloning vector.

Origin & function

All human and murine genes were cloned using appropriate mRNAs derived from appropriately stimulated cells.
Adenovirus E1A was cloned from wild type Ad5 virus obtained from the ATCC (United States).
The function of these genes is detailed in Section 5 above and in Delivered Genes in Section below.

Evaluation of foreseeable effects

Recipient organisms. The inherent risks in using our bacterial strains are very low. All are commercially available and are disabled so that they can neither survive outside the laboratory nor transfer or recombine genetic material.
Our wild type mammalian cell lines are also commercially available and have been grown in continuous culture for many years. They have not been found to contain any adventitious agents.
The normal mice and transgenic mice are commercially sourced. We do not anticipate any additional risks to the environment when using these mice in our experiments.
The SCID mice and severely immuno-compromised and so would be unable to survive outside the laboratory.

Vectors. The antibiotic resistance markers carried in our plasmids theoretically could be transferred to wild type bacteria causing them to gain resistance to kanomycin and penicillin.
For lentiviral gene transfer, a minimal vector is used which has three levels of safety incorporated in it. These deletions render the virus replication defective and incapable of producing infectious viral particles in the target tissues. However there is a very small but possible effect that there may be recombination between wild type viral sequences, latent in the patient derived tissues, and the recombinant vectors. It is considered that this possibility is extremely remote.

Delivered genes. We propose to use the cDNAs encoding CD80, a T cell ligand which is usually expressed at low levels on ‘professional’ antigen presenting cells such as macrophages and dendritic cells. We also propose to use the antigen presenting cell derived cytokine Interleukin-12 (IL-12) which plays a central role in the immune system, principally for its ability to promote the development of CD4+ T helper (Th1) cells from naive T cells.
Additional experiments will use the Adenovirus E1A protein. E1A has pleiotropic effects on cells including, for the 243 amino acid variant, tumour suppressive activity in some human cell lines.
GMOs will not be delivered directly to animals but GMOs will be used to infect cells which will be checked for expression and these cells containing disabled GMOs will be injected into the animals.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All of the GM animals will be housed in cages separate from their non GM controls. They will not be allowed to mix. All animals will be of the same sex (female) and therefore will not have the opportunity to breed. At no point will the GM and non GM animals come into contact when they are alive.

All animals will be housed in the Comparative biology unit at the Royal Free Hospital which can be accessed only by authorised personnel.

The Comparative Biology Unit (CBU) where the mice will be housed has been purpose built and containment was an important design consideration. There are several levels of containment: the cages are secure and escapes are extremely infrequent. An animals that escapes from its cage would have to pass through two doors before being outside the Unit. The doors are close fitting and rodent barriers are strategically placed which are designed to prevent this happening. Further, in contrast with micro-organisms, all mice are accounted for by counting on a daily basis.

The SCID animals, due to their immune deficiency will be housed separately in cages with filtered airflow. In addition to the containment described above, these animals are further contained by being housed in a unit within double air-locked door.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All material contaminated with genetically modified organisms (GMOs) or naked DNA will be rendered non-infective before disposal according to the Royal Free Campus arrangements and the Departmental Code of Practice for GMO work.

Complete inactivation of viable GM material is achieved by chemical disinfection or autoclaving.

Solid waste is disposed of in plastic bags designated for autoclavable waste. Sharps (e.g. pipette tips) are collected in containers suitable for protection of the bags and for subsequent autoclaving. Sharp use is actively discouraged in the Flow Hood. Lids are loosely sealed to ensure the appropriate penetration of steam. Where applicable, solid waste contaminated with GMOs eg tissue culture flasks are treated with Chlorine ions at 10 000 ppm (Milton Fluid) before disposal in autoclavable waste. The bags are collected regularly and disposed of by the appropriate Hospital authorities at 121 degrees C for 20 minutes.

Liquid waste containing GMOs eg tissue culture supematant, is treated with free chlorine at 10 000 ppm (Milton liquid)

Is an emergency plan required according to regulation 20?

N

Please enter comments on the GM safety committee on the risk assessment
I understand that, after consultation between the Assistant Biological Safety Officer of the Royal Free Hospital and a member of the HSE, it was felt that this is a borderline case between Class 1 and Class 2.

The local safety committee has seen the proposal, submitted and provisionally approved as a Class 2 project. Therefore I am required to submit the project to the HSE for ratification as a Class 2 project.

Purposes of the contained use

Propagation and in-vitro characterisation of attenuated MVs expressing murine and human GM-CSF and IL-12 in-vivo characterisation in mice transgenic for the human...
**MV receptor, CD46. Determination of in-vivo oncolytic effects in relevant tumour models.**

**Recipient or parental organism**

Attenuated (vaccine) strain of MV

**Host/vector system**

Vector: cDNA encoding murine and human growth factors expressed as additional transcription units of attenuated MV.

Hosts:
1. For DNA preparation, K12 strains of E. Coli will be used, typically TOP10 strain.
2. Attenuated (vaccine) strains of MV will express the growth factors.
3. Established mammalian cell lines will be infected by the modified viruses: 293 (human embryonal kidney) Vero (African green monkey kidney), Raji, DOHH2, (human B cell lymphoma). 293-3-46 (modified 293 cells expressing attenuated MV proteins, intended for the rescue of infectious MV from the full-length anti-genomic plasmid).
4. Mice transgenic for the human MV receptor, CD46 and SCId mice bearing humaning tumour xenografts will be intentionally infected by these viruses by various route of infection.

**Origin & function**

Origins:
- cDNA encoding GM-CSF cDNA originally purchased from commercial sources (In-vivogen (murine) and ATCC (human)).
- Full-length MV plasmid obtained from Dr Roberto Cattaneo, Mayo Clinic, Rochester, MN, USA. This plasmid and its use to rescue infectious MV owas originally described in Radecke F, et al Rescue of measles viruses from cloned DNA. EMBO J. 1995, 14:5773.
- MV GM-CSF constructed in the laboratory of the applicant from starting materials above (Grote et al Cancer Res 2003; 63 6463)
- MV-IL-12 obtained from Dr Roberto Cattaneo (Singh M, Billeter MA. A recombinant measles virus expressing biologically active human interleukin-12. J Gen Virol. 1999,8:101)

Intended functions:
- Infectious MV expressing murine GM-CSF has been used by the applicants laboratory as an oncolytic agent in murine models (Grote et al Cancer Res 2003;63 6463) and is shows greater efficacy than the unmodified parental MV by virtue of stimulating a neutrophil infiltration of the tumors. We are currently further assessing its activity and mode of action. MV expressing human GM-CSF will be used to evaluate the effect on various human cell lines in-vitro. MV expressing murine and human IL-12 will be used similarly.

**Evaluation of foreseeable effects**

We and others have previously worked with attenuated MVs expressing growth factors and have had the opportunity to evaluate their effects in 2 different in-vivo models. A transgenic murine model expressing human CD46 (which has been accepted by the USA Food and Drug Administration as a suitable model in which to evaluate the toxicity of genetically modified MVs about to enter the clinic in phase 1 human studies) has been used to study the in-vivo effects of attenuated MV expressing murine GM-CSF. Second, a non-human primate model h as been used to evaluate an MV expressing human IL-12. In this application, we are thus able to consider the theoretical effects of accidental infection with a growth factor expressing, replicating attenuated MV in the light of in-vivo data. Naive mice were infected by various routes using MV expressing murine GM-CSF and suffered no ill effects. A low level of GM-CSF was detected in the blood at day 3 post-infection, which returned to background levels after that time. No effect was observed on the blood counts. Infection was terminated by an immune response. (Grote et al Cancer Res 2003-63 6463). MV
expressing human IL-12 has been administered to non-human primates without ill effects. The virus was eliminated by an immune response (R Cattaneo, personal communication).

Potential Effects on Human Health
The vaccine strains of MV themselves are not pathogens in immune competent individuals, but can cause fever and sometimes a mild rash in approximately 10% of vaccinees. Should humans become accidentally infected by attenuated MVs expressing a growth factor, it is considered that the virus would propagate to a limited extent, allowing some local production of growth factor before being limited by an immune response. By extrapolation from the animal data, it would not be expected that sufficient quantities of growth factor would be produced to cause systemic effects. All workers will be ensured to be immune to MV. Additionally, should all containment be breached, most adult individuals in the Western world, either by prior infection of vaccination. In the very remote case of an unimmunised individual being infected unintentionally, an immune response would be expected to limit infection albeit slightly slower than in a previously immune individual.

Growth factors such as GM-CSF and IL-12 are known to have pleotropic effects on human cells and their functions. Both of these growth factors have been used clinically and their range of effects are well characterised in humans in a variety of clinical scenarios. GM-CSF is a licensed product in fairly common clinical use. IL-12 has also been evaluated in clinical study. At very high doses, however, both GM-CSF and IL-12 can have harmful effects. Our animal data suggested that such toxic dose levels are not achievable when the growth factors are expressed from an attenuated replicating MV.

Bacterial vectors:
MV is a negative strand RNA virus, cDNA encoding the anti-genomic MV plasmid is not infectious, nor can it be used alone to generate infectious virus. Thus there is no foreseeable harm to human health from propagating standard laboratory strain of E coli harbouring MV plasmids since no expression will occur.

Cell lines:
When mammalian cell lines are infected by MVs expressing growth factors, infectious virus is released from the cells, although most of the virus remains cell-associated. Growth factor is secreted into the medium. Concentrations of GM-CSF in the medium are in the ng/ml range. MV-infected cells are the source of stocks of virus to be generated by freeze-thawing of infected cells. Virus concentration in stocks is usually about a million to ten million plaque forming units per millilitre. Average volumes harvested are around 1 to 3 ml. Sharps are not used when working with the cells, accidental inoculation with virus-infected cells is unlikely.

Mice:
Mice do not excrete MV in appreciable quantities. In the event of a worker being bitten by a mouse infected with MV expressing murine GM-CSF, it is unlikely that any harm would ensue, since the worker would be immune to MV, as discussed above. Additionally, where murine experiments take place, the murine growth factor is expressed. In the case of GM-CSF, there is little or no activity of the murine factor at the human receptor.

Potential Effects on the Environment
Bacterial Vectors
There is no foreseeable risk to the environment in the event of release of bacterial vectors.

Cell Lines
Would not survive outside the controlled environment of the laboratory and thus present no risk to the environment.

Mice
The only natural host for MV is humans. Normal mice are not infectable by MV, hence there is no risk to other mice in the facility nor to animals outside the facility, should a total breach of containment occur. Should MV-infected SCID mice escape into the environment, they would not survive beyond the confines of the laboratory and rapidly perish. Should the MV-infected SCID mice escape into the environment, they would not survive beyond the confines of the laboratory and rapidly perish. Should the MV-infected CD46 transgenic mice escape to the environment, they would also prevent no foreseeable threat. They would not be able to infect normal mice with MV. If by chance, these mice bred with local mice, and lost homozygosity for CD46, they would no longer be infectable by MV. It should also be noted that CD46 transgenic mice
CANNOT BE INFECTED BY WILD TYPE MV, which uses SLAM and not CD46 as a receptor. Finally, the mouse escape policy from the CBU at the RFH, which demonstrates the very unlikely nature of such an escape, is appended.

Spillage of virus stocks
In the very unlikely event of a pill outside the laboratory, where decontamination procedures for some reason were not able to be applied, which is extraordinarily unlikely, survival outside a host is brief. MV is inactivated by heat and light. Aerosols remain infectious for approximately 30 minutes and survival on surfaces is less than 2 hours. The virus is very unlikely to encounter wild-type strains, for the same reason, and also because in general such strains are usually not circulating in the community. However, considering this very remote possibility, MV is extremely genetically stable and recombination is very unlikely.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste generated will fall into the categories below:

Contaminated tissue culture plastics.
Solid waste, for example plastics will be decontaminated within the hood with 1% Virkon before disposal within autoclave bags to be autoclaved before eventual disposal according to the institutional system.

Plastic pipettes and pipette tips.
Will be placed into a rigid container within the hood and eventually, the capped container will be autoclaved before disposal, as above.

Liquid waste
Will be decontaminated with 1% Virkon or 1% sodium hypochlorite before disposal in the drains.

Animal carcasses
Animal carcasses will be disposed of within autoclave bags and autoclaved before disposal according to the institutional system.

Sharps (used during inoculation of animals)
Will be disposed of within an approved sharps container.

Virkon or sodium hypochlorite can destroy the virus so that no detectable virus remains after contact with the agents. No special monitoring will be necessary to monitor decontamination.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
Comment: Will any primary cells be used?
Reply: There are no immediate plans to use primary cells.

Comment: Consider any risk from various MV-infected mice to humans or the environment.
Reply: possible risks to staff working with MV-infected mice.

Work carried out over the past 4 years at the Mayo Clinic did not require veterinary technical staff performing general housekeeping duties with mice used for similar projects be subjected to the same Occupational Health concerns as staff employed specifically for the projects. Mice infected with vaccine strains of MV do not excrete the virus to any quantifiable extent. In fact, it is rarely even possible to re-isolate the virus directly from MV-infected tissues (for example, lung, spleen) of CD46 transgenic mice by co-culture of tissue with highly permissive cells. Thus, the risk of workers handling the mice and cages for husbandry purposes actually coming into any contact with the virus can be supposed to be extremely low. The case of a person being bitten by a GM MV-infected animal has been considered in this assessment. This situation was discussed at length during the establishment of the policies at the applicant's previous institution. It was felt that no specific action would be needed in the case of an appropriately vaccinated worker, other than general measures, appropriately recording the incident and monitoring the health of the worker. In fact, this incident did occur, approximately 2 years ago, during the applicant's previous post. No harm ensued.

Comment: If new workers join the project, will these issues be addressed through the occupational Health Dept?
Reply: Yes, when new workers join the project, the issue of MV immunity will be addressed through Occupational Health.

Comments:
- Pipettes, tips, culture plates etc. do not require disinfection prior to autoclaving.
- Dry discard containers with screw caps should be used for tips rather than discard pots.

Reply: Comments are duly noted and will be acted upon.

Comment: Can project staff be named?
Reply: A technician has now been appointed and named.

Comment: Does vaccine mediated immunity protect equally well against the proposed genetically modified strains?
Reply: Murine data from our lab suggest that immunity to the GM-CSF-expressing genetically modified strain of MV is the same in magnitude and timing as to the unmodified MV.

? has sent these comments in after closure regarding your projects.

Comment: It will be important to monitor levels of anti MV immunity in people on the project and in people closely associated with it and to have a program of vaccination in place to boost levels of low response.

Reply: Titres will be checked at starting and if inadequate (<25iu/ml), project workers will be immunised. Regarding further boosting: immunity to MV after natural infection or adequate vaccination is generally accepted to be lifelong. It should not be necessary to boost. There are no data on which to base a scheme of re-testing and possible re-vaccination, this would have to be empirically determined. If it is deemed necessary, I would consult with virology and vaccine experts to try and devise an appropriate scheme.

Project Containment
**Project Additional Information**

**Purposes of the contained use**

Primary human cells will be isolated from patients: either liver taken at resection or time of transplant, placenta, amnion, bone marrow or peripheral blood, will be immortalised and transformed either by retroviral vector mediated, lentiviral mediated, lipofection, or by electroporation introduction of genes associated with cell cycle and senescence; some of these will be oncogenes. The resulting cells will be grown in vitro, to establish their proliferative and differentiative properties. Suitable cell lines may be chosen as the biological component of a bio-artificial liver machine (should this project be successful their use in a bioartificial liver would be the subject of a future application). A subsequent addendum to this application will be made if and when cell lines have been generated to test the proliferative capacity of these cells in vivo, by injection into nude mice; this will be in conjunction with a home office licence application to use nude mice.

**Recipient or parental organism**

Retroviral viral vectors based on murine moloney leukaemia virus: Vectors lack pol and env sequences and only encode a short sequence of ATG negative gag. Third generation Lin X (derivative of 293T) packaging cell lines will be used to produce replication-incompetent virus. The gag, pol and env genes are integrated into the genome.
or expressed from a Bovine Papiloma Virus based episomal vector that contains no regions of homology to the MMLV based vectors. Three separate recombination events would be required to produce replication-competent virus. The cell line has been tested exhaustively for production of replication competent virus; none was detected. The combined choice of the packaging cell lines and the replication defective nature of the vector used will prevent the production of helper/replication competent virus by the transduced cells, reducing the risk to the environment. Lentivirus vectors: cPPT-CMV and pCMV 8.91plasmid) vector is an HIV based vector described in full by Zennou et al (2000). The replication defective virus is produced in TRANS with structural components supplied by the pCMVr8.2 helper plasmid carrying gal, pol, tat, and rev. The vector is pseudo-typed with VSV-G, supplied in trans by the plasmid pMDG. At least 2 independent recombination events with a helper free genome would be required to recreate a viable pathogenic genome.

The second lentiviral gene delivery system involves three plasmids that are transfected into virus producing cell line, the 293t cell line. The lentiviral system is secured by gene removal such that no new particles can be produced from infected cells. This system functions as the host 293t cell express.

1. The viral envelope protein (CVSV-G envelope) from pVSVg.
2. The modified HIV-1 genome with the transgene (modified HIV-1 with deleted envelope and accessory genes)
3. The HIV-1 genome (from the pCMV plasmid 8.91)

The vector can stably integrate into DNA for sustained long-term expression of the transgene. The vector has the ability to infect human primary and stem cells, with subsequent expression of the foreign gene in these cells and their progeny. No new HIV-1 virions can be synthesised by the infected cells due to the deletions in the genome - and they are termed self-inactivating. The VSV-G envelop allows a broader cell target range than HIV1 and is included for this reason.

Host/vector system

Hosts: E.coli strains DH5alpha, DH10B, mammalian cells; primary epithelial and mesenchymal cells derived from human liver, peripheral blood, human placenta and amnion, human stem cells Hepatocyte cell lines Hep G2, human fibroblasts and lines ImR90, packaging cells LinX A and LinX E, 293T cells.

Vectors: pBabe, pWZL, MARX vectors (Genetica Inc, Cambridge, MA USA); LN series (LN, LNSX, LNCX, Miller et al 1989); cPPT-CMV-(eGFP); cPPT-CMV-(hTERT); pCMV 8.91

Origin & function

hTERT (telemerase), myc oncogene E7 oncoprotein, p53 tumour suppressor, E1A (early region 1A adenoviral sequence), mdm2oncogene, cyclin D1, p16 and p189 cyclin dependent kinase inhibitors, SV40 large t antigen, GreenFluorescentPortein, B-galactosidase.

All oncogene-virus constructs will be obtained from Wolfson Institute for Biomedical Research, UCL.

Evaluation of foreseeable effects

Primary human cells may contain adventitious agents and should be handled in containment level 2 according to COSHH. The other human cell lines are established long term lines ana can be regarded as belonging to ACGM activity class 1. The linX amphotropic virus is incapable of replication outside of its packaging cell for following reasons. Third generation LinX (derivative of 293T) packaging cell lines will be used to produce replication-incompetent virus. The gag, pol and env genes are integrated into the genome or expressed from a BPV based episomal vector that contains no regions of homology to the MMLV based vectors. Three separate recombination events would be required to produce replication-competent virus. The cell line has been tested exhaustively for production of replication competent virus; none was detected. The combined choice of the packaging cell lines and the replication defective nature of the vector used will prevent the production of helper/replication competent virus by the transduced cells, reducing the risk to the environment.

Lentivirus vectors: cPPT-CMV and pCMV 8.91plasmid) vector is an HIV based vector described in full by Zennou et al (2000). The replication defective virus is produced in TRANS with structural components supplied by the pCMVr8.2 helper plasmid carrying gal, pol, tat, and rev. The vector is pseudo-typed with VSV-G, supplied in trans by the plasmid pMDG. At least 2 independent recombination events with a helper free genome would be required to recreate a viable pathogenic genome.

The second lentiviral gene delivery system involves three plasmids that are transfected into virus producing cell line, the 293t cell line. The lentiviral system is secured by
gene removal such that no new particles can be produced from infected cells. This system functions as the host 293t cell express.

1. The viral envelope protein (CVSV-G envelope) from pVSVg.
2. The modified HIV-1 genome with the transgene (modified HIV-1 with deleted envelope and accessory genes)
3. The HIV-1 genome (from the pCMV plasmid 8.91)

The vector can stably integrate into DNA for sustained long-term expression of the transgene. The vector has the ability to infect human primary and stem cells, with subsequent expression of the foreign gene in these cells and their progeny. No new HIV-1 virions can be synthesised by the infected cells due to the deletions in the genome - and they are termed self-inactivating. The VSV-G envelop allows a broader cell target range than HIV1 and is included for this reason.

The HIV-1 vectors being used are attenuated and cannot replicate once cells have been infected. The transgene has the potential to be expressed in infected human cells. Because some of the transgenes are potential oncogenes they could, when expressed in cells, give the cells the ability to proliferate. The vector does not replicate, reducing the risk of harm significantly. Aerosol contamination is not possible - the virus can only infect when normal barriers (skin/mucosal membranes) have been penetrated. All work will be carried out in a containment level 2 laboratory, with protective clothing and no sharps inside the safety cabinets. The vector has a small and insignificant potential to become replication competent if combined with wild-type vector. We prevent this by having no live HIV-1 experimentally in the laboratory. All workers on the project will be required to attend Occupational Health department to discuss the risk potential. The overall risk of infection and harm is therefore low.

The project involves the generation of cells with a prolonged cellular lifespan; it is possible that one or several oncogenes could be enriched in some of the cell lines. Genes could belong to any of the categories above but only genes involved with senescence, cell cycle and differentiation will be selected for. Several oncogenes will be used as controls for the experiments. The effect of an oncogene or tumour suppressor on different cell types is very difficult to predict. For example, myc immortalises prostate epithelial cells but causes terminal differentiation in keratinocytes. Introduction of a single oncogene, however rarely results in malignant transformation. The hazards involved in naked oncogenic DNA will be addressed according to COSHH. Specifically naked oncogenic DNA will be handled in accordance with the "Advisory Committee on Genetic Modification Compendium, Part 3A - Annex 1. Containment level 2 is appropriate. The risk from the viral vectors themselves are minimal.

The main risk is introduction of an amphotropic virus containing an oncogenic sequence into the cells of a worker via a needlestick injury. This may result in the infection of the workers' cells and expression of the oncogene. The number of cells is likely to be small. Entry would have to take place through broken skin or mucosal tissue. The virus is incapable of replication once in the cells and the introduction of a single oncogene into a small number of cells is unlikely to result in tumour formation. This is before we consider the protective measures afforded by level 2 containment required and the class II cabinet that work must be conducted in, without the use of sharps in the hoods. The other risk is that transformed human cells may be introduced via needlestick or mucosal spillage. Because the cells are not derived from the worker they are unlikely to survive for long after entry.

There is no foreseeable risk to the environment in the event of the release of the bacterial vectors or GMMs. The transformed cell lines would not be able to survive outside of the laboratory and also present no risk to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Containment level 2: negative pressure relative to the pressure of the immediate surrounds: "required where and to the extent the risk assessment shows it is required". The tissue culture laboratories are constructed to Medicines Control Agency specifications and are therefore at a slight positive pressure with respect to their immediate surroundings, the anteroom. The anteroom is negative pressure with respect to the corridor (ie with respect to outside the tissue culture suite). Cell cultures will be manipulated only in Class II microbiological safety cabinets which are at negative pressure. In the event of a breach of containment outside the safety cabinet, GMM cell lines would not survive and would not pose a risk by the respiratory route.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Cell culture: All work with mammalian cells will be manipulated in Class II safety cabinets in designated tissue culture laboratories. All laboratory areas are designated containment level 2. Level 2 procedures will be observed.

Liquid waste: Liquid waste is treated with 1% Virkon or 1% Presept overnight and autoclaved before being discarded down the sink.

Solid waste: non-sharps plastics will be decontaminated within the class II cabinet, before autoclaving at 131 degrees C for 30 min and subsequent discarding as clinical waste.

Plastic pipettes and tips are decontaminated in a rigid but autoclavable container before disposal as per other solid waste.

Sharps: Sharps put into a sharps bin for off-site incineration.

</tr>
</tbody>
</table>

The expected level of kill should be included. This need not be precise eg "approximately 4 logs reduction in viability" or "below detectable level" is acceptable.

#Contact time should be at least one hour.

Autoclave: Length of sterilisation cycle (min): 30
  Temperature of sterilisation cycle: 131 C

This is checked using autoclave tape and by inspection of the printout of each autoclave cycle.

Note: If no validation for a disinfectant exists (ie the degree of kill for a particular organism is unknown) then laboratory testing could be required to establish its efficacy.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMSC considered
- Containment level is sufficient
- that sharps injury may be considered serious when handling immortalised cells
- the consideration of using temperature sensitive antigens instead of wild type
- the handling of one oncogene containing cell line at one time
- the production of transient cultures rather than stable cell lines for vector production
- the storage of vectors and cells
- risk to health of accidental insertion of the gene sequence into humans
- checks in place to ensure that staff are immunocompetent
- the laboratory facilities and procedures

Date of Significant Change

Project Additional Information

Purposes of the contained use

Recombinant vaccinia viruses (NYCBH strain) expressing two HSV-2 genes (UL-7 and UL-46) will be used to infect BSC-40 cells and the cell lysates used in immunological assays. These HSV genes encode viral tegument proteins which are present in the virus particle as well as infected cells and have recently been shown to be targets of the cellular immune response. The viruses have already been prepared by University of Washington, USA. The ability of the vector to replicate is not affected by the insertion of either of the two HSV-2 genes.

Recipient or parental organism

The two HSV-2 genes encoded by the recombinant vaccinia viruses are highly unlikely to alter the tropism of vaccinia or to enhance (or diminish) its inherent pathogenic
potential. The tropism of vaccinia virus will not be affected by the expression of these two HSV proteins, which although present in HSV-2 virus particles, are internal in that structure and not known to play a role in the attachment and receptor-mediated entry of HSV-2 into target cells.

Host/vector system

Homologous recombination is a recognised natural event in the replication of poxviruses and although we may grow wild type vaccinia virus the possibility of erroneously co-infecting cells resulting in the acquisition of the HSV-2 genes is extremely low. The two HSV-2 genes would not be predicted to alter the tropism and replication properties of the vaccinia vector alone. Vaccinia virus is not present in the human population and therefore in the case of an individual becoming infected with recombinant vaccinia, there would be no opportunity for wild-type virus to acquire the inserted genetic sequences. Vaccinia virus can infect a number of animal species and any risk of release of virus into the environment by an animal source will be avoided by the physical containment of the work within a restricted access (keycode entry) category 2 containment laboratory. Acquisition of the HSV-2 sequences could not occur in a related micro-organism in the environment as wild-type vaccinia virus is not present in any animal species in the UK. No genetic modification work will be carried out, as the recombinant construct will only be propagated in BSC-40 cells.

Origin & function

Recombinant vaccinia expressing two HSV proteins obtained from our collaborator will be grown in BSC-40 cells and the lysates will be used for immunological assays.

Evaluation of foreseeable effects

Vaccinia virus, classified as a hazard group II pathogen, may cause severe disease in people with active skin disorders such as eczema or psoriasis or in immunocomprised individuals such as those with HIV. The addition of an HSV regiment protein gene in the recombinant vaccinia would not be predicted to enhance or diminish its ability to cause disease in comparison to the vaccinia virus vector alone (NYCBH strain). All the work will be carried out at containment level 2, in a single laboratory with restricted access (keycode entry, laboratory personnel only, the Department of Virology has swipe card entry system) and appropriate signs will be posted to indicate vaccinia work is being conducted, outlining persons who are potentially at risk. All members of the department will be informed. Vaccinia virus is not present in the human population and therefore in the case of an individual becoming infected with recombinant vaccinia, there would be no opportunity for wild-type virus to acquire the inserted genetic sequences.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

General disinfectant will be 70% ethanol (contact time, 5 min). Bench disinfectant to be used will be Chloros at 1000 parts per million. All liquid and solid/plasticware waste will be double-bagged in autoclave bags and transported in metal tins to the autoclave facility housed within the Department of Virology. For plasticware, autoclave conditions are 10 min sterilisation cycle at 134 degrees C and for fluids, 25 min at 123 degrees C. Each run on the autoclave is validated (pass/fail) and written records kept and the autoclave is services every 6 months by specialist engineers. Spillage procedures are displayed in the laboratories where the work will be carried out (titled 'Disinfection procedures for GMO spillages'). No sharps will be used, and aerosols will be kept to a minimum as all handling of the viral cultures will be in a class II microbiology safety (serviced every 6 months).

- Purposes of the contained use

To gain an understanding of the entry pathways of herpesviruses and the roles played by individual viral proteins in mediating virus entry.
Recipient or parental organism

<table>
<thead>
<tr>
<th>Recipient/parental viruses:</th>
</tr>
</thead>
<tbody>
<tr>
<td>HSV and HCMV are category 2 human pathogens. They can be propagated and handed under category 2 laboratory condition &amp; They are routinely cultured in this laboratory under category 2 condition. Both viruses are common in the general population and are clinically benign in immunocompetent individuals. Close contact is generally required for transmission of HSV and HCMV. Laboratory associated infection with HSV might occur if virus is introduced to the eyes (e.g. by splashing) This risk is minimised by wearing eye protection and working in a class 2 hood. Laboratory associated infection with HCMV is considered to be highly unlikely. Environmentally, these viruses pose a very low risk. Herpesviruses are enveloped and consequently are labile. Infectivity is completely destroyed by dessication, which is likely to occur in the event of a small laboratory spill. Neither virus has any natural host other than humans, so persistence in the environment, such as in rodents or insects, is considered to be very unlikely. All the viruses covered by this application retain the necessary genes to confer sensitivity to the licensed anti-viral drugs.</td>

<tr>
<td>The recombinant viruses fall into two groups; i) Those in which a gene (or genes) has been disrupted by addition of a stop codon or deleted and replaced with betagalactosidase, green fluorescent protein (GFP), or derivative, or other marker gene; these viruses are used to probe the function of the deleted gene product. ii) Those in which GFP (or derivatives) is fused to one or more viral proteins; Incorporation of GFP into these viruses means that they are fluorescent. These viruses are used to track the pathways used for entry into the cell.</td>
</tr>
</tbody>
</table>

Forseeable effects

A: Health

i) Deletion mutants: There is no reason to suppose that the pathogenicity of these viruses is, or will be, increased. Some of the viruses are attenuated in animal models, others are equivalent to wild type. None is known to have enhanced pathogenicity. ii) Fluorescent viruses; In all cases, these viruses are indistinguishable from wild type (other than the presence of the transgenes), indeed they would be of no use experimentally if they did not mimic wild type virus. Summary; The viruses are considered to be either equivalent to wild type virus or less pathogenic than wild type virus. HSV and HCMV are category II pathogens, thus handling of the recombinant viruses under category II laboratory conditions is considered to be sufficient for containing the risk to health. In general, close contact is required to infect an individual with HSV or HCMV. The risk of this is minimised by handling the viruses under category II laboratory conditions. Wild type HSV and HCMV are handled routinely and safely in the laboratory in this way. |

B: Environment

Herpesviruses are encased in a lipid envelope and thus are labile. They are rapidly inactivated by dehydration or mild detergent. They are very unlikely to persist in the environment. Neither HSV nor HCMV is known to have any natural non-human hosts, (although HSV can infect laboratory rodents). This lack of natural hosts combined with the environmental instability of the virus particle makes inadvertent transmission to rodents or other wild animals very unlikely. |

Origin & function

<table>
<thead>
<tr>
<th>Origin of viral genomic DNA:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mutant viruses are constructed by homologous recombination. For HCMV the starting material is a bacterial artificial chromosome (BAC) clone of the HCMV genome. For HSV, purified wild type viral DNA is used. In each case, virus is reconstituted by transfection into a producer cell. All procedures in the protocol prior to the transfection are carried out in E.coli and as such present no infection risk. Herpessiral genomic DNA can initiate virus production when introduced into a target cell. However, this is very unlikely to happen to a laboratory worker during laboratory manipulation &amp; Sharps are not used and good laboratory practice means the risk is negligible. The viruses fall into two categories: i) Deletion mutants: in which a viral gene is deleted and replaced by marker gene expression cassette encoding betagalactosidase, GFP (or derivatives), or another</td>
</tr>
</tbody>
</table>
fluorescent protein. In these viruses the function of the inserted genetic material is a) to facilitate selection of recombinant viruses and b) to use as a marker of infection.

ii) Fluorescent viruses: in which one more viral genes is fused in frame with GFP (or derivatives), or other fluorescent protein-encoding genes. These viruses are intrinsically fluorescent and are in all other respects comparable to wild type.

In these viruses the function of the inserted genetic material is to make the virus particles fluorescent, while retaining other wild type characteristics, so that the viruses can be used in fluorescence-microscopic studies of viral entry pathways.

Origins of the inserted genetic material:
Beta-galactosidase: this gene encodes an enzyme that digests lactose or other related substrates. It is widely used in molecular biology. The gene originates from E.coli.
GFP (and related fluorescent proteins): these genes are obtained from jelly fish (Aequoria victoria). They form distinct globular domains that can be fused to other proteins retaining function and rendering those proteins fluorescent, They are widely used in molecular biology.

Evaluation of foreseeable effects

These are detailed in the above sections.

Summary: HSV and HCMV are category II pathogens and so can be handled safely in the laboratory under category II working practice. Close contact is required for infection to occur. Laboratory associated infection is a small risk and this is reduced by the use of appropriate protective clothing.

None of the recombinant viruses is anticipated to be more pathogenic than the parental virus.

HSV and HCMV are rapidly inactivated by dessication and neither virus has a natural non-human host so the risk to the environment in the event of a spill is judged to be minimal.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Herpesviruses are 100% inactivated by autoclaving.
All GMM waste, solid (eg flasks, tubes, tips, plates) and liquid (eg culture medium, used virus aliquots) is autoclaved in the department. (Standard discard cycle is 135 degrees C, 3150 mBar, 10 minutes)
Temperature and pressure parameters of each autoclave cycle are recorded and reviewed. Additionally, Browns tubes and autoclave tape are used to assess each run.
The autoclave is maintained to a high standard, sufficient for HPA accreditation, by regular servicing and testing with a 12 point thermocouple. Records are kept in the Department.
All autoclaved waste is placed in yellow biohazard bags and taken for incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
This project (local (GM99) reference: F1C36/07) received approval from a panel of advisers representing the Centre GM Safety Committee at a meeting held on Thursday 8 November 2007. The panel agreed with the classification of the activity and further agreed that the precautionary measures stated in the risk assessment were suitable for these laboratory procedures.

#### Project Ref 99/09.1

- **CU2 Project Title**: GENERATION OF RECOMBINANT HIV-1 TO STUDY THE EFFECTS ON VIRUS PHENOTYPE OF VARIATIONS WITHIN VIRAL GENES ENCODING PROTEINS TARGETED BY ANTIRETROVIRAL THERAPY (POL, GAG AND ENV)

- **Class**: Class 3
- **Culture Volume Class 2**: <150 ml
- **Non-GMM**: Consent Granted
- **Consent Granted**: Being Processed
- **Tick if notifying a connected programme of work**: N
- **Historical Date of Additional Info**: Project transferred to GM554
- **Significant Change ID**: 99/09.1a
- **Date of Significant Change**: 25/03/2013

### Project Additional Information

- **Purposes of the contained use**: To study the effect of mutations encoding antiretroviral resistance upon replicative function and drug susceptibility
- **Recipient or parental organism**

02/03/2022
Introduction

Wild type HIV-1 (wt HIV-1): Wild type HIV-1 describes infectious HIV-1 viruses that do not exhibit resistance to therapeutic drugs and lack the according resistance mutations. These are produced by eukaryotic cells transfected with plasmids such as pHXB2D, pNL4-3 and pMJ4. All plasmids contain single retroviral genomes (proviruses) derived from patient isolates or laboratory strains and produce infectious viruses when transfected into permissive cells.

HIV-1 vectors: HIV-1 vectors are plasmid clones of HIV-1 proviruses derived from lab strains which are NOT replication-competent. Those vectors used within this project have deletions within their genes to prevent production of infectious virus. Such deletions will be contained within either the gag (protease), pol (RT) or env genetic regions. Such vectors also carry a resistance gene e.g. ampicillin, in order to enable the selection of vector containing prokaryotic cells. The risk from these vectors is minimal in prokaryotic cells e.g. E. coli, as the HIV-1 genes are unable to be expressed. As a result work involving these vectors may be carried out under ACGM class 1 conditions as the clone itself is non-infectious. Once transfected into an appropriate cell line in the presence of full length genes (for which the vector is defective) infectious virions are able to be produced. Vectors used within this investigation will be defective due to deletions in the gag, pol and env genetic regions.

Drug resistant HIV-1: Genes of interest encoding mutations will be amplified from clinical material derived from patients exhibiting resistance to drugs after therapy, or generated by site specific mutagenesis upon wt genetic material. These mutations within the gene of interest will encode for an HIV-1 with a phenotype of resistance to a particular, or a combination of, antiretroviral drugs.

Recombinant viruses: Recombinant viruses will be constructed by homologous recombinations between the HIV vectors (with deletions in the appropriate genes) and genetic material derived from either laboratory strains (simulating wild type virus) or 'normal' genes in the context of the same viral background. The presence of both components is required within the appropriate cells before recombination can take place.

Risk of infection

Levels of infectious recombinant virus produced (under containment conditions) during this investigation are anticipated to fall within the ranges measured in the blood of persons infected with HIV-1, although many viruses with drug resistance mutations replicate at reduced rates compares to wt virus. The risk of HIV-1 infection following exposure to infected blood through sharp injury is estimated to be around 0.3% , whereas that associated with a splash exposure with blood is in the region of 0.09%. This in absence of Post - Exposure Prophylaxis (PEP).

Management of Infection

If exposure does occur, it is managed through the administration of PEP constituting a four week course of antiretroviral drugs. Although the success rate of this course is high, it is not 100%. Some recombinant and wild-type viruses contain mutations which render them of increased susceptibility to particular antiretroviral drugs. Some resistance mutations may affect more than one drug; however there are sufficient drug combinations currently available against drug resistant HIV-1.

Other risks

The potential integration of a complete retroviral vector into the host genome may also have the potential to affect host cellular function i.e. insertional mutagenesis, leading to the possibility of tumour formation, subsequent to exposure to wt lentiviral vectors and HIV-1 lab strains. Integration of complete lentiviral vectors into host cell genomes has been recently described however the overall likelihood of such events is thought to be low (J. Virol. 2008 Oct 22). Additionally, it may be speculated that the transduction of eukaryotic cells with expression vectors, or infection of such cells with recombinant HIV-1 or retroviral vectors may also result in the immortalisation of the cell line with altered properties. Such cells may retain the ability to establish tumour formation within exposed laboratory workers following a significant exposure although the likelihood of such an event is considered extremely remote. Even in such a rare occurrence, the chances of such cells becoming established and productively proliferating within the worker would be further limited by immune defence mechanisms such as MHC mismatching. Furthermore, mutations within the env region may result in the altered tropism of viruses. Such events as these however would be unlikely to influence the susceptibility of the virus for particular drug therapies in the event of
Environmentally, these viruses pose a minimal risk. HIV-1 is an enveloped particle and is consequently labile. There is no reason to suspect that mutations will result in structural changes to progeny virions, thus it is unlikely that any changes to viral genes will affect its interactions within the physical environment. Infectivity of wt HIV-1 is completely destroyed by desiccation or disinfection and waste disposal protocols implemented within the containment level 3 (CL3) laboratory, the chance of residual virus remaining infectious is unlikely.

Virus producing cell lines

The cell lines, MT4 and C8166 that will be used to propagate the virus in vitro are persistently infected with HTLV-I (although C8166 cells carry, but do not express the HTLV-I genome). C8166 is derived from umbilical cord blood cells (Virology. 1983; 129:51) whereas MT4 is a human T cell lymphoma cell line (Acta Microbiol Hung. 1992; 39(3-4):271-9). Both have been immortalised by HTLV-I virus. Cell lines were chosen as they exhibit characteristic morphologies when infected by HIV-1. There is a risk of exposure to HTLV-I when working with MT4 cells, although the virus is known to be highly cell-associated and the chance of infection is low. Additionally, the risk of HTLV-I virus particles recombining with lentiviral vectors is minimal, as is the likelihood of recombination with recombinant HIV.

In summary: the main consequence of exposure to vectors engineered to express viral genes is the potential transfer of GMM to the laboratory worker. Laboratory associated exposure to the recombinant virus would carry similar implications as exposure to the 'non-resistant' wild type HIV-1 (grown from clones in cells) and drug resistant HIV-1 (derived from patient material). In spite of any such mutations effective drugs remain available to treat infection with recombinant viruses. Additionally, such risks working with such GM organisms are further reduced by good working practice and adherence to SOPs under CL3 conditions. The availability of PEP further reduces the risk of infection after a significant exposure. Therefore the overall likelihood of infection is very low. Should infection occur despite PEP then consequently the health risks are those associated with wt HIV-1 infection.

**Host/vector system**

**Characteristics of the GMO**

Recombinant viruses will fall into three groups:

1) Those in which inserted regions, cloned directly from patient samples, contain mutations which encode for resistance to particular (or a combination of) antiretroviral drugs.

2) Those in which inserted regions are cloned directly from wild type HIV-1 laboratory strains such as pHXB2.

3) Those in which inserted regions contain mutations generated in vitro which represent intermediate 'halfway' stages between drug resistance and wild type

**Forseeable effects**

1) Health

There is no reason to expect that viruses generated by this work will be more pathogenic than 'non-resistant' wtHIV-1 virus. There is also the possibility that exposed laboratory workers may acquire a mixed infection (of both resistant and non-resistant HIV-1) although this risk is reduced as the viruses will be cultured under CL3 containment conditions however any such exposure to mixed viral populations is considered to pose no greater danger than infection by either virus individually. Although resistance mutations may affect more than one drug there are considered to be sufficient numbers of drugs, with different mechanisms of action, currently available for application against drug-resistant virus.

2) Environment

The presence and persistence of recombinant viruses within the environment is extremely limited and therefore adherence to disinfection and waste disposal protocols implemented within the CL3 laboratory further reduces the chances of viruses' surviving within the environment.
Cells proposed for use within this project will fall into 2 classes:

i) Prokaryotic cells required for the propagation of HIV-1 vectors. These include E. coli DH5α, TOP10 and equivalent cells.

ii) Eukaryotic cells required for construction and propagation of recombinant HIV-1. These include 293T, MT4, C8166 and equivalent cells.

Origin of viral genomic genetic material

Several HIV-1 vectors are intended for use within this investigation. Genetic regions of these vectors will be replaced with regions of interest in order to study the effects regarding susceptibility to certain antiretroviral drugs and on viral replication.

The pHIVΔRTBstEII vector contains the complete provirus of the HIV-1 laboratory strain HXB2D with a 1.4kb deletion within the RT region. The clone is non-infectious but when transfected into an appropriate cell line with full length RT coding sequence provided in trans infectious virus is produced by homologous recombination. All procedures within the protocol prior to transfection are carried out in E. coli and present no infection risk. This vector is unable to initiate virus production when introduced into a target cell in the absence of a full length RT coding sequence and therefore is unlikely to regain wild type phenotype in the absence of RT. This minimises the level of risk to the laboratory worker to the vector during laboratory manipulations. Sharps are not used and good laboratory practice means the risk to workers is negligible.

This plasmid and its equivalents [containing deletions/mutations within the gag (protease), pol (Integrase) and env] will be used to determine the impact of mutations within these regions upon resistance

All molecular clones used within this investigation will be obtained from the National Institute of Health AIDS Research and Reference Reagent program (www.aidsreagent.org)

Origins of the genetic material to be inserted into replication-deficient vectors

Inserts encoding for drug resistance: Genes of interest encoding mutations will be amplified from clinical material derived from patients exhibiting resistance to drugs after therapy. These mutated genes of interest will encode for an HIV-1 with a phenotype of resistance to a particular, or a combination of, antiretroviral drugs.

Inserts coding for 'non-resistant' wild type HIV-1: Genes of interest (gag, pol and env) will be cloned from the HIV-1 laboratory strains pHXB2D, pNL4-3 and pMJ4. All three plasmids contain proviruses derived from patient isolated and laboratory strains which produce infectious virus when transfected into appropriate cells. Such inserts will encode for an HIV-1 virus without a resistance phenotype.

Inserts containing intermediate mutations for HIV-1 drug resistance: Genes of interest will be cloned from the HIV-1 laboratory strains and isolates. Sequences will then be altered using in-vitro mutagenesis to induce partial sequence identity to drug resistance motifs, simulating intermediate stages in the development of drug resistance to particular (or a combination of) antiretroviral drugs.

Cloning vectors: Theses are commercial vectors used for the purpose of cloning and amplifying regions of interest and include pCR2.1TOPO derivatives, pUC vectors, pBLUESCRIPT vectors, pcDNA3.1, pCMV/Zeo and pEGFP-1.

Evaluation of foreseeable effects

These are detailed in the above sections.

To summarise: The main risk is accidental exposure of laboratory workers to infectious recombinant and wild-type HIV-1.
The handling of bacterial cultures and plasmids for cloning is carried out under ACGM class I conditions and therefore poses little risk, if any. At this stage of the work the risk of exposure of workers to infectious virus is minimal.

The HIV-1 vectors are derived from well characterised laboratory strains of HIV-1. These are not able to form infectious particles unless in the presence of a full length RT region in trans (either wild type or mutated). Such an event would ONLY occur within the contained environment of the CL3 suite. An additional foreseeable risk is the oncogenic potential of the vector to the host genome upon potential exposure. The probability of such an event is extremely low and in this respect these vectors pose a minimal risk.

The defective HIV-1 vectors can ONLY form replication-competent viruses when both the HIV-1 vector and genetic region of interest are present within the cell. Recombination in the absence of either is extremely unlikely, as is the chance of spontaneous recombination with retrovirus genomes within, or associated with the aforementioned cell lines. The presence of replication competent recombinant HIV-1 poses the main risk to laboratory workers, although the risk is no more significant than that posed by handling wild type HIV-1 virus. The main risk of exposure in the laboratory is via cuts and abrasions with contaminated sharp instruments, or splash exposures as HIV-1 is not readily transmitted by aerosol. Through adherence to CL3 working guidelines and good laboratory practice, this risk is significantly reduced. The use of PEP after accidental exposure makes the risk of an established infection very low. Should infection occur, the recombinant viruses are unlikely to be any more pathogenic than those circulating in infected patients. No genes of the source strain of HIV-1, from which the lentiviral vector has been derived, have been shown to be oncogenic or teratogenic.

The potential risk of exposure to HTLV-I during this work has been discussed previously, however as work with this cell line is confined to the CL3 suite; the risk of exposure to this virus is minimal.

Environmentally, providing correct guidelines upon disinfection and waste are followed there are no foreseeable risks posed by either the wild type or recombinant viruses due to their nature as enveloped viruses.

Container and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Laboratory workers are responsible for the following procedures:

Class 1 GMM products include HIV-1 genetic regions of interest derived from clinical samples or laboratory strains which have been cloned into plasmid vectors and the production of replication defective viral vectors.

Method of Class I GMM waste disposal

All GMM waste both solid (e.g. flasks, tubes and plates) and liquid (e.g. culture medium) is double bagged into clear autoclave bags and placed into metal autoclave tins for autoclaving. Autoclaving conditions follow the NHS diagnostic guidelines and adhere strictly to the requirements of the Clinical Pathology Accreditation. Standard autoclave cycle conditions are 135°C at 3150 mBar for 10 minutes. Temperature and pressure parameters of each autoclave cycle are recorded and reviewed. Additionally, Brown's tubes and autoclave tape are used to assess each run.

Spillages are dealt with using KLORSEPT granules. Disinfected spillages are then absorbed onto paper towels which are then autoclaved.
Methods of Class 3 GMM waste disposal

Class 3 waste products will include cell culture medium containing antiretroviral drugs, cells and wt/recombinant HIV-1 virus.

All CL3 GMM liquid waste is emptied from plastic culture flasks into a sweetie jar within the MSC containing 2x6g sachets if Vernagel gelling agent. All CL3 GMM solid waste (e.g. flasks, tubes, tips and plates) are then immersed in a container of 10% Trigene Advance located within the microbiology safety cabinet and allowed to disinfect for at least 16 hours. Lids are sealed upon 2L lidded containers and liquid contents are allowed to gel before being double bagged, and loosely swan-necked prior to disinfection and placed within a sealable plastic autoclave bucket.

After disinfection of solid waste is allowed to take place the container is removed from the hood. Disinfected solid waste is poured into a sieve placed over a sink whilst disininfected liquid waste is poured down the sink and washed down the mains drainage with copious amounts of water. All disposable solid waste from the sieve is placed into double autoclave bags which are disinfected and swan-necked loosely. Laboratory plasticware including jugs are double bagged and loosely sealed by swan-necking prior to further disinfection. Bagged and sealed plastic ware (i.e. beakers and jugs) are then placed in a sealable metal tin for autoclaving. The remaining disinfected solid waste is placed (using the sieve) into double autoclave bags. These are loosely sealed prior to disinfection and placed into sealed yellow autoclave bins.
After each work session all surfaces are disinfected with 5% Trigene Advance in order to eliminate any residual cirus. At the end of each work day, autoclave bins and sealed metal tins are surface disinfected with 5% Trigene Advance before they are placed in a lockable trolley by a trained member of the CL3 team, and transported directly to the local autoclave (within the department) for immediate incineration under standard autoclaving cycles. No GMOs will remain viable after treatment.

After autoclaving, sealed plastic autoclave bins will be labelled and sent off site for incineration. Metal transport tins and any plastic ware from the CL3 are returned directly to the CL3 suite in order to prevent them entering general laboratory circulation.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

The projects covered under this application aim to exploit lentiviral vectors as gene delivery systems for immunotherapy. To this end we have 2 complementary approaches. The first involves the use of lentiviral vectors to deliver immune-modulating (for example, T cell receptors, co stimulatory molecules or cytokines) into immune cells. Genes encoding immune modulating genes will be cloned into lentiviral vectors, and lentiviral particles will be used to transduce mouse or human immune cells or haematopoietic cells for the production of modified immune cells which can be used for immunotherapy of cancer. The second approach involves using lentiviral vectors for vaccination strategies. In this case lentiviral vectors encoding model or tumour-associated antigens are used to immunise mice. It has previously been shown that lentiviral vectors are very potent immunising agents and we will be investigating how the immune responses are activated, and whether they would be appropriate immune responses to control an emerging tumour, for example in an in vivo model of leukaemia.

GMO is the lentivector: 3rd generation HIV vector with virulence genes deleted, on split plasmids
Lentiviral particles will be used to transduce a range of cells in the laboratory: standard laboratory cell lines (e.g. 293T, HeLa, NIH3T3 etc.). Human and mouse haematopoietic cells (in particular T cells and Dendritic cells as well as other immune cells).

The viral vectors themselves are not pathogenic to humans, all virulence genes have been deleted from the original parent viral sequences. However, since these vectors have the potential to integrate into human DNA there is a low risk that infection could damage the health of the laboratory worker directly handling the viruses. We are planning to use self-inactivating (SIN) vectors to make viral particles that have been shown to significantly reduce the risk of insertional mutagenesis. In addition lentiviral vectors have been demonstrated to insert preferentially into coding regions of DNA, rather than the more risky promoter or control regions. Therefore, when considering all
these factors the risk to humans is very low.

Because the lentiviral vectors are replication deficient and undergo a single infection of initial target cells, there is no risk of spread to other recipients. The vectors will only be used as an antigen delivery system to immunise, once the viral vector is injected into mice the immunised animal is not considered genetically modified and the viral vector no longer exists. Thus, there is no risk from this point.

A WPRE element is included in these vectors to aid translation of the inserted gene. This encodes a putatively oncogenic protein (protein X) which has been mutated in all vectors. The X protein could potentially be a risk factor, but the use of vectors with non-functional X proteins negates this risk.

The vector particles are produced with a broad host specificity by using the Vesicular Stomatitis virus (VSV) G protein or other coat proteins. This may increase the susceptibility of different cells to the virus, but will not increase the risk of insertional mutagenesis.

**Host/vector system**

Vectors are standard microbiology plasmids. All cloning is performed using commercial disabled bacterial strains that are not harmful to health or the environment. The promoters used for gene expression in the lentivector are not generally expressed in bacteria.

pUC derivatives or standard molecular biology cloning vectors such as the following, or related vectors: pCMVR8.91 (packaging plasmid), pMD-G (VSV-G envelope plasmid) & pHRSIN (vector plasmid Dermaison et al (2002) Human Gene Therapy 13:630-640.).

Some vector plasmids obtained from Prof. M C’s laboratory at UCL may contain sequences to enhance expression in transduced cells (vFLIP latent gene expressed by KSHV) such as dendritic cells or T cells. Human and mouse genes of the NF-kB pathway. MAPK activators: MKK6EE kinase (p38 activator), MEK1 N3 ED kinase (ERK activator) and MKK7-JNK1 (JNK1 activator.)

**Origin & function**

The genetic material will be of bacterial origin for cloning as follows:

HB101, DH5alpha & other common disabled E. coli K-12 or B derivatives. Only disabled bacterial strains will be used.

The inserted sequences may be amplified originally from mouse or human genomic DNA or cDNA before cloning into bacteria.

For work investigating lentivectors as immunisation agents, the majority of the inserted nucleic acid encodes model antigens. These are inert gene products that do not have a biological function in the transduced cells, and will not effect growth and survival of cells receiving these vectors. For the delivery of immunomodulating genes there are genes encoding immune modulating proteins which may alter the immune function of the cells they are expressed in, but it is highly unlikely that this would lead to transformation of the cells in question.

Genes such as the vFLIP latent gene from KSHV or MAPK activators may occasionally be incorporated into lentiviral vectors to enhance immune responses to the inserted gene. It is not expected that these genes will alter the biological activity of inserts encoded in the same vector. However these sequences do have the potential to effect expression of an oncogene or tumour progression factor depending on the site of integration of the vector.

A WPRE element is also included in the vector plasmid to aid translation of the inserted gene or sequence. This encodes a putatively oncogenic protein (protein X) which has been mutated in all vectors and is not functional.

The model antigens, genes encoding immune modulating genes and mutated WPRE element are unlikely to cause harm if accidentally transferred into humans. We do identify an increased risk when using KSHV or MAPK activating genes. It is possible that in the unlikely event of a breach of containment, accidental injection into workers may result in the undesirable insertion of these genes next to an oncogene. However, this risk on insertion at a site such as this is extremely low and it is unlikely that any one gene has the capacity to act as an oncogene on its own.
Evaluation of foreseeable effects

For generation of lentiviral vectors only disabled bacterial strains will be used and we do not foresee any effects.

The most hazardous GMMs are the HIV-based vectors. The most hazardous step and the only risk that we identify at the moment is injection of the transducing particles into mice because this involves the use of needles and the risk of personal injury.

Containment and control measures for GMOs that are not micro-organisms (e.g. GM animals & plants)

All GMOs in this assessment are micro-organisms.

For immunisation of mice with lentiviral particles it is requested that the animals are injected in a level 2 designated room, but outside a laminar flow hood. Lentiviral particles are extremely sensitive to desiccation and no risk associated with infection due to air-borne particles has been identified. Injection of mice while in a laminar flow hood restricts the movement and in fact increases the risk of needle stick injuries due to the difficulty of manouevring in the confined space. The site of injection is sprayed with ethanol to inactivate any lentiviral particles leaking from the injection site (though this volume is typically less than 10-20 l).

Once the lentiviral particles are injected into mice, the inserts will be permanently integrated into the genomes of host cells, and no new viral particles will be produced. Therefore, subsequent to immunisation the mice are not considered genetically modified organisms and no risk is associated with their handling and housing. All waste from the housing of mice is disposed of by incineration and this therefore remains the appropriate method of disposal for waste from animals immunised with lentiviral vectors. Likewise cadavers will also be disposed of by incineration according to standard UCL procedure.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GMM/1: line 1.29 or GMM/2: lines 2.13 (as applicable)

For routine cleaning, all surfaces will be wiped down with 70% alcohol after use which is known to be effective against enveloped viruses. Liquid GMM waste will first be disinfected using Presept overnight (effervescent disinfection tablet containing Troclosene Sodium) to give a final concentration of 2500ppm available chlorine (1x2.5g tablet/500ml waste) before being disposed of down the sink. This is a standard procedure and viability is below detectable levels. Solid GMM waste will be placed in autoclave bag, and autoclaved via the central collection service for GM waste.

The autoclave sterilizing cycle is carried out at 135°C for 5 minutes. All sharp objects, such as pipette tips are placed in a rigid plastic container prior to disposal in autoclave bags. Needles (without dissociation from the attached syringes) are placed in sharps bins which are sealed before being added to the autoclave bag.

It is not possible to estimate a degree of kill for a non-replicative virus. However, autoclaving and 2500ppm available chlorine is sufficient for a 100% inactivation of enveloped viruses.

For immunisation of mice all needles will be disposed of in dedicated sharps bins (without dissociation from the attached syringe). The sharps bins are then placed in autoclave bags and autoclaved via the central collection service for GM waste.

Note that in the event of spills, 70% ethanol will be used for surface disinfection. This agent is effective and widely used for inactivating enveloped viruses. Absorbent tissues will be used to mop the affected area and will then be disposed of by autoclaving as described above.

Temperature and pressure parameters for each autoclave run are recorded on a printout and reviewed. The autoclave is checked weekly and a 12 point thermocouple test is performed annually. The autoclave validation records are audited annually and a certificate is issued.

All solid waste (including sharps) are placed in autoclave bags and collected from the department to be taken to the central autoclave. The bags are transported to the
autoclave in a rigid, lidded container.

1.10-1.13 These sections seem to be rather generic with no real detail as to what genes they will be inserting (described for example as "immuno-modulating genes"), what micro RNA/siRNA sequences they will be inserting, which cell types will be used etc?

1.10 Immuno-modulating genes such as T cell deceptors, co-stimulatory molecules, cytokines/chemokines and the receptors for cytokines/chemokines will be studied for their function in the engineered cells. MicroRNA or siRNA sequences to control expression of inserted sequences in specific cell types. For example, the microRNA mir142 restricts expression of upstream genes to non-haematopoietic cells only (Brown et al (2006) Nat Med 12:585). Alternative micro RNA sequences may be used to allow expression only in immune cells, especially dendritic cells. SIrNA would be used to specifically down-modulate protein levels of a gene of interest in transduced cells, for example, a co-stimulatory molecule or cytokine or the endogenous T cell receptor genes.

1.12 Some vector plasmids obtained from Prof. M Cs' laboratory may contain sequences to enhance expression in transduced cells such as dendritic cells or T cells.

1.13 Cells: standard laboratory cell lines (e.g. 293T, HeLa, NIH3T3 etc.). Human and mouse haematopoietic cells (in particular T cells and Dendritic cells as well as other immune cells).

1.25 They indicate the autoclave waste will be "autoclaved later" is there any issue with waste hanging around to be autoclaved and how long "later" actually would be?

All GM waste is placed in Autoclave bags which are changed on a regular basis. All autoclave bags are kept in rigid containers. All sharps are placed in lidded containers. They are then collected by the porter, who autoclaves them on the service floor. This is what was meant by autoclaved later.

GMM2

2.16 Question: Does you laboratory operating procedure permit the use of sharps (including glass pipettes)?

Answer: No. But they intend to use sharps to inject the lentiviral vectors into mice or does the question relate only to the portion of the work which will be done in the lab rather than in CBU.

Yes, we meant that no sharps are used in the laboratory setting, but of course they are used in the animal house.

Project Additional Information

Purposes of the contained use

The interaction between tomato and the leaf mould pathogen C. fulvum is being investigated. A large number of C fulvum secreted proteins are recognised by specific tomato disease resistance proteins (Cf proteins) to activate a plant defence response. The purpose of this project is to construct vectors that facilitate transient expression...
of the ECP1, ECP2, ECP4, ECP5, Avr4 and Avr9 genes in tobacco and tomato to investigate their capacity to induce a hypersensitive plant defence response (HR). The assay provides a robust and sensitive procedure for detecting Cf resistance gene function and will obviate the need to perform conventional pathogen inoculation tests.

Recipient or parental organism

The C. fulvum Avr and ECP genes will be cloned into potato virus X (PVX). A cDNA copy of PVX cloned into the pGREEN vector (see www.pgreen.ac.uk) containing cloned ECP or Avr genes will be maintained in E coli DH5a or DH10B which are both K12 derivatives. For infection of plants the recombinant PVX clones will be introduced into Agrobacterium tumefaciens strain GV3101 containing the pGREEN helper plasmid pSOUP. Potato virus X is a mechanically transmitted plant virus whose host range is restricted to solanaceous plants such as tomato, potato and tobacco. PVX is unable to infect animals. The A tumefaciens strain GV3101 is non-pathogenic to humans, and other animals.

Host/vector system

Recombinant PVX will be introduced into tobacco and tomato seedlings by inoculation with Agrobacterium. With respect to plants, A. tumefaciens GV3101 is a 'disarmed' strain that is unable to cause disease. The ECP and Avr proteins are cysteine-rich pathogenicity determinants for C fulvum infection of tomato, its only known host. These fungal proteins are considered unlikely to enhance the pathogenicity of bacterial or viral pathogens such as Agrobacterium and PVX. The major environmental concern regards the possible escape of Agrobacterium containing cloned PVX, which is normally only mechanically transmitted. In the form of a recombinant plasmid in Agrobacterium this provides a potentially novel route of infection to a broad range of plants that are susceptible to Agrobacterium infection. The consequence of expressing recombinant PVX expressing Avr4 or Avr9 in tomato plants that express the cognate resistance protein (Cf-4 and Cf-9) is plant death. However, studies have shown (Thomas et al., 2000) that recombinant PVX is less virulent and cloned inserts are unstable and rapidly lost. Cloned inserts are therefore unlikely to be propagated. No deleterious effects of expressing the other ECP genes in tobacco and tomato are envisaged.

Origin & function

The ECP and Avr genes have been isolated from the plant pathogenic fungus Cladosporium fulvum. The ECP and Avr proteins are secreted into the leaf apoplast during infection and most likely function as pathogenicity determinants. These secreted proteins are recognised by specific tomato disease resistance proteins (Cf proteins) to activate a plant defence response. The purpose of this project is to construct vectors for transient expression of the ECP1, ECP2, ECP4, ECP5, Avr4 and Avr9 genes in tobacco and tomato to investigate their capacity to induce a hypersensitive plant defence response (HR).

Evaluation of foreseeable effects

In the case of the bacterial hosts that will be utilised the strains are E coli K12 derivatives that are unable to grow in nutrient-poor conditions ie they are unlikely to grow outside normal laboratory conditions. Potato virus X is a mechanically transmitted plant virus whose host range is restricted to solanaceous plants such as tomato, potato and tobacco and is unable to infect animals. Therefore, all of the recombinant clones are extremely unlikely to present a greater hazard to human health than the non-modified hosts ie equivalent to ACDP hazard group 1.

The major environmental concern regards the possible escape of Agrobacterium containing cloned PVX, which is normally only mechanically transmitted. In the form of a recombinant plasmid in Agrobacterium this provides a potentially novel route of infection to a broad range of plants that are susceptible to Agrobacterium infection. The consequence of expressing recombinant PVX expressing Avr4 or Avr9 in tomato plants that express the cognate resistance protein (Cf-4 and Cf-9) is plant death. However, studies have shown (Thomas et al., 2000) that recombinant PVX is less virulent and cloned inserts are unstable and rapidly lost. Cloned inserts are therefore unlikely to be propagated. No deleterious effects of expressing the other ECP genes in tobacco and tomato are envisaged.

In theory, Agrobacterium could survive in the environment. However, in the absence of appropriate selection, and a potential fitness advantage, the recombinant plasmids are unlikely to be maintained. ecological studies have demonstrated that only natural non-pathogenic strains are successful saprotrophs, implying that naturally pathogenic strains are poorly adapted to survival in the absence of the host. Therefore a disarmed pathogen A tumefaciens strain GV3101 is unlikely to survive for long in the environment. In addition, the pGREEN vector has been specifically chosen for these experiments since its mobilization functions have been removed, and it could not be transferred to other agrobacterium species, and it's replication is dependent upon functions located on the plasmid pSOUP.

The chances of transforming indigenous species with Agrobacterium is therefore extremely unlikely tiven the level of containment that will be applied (see below). The
chances of plasmid maintenance are also extremely low. If indigenous plant species were transformed by Agrobacterium, PVX infection is unlikely to occur since the host range is restricted to solanaceous species. The cloned ECP sequences are unlikely to be maintained in PVX since they significantly reduce viral fitness, and in any case, no deleterious effects, or fitness benefits, of ECP expression are envisaged in plants.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Tomato or tobacco seedlings will be grown in containment level 2 plant growth rooms and away from glasshouse facilities that contain other tobacco and tomato plants. Two doors separate each of the rooms from the corridor and access is restricted to authorised personnel only. Dedicated laboratory coats are worn at all times and are not taken beyond the outer door (except for sterilising and cleaning). No plants will be allowed to grow beyond the two-leaf stage and no plant material will be removed from the growth rooms for analysis. All plant material will be sealed in appropriate bags before removal from the growth rooms and transporting to the autoclave for destroying.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For E.coli and Agrobacterium work all manipulations will be performed in a containment level 2 laboratory with the appropriate handling procedures. All contaminated material will be destroyed by autoclaving (130°C for 15 minutes) before disposal down a drain.

For PVX-infected plant material appropriate disinfection and waste management procedures will be instituted in the growth rooms. All plants, growth media, plant pots and seed trays will be bagged within the growth rooms and then destroyed by autoclaving (130°C for 20 minutes) using a facility located on the same floor. All autoclave plant material will then be disposed of in a landfill site. Growth rooms will be maintained to a high level of cleanliness. Periodically rooms will be emptied and surfaces will be disinfected with bleach. These measures will reduce the likelihood of all hazards to negligible.

All concerns raised by Committee members have been addressed by the current version of the risk assessment.

02/03/2022
We will study genes and their enzyme products that mediate nitric oxide resistance mechanisms in Salmonella enterica LT2a. We will also study regulatory genes encoding nitric oxide responsive transcription factors that are responsible for activating the expression of nitric oxide resistance genes.

The GMOs are (i) S. enterica LT2a-derived strains containing mutations in the nitric oxide resistance pathways mediated by flavohaemoglobin (Hmp), flavorubredoxin (NorV) and nitrite reductase (Nrf), and mutations in regulatory genes responsible for activating expression of these pathways (norR and fnr); (ii) mutant strains complemented with the cognate genes expressed from multi-copy plasmids; (iii) E. coli K12 derivatives containing S. enterica structural and regulatory genes involved in nitric oxide resistance carried on multi-copy plasmids, in some cases under the control of inducible promoters.

The expressed proteins in (ii) and (iii) are involved in mediating resistance to nitric oxide (NO), by reducing it to nitrous oxide or ammonia. Enteric pathogens such as S. enterica encounter NO in the phagolysosome of activated macrophages and neutrophils. There is some evidence to suggest that NO resistance mechanisms may confer a selective advantage on Salmonella strains growing in the host environment. S. enterica LT2a is a laboratory-attenuated strain, has low colonising potential for humans and animals and is not useful for pathogenicity studies. S. enterica LT2a does not contain toxin or invasion genes, and thus in a human or animal host is incapable of crossing the intestinal epithelium and never gets as far as the blood-and lymph-norne phagocytic cells. Thus the expression of NO resistance genes in complemented mutants of this strain is deemed highly unlikely to produce a phenotype that is very harmful to humans or animals. Likewise, E. coli K12 strains are recognised as non-colonising, and the risks associated with expressing S. enterica genes in E. coli K12 are deemed negligible. S. enterica LT2 strains have been widely used for more than 30 years as model organisms in which to study basic biological processes. Numerous S. enterica genomic and expression libraries have been constructed and maintained in E. coli.
K12 strains. It is, therefore, likely that any hazardous effects of expressing LT2 genes in E. coli would, if they exist, have been identified by now.

**Host/vector system**

E. coli K12 strains are recognised as non-colonising and disabled and may be considered to be equivalent to ACDP hazard group 1. They are not considered pathogenic to humans or animals. They are expected to have limited survivability in the environment and most have auxotrophic requirements which are unlikely to be satisfied outside laboratory culture. S. enterica is an ACDP hazard group II organism. Strain LT2 is an attenuated derivative, which does not express toxin or invasion genes, and is not regarded as pathogenic towards humans.

The vectors used are either non-mobilisable 9pUC series, pLitmus series, pBluescript series, Supercos, pREP4, pT7 series) or mobilisation-defective (pET series, pQE series, pBR322 derivatives).

**Origin & function**

Genes from S. enterica LT2a coding for functions involved in nitric oxide metabolism, specifically flavohaemoglobin, flavourubredoxin and nitrite reductase, and the regulators of their expression. Mutants defective in these systems will be constructed by a PCR-based methodology, and the mutations will be complemented by the cognate genes expressed from their own promoters on multicopy plasmids. In some cases, expression of genes will be from promoters (for example paraBAD) that allow regulatable expression; though over expression will not be attempted. E. coli K12 strains will be used as intermediates in cloning procedures.

**Evaluation of foreseeable effects**

Enteric and other bacterial pathogens encounter nitric oxide (NO) synthesised by the inducible NO synthase in activated macrophages. NO is thought to be made in response to bacterial infection, and is part of the host's non-specific defence mechanisms. Pathogens have therefore evolved mechanisms to counter the toxic effects of NO, those that have been characterised include flavohaemoglobin (HmP), flavourubredoxin (NorV) and nitrite reductase (NrF). The objective of this study is to construct S. enterica mutants defective in one or more of these pathways and to test the sensitivity of strains to NO in pure culture. To complete the analysis, mutants will be complemented with their cognate genes expressed from non-mobilisable or mobilisation-defective plasmids. E. coli K12 strains will be used as intermediates for cloning procedures. The use of non-mobilisable and mobilisation defective plasmids will ensure that the NO resistance genes are most unlikely be transferred to other pathogens or potential pathogens in which they could conceivably confer a selective advantage. The use of attenuated strains of S. enterica and E. coli will ensure that moderately enhanced expression of NO resistance genes (from multi-copy plasmids) will not confer a selective advantage, since these strains are incapable of invasion and colonisation in animal hosts. Our S. enterica mutants will be made available to collaborators, who will transfer the mutations into other strains by phage-mediated transduction and will conduct pathogenicity trials. Risk assessments and notification of these future aspects of the work will be prepared separately.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste medium from small-scale cultures (<0.5 litres) is autoclaved. All contaminated glassware and plastics are treated either by autoclaving or with a broad-spectrum disinfectant. Liquid waste, once treated, is disposed to drains; solid disinfected waste (plastics, agar) is incinerated. The methods of waste disposal have been validated and it is known that no viable GMOs remain after treatment.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Purposes of the contained use

To construct gene libraries from bacterial genomic DNA obtained directly from environmental populations and with no prior culturing. The libraries to be screened in different, non-pathogenic, bacterial hosts for any clones that contain genes that determine phenotypes of importance in the nitrogen cycle and in certain biotechnological applications.

Recipient or parental organism

The hosts will be Escherichia coli K12 and derivatives thereof, Rhizobium leguminosarum, Paracoccus, Streptomyces spp, Bacillus subtilis, Azotobacter vinelandii, Rhodobacter spp and Nitrosomonas spp. E. coli K12 is not recognised as a colonising strain of this species and the other genera are, as far is known unable to colonise or cause any damage to animals, plants or the environment. These strains will be hosts for Metagenomic libraries containing DNA fragments obtained directly from bacteria isolated from the environment and cloned in cosmid vectors. By their nature, such libraries and the individual recombinant plasmids within them will be very varied in their identities. Therefore, the characteristics of any given GMO are impossible to predict.

In terms of the effects, therefore, of any given GMO, the worst-case scenario might be that inadvertently, a region of DNA that has the determinant for an unknown toxin is cloned and that the GMO that harbours that gene is accidentally released, such that it, or the cosmid carrying the gene has at a selective advantage, causing a significant increase in the population size of bacterial strain that carried it. However, one has to say that the list of possible detrimental gene functions found in bacteria in natural communities is limited only by one's imagination. This is particularly the case here since the genes in the library will, in many cases, be from bacteria that have not even been cultured and are therefore totally uncharacterised.

Although this sounds rather scary, in reality, it is no more so than when uncharacterised environmental samples are plated out and/or bacteria are cultured in laboratory conditions after enrichment cultures. Increasingly such environmental sampling occurs, using a very wide range of different sites, from deep smokers to ovine rumen, and employing very varied and sometimes sophisticated methods to encourage the in vitro culture of taxa that are normally recalcitrant to culture. In the proposed study, the environmental bacteria themselves will NOT be grown, but their DNA will be present in defined bacteria with no known harmful properties. Therefore any risk would have to be in terms of the massive selective advantage that any newly acquired gene might confer. Given that there is compelling evidence for large-scale alter gene transfer among very unrelated bacterial taxa, if the transfer of a single gene did confer massive selective advantage then this would have occurred in any event. Note, too that the volumes of GMOs will be no more than 10 mls, that they will be handled under Category 2 conditions, more regorous than would be the case for bacterial samples directly obtained from all environments with the exception of diseased animals.

Host/vector system

The hosts will be members of the genera shown above. They are not pathogenic to humans or animals and are indeed, very severely inhibited for growth in the mammalian GI tract. They have no known detrimental effects on the environment. However, we will use auxotrophic or otherwise debilitated mutants of these bacteria, further compromising their fitness in most environments.

The vectors will be based on the P1-group wide host-range vector pLAFR1. This has a wide host-range among bacteria, but is itself completely transfer-defective. For any transfer to occur, it also requires an unusual, mobilising plasmid to be transferred by conjugation. In some cases "hybrid" vectors, based on pLAFR1 but also containing sequences that allow the plasmid to be stably incorporated into the genome of non-pathogenic, auxotrophic Streptomyces spp will be used allowing the libraries to be mobilised into these bacteria.

Origin & function

DNA will be obtained, en masse, from bacterial cells in natural populations from a range of environments. These will include unpolluted marine and other aquatic samples, soils, the epidermal surfaces of healthy animals and plants.

The functions to be tested initially will be the ability to confer individual steps in the Nitrogen cycle - nitrogen fixation, nitrification and denitrification. However, the libraries will also be screened for genes involved in other, known bacterial transformations including the synthesis of enzymes (eg protease and lipase) of biotechnological value and for the presence of tenes (eg for polyketide synthesis) involved in the synthesis of novel antibiotics. Other genes may be sought but in no case will these include functions
(eg toxin production) that are immediately deemed to be hazardous.

**Evaluation of foreseeable effects**

As stated above, exact foreseeable effects are hard to determine, just as would be the case when plating out samples of soil, mud deep ocean water etc on appropriate microbial growth media. However, the hosts to be used for the libraries are compromised, non-colonising and will be grown in small volumes. Therefore it is extremely unlikely that any large-scale escape will occur and that even in the unlikely event of a single clone having a vast selective advantage, compared to the parental strain, the numbers involved would be so low as to compare with the natural exchange of genetic material between different bacteria in the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Waste medium from small-scale cultures (<10 ml) will be autoclaved. All contaminated glassware and plastics will be treated either by autoclaving or with a broad-spectrum disinfectant. Liquid waste, once treated, will be disposed to drains; solid disinfected waste (plastics, agar) will be double-bagged in secured containers then incinerated. The methods of waste disposal have been validated and it is known that no viable GMOs remain after treatment.

### Project Additional Information

**Purposes of the contained use**

The aims of the project are to

- Express the above genes that are then studied in further biochemical, cell biology and spectroscopic study
- Study the effects of the expression of these genes on gene expression in host cells
- Use RNAi technology to knockout the endogenous expression of the above genes.

**Recipient or parental organism**

All adenovectors to be used in this study are E1-deleted first generation adenoviral vectors based on the pJM17 system (NMcGrory, W. J., Bautista, D. S. and Graham, F. L. A simple technique for the rescue of early region 1 mutations into infectious human adenovirus type 5. Virology 163: 614-617, 1988). In brief, adenoviruses are generated by recombination resulting in the deletion of the E1 region of the viral genome and replacement with the expression cassette. This renders the adenoviruses replication defective. However, with these first generation viruses there is still a small risk of recombination with the E1 region in 293 helper cells used to propagate the viruses. All stocks are therefore routinely rested for the presence of replication-competent adenovirus (RCA) and will be negative. All stocks will also be purified on caesium chloride gradients. E1-deleted adenoviruses cannot replicate unless the E1 function is complemented in trans. Therefore the disabled vector is considered a biological agent unlikely to cause human disease and is assigned to hazard group I with containment level I as the minimum requirement. However, all the inserted genes are biologically active. The inserts are eukaryotic cDNA. The insert genes cannot be reasonably assessed as conferring no increased risk since all the genes of interest in this study are components of biologically active cell growth signalling pathways. Because, however, the vector is replication deficient and reacquisition of replication competence by homologous recombination with wild-type adenovirus would lead to deletion of the insert, the GMO can be considered to pose minimal risk to human health and the environment. The transgene is inserted at the E1 site where the transgene is unlikely to confer increased risk to human health or to the environment. The modifications do not confer a selective advantage even if transferred to wild type virus or host cells. Therefore the hazard is negligible. All transgenes will be under the control of the CMV promoter. There will be a minimal risk of harmful effect of these genes in organs/tissues. If the replication-defective adenovirus is inadvertently released into the general environment, immune cells will target any infected cells. It is generally accepted that the adenovirus will be inactivated almost immediately by the
immune surveillance cells located in the peripheral system. The recombinant adenovirus will pose less of a threat once in the animal than most expression vectors as they will definitely not replicate or integrate into the host genome. Furthermore, the natural tropism of the adenoviral vectors are not altered from wild type adenoviruses in the viruses proposed for use.

**Host/vector system**

The adenoviral vectors are generated by homologous recombination between pJM17 and shuttle vectors containing transgene expression cassette and flanking E1 sequences. Following homologous recombination in helper 293 cells (which express the helper E1 function in trans), replication-defective first generation adenoviruses are produced. This methodology has been used for many years for the development of recombinant adenoviruses.

**Origin & function**

The adenoviral vector DNAs are standard and originated from the laboratory of Dr F Graham (McGrory, W. J. Bautista, D. S. and Graham, F. L.: A simple technique for the rescue of early region I mutations into infectious human adenovirus type 5. Virology 163: 614-617, 1988). The cytomegalovirus immediate early promoter is a standard viral promoter used for gene expression studies in vitro and in vivo to generate high-level gene expression in all cells transduced by the adenovirus. All transgenes have been constructed from full length cDNAs obtained either from the investigators own laboratories or from other research institutes and verified prior to subcloning into the relevant vectors.

**Evaluation of foreseeable effects**

There will be a minimal risk of harmful effect of these genes in organs/tissues. If the replication-defective adenovirus is inadvertently released into the general environment, immune cells will target any infected cells. It is generally accepted that the adenovirus will be inactivated almost immediately by the immune surveillance cells located in the peripheral system. The recombinant adenovirus will pose less of a threat once in the animal than most expression vectors as they will definitely not replicate or integrate into the host genome.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

All measures as per HSE containment level 2.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Experiments will be carried out so as to limit possible exposure to virus (minimise amounts made, good laboratory practice, gloves worn, sharps avoided, enclosed containers and avoid creation of aerosols etc.). Contaminated tips/gels etc will be disposed of by the appropriate disposal methods. Spillages, if they occur, will be cleaned up immediately and the cleaning materials (tissues etc.) disposed of as for contaminated waste. All waste materials will be routinely autoclaved. All liquid waste is treated with chlorine-based disinfectants for at least 24 hours prior to disposal.

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

For the genetic transformation of the pathogen Trypanosoma brucei.

Project follows my discovery of membrane heterogeneity in the Trypanosoma brucei glagellum, in particular concentration of "so called" lipid rafts. Such domains may represent a drug target. I am proposing a functional evaluation of the role of these structures in parasite biology and an evaluation of their potential for as drug targets utilizing genetic transformation to modulate gene expression.

**Recipient or parental organism**
GMOs generated are anticipated to be attenuated from the parental type, perhaps conditionally lethal due to the key roles the enzymes targeted play in lipid homeostasis. They do not foreseeably represent an increased risk to the environment compared with the parental strains. The parental strains we will employ are not normally infectious to humans and so represent a minimal risk to human health. T. brucei has an obligate dependence on the tsetse fly for transmission; tsetse are not indigenous to Britain and would therefore be unable to survive in the cooler climate. In the absence of this vector, the parasite is of little risk to the environment. Parasite should be readily contained by ACDP2 provision.

Host/vector system

Host: Trypanosoma brucei Tb 427, Tb 927
Vectors: pZJM, pLEW82, pHD1, pHD496

Origin & function

Insert: tbSMT (sphingomyelin transferase), tbNMT (myristoyl transferase) and tbLS (lanosterol synthase) are considered house-keeping genes, they are derived by amplification and cloning of the coding genomic DNA. Genomic DNA was prepared directly from parasite cultures (at Northwestern University, Chicago). All genes have key roles in lipid metabolism which are likely closely regulated. Perturbing expression of these genes is likely to result in extreme damage to parasite homostasis and likely cell death. The choice of vectors makes it very unlikely that inserts could be expressed in humans since the promoters are parasite polymerase specific. For expression, the requirement for trans-splicing in order to be translated cannot be met in human cells. Moreover for ablation, RNAi constructs will not be of close enough sequence to the human homologues to cause ablation.

The purpose of this project is to use the whole coding sequence or gene fragments for RNAi to modulate the production of raft associated molecules and hence raft stability. In this way it is hoped to derive specific information about the roles rafts are actually fulfilling to trypanosome biology.

Evaluation of foreseeable effects

Host: Trypanosoma brucei brucei is not infectious to man, but is morphologically indistinguishable from subspecies that are and is therefore considered as a potential human pathogen. It is designated by COSHH as ACDP2. We will culture bloodstream and procyclic forms. Only bloodstream forms are infectious. Risk of is solely by direct introduction of parasites into the blood, aerosol transmission has never been demonstrated.

Vectors: The stable vectors used contain neomycin (pHD496) or hygromycin (pZJM, pLEW82) cassettes and are integrated into the Ribosomal spacer region of the genome by homologous recombination. Neither of the drugs for selection are used in the treatment of disease caused by this organism. Integration of the vector is considered to have a likely negative effect on organism survival as evidenced by the spontaneous loss of drug resistance in cultures over time when selective pressure is released. The transient pHD1 plasmid contains a GFP fusion cassette. GFP expression generally has a negative effect on organism survival due to the generation of toxic free radicals during fluorescence.

All vectors can propagated in E. coli and express the bacterial resistance marker Ampicillin for selection. The bacterial promoter will not drive transcription of the inserted genes. In any case, if the inserts were transcribed, the requirements for postranscriptional modification of the insert are incompatable with E. coli and translation could not occur.

The severely disabled DH5a strain of E. coli will be used for propagation of plasmids. This commonly used laboratory strain is auxotrophic and although its ability to colonize humans and animals has not been assessed to my knowledge, however, it is likely to be considerably less fit than wild type E. coli.

Insert: tbSMT, tbNMT and tbLS are considered house-keeping genes. All have key roles in lipid metabolism which are likely closely regulated. Perturbing expression of these genes is likely to result in extreme damage to parasite homostasis and likely cell death. The choice of vectors makes it very unlikely that inserts could be expressed in humans since the promoters are parasite polymerase specific. For expression, the requirement for trans-splicing in order to be translated cannot be met in human cells. Moreover for ablation, RNAi constructs will not be of close enough sequence to the human homologues to cause ablation.

GMO: Since expression of the inserts proposed is likely to be detrimental to the parasite GMO's produced during this project are extremely unlikely to prevent a greater
hazard to human or animal health. (ie equivalent to ACDP hazard group 2). The major environmental concern regards possible escape of T. brucei bloodstream forms into UK domestic stock and wildlife. In order to infect a susceptible animal, the parasite would need to be introduced directly into the blood of such an animal. It is difficult to imagine a scenario in which this could occur. Moreover, T. brucei is transmitted through an obligate cycle within the tsetse fly. In the absence of the tsetse fly infection cannot be propagated. Tsetse flies are restricted geographically to subsaharan Africa and there are, to our knowledge, no tsetse flies in East Anglia in research facilities or otherwise. Moreover, it is highly improbable that released tsetse could survive in the British Climate. In the absence of tsetse fly, T. brucei release does not represent a significant risk to the environment. Further even in Africa, the GMOs produced by the project would be subject to a severe fitness penalty exerted by the integration of insert and selection genes upon these organisms and making their survival doubtful.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Culture of organisms will be within designated, closed and clearly marked incubators within the laboratory. Spillages of pathogene will be cleaned up immediately with absorbent tissue soaked with 1% chloros, detergent or 70% ethanol. Reagents to which trypanosomes are especially susceptible. In accordance with standard disinfection procedures for these organisms.

For disposal of infectious material, liquids will first be mixed with Chloros to 1% final concentration (visually confirmed by bleaching effect). Within the laboratory, contaminated waste will be contained and as biohazard waste. This includes disposable contact materials. Biohazard waste will be autoclaved prior to disposal, in accordance with microbiological waste management procedures. All contact areas will be cleaned and disinfected.

Project Containment
THE TAT-DEPENDENT AMIDASES OF E. COLI K-1 AND THEIR ROLE IN VIRULENCE

We already know that pathogenic E.coli K-1 and pathogenic Pseudomonads lacking active twinarginine transport (Tat) systems are attenuated. We also know that E.coli tat mutants have defects in outer membrane assembly due to problems in targeting cell-wall amidases. We wish to determine whether the lack of active Tat-dependent amidases is the predominant contributing factor which results in the avirulence of tat mutant E.coli strains.

E.coli contains three cell-wall amidases AmiA, AmiB, and AmiC. We have already constructed unmarked deletions of each in E.coli K-12 using the well-established pMAK705 system. We will use our pre-existing pMAK705-based deletion constructs to generate gene knockouts in E.coli K-1. In collaboration with Dr Christoph Tang (Centre for Molecular Microbiology and Infection, Imperial College, London) the modified E.coli K-1 strains will be tested for their ability to infect a mouse model system. (NB. No virulence testing will be done at UEA)

Host: Escherichia coli K-1 is classed as an ACDP category 2 organism. It does not express verocytotoxin. It is a common cause of neonatal meningitis and it invades the bloodstream from the nasopharynx or GI tract. Note that such invasion is rare even in neonates and healthy adults do not suffer from this condition. Mutant strains of E.coli K-1 generated by this project are most likely to have drastically reduced virulence.

Recipient or parental organism

Host/vector system

Vector: the vector used (pMAK705, chloramphenicol resistant, temperature sensitive for replication) is a derivative of pBR322 and is thus mobilization defective. It is extremely unlikely that pMAK705 will be transferred to other bacteria. The antibiotic resistance gene of pMAK705 is only transiently transferred to the chromosome of the host strain in the early stages of the mutant construction protocol. None of the mutant strains constructed will be chloramphenicol resistant.
Inserts: All mutant strains will carry unmarked gene deletions. There will be no insertion mutations resulting from this work.

Origin & function

this project does not involve the use of ‘foreign’ DNA in the host organism. All GMO’s will lack genes encoding native amidase enzymes.

Evaluation of foreseeable effects

Final GMO: Manipulated strains are most unlikely to be enhanced in terms of their virulence. The available literature suggests strongly that the mutant strains will be severely attenuated and thus probably non-pathogenic.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Cultures will be grown in small volumes of liquid medium (10 ml or less, generally 5 ml) and on solid medium in the form of petri-dishes. All solid media will be inactivated by extensive heat and high-pressure treatment in an autoclave. This kill method is 100% effective and will result in no viable organisms remaining. Liquid cultures can also be killed absolutely by this method. Alternatively liquid cultures will be treated with broad-spectrum disinfectants. No viable organisms will survive this treatment. Killed liquid is suitable for disposal through the general drainage system. Killed solid waste is suitable for landfill disposal.

**Significant Change ID**

**Date of Significant Change**

### Project Additional Information

**Purposes of the contained use**

To generate a non-toxic E. coli heat labile toxin B (LT-B) sub-unit variant in a class 2 Vibrio strain. This host is being used to ensure no contamination from the wild-type E. coli host protein, which might arise from over-expression of the desired LT-B variant in E. coli. Only the A sub-unit of LT-B is toxic per se; the B sub-unit is simply employed in nature to permit adhesion of the A sub-unit to cell surfaces prior to endocytosis.

**Recipient or parental organism**

The host, Vibrio sp60 (a non-pathogenic marine bacterium), is a class 2 microorganism. It is non-pathogenic to humans, animals and plants. Should any breach of containment occur, survival of this marine microorganism outside the containment lab would be expected to be transient and unlikely to have an impact on the environment.

**Host/vector system**

This study will use a pre-existing vector and host system that has been described in the literature (pTRH101R in vibrio sp60; Vaccine, 1999; 17, 1442-1453) for the production of the so-called LT-B Pk-cys fusion protein. The vector being used is non-mobilisable, reducing possible hazards from gene transfer, and confers resistance to ampicillin. The expressed protein is non-toxic. Transfer of a single gene from Vibrio sp60 is unlikely to confer a pathogenic phenotype on another host.

**Origin & function**

This study will use a pre-existing vector and host system that has been described in the literature (pTRH101R in Vibrio sp60; Vaccine, 1999; 17, 1442-1453) for the production of the so-called LT-B Pk-cys fusion protein.
Evaluation of foreseeable effects
The final GMO is unlikely to be more hazardous than the host (i.e., it is expected to be non-pathogenic) and, should any breach of containment occur, survival outside the containment lab would be transient and unlikely to have an impact on the environment.

Containment and control measures for GMOs that are not microorganisms (e.g., GM animals & plants)
Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Non applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Waste medium from cultures will be autoclaved. All contaminated glassware and plastics will be treated either by autoclaving or with a broad-spectrum disinfectant. Liquid waste, once treated, will be disposed to drains; solid disinfected waste (plastics, agar) will be double bagged in secure containers then incinerated. The methods of waste disposal have been validated and it is known that no viable GMOs remain after treatment.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The committee recommended “Class 2” on the basis of classification of the parent organism.

Project Ref 101/07.1

Date Ackn'd CU2 Project Title Class CultureVolClass2 CultureVolumeClass3-4
02/03/2022
Systems approach to dissect the regulatory mechanisms Salmonella enterica employs to respond to its environment.

Project Additional Information

Purposes of the contained use

Mutations in genes known or proposed to be involved in the response of Salmonella to its environment will be constructed by inserting linear DNA fragments often containing a selective antibiotic marker. These mutations will be complemented by transformation of these strains with a low copy number plasmid harbouring the gene deleted from the chromosome. Complementation may require subcloning in E.coli K12 derivatives, Promoters of several Salmonella genes will also be fused with reporter genes and these fusions will be inserted into the chromosome.

Recipient or parental organism

Serovars of Salmonella enterica are classified as group 2 pathogens, as determined by the ACDP. E.coli K12 derivatives are classified as ACDP hazard 1, since these strains are considered non pathogenic and contain several auxotrophic mutations they are not expected to survive in the environment.

Host/vector system

Complementation will employ a low copy-number (5-10 copies per cell) such as pSC101-derived, non-mobilisable, ampicillin-resistant plasmid, pWKS30, containing the gene that has been deleted from the chromosome. Whilst cloning the various DNA fragments, we will initially employ the widely available general-purpose cloning vectors such as pUC18 and 19. These vectors are non-mobilisable, as they lack a bom site.

Origin & function

All genetic material will derive from serovars of Salmonella enterica or from the vectors/reporter genes described. The overall intended function of manipulations in both sets of experiments is to study the environmental regulation of genes in these strains. In all cases, genes of interest will be mutated, or their promoters will be fused to a reporter gene. We will be performing detailed phenotypic analyses to determine the consequences of the mutations. We will perform in vitro tissue-culture based assays to study the interactions of the wild-type and mutant strains with cultured cell lines. We will investigate host-pathogen interactions in murine Salmonella infection models. We will isolate RNA from the bacteria to measure gene expression by micro array and RT-PCR, and use protein-based techniques such as SDS-PAGE and Western blotting to confirm results obtained by RNA analysis. In some cases the mutants will be grown in continuous culture systems. Cellular differences in the level of GFP expression will be studied.
by fluorescence microscopy and Fluorescence Activated Cell Sorting (FACS).

**Evaluation of foreseeable effects**

We will be mutating genes though to control environmental gene regulation of Salmonella. In most cases these genes are also found in all non-pathogenic strains of Escherichia coII. As such, they do not contribute to pathogenesis in the absence of other factors and are therefore not considered to be virulence factors. Although subsequent complementation in pWKS3O, will increase the copy-number of the genes and could conceivably result in higher levels of the cognate proteins, significant over expression is unlikely, since these genes are subject to negative feedback regulation. Where Salmonella specific genes are mutated it is extremely unlikely that the virulence will be significantly higher than the isogenic parent and as such will still be a category 2 organism.

The system for introducing linear DNA constructs into the bacterial chromosome involves the presence of the temperature-sensitive plasmid, pKD46. None of the genes encoded by the plasmid are considered likely to enhance the virulence of the strains harbouring them. Since plasmid pKD4S and its derivatives cannot replicate at 37°C the plasmid would normally be lost following ingestion of the bacteria by a mammalian host. We are not aware of any potential for this plasmid to be mobilised and transferred to other strains although the theoretical possibility does exist whilst the strains harbouring the plasmid are in the gut. Thus, there is a minimal risk of antibiotic resistances encoded by this plasmid being transmitted to other strains. The alternative allelic exchange system proposed in both projects will be performed using the suicide vector pCVD442. The fusions can also be cloned onto a ColEl or pMBI replicon such as pBR322. The pBR322 vector is mobilisation defective and will only contain the promoter sequences for virulence genes. Although pBR322 is not conjugable itself, the plasmid could be mobilised in the presence of a helper plasmid. The risk is considered very low. Moreover, the contents of the plasmid would not increase the pathogenic potential of a recipient strain.

(continued on separate sheet)

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

“All GMOs will be contained in the appropriate conditions relative to the individual GMO. Where CMOs are combined the most severe containment conditions applicable will be used, which in the case of this notification will be in a category two facility. CMOs which have not been constructed in house will be obtained from regulated suppliers and transported under containment conditions. At the end of the experiment all CMOs will be disposed through autoclaving and/or incineration”.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Infectious doses for use in the murine model will be prepared in BIG and transported to the DMU in secondary containment. Once infected, the mice will not be moved from the designated category 2 area until the end of the experiment. During the experiment, animal waste and bedding will be autoclaved before being incinerated. Because rodents tend to eat their stools, water bottles can be contaminated when infected animal drink. Therefore, spillage of water from these bottles should be treated as potentially contaminated as soon as animals are infected. If a spillage occurs they will be treated as liquid spills as detailed below. At the end of the experiment, the mice will be humanely killed and then dissected to remove organs for further analysis. Organs will be transferred to sealed containers and transported to 80°C for further processing. The remains of the animals and any materials in contact with the infected animals will be autoclaved and incinerated. This approach reflects “best practice” used at the Cambridge University Veterinary School and the Hammersmith Hospital, London.

1. Liquid spills

Small spills of liquid cultures shall be treated for 10 minutes with an approved disinfectant, 1% solution Virkon. This concentration had been validated by the manufacturers and in house testing with the strains used. For large spills, add undiluted disinfectant to achieve the correct final concentration (1%). The treated area should be mopped up with paper towels which should be sent for autoclaving.

(Continued on separate sheet).
Minor changes and points of clarification were suggested by the local GMO committee and the proposal was then accepted.

Please enter comments on the GM safety committee on the risk assessment:

**Date of Significant Change**
Project Additional Information

Purposes of the contained use

Lentiviruses will be used for high level expression of viral and cellular proteins in cells in order to image their subcellular localization, find host proteins which bind to them and their interaction with molecular signal transduction pathways. Lentiviruses will also be used for delivery of short-hairpin RNAs (shRNA) to suppress expression of cellular proteins for functional evaluation of their role, e.g. FGFR-receptors (FGFR5), proteases, signalling proteins.

Recipient or parental organism

Mammalian primary cells and cell lines from human, monkey, mouse, origin, including epithelial, vascular endothelial, muscle, HeLa, Vero, 293FT, U87, U251 PC3, DU145, LNCaP, MCF-7, CHO, MDA-MB231, SW1353, MRC-5 cells, 1OT1/2 and 3T3, myeloblastic cell line, Eol-1, TF-i, HL-60, THP-i; airway epithelia, AS49 and RPMI 2650; monocytic and macrophage. Chicken embryo fibroblasts. E. coli DH5 and TOP10

Host/vector system

Defective lentiviruses are generated using a lentivirus vector plasmid with viral genes replaced by inserted gene driven with either a SFFV promoter or CMV promoter, and retaining LTR for integration. This is co-transfected with envelope pVSV-G, encoding the VSV envelope proteins under the control of the CMV promoter, and pCMVDR8.91 encoding replication proteins (gag-pol). The resulting virus secreted from 293 producer cell line is defective in packaging signal and will be used for infection of recipient cells

Origin & function

Provides stable, long-term expression of a target gene. Target genes include reading frames that encode viral proteins from the flavivirus classical swine fever virus (CSFV), including the N terminal autoprotease (Npro) and other nonstructural proteins (NS2, 3, NS4a and band NS5a and b). Foot and mouth virus non-structural proteins 2C, 2BC, 3A which anchor the viral replicase to membranes and has no enzyme activity. Reading frames encoding viral proteins from the coronavirus IBV (infectious bronchitis virus) Cellular proteins that regulate autophagy (LC3, p62, mTOR, Raptor, Rictor) and genes from the NF-kappa B and interferon signaling pathways (including NF-kappaB, I-kappa B, IRF3, IRE 7, I kappa B kinases)

Proteins involved in extracellular proteolysis and regulatory factors controlling their expression, activation or function, including matrix metalloproteinases (MMPs), adamalysins, tissue inhibitors of metalloproteinases (TIMPs), serine proteases and serpins, receptors associated with binding of proteases (integrins, urokinase plasminogen activator receptor, uPAR), CD44, LYVE-i, Prox-i and other transcription factors. Human Siglecs (sialic acid binding immunoglobulin like lectins; a putative regulator of receptor signaling threshold) Human calcium activated chloride channels, CLAC1/2/3. Ficolins L/H and M which are innate immune lectins. Components of the Wnt,Notch and BMP signaling pathways (e.g. APC, beta-catenin) including gain/loss of function receptors. Components of the TNF receptor signaling pathway (eg FLIP, HO-i) and gain/loss of function mutants. BCL-abl kinase and dominant negative mutants.

Evaluation of foreseeable effects

Human Health: Risk of human infection is very, very low.

Host cells: The mammalian cell hosts are non-pathogenic and unlikely to survive outside cell culture. It is recognized that lentivirus vectors can in principle cause insertional mutagenesis in the cells that they enter, but the likelihood of a worker infecting themselves and causing a hazard in this manner is extremely low.

Vector: The replication incompetent lentivirus is not a risk as it will not infect further cells. That the lentivirus has a genome split into 3 plasmids means that recombination between packaging helper and vector is very low and the potential for generation of replication competent lentivirus is extremely reduced. The virus envelope is from VSV and there is no I-III envelope protein in the system and the minimal required HIV functions are from the helper plasmid that contains no packaging or LTR sequences. There is no chance that it will recombine with HIV from a HIV infected worker

Insert: The inserted transgenes are viral proteins with no known homologues in mammals and they are not oncogenes. The CSFV Npro protein can inhibit innate immune responses by targeting interferon response factor 3 for degradation. Since this gene will be expressed from a defective lentivirus vector, it will not self-replicate. The inserted genes which are cellular are not oncogenes, except for some of Wnt/Notch/BMP signaling pathway components are oncogenes (e.g. beta catenin) or tumour suppressor genes (e.g. APC). Lentiviral delivery of such genes in vitro is practiced worldwide. Tumourigenesis in humans is a multistep process and requires multiple genetic changes. Thus, the risk for tumourigenesis, should an individual become infected, is expected to be very low. TNF signaling pathways include apoptotic and...
anti-apoptotic genes which affect proliferation or cytotoxic mechanisms within cells. None of the TNF pathway genes targeted are classed as oncogenes.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

GMO contained in Cat 2 labs. Plasticware and waste are autoclaved. Liquids are inactivated using 1% Trigene. All procedures performed in category 2 tissue culture hoods in a designated tissue culture laboratory. Workers wear lab coats, nitrile gloves. Spilled liquid to be treated with 1:10 Trigene.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be decontaminated in 1% Trigene for 60 minutes which has been shown to inactivate 100% of lentivirus. All plasticware and waste products will be autoclaved to provide 100% kill. No GMQ will survive treatment.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Minor points of clarification were raised by the local GMO committee and the proposal was then accepted.

**Project Additional Information**

**Purposes of the contained use**

For contained handling of these parasites

**Recipient or parental organism**

Trypanosoma brucei ssp,
Trypanosoma cruzi,
Trypanosoma rangeli,
Leishmania sp.

**Host/vector system**

For T. cruzi, T. rangeli and Leishmania sp. pTEX plasmid,
For Leishmania only pXG-GFP plasmid,
For T. cruzi, T. rangeli pCos TL
For T. brucei pLEW82/pHD series

**Origin & function**

pTEX, pCosTL - LSHTM, University of London (Kelly lab)
pXG - Washington University (Beverley lab)
pLEW82/pHD series Oxford University (Gull lab)

In all cases the plasmids will be used for the expression of CDNAs with the purpose of either localizing (using GFP or epitope tags), reducing (by knockdown or knockout) or modulating expression of parasite proteins in order to infer function.

**Evaluation of foreseeable effects**

All experiments involving construction and establishment of New GMO's will be individually risk assessed by the Wolfson Pathogen Unit Management Committee. In general terms expression of endogenous proteins with epitope tags or fluorescent proteins can be expected to be functionally neutral and in the case of fluorescent proteins deleterious to the well being of the parasite due to the increased levels of free radicals and misfolded protein generated. Similarly modulating protein expression particularly...
by knockdown or knockout of endogenous proteins is normally deleterious to the parasite and is frequently fatal. Understanding how fatality occurs can be highly informative and where fatality occurs this is indicative that the gene targetted may encode a potential drug target.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

We will utilize a containment level 3 suite for the handling of these organisms according in line with ACDP guidance and according to the Standard Operating Protocols provided. Trypanosoma cruzi, Leishmania donovani and Trypanosoma brucei rhodesiense are HG3 trypanosomatid parasites and it is appropriate to contain them in this manner, however, because of their large size (circa 10 microns in length) they are not readily aerolized. In light of this we request derogation of the requirement for working at negative pressure with these organisms.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Decontamination is with 0.1% chloros or 2% trigene. Waste is placed in a steel box lined with a clear autoclave bag. And is subjected to pass through autoclaving. Once cool, the autoclave bag is removed from the box and placed in a black bin bag weighed and labelled with researcher details. The bag is then placed with incineration waste in the wheelie bins of the Disease Modeling Unit and is collected by Vet Speed and taken to Cambridge Pet Crematorium for incineration.

Please see attached SOPs and publication for specific detail.

---

02/03/2022
Prior to review by the UAE Biohazards and Genetic Modification Subcommittee had the protocols reviewed by the external specialists and specialists on the Wolfson Pathogen Unit Management Committee.

Upon their review of the finalized protocols
The UEA Biohazards and Genetic Modification Subcommittee 10/03/08 noted that:

A new paragraph will be entered into the Standard operating procedures to cover who is allowed to access the CL3 Suite.

Training for using the CL3 suite has taken place at Portland Down and all PIs will undertake this Portland Down CL3 course.

A list of trained staff should be provided to Occupational Health to assess health surveillance requirements.

Advice will be offered to estates on who should be allowed to access the Plant Room above the CL3 Suite.

Following appropriate consultation with Estates a protocol on Plant Room access will be written.

These recommendations have been attended to in the submitted documentation.

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

Generation of Sindbis virus RNA in mammalian cells to study the sites of replication and the production of double-stranded RNA. Cellular responses to double-stranded RNA produced during infection will be studied, including RNAi, interferon and autophagy pathways.

**Recipient or parental organism**

Mammalian cells including HEK293, MCF7 cells, Vero, BHK cells

**Host/vector system**

A plasmid cDNA containing a SP6 RNA polymerase promoter upstream of the structural and non-structural proteins of Sindbis virus SinTTP1011 and Sin DSTE12Q.

Sindbis virus RNA transcripts are synthesized from SP6 RNA polymerase promoter.

Sindbis viruses are enveloped particles with an icosahedral capsid. Its genome is a single stranded RNA approximately 11.7kb long. It has a 5' cap and 3' polyadenylated tail therefore serves directly as mRNA in a host cell. The genome encodes four non-structural proteins at the 5’ end and the capsid and two envelope proteins at the 3’ end. The genomic RNA is partially translated at the 5’ end to produce the non-structural proteins which are then involved in genome replication and the production of new genomic RNA and a shorter sub-genomic RNA strand. This sub-genomic strand is translated into the structural proteins. The viruses assemble at the host cell surfaces and acquire their envelope through budding.

The RNA is self-replicating and provides for transcription in a host cell.

**Origin & function**

The infectious clone is a cDNA copy of a functional Sindbis virus RNA genome cloned into a plasmid with a SP6 promoter. TOTO1101 is partly shortened at 5’ and 3’ end from the full-length cDNA clone HRSp (see Rice et al J.Virol. 1987). It is self-replicating and not disabled. SinDSTE12Q is in a plasmid derived from TOTO 1101 with a modified polylinker.

The function is to provide a replicating RNA virus in mammalian cells. Double-stranded RNA is generated as an intermediate during viral replication. Infected cells die by apoptosis 24 hours post-infection.

**Evaluation of foreseeable effects**

Human health: Sindbis virus infects Humans, mammals, birds. The infectious dose is not known.

The mode of transmission is by the bite of an infectious mosquito.

INCUBATION PERIOD: less than 7 days.
COMMUNICABILITY: No evidence of person-to-person transmission documented

SYMPTOMS: Self-limiting febrile viral disease. Sudden onset of fever, rash, arthralgia or arthritis, lassitude, headache and myalgia; rash may precede or follow joint
manifestations by 1-2 days; exanthem on trunk progressing to face, legs, palms, soles and lasts on average 10 days; sign of jaundice and myocardial damage are reported
but rare; often no recognized clinical disease manifestations

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Biosafety level 2 practices and containment facilities will be used for all activities involving the virus. Infected cells die by apoptosis 24 hours post-infection

PROTECTIVE CLOTHING:
Laboratory coat; gloves.

STORAGE: In sealed containers that are appropriately labelled at -80C

PHYSICAL INACTIVATION: Sensitive to heat, UV and gamma irradiation and freezing

SURVIVAL OUTSIDE HOST: Survives in blood up to 2 days at room temperature. Avoid contact with mucus membranes.

Needles will no be used. Cultures will be grown in tissue culture flasks (T75 cm3) or dishes (P100s) in DMEM tissue culture media containing 5% FCS. The cultures will be
grown in designated incubators.

Liquids are inactivated using 1% Trigene and 70% ethanol. All procedures will be performed in category 2 tissue culture hoods in a designated tissue culture laboratory.

DISPOSAL: Decontamination all wasted before disposal; steam sterilization, incineration, chemical disinfection

All liquid waste will be decontaminated in 1% Trigene for 60 minutes which has been shown to kill 100% Sindbis virus. All plastic ware and waste products will be
autoclaved to provide 100% kill.

Use of replication deficient, recombinant adenoviruses for transfer of genetic material encoding cellular, viral and green fluorescent protein into eukaryotic cells and tissues

Class 2 < 1 Litre

Non-GMM Consent Granted

Project notified under transitional arrangements □
This risk assessment consolidates closely related research projects which use adenovirus vectors for delivery of genetic material to mammalian cells. The aims are to investigate diseases for translational medicine research. The research projects relate to human health and biomedicine, to further our understanding of the cell and molecular mechanisms underpinning several human diseases.

In particular we will use recombinant adenoviruses to express recombinant proteins in primary organs and organoids generated from gut, intestinal crypts, kidney cysts, slow and fast twitch mouse and rat muscle fibres, and in muscle in vivo by intramuscular injection of mouse tibialis anterior.

We will investigate:

- the innate immune responses to expressed viral proteins from FMDV, IBV and CSFV encoded by less than 10% of the viral genome using proteins fluorescently-tagged with GFP/RFP
- Tetracyclin inducible expression of viral proteins.
- Express inhibitors of protein expression such as shRNAs and siRNA targeted against innate immune autophagy proteins and DNA repair system components.
- The role of DNA repair systems in aging and cataract formation
- Express recombinant cellular proteins include protein fused to fluorescent tags eg: GFP, RFP, includings cytokines, defensins, inflammatory proteins, interferon signal transduction proteins, NF-kB signal transduction proteins, RNA helicases, autophagy proteins including ATG5, 16, LC3, p62 sequestasome, DNA repair proteins tagged with GFP, RFP DNA repair proteins including Ku70, Ku 80 and Lig4
- Gene reporter constructs including inducible promoter elements fused to GFP/luciferase promoter luciferase/GFP contracts
- Express Cre Recombinase to excise sequences between LoxP sites in transgenic cells and tissues

Recipient or parental organism

- Mammalian cell lines (HEK293), HeLa, MEFs, Vero, Raw 264, FHL 124 BHK, CHO
- Primary human crypt biopsy tissue
- Mouse small and large intestine crypt and organoids cultures
- Kidney cysts
- Mouse brain tissue and muscle
- Porcine lens cultures
- Donor human lens tissue culture
- Fast and slow twitch muscle isolated from rat and mouse

Host/vector system

A Easy-1 Invitrogen ViraPower system
Adeno-X (Clontech system)
Adenovirus Type 5
The function of the adenovirus genome is to efficiently transduce a wide variety of mammalian cells. It can infect resting cells, proliferating cells, undifferentiated cultured cells, and differentiated cells. The gene of interest is highly and transiently expressed.

Origin & function
The function of the adenovirus genome is to efficiently transduce a wide variety of mammalian cells. It can infect resting and proliferating cells, differentiated and undifferentiated cells. The gene of interest is highly and transiently expressed.

Evaluation of foreseeable effects
Recombinant Adenovirus vector contains mammalian and viral proteins protein. The recombinant Adenovirus is replication deficient and therefore can only replicate in cells which carry complementing regions of the E1 genes. It will not replicate in other in vivo or in vitro cells. Furthermore since the modified virus is replication deficient it is less pathogenic than the wild type and there is minimal capacity for colonisation. If it is exposed to the environment it is unlikely to survive for extended periods. Human Adenovirus Type 5 is ubiquitous causes only a mild respiratory disease in humans which is self limiting and does not require any specific treatment. The Adenovirus viral vectors are replication defective owing to the removal of the E1 and the E3 regions. The genetic inserts pose no risk to animal/plant health or the environment. Modified adenovirus may mimic some of the characteristics of the wild-type or may pose a risk to immune-compromised individuals causing only a mild respiratory disease in humans which is self limiting and does not require any specific treatment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Personnel will wear lab coats and gloves, which will be disposed of in waste to be autoclaved. Recombinant Adenovirus can only replicate in complementing cells such as Ad-HEK293 and consequently poses a low risk to animal/plant health and the environment. Level 2 containment measures will be in operation and the principles of Good Microbiological Practice will be applied. All surfaces will be decontaminated in 10% Trigene. In conjunction with this access to the laboratory will be restricted when work with infectious agents is in progress. Persons at increased risk of acquiring infection or for whom infection may have serious consequences will not be allowed to enter the laboratory. A biohazard sign will be posted at the laboratory entrance bearing appropriate information including the agent(s) in use, containment level, the investigator's name and telephone number, personal protective equipment requirements and exiting procedures if any.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Virus will be inactivated in 10% Trigene. All plastics and in contact items will be left in 10% trigene detergent for 30 minutes before placing in clear bags in yellow boxes and autoclaving. Plasticware will be autoclaved. Liquids are inactivated using 10% Trigene. Spilled liquid will be treated with 1:10 Trigene. All of these are validated methods of adenovirus destruction.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Date of Significant Change

Project Additional Information

Purposes of the contained use

Mutations in the genes, mexT, PA5017, PA0296, PA0602 and wspF will be individually genetically engineered into P. aeruginosa PA01 (ATCC 15692). They will be studied to understand the phenotype of these mutations and effect on antibiotic susceptibility, growth and biofilm formation.

The experiments entail standard molecular biology techniques which carry no special risk and all are conducted in...
accordance with health and safety guidelines of UEA. GMOs will be cultured at 37°C for 24-48 hrs in a maximum
volume of 10 ml. Antibiotic susceptibility and growth will be analysed using standard growth assays in a 96-well plate.
Biofilm flow cell experiments will require seeding flow cell channels (a microscope slide sized area) with P. aeruginosa
for a limited period of time (4 hours max) and passing growth medium over this to study biofilm growth (7 days max).
The GM organisms will be handled at all times within a C12 laboratory and so escape into the environment is
minimised. Survival in the environment is not expected to be increased over wild type and the risk to humans is low -
(it is an opportunistic pathogen).

Recipient or parental organism

P. aeruginosa is not considered a primary pathogen but rather an opportunistic agent in hospital acquired
infections. It exists as a normal inhabitant of human intestinal flora and is also associated with infection within an
immunocompromised host. Additionally, it is non-spore forming and is widely dispersed in the hospital and
environment. P. aeruginosa PA01 is a laboratory strain that was originally isolated from a wound in 1954 in
Melbourne, Australia. This strain is capable of survival in the environment but the risk to human health is no worse
than any other P aeruginosa strain, and containment at level 2 is appropriate.

Host/vector system

The vector called pTS is grown in E.coli. The vector contains a tetracycline marker to allow positive selection, sacB, a
counter selecti marker and a ColE1 origin in which pre ents replication of the plasmid in P. aeruginosa. The
tetracycline marker will be lost during the genetic engineering process and therefore poses no additional safety
risks compared to wild type P. aeruginosa.

Origin & function

Evaluation of foreseeable effects

Mutations genetically engineered into P. aeruginosa PA01. Gene names and positions are from P. aeruginosa PA01
(GenBank accession no. NC002516.2)
mexT deletion, TGGCCAGC (Position:2807693)  
mexT insertion, TCE (Position:2807965)  
mexT deletion, TGGCCAGC (Position:2807693) together with the mexT insertion, TCE (Position:2807965)  
Cag/Tag in PA5017 (Position: 5642054)  
tTcLtC within PA0295 (Position:332051)  
GtvAt in PA0602 (Position: 663845)  
cAg/cGg in wspF (Position:4144991)  
Mutants will be created that will have an effect on biofilm phenotypes. As mentioned in the risk assessment, mutants
created with the mexT gene deletion may alter antibiotic susceptibility to chloramphenicol, norfloxacin (and possibly
other fluoroquinolones). Production of virulence factors (pyocyanin and type three secretion) and swarming
characteristics in P. aeruginosa will be reduced (Luong et al., 2014). The TCC insertion has not been characterized
however it is known that mutations within the mexT gene alter expression of the MexEF-OprN efflux pump which can
result in reduced antibiotic susceptibility to norfloxacin and chloramphenicol (Maseda et al, 2000). All GM strains
remain susceptible to several clinically relevant antibiotics including gentamicin. Norfloxacin and chloramphenicol are
not commonly used to treat P. aeruginosa infections (Driscoll et al., 2007). Changes in the PAS017 gene may affect
flagella motility (Kulasekara et al., 2013) and hence biofilm dispersal. PA0295 and PA0602 are putrescine-binding
periplasmic proteins and mutations within these genes may have an effect on transport of small molecules across the
membrane (Imperi et al., 2009). P. aeruginosa engineered with the wspF mutation is likely to show increased biofilm production (D’Argenio et al., 2002). The mutants that will be created were initially identified as mutations in variants of the laboratory strain, P. aeruginosa PA01, using comparative genomic studies. The consequences, of the harmful effect (were it to occur) is most likely to be no worse than wild type P. aeruginosa. All mutants will be handled in a containment level 2 laboratory. P. aeruginosa is capable of survival in the environment but the risk to human health of the GM isolates is no worse than for P. aeruginosa wild type, and containment at level 2 is appropriate.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Contaminated glassware, bacterial cultures and contaminated disposables e.g. Pipette tips, tissue paper, culture vials and plates, etc., will be sealed and disposed of in yellow biological waste bins, to be autoclaved on a kill cycle at 126 degrees Celsius for 20 min. Processed waste in autoclave bags are over wrapped in black bags and placed into a 'e wheelie bin in the autoclave lab for disposal as landfill. Processed glassware will be emptied and washed. t ,~ase see the attached SCRE yellow box standard operating procedure and risk assessment. Sharps materials are disposed of in cin-bins (UN 3291 compliant). Cin-bins are removed by the registered waste contractor Novus Environmental.

Accidental spillages (less than 0.5 mLs) will be cleaned with Actichlor disinfectant (Ecolab, Leeds, UK) at a final concentration of 1000 ppm, wiped with a clean paper towel immediately and discarded in the biological waste bin. Larger spills (over 0.5 mLs - 10mLs) will be treated with Actichlor to a final concentration of 1000 ppm. This will be covered with a blue paper towel, appropriately labeled and left overnight before being wiped with a clean paper towel and discarded in the biological waste bin.

### Project Additional Information

**Purposes of the contained use**

Lentivirus will be used for overexpression of proteins of interest in cells to image subcellular localization and find host binding proteins by pull-down analysis. Lentivirus will also be used for delivery of small RNAs (shRNA and miRNA) for functional evaluation of cellular pathways.

**Recipient or parental organism**

The lentivirus will be used to infect human cell lines and primary samples in vitro.

**Host/vector system**

Host: The mammalian cell hosts are non-pathogenic and unlikely to survive outside cell culture. It is recognized that lentivirus vectors can in principle cause insertional mutagenesis in the cells that they enter, but the likelihood of a worker infecting themselves and causing a hazard in this manner is extremely low. Primary human lymphocytes,
monocytes, stromal cells, adipocytes, and leukaemia cells will be screened for HIV at the Norfolk and Norwich Hospital before being brought into the laboratory. Vector: The replication incompetent lentivirus is not a risk as it will not infect further cells. That the lentivirus has a genome split into 3 plasmids means that recombination between packaging helper and vector is very low and the potential for generation of replication competent lentivirus is extremely reduced. The virus envelope is from VSV and there is no HIV envelope protein in the system and the minimal required HIV functions are from the helper plasmid that contains no packaging or LTR sequences. There is no chance that it will recombine with HIV from a HIV infected worker.

Origin & function

Inserts:
Components of the TNF receptor signaling pathway (e9 FLIP, HO-1) and gain/loss of function mutants. Specific shRNA and miRNA sequences for various proteins of NFkB and NRF2 pathways. Fluorescent proteins (e9 GFP, eGFP, emGFP, OsRed, mCherry)

Evaluation of foreseeable effects

Defective lentiviruses will be generated using a lenivirus vector plasmid which contains the LTR from HIV or MLV with SFFV, CMV orland U6 promoters. This plasmid will be co-transfected with packaging plasmids: pVSV-G (encoding the VSV envelope proteins under the control of the CMV promoter) and pCMVDR8.91 (encoding replication proteins). The resulting virus secreted from 293T/FT producer cells is defective in packaging signal and will be used for infection of recipient mammalian cells listed above. No productive virus that is infectious will be created. Fluorescent proteins is non-toxic and have been used in many laboratories over years with no adverse effects. TNF signaling pathways include apoptotic and anti-apoptotic genes which affect proliferation or cytotoxic mechanisms within cells. None of the TNF pathway genes targeted are classed as oncogenes. The genes that will be targets for knock down by lentiviral delivery of shRNAs and miRNAs play functional roles in the cell-matrix interactions of mammalian cells. As such they have effects on cell growth, but their knockdown would in general be expected to compromise growth or other aspects of cell behavior. However, some of the proteins could act in certain cell types as tumor suppressor functions, and their knock-down could therefore pose a potential risk if a worker infected himself/herself. However, cancer formation is a multi-step process in humans requiring at least six genetic changes, so it is highly unlikely that an infection would contribute to tumourigenesis. Also, as the lentiviral vectors are replication-defective they would not propagate in an infected worker.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All contaminated items will be left in contact with min 1% Chemgene or any other approved detergent for 5 minutes before autoclaving. Liquids are inactivated using 1% Chemgene or 70% ethanol. If contamination of lab coat occurs it will be autoclaved prior to laundering. Liquids will be incubated in 1% Chemgene solution for 5-10 minutes, then will be poured down laboratory sink with copious water. Solid wastes will be disposed of via the 'yellow box' route (autoclaved prior to disposal by landfill). Small spills (less than 10ml) will be mopped up with disposable towels soaked in 10% Chemgene; big spills (up to 1 L)
will be mopped with absorbent material from the spill kits which available from room 214/1.42 and outside 214/27. Contaminated surfaces will be sprayed with 2% Chemgene spray, left for 1 minute and wiped with disposable towels. Any towel and absorbent material waste from spillages will then be disposed of in a yellow box and autoclaved. Plastic ware, tips, gels and other contaminated items will be autoclaved directly before disposal. Needles or sharps will not be used

Staphylococci are clinically-relevant bacteria that can form biofilms. The aim of this work is to construct and sequence transposon libraries of staphylococci to increase our understanding of the genes involved in biofilm formation. The work will be conducted in accordance with the UEA health and safety guidelines and GM organisms will be handled within a CL2 laboratory according to the contained use guidelines.

Coagulase-negative staphylococci and (coagulase-positive) Staphylococcus aureus are part of the normal skin flora and are widely-dispersed in the environment including hospitals. The parent strains were obtained from hospitals and the natural environment and are able to survive outside of the laboratory. These bacteria are not considered primary pathogens and are typically associated with infection in an immunocompromised host and infections can be treated with antibiotics. Staphylococci are non spore forming bacteria and will be contained within a CL2 laboratory. Overall, the risk to healthy individuals is low.

Recipient or parental organism

Coagulase-negative staphylococci and (coagulase-positive) Staphylococcus aureus are part of the normal skin flora and are widely-dispersed in the environment including hospitals. The parent strains were obtained from hospitals and the natural environment and are able to survive outside of the laboratory. These bacteria are not considered primary pathogens and are typically associated with infection in an immunocompromised host and infections can be treated with antibiotics. Staphylococci are non spore forming bacteria and will be contained within a CL2 laboratory. Overall, the risk to healthy individuals is low.

Host/vector system

1) A Tn5 transposon (containing an antibiotic marker) and suitable transposase (e.g. Epicentre Tn5 system)

2) A Tn5 transposon (containing an antibiotic marker) and transposase on a conjugative plasmid

The transposon systems in 1 & 2 will be maintained in HG1 E. coli or HG1 staphylococcus strains before introduction into target staphylococcus strains for construction of libraries.

3) A Tn5 transposon (containing an antibiotic marker) and transposase on a mobilisable plasmid.

The transposon will be introduced into target strains from a staphylococcus donor with transfer genes encoded in the genome as well as a sacB counter selection gene integrated into the genome.

Origin & function

Host-vector systems 1 & 2) Transposons are naturally-occurring mobile DNA elements that are inserted into DNA by a transposase. A transposon will be used as linear DNA with a suitable transposase which allows direct introduction into the target strain for insertion into the genome. A transposon (e.g. Tn5) my also be used on a conjugative plasmid alongside the corresponding transposase for introduction into an intermediate Staphylococcus
strain for subsequent transfer by conjugation to the target Staphylococcus strain for insertion into the genome. The selective marker on the transposon enables selection of bacteria that contain the transposon. The genomic insertions will allow investigations into the function of genes.

Host system 3) A transposon may be used to introduce genes into a HG1 Staphylococcus strain to generate a donor for transfer of transposons to other Staphylococcus strains. The sacB counter selection gene in the genome of the donor strain confers sensitivity to sucrose and allows selection against the donor after DNA transfer. The transfer (tra) genes in the genome allows the transfer of mobilisable plasmids to target strains.

Evaluation of foreseeable effects

Staphylococcus are part of the skin microbiome and the risk posed to healthy individuals is low. Transposons are naturally occurring mobile DNA elements that will be modified to contain a resistance marker found naturally within the staphylococcal population. The transformed staphylococci will carry additional resistance genes and may provide a reservoir of mobilisable resistance genes for other staphylococci. However, constructs and GM strains will carry a maximum of two natural resistance genes and all transformed strains will remain susceptible to many antibiotics normally used for treatment of staphylococcal infection, including; vancomycin and metacillin and the risk from transformed strains is low.

A staphylococcus transposon donor strain will contain transfer genes to allow transfer of mobilisable plasmids such as those that already exist within the population. The donor strain will also allow the transfer of the target transposon plasmid which facilitates the introduction of resistance genes, on plasmid ids, into the genome of the recipient Staphylococcus strain. Conjugal and mobilisable plasmid ids and the resistance genes in this work already exist within these bacteria. The antibiotic markers will be limited to two natural resistance genes ensuring that antibiotics used for treatment of infections remain efficacious. The sacB counter selection gene in the plasmid donor strain confers sensitivity to sucrose which is most likely to reduce the fitness of the bacterium.

The resulting transposon mutant libraries may contain bacterial cells with upregulated genes as well as inactivated genes; this may alter phenotypes such as biofilm formation. This work will initially be performed with isolates of coagulase-negative staphylococci which can rarely cause infection in healthy individuals. Transposon insertion libraries of Staphylococcus aureus may then be constructed which could potentially upregulate virulence genes. Staphylococcus aureus infections can be more severe but typically only affect immunocompromised individuals. We will assess the antimicrobial resistance profile of Staphylococcus aureus strains prior to transposon mutagenesis work and only proceed with strains susceptible to multiple antibiotics. The staphylococcus aureus mutants will contain an additional natural resistance gene and no non-native genes and are not expected to exceed HG-2.

The consequences, of the harmful effect (were it to occur) is most likely comparable to wild-type Staphylococcus. Staphylococcus can survive in the environment but the risk to human health of the GM isolates is likely to be comparable to variants in the natural population, mutants will be handled in containment at level 2 which is appropriate for this work.

Evaluation of foreseeable effects

Staphylococcus are part of the skin microbiome and the risk posed to healthy individuals is low. Transposons are naturally occurring mobile DNA elements that will be modified to contain a resistance marker found naturally within the staphylococcal population. The transformed staphylococci will carry additional resistance genes and may provide a reservoir of mobilisable resistance genes for other staphylococci. However, constructs and GM strains will carry a maximum of two natural resistance genes and all transformed strains will remain susceptible to many antibiotics normally used for treatment of staphylococcal infection, including; vancomycin and metacillin and the risk from transformed strains is low.

A staphylococcus transposon donor strain will contain transfer genes to allow transfer of mobilisable plasmids such as those that already exist within the population. The donor strain will also allow the transfer of the target transposon plasmid which facilitates the introduction of resistance genes, on plasmid ids, into the genome of the recipient Staphylococcus strain. Conjugal and mobilisable plasmid ids and the resistance genes in this work already exist within these bacteria. The antibiotic markers will be limited to two natural resistance genes ensuring that antibiotics used for treatment of infections remain efficacious. The sacB counter selection gene in the plasmid donor strain confers sensitivity to sucrose which is most likely to reduce the fitness of the bacterium.

The consequences, of the harmful effect (were it to occur) is most likely comparable to wild-type Staphylococcus. Staphylococcus can survive in the environment but the risk to human health of the GM isolates is likely to be comparable to variants in the natural population, mutants will be handled in containment at level 2 which is appropriate for this work.
ChemGene HLD4-L will be used for disinfection and works by denaturing nucleic acids. ChemGene is biodegradable with no known health hazards. ChemGene disinfectant will be used at 5% concentration for bio-hazard contamination (small culture splash/spillage, < 5 mL) by washing surfaces with paper towels and allowing surfaces to dry before disposal of contaminated materials by autoclaving. For larger spills (> 5 mL): If aerosols may have formed, leave the area for 10 minutes and ensure no other staff enter. Culture should be covered in absorbent material soaked in 10% ChemGene which is then collected in an autoclave bag within a ‘Yellow Box’ for autoclaving. Surfaces should be treated with 2% ChemGene, left for 1 minute and wiped with disposable towels. Contaminated materials will be autoclaved as below.

For general disinfection, ChemGene will be used at 2% concentration. ChemGene is fast-acting and an effective kill should occur in 20 minutes. ChemGene is active against Staphylococcus and E. coli and is a suitable disinfectant for this project. Reference - http://www.medi-mark.co.uk/.

Biological waste, contaminated glassware and contaminated disposables will be autoclaved prior to disposal. Autoclave cycles: 126°C for 10 minutes for plastic discard, 126°C for 20 minutes for mixed/fluid discard, 134°C for 5 minutes for fabrics. The autoclave service and validation is organised by facilities management. Biological waste disposal will proceed according to the ‘Yellow Box’ SOP. Sharps will not be used with viable bacteria.

Project Ref 101/17.2
To study genomic events in S. Typhi using a safer attenuated derivative suitable for use at CL2.

S. Typhi BRD948 (aroC aroD htrA, also known as CVD908-htrA) harbours three independent, non-reverting mutations that have been fully sequenced and shown to be inactivating. It has been extensively studied in human volunteers and shown to be a safe and highly attenuated vaccine candidate. It fails to colonise the human host, and (as the parent S. Typhi) is unable to colonise plants or animals.

BRD948 is fully antibiotic sensitive.

All DNA is derived from S. Typhi Ty2, with no imported DNA. BRD948 harbours 3 specific DNA deletions intended to stably attenuate the strain.

BRD948 has been shown to be highly attenuated in multiple studies of human volunteers. This organism should not lose its attenuated phenotype as the genetic lesions have been well characterised in multiple in vivo and in vitro systems. The derivatives have been used by different groups in the UK for many years safely at CL2. BRD948 was originally recognised by HSE as disabled in 1993. Although BRD948 is designed to induce an immune response in humans it is most unlikely that such a response could be harmful, particularly as this immunisation favours a Th1 (non-allergic) response. Also, at least 10^8 bacteria in acid neutralising buffer are normally ingested to get any type of detectable response.
The microorganism is derived from Salmonella Typhi, but will be derogated to CL2 as it is highly attenuated and unable to colonise the human host. This derivative has an excellent safety record being handled at CL2 with no evidence of human infection either in the UK or abroad. This microorganism will be handled at CL2 at all times.

Disinfectant regime:

ChemGene HLD4-L will be used for disinfection and works by denaturing nucleic acids. ChemGene is biodegradable with no known health hazards.

ChemGene disinfectant will be used at 5% concentration for bio-hazard contamination (small culture splash/spillage, < 5 mL) by washing surfaces with paper towels and allowing surfaces to dry before disposal of contaminated materials by autoclaving. For larger spills (> 5 mL): If aerosols may have formed, leave the area for 10 minutes and ensure no other staff enter. Culture should be covered in absorbent material soaked in 10% ChemGene which is then collected in an autoclave bag within a “Yellow Box” for autoclaving. Surfaces should be treated with 2% ChemGene, left for 1 minute and wiped with disposable towels. Contaminated materials will be autoclaved as below.

For general disinfection, ChemGene will be used at 2% concentration. ChemGene is fast-acting and an effective kill should occur in 20 minutes. ChemGene is active against Salmonella and is a suitable disinfectant for this project. Reference - http://www.medi-mark.co.uk/.

Biological waste, contaminated glassware and contaminated disposables will be autoclaved prior to disposal. Autoclave cycles: 126°C for 10 minutes for plastic discard, 126°C for 20 minutes for mixed/fluid discard, 134°C for 5 minutes for fabrics. The autoclave service and validation is organised by facilities management. Biological waste disposal will proceed according to the “Yellow Box” SOP.

Sharps will not be used with viable bacteria.

### Project Additional Information

**Purposes of the contained use**

To investigate fundamental properties of Pseudomonas such as gene regulation, gene and genome copy number, features involved in virulence and pathogenesis, persistence and antimicrobial resistance.

**Recipient or parental organism**

The following Hazard Group 2 bacteria:
- Wild-type isolates of Pseudomonas species
- Laboratory strains of Pseudomonas aeruginosa, such as PA01, PA14
- Engineered P. aeruginosa strains (e.g. with mexT deletion/insertions).

The following Hazard Group 1 bacteria:
- Wild-type isolates and laboratory strains of Pseudomonas species
- Attenuated laboratory Escherichia coli strains such as DH5a, BL21, K12
- Engineered E. coli laboratory strains for conjugal transfer of plasmid DNA such as E. coliST18.

**Host/vector system**

Initial vectors to be used are listed below, but other vectors with similar properties, hazards and risks to those listed below may be used.

**Cloning vectors:**
- pGEM-T vectors
- pUC19
- TOPO vectors

**Expression vectors:**
- pGEX vectors
- pET vectors
**Custom Tn5 transposon mutagenesis vectors such as:** · pMOD-2 EZ-Tn5 <MCS> from Epicentre Biotechnologies · pALMAR3 · p298

### Origin & function

To be inserted into wild-type and laboratory strains of Pseudomonas aeruginosa and others such as Pseudomonas putida:

Transposons (e.g. Tn5, Himar) for insertion into target DNA (when introduced alongside a suitable transposase).

- Primer binding sites are included in the transposon for sequencing the resulting insertion libraries. The transposon will be modified to include a custom antibiotic resistance gene that naturally occurs in Pseudomonas. Transposons may also be modified by the addition of promoters of varying strength or fluorescent proteins to explore differences in expression,

- Variants of bacterial genes interrupted by the insertion of a selectable marker, such as naturally-occurring antibiotic resistance genes or other selectable markers such as tellurite resistance, to create gene knock-outs.

- Variants of bacterial genes altered, for example by site-directed mutagenesis, to replace or remove key sites in order to reduce or abolish the activity of the gene product.

Genes that can be used for counter-selection e.g. sacB

To be inserted into attenuated laboratory E. coli:

- Transposon mutagenesis vectors carrying transposons (e.g. Tn5, Himar)

- Variants of bacterial genes interrupted by the insertion of a selectable marker, such as naturally-occurring antibiotic resistance genes or other selectable markers such as tellurite resistance, to create gene knock-outs.

- Variants of bacterial genes altered, for example by site-directed mutagenesis, to replace or remove key sites in order to reduce or abolish the activity of the gene product.

Genes taken from Pseudomonas isolates known or thought to confer a phenotype of interest, such as antibiotic resistance.

### Evaluation of foreseeable effects

**Host strains:**

- Hazard group 1 bacteria are unlikely to cause human disease in healthy individuals, Hazard Group 2 bacteria can cause human disease but it is unlikely to spread into the community and effective prophylaxis and/or treatment is usually available.

**Identified risks:**

- Risk of infection due to inhalation of aerosol containing bacteria.
- Risk of infection through the skin due to contact of bacteria with cuts or abrasions on the skin.
- Risk of infection due to ingestion of bacteria
- Risk of environmental contamination through accidental release

**Severity of harm from Hazard Group 1 organisms is negligible in healthy individuals. Healthy individuals can be harmed by Hazard Group 2 organisms, but effective prophylaxis and/or treatment is generally available. Hazard Group 2 Pseudomonas species (i.e. Pseudomonas aeruginosa) are opportunistic nosocomial pathogens. They exist as a normal inhabitant of human intestinal flora and are widely dispersed in the environment. As opportunistic pathogens, they require an immunocompromised host in order to establish an infection, and as such the risk to individuals working in the containment level 2 laboratory is low.**

No hazards are associated with routine E. coli DH5α cloning strains which are E. coli K-12 derivatives. E. coli K-12 has a history of safe use, limited ability to survive in the human gut and does not produce toxins (HG1). E. coli ST-18 is an auxotrophic strain encoding conjugal transfer genes for mobilisation of DNA. This auxotrophic strain has limited ability to survive unless cultures are supplemented with 5-aminolevulinic acid.

**Vector/inserts:**
Vectors used in this work include routinely used commercial vectors. These vectors are not known to present a hazard. Other custom vectors may be mobilisable. Conjugative and mobilisable plasmids naturally occur within Pseudomonas populations and the resistance genes selected in this work already exist within these bacteria. The transposon mutagenesis vectors contain a single standard antibiotic selection gene (e.g. ampicillin) for propagation in E. coli. Transposon inserts will carry a naturally-occurring antibiotic resistance marker for selection of Pseudomonas (e.g. tetracycline) and an outward facing promoter. Constructs will carry a maximum of two resistance genes which poses minimal risk in the spread of environmental resistance. These antibiotics are not used for the treatment of Pseudomonas infections.

Genetically-modified organisms:
Transposon-transformed Pseudomonas will carry a resistance gene cassette (e.g. tetracycline). Mobilisable resistance genes occur naturally and the risk from the transformed strains is low. All transformed strains will remain susceptible to many antibiotics normally used for treatment of Pseudomonas infection, including beta-lactams and aminoglycosides. The resulting transposon mutant libraries may contain bacterial cells with activated genes as well as inactivated genes; this may alter phenotypes such as biofilm formation. However, any given transposon-mutated cell will likely only contain a single altered gene. It is therefore unlikely that any changes in gene regulation and subsequent phenotype will differ from those that can occur naturally. Pseudomonas aeruginosa infections can occur in immunocompromised individuals but are unlikely in healthy individuals. We will assess the antimicrobial resistance profile of Pseudomonas aeruginosa strains prior to transposon mutagenesis work and only proceed with strains susceptible to clinically-relevant antibiotics. The transposon mutants will contain an additional natural resistance gene and no non-native genes and are not expected to exceed HG-2.

Wild-type or laboratory strains of Pseudomonas will be transformed with functional gene sequences that have been modified to reduce or abolish their function, or with interrupted gene sequences or selective markers. These procedures will result in GMOs that in most cases are reduced in their ability to cause infection, or are phenotypically indistinguishable from the unmodified parent strains. As such these modified bacteria will pose either the same, or a reduced, hazard relative to their un-modified parents.

Attenuated lab E. coli may be transformed with functional or non-functional Pseudomonas gene sequences of interest. In the case of functional gene sequences, this may alter the E. coli phenotype to make them, for example, more resistant to a limited number of antibiotics or produce more biofilm, than their parent. As the E. coli are only being transformed with individual Pseudomonas genes, it is unlikely that they will substantially alter their phenotype relative to the unmodified parent. E. coli will also be transformed with modified genes that have been modified so as to reduce or abolishing the function of the gene product. These genes are therefore expected to have a minimal effect upon the phenotype of the E. coli. These laboratory strains of E. coli are attenuated, and as such would be out-competed and not survive in a non-laboratory environment. Therefore, even in the case of carrying functional gene sequences, the E. coli are unlikely to cause a greater hazard than their Hazard Group 1 parents. However, as a precaution all work will be conducted at Containment Level 2 and the E. coli treated as if they were Hazard Group 2 organisms.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The autoclave located in the BCRE CL2 main laboratory will be used to remove contaminated waste. Biological waste should be disposed of via the 'Yellow Box' route (as per the SOP) for steam sterilisation prior to
disposal. The waste will be contained in an unsealed autoclave bag and autoclaved once 1/2 full. Glassware containing contaminated cultures should be no more than half full. Yellow Boxes must have a biohazard label and the originators initials and lab must be recorded. Autoclave tape must be used in every run.

Autoclaving:
126°C for 20 minutes for plastic discard
126°C for 20 minutes for mixed/liquid discard
134°C for 5 minutes for fabrics.
The autoclave service and validation is organised by facilities management.
The autoclave runs are performed by trained staff.
Autoclave cycles will be monitored using the chart recorder to show a cycle has performed correctly.
Autoclaves are maintained and serviced by the facilities management in BCRE.

Is an emergency plan required according to regulation 20?  
If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

No concerns were raised.

Project Ref 101/19.1

Date Ackn'd 27/03/2019  
CU2 Project Title Manipulation of human induced pluripotent stem cell gene expression

Consent Granted

Class 2  
< 1 litre
The availability of human pluripotent stem cells (hiPSCs), capable of self-renewal with the potential to differentiate into multiple cell types, offers a powerful disease modelling tool. We will utilise advances in gene editing technologies that can manipulate gene expression to gain deeper insights into the molecular and cellular pathophysiological mechanisms underlying inherited diseases.

### Recipient or parental organism

The following Hazard Group 1 bacteria:
- Laboratory strains of E. coli, such as Ten10

The following Hazard Group 2 mammalian cells:
- Human fibroblasts
- Human pluripotent cell lines

### Host/vector system

Initial vectors to be used are listed below, but other vectors with similar properties, hazards and risks to those listed below may be used.

**Expression Vectors**
- dCAS9-VP64_GFP
- MS2-P65-HSF1_GFP
- CTS CytoTune KOS
- CTS CytoTune hL-Myc
- CTS CytoTune hKlf4

**Cloning Vectors**
- sgRNA(MS2) cloning backbone

### Origin & function

To be inserted into laboratory strains of E. coli and others such as Top10.
Vectors (e.g. dCAS9-VP64_GFP) to be inserted into laboratory strains of E. coli for replication. Selection will occur through antibiotic resistance e.g. Ampicillin.
To be inserted into mammalian cells, such as fibroblasts and iPSCs.
sgRNA(MS2) uses a short 20bp sequence to guide dCAS9-VP64_GFP bind to a DNA target site, combine with MS2-P65-HSF1_GFP activator helper complex to modify gene expression. This system can be used to enhance gene expression at target site in genome. GFP fluorescence can be used to identify successfully transfected cells.
Sendai virus non-integrating expression vectors that include the four Yamanaka factors, Oct3/4, Sox2, Klf4, and L-Myc (CTS CytoTune KOS, CTS CytoTune hL-Myc, CTS CytoTune hKlf4) to be inserted into mammalian cells such as fibroblasts to reprogram them into iPSCs.

Evaluation of foreseeable effects

No hazards are associated with routine E. coli cloning strains which are E. coli K-12 derivatives. E. coli K-12 has a history of safe use, limited ability to survive in the human gut and does not produce toxins (HG1).
Modified mammalian cells are a biohazard if inhaled, swallowed or absorbed through skin or needle stick. Therefore a risk of disease to humans and hazard group 2.
Plasmids contain an antibiotic selection gene (e.g. ampicillin) for propagation in E. coli, and an alternative antibiotic resistance marker for selection in hiPSCs (e.g. Puromycin). Constructs will carry a maximum of two resistance genes which poses minimal risk in the spread of environmental resistance. There is minimal risk of the plasmid being transferred to the environment.

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

**Project Additional Information**

**Purposes of the contained use**

To efficiently infect non replicating cells in vitro so that proteins or modified proteins which participate in signal transduction can be studied.

**Recipient or parental organism**

Recombinant vaccinia virus deficient in thymidine kinase. Has potential to infect humans. Immunodeficient or individuals with skin diseases will not work with virus. Expressed proteins are unlikely to alter growth/survival characteristics of infected cells as virus causes cell lysis.

**Host/vector system**

Recombinant vaccinia virus deficient in thymidine kinase to attenuate replicative capacity and virulence will be used to infect monkey kidney cells human and murine B and T lymphocyte tumour lines and murine primary lymphocytes.

**Origin & function**

cDNAs encoding human or mouse Vav proteins as well as mutated forms of Vav proteins in which specific domains have been rendered non functional either by truncation, deletion or point mutation. These mutants will be used to infect lymphocytes purified from mice which lack Vav protein expression.

**Evaluation of foreseeable effects**

Vaccinia Virus (VV) infection would be expected to result in sub-cutaneous disease, but this should be rapidly resolved by the immune system of non-immunocompromised individuals. Infection may give rise to mild fever. As the virus replicates poorly, systemic infection or transfer to other individuals is extremely low. Infection of certain areas, such as the eye or the skin of patients with eczema can lead to severe complications, as can infection of immunodeficient individuals. The virus is not spread by aerosols and we are not proposing to inject the virus into animals therefore needle stick injuries, which could lead to infection will be avoided. The so-called oncogenic forms of Vav have been defined on the basis of altered morphology of 3T3 cells and have not been shown to give rise to tumours that persist in nude mice. In any event since VV infection leads to cell death, transformation is unlikely to occur. The inserts will affect signal transduction within infected cells, but we anticipate these will be deleterious for cell survival. Mis-expression of signalling proteins is unlikely to manifest systemic effects. Moreover as infections with thymidine kinase negative VV are generally self limiting, the consequences of foreign gene expression are likely to be transient. The expressed genes are not anticipated to increase virulence. The virus has the potential to infect animals but not plants, and there are documented cases of VV transmission from humans to domestic animals, but VV has been shown to be very poorly transmitted in the wild. Recombinant VV are expected to be attenuated and transmit poorly between individuals or animals. Infected cell lines and primary lymphocytes will not thrive outside of the laboratory environment. VV can survive for a few days in dried material. The potential route for transmission to the environment
could occur via waste disposal. VV will be handled in Class II biological safety cabinets and the waste will be inactivated before disposal by autoclaving.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Tissue culture waste/bug waste etc is autoclaved at 126 C for 10’ at 2 bar. This programme is installed in the autoclave and cannot be changed by the Operator. All details of each run are printed out and kept for reference. The waste is then removed from the building, stored in a cold store until such time that it is transported to an off-site incinerator. These parameters are those suggested by the MRC and other safety groups.

Liquid waste (media) is autoclaved (bottled), then the contents are disposed of down the sink.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The Committee considered the proposal to be at Class 2. Full containment level 2 should be applied.

The Committee also emphasised the need to ensure that immunologist individuals or those with skin diseases do not work with viruses.

Project Ref 105/05.1
Purposes of the contained use
The overall aim is to produce lentiviruses that direct the expression of small hairpin RNAs (siRNAs) that interfere with the expression of the catalytic subunits of class I phosphoinositide 3-kinases (PI3Kinases) and thereby lower the levels of expression of these subunits in the mammalian cells into which they have been introduced.

Recipient or parental organism
The recipient organism will comprise several well characterised mammalian cell lines maintained in tissue culture; these are the HeLa, PLB-985, MDA-MB-231 and MDA-MB-468 cell lines.

Host/vector system
The lentiviral vector (pLV-TH) system is derived originally from human T-cell lymphotropic (HTLV) but has been extensively modified to increase its biosafety characteristics. In essence this is a 'third generation' system designed to minimise the risk production of viable virus in the destination cell type.

Origin & function
The inserted DNA is synthetic and directs the synthesis of short RNA sequences that are complementary to the target PI3Kinase subunit mRNAs.

Evaluation of foreseeable effects
The lentiviral vector itself engineered such that it cannot replicate in the recipient cells. Therefore any productive infection of host cells is very unlikely to occur. However, as the GMM is capable of infecting human cells, the nature of the insert is of importance.

The insert does not encode an oncogene or toxin protein. Therefore, whilst it is possible that production of the siRNA could disrupt normal function in a single infected cell, it is unlikely that this effect will propagate further.

The control measures in place to protect human health should result in minimal release of the GMM and therefore little associated environmental effects. Although the lentiviral vector is capable of infecting a wide range of mammalian cells the virus will be incapable of replicating in those cells and therefore no spread of the GMM can be visualised.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste will be autoclaved using an autoclave in the same building prior to disposal.

Liquid waste will be inactivated by the addition of Virkon to a final concentration of 1% (w/v) prior to disposal.

Both of these disposal methods will achieve 100% inactivation of the GMM.

Project Ref 105/05.2

Date Ackn'd 06/12/2005

CU2 Project Title Use of lentivirus to deliver shRNAs directed against regulators of cell death in human

Class 2

Culture Volume Class 2 < 1 Litre
The overall aim is to produce lentiviruses that direct the expression of small hairpin RNAs (shRNA) that interfere with the expression of members of the Bcl-2 family of proteins and also others that interfere with the expression of components of MAP Kinase signalling pathways, notably the oncogenic form of B-RAF.

The recipient organism will comprise several well characterised tumour cell lines maintained in tissue culture: these are Colo205, HT29, Co115, LS411, RKO, HCT116, SW620, BE, Lovo, SW48, SW480 and CCL39, also the adenoma cell lines, PC/AA/C1 and S/CG/C2.

The lentiviral vector (pLV-TH) system is derived originally from Human T-cell lymphotrophic virus (HTLV) but has been extensively modified to increase its biosafety characteristics. In essence this is a "third generation" system designed to minimise the risk of production of viable virus in the destination cell type.

The inserted DNA is synthetic and directs the synthesis of short RNA sequences that are complementary to the target mRNAs.

The lentiviral vector itself is engineered so that it cannot replicate in the recipient cells. Therefore any productive infection of host cells is very unlikely to occur. However as the GMM is capable of infecting human cells the nature of the insert is of importance.

The inserts do not encode oncogenes or toxic proteins. They actually encode shRNAs directed against various proteins involved in the regulation of apoptosis. One group contains shRNA directed against components of the MAP Kinase signalling pathway, in particular an oncogenic form of B-RAF, and so if anything the insert would be predicted to have an anti-oncogenic effect. Whilst it is possible that shRNA against any normal protein could disrupt normal cellular function, the B-RAF shRNA is specific for a point mutated form of B-RAF and so, due to mismatch, shouldn't impact on the expression of normal B-Raf protein. In addition, successful knockdown of components of the MAPK pathway would be expected to reduce cell survival and so any infected cell would be more likely to die and therefore be unable to propagate further. The other constructs are directed against members of the Bcl-2 protein family. These are regulators of apoptosis and in some cases are themselves regulated by the MAPK pathway downstream of B-RAF. Successful shRNA-mediated knockdown of these proteins might provide a survival signal but this would be cell autonomous, being confined to a single infected cell; any effect would not propagate further due to the fact that the construct is replication defective and lacks key genes (such as Tax) which would be
required to facilitate survival and proliferation of infected cells. In addition, it is close to impossible to envisage these inserts being transferred to other organisms except by recombination with WT HTLV.

The control measures in place to protect human health should result in minimal release of the GMM and therefore little associated environmental effects. Although the lentiviral vector is capable of infecting a wide range of mammalian cells the virus will be incapable of replicating in those cells and therefore no spread of the GMM can be visualised.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste will be autoclaved prior to removal for off-site incineration i.e. the waste is inactivated on site.
All solid waste will be treated with Virkon (final concentration of 1% (w/v) prior to being sealed in a burn bin and disposed of by incineration.
Liquid waste will be inactivated by the addition of Virkon to a final concentration of 1% (w/v) prior to disposal.
Both of these disposal methods will achieve 100% inactivation of the GMM.

**Project Additional Information**

**Purposes of the contained use**

The aim of this project is to use a lentiviral vector system to introduce the neuroprotective factor WldS and some mutants and potential modifiers of this factor into mammalian neurons in primary culture in order to verify the importance of specific sequences of the WldS protein in conferring the protective phenotype.

**Recipient or parental organism**

The recipient organism will comprise various characterised mammalian primary neurons maintained in tissue culture.

**Host/vector system**

The lentiviral vector system is derived originally from HIV-1. However the vector has been extensively modified (a "third-generation system) to increase its biosafety characteristics. In particular the system is designed to reduce the risk of production of viable virus in the destination cell type.

**Origin & function**

The inserted DNA is synthetic and directs the synthesis of a neuroprotective factor for axons, WldS, or mutants or potential modifiers of this factor that will lose or maintain the capability to induce neuroprotection.

**Evaluation of foreseeable effects**

The lentiviral vector itself is engineered such that it cannot replicate in the recipient cells. Therefore any productive infection of host cells is very unlikely to occur. However as the GMM is capable of infecting cells, the nature of the insert is of importance.

The insert does not encode either an oncogene or a toxic protein. High levels of expression of the inserts in mammals (mice and rats) in vivo are harmless. Therefore, it is unlikely that the insert will be harmful.
The control measures in place to protect human health should result in minimal release of the GMM and therefore little associated environmental effects. Although the lentiviral vector is capable of infecting a wide range of mammalian cells the virus will be incapable of replicating in those cells and therefore no spread of the GMM can be visualized.

Project Ref 105/06.2
**Project Additional Information**

**Purposes of the contained use**

The purpose is to study the effect of modulating the levels of proteins involved in intracellular signalling pathways or transcriptional regulation in either mammalian cell culture or in transgenic mice either by protein over-expression or the use of siRNA or antisense RNA technologies to reduce mRNA levels of the corresponding proteins.

**Recipient or parental organism**

The recipient organisms will comprise either various characterized mammalian cell lines maintained in tissue culture or single cell embryos.

The mammalian cell lines fall into two types:
- A packaging/helper cell line into which lentiviral DNA will be introduced, and from which infectious virus will be secreted into the medium to high titre. The media from these cell-lines poses a risk because of the high viral titre. As such this could provide a risk of infection to personnel working with the media.
- Recipient cell lines in culture. These cells will initially be exposed to a high titre of virus to permit infection (virus derived from (a) above). However the infected cell lines will be incapable of themselves producing active virus and as such are no more dangerous than the parental cell lines i.e. a negligible risk.

The single cell embryos are derived from standard mouse or rat laboratory strains. Following infection and culturing, the embryos will be extensively washed to remove free virus before transfer to recipient mothers. As such the embryos pose no more risk than that associated with culturing other mammalian cells.

In particular it should be noted that following implantation the embryos develop normally to term, and because of the nature of the lentiviral vector, no active viral particles will be made i.e. neither the mother nor offspring will be producing infectious virus.

**Host/vector system**

The lentiviral vector systems are derived originally from HIV-1. However the vector has been extensively modified (a "second-generation" system) to increase its biosafety characteristics. In particular the system is designed to reduce the risk of production of viable virus in the destination cell type. However it should be noted that the lentiviral vector systems carry the potentially oncogenic woodchuck post-transcriptional regulatory element (WPRE) sequence which has been implicated in causing cancer.
Origin & function

The inserted DNA are of three types:

a) Synthetic DNA sequences are designed to code for short RNA sequences (siRNA sequences) to cause a targeted reduction of the levels specific mRNAs and hence proteins involved in intracellular signalling pathways or transcriptional regulation in mammalian cells.

b) Mammalian cDNA sequences inserted into the lentiviral vectors to result in the synthesis of "antisense" RNAs complementary to specific mRNAs encoding proteins involved in intracellular signalling pathways or transcriptional regulation in the cell - resulting in selective reduction in the levels of those mRNA species and hence proteins in mammalian cells.

c) Mammalian cDNA sequences designed to result in over-expression of encoded proteins involved in intracellular signalling pathways or transcriptional regulation in mammalian cells.

Evaluation of foreseeable effects

The lentiviral vector itself is engineered such that it cannot replicate in the recipient cells. Therefore any productive infection of the host cells is very unlikely to occur. However as the GMM is capable of infecting human cells, the nature of the insert is of importance. Whilst it is possible that production of individual siRNAs or antisense RNAs could disrupt normal function in a single infected cell, it is unlikely that this effect will propagate further. The worse case scenario might be the reduction in the levels of a protein that normally facilitates cell apoptosis i.e. a pro-apoptotic protein. In this circumstance, cells that would normally die could survive. Even in this case the risk of serious effect is unlikely to be high as firstly, before cells could begin to proliferate in an uncontrolled manner, accumulation of additional mutations would need to occur, and secondly a large body of previous work on siRNAs suggests that the overall level of "knockdown" achieved does not generally exceed 80% and hence complete growth control is unlikely to be lost. More caution is required with respect to the lentiviral vectors directing expression of mammalian proteins. The worst case scenario is likely to be expression of a potential oncoprotein. Clearly this could result in transformation of infected cell. However, over-expression of proto-oncogenes in primary mammalian cells tends to result not in transformation; instead the result is either the induction of cellular senescence or the activation of apoptotic pathways resulting in cell death. Moreover, as the lentiviral vector itself carries the WPRE sequence that itself may have oncogenic potential, it seems likely that even in this worst case scenario that the recombinant virus would be more dangerous than the parental lentiviral vector.

The control measures in place to protect human health should result in minimal release of the GMM and therefore little associated environmental effects. Although the lentiviral vector is capable of infecting a wide range of mammalian cells the virus will be incapable of replicating in those cells and therefore no spread of the GMM is visualized.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The activity is restricted to the infection of cultured single-cell mouse or rat embryos. As such the containment and control measures will be exactly as described for infected mammalian cells in culture.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste material will be inactivated by treatment with 1% (w/v) Virkon solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (Vetspeed - Their GM authorization is GM 898) according to disposal notification GM 105/04.1).

This disposal method is expected to achieve 100% inactivation of the GMM. The data sheets describing inactivation by Virkon are attached.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
The local genetic modification safety committee approved the risk assessment at a meeting on 13/10/06. The committee discussed the transgenic rodents that would be finally generated from the lentiviral infected embryos. It was felt that for most transgenic animals, that this was likely to be a Class 1 activity and therefore need not specifically assessed in their proposal.

### Project Additional Information

#### Purposes of the contained use

Mice will be infected with various GM bacteria or fungi (altered to express marker proteins) and their ability to clear the infections and to raise effective immune responses will be monitored.

#### Recipient or parental organism

- **Aspergillus fumigatus** Allergens, aspergillosis ACOP 2
- **Listeria monocytogenes** Septicaemia; fever; diarrhoea ACDP 2
- **Helicobacter pylori** Gastritis; peptic ulcer ACDP 2
- **Salmonella typhimurium** Enteritis ACDP 2
- **Staphylococcus aureus** Toxin production abscesses, boils, and it can infect wounds ACDP 2

#### Host/vector system

r61A coding for various marker proteins will be introduced into the micro-organism either as a plasmid (with standard specific promoters for each micro-organism) or inserted into the genome of the micro-organism by homologous recombination. Genes allowing for selection of the GM micro-organism (e.g. kanamycin resistance) would also be included. N.B. The antibiotic resistance gene would not correspond to the antibiotic normally used to treat each pathogen.

#### Origin & function

cDNA coding for various proteins that can be used as 'markers' for the presence of the pathogen, for example, ovalbumin (a component of chicken eggs) and Luciferase (a gene from the firefly that can emit light).

#### Evaluation of foreseeable effects

The cDNAs introduced into the pathogens code for proteins which present negligible hazard to humans or animals. 'Infections with all organisms are treatable (see attached risk assessment information sheet). Antibiotic selection markers will not correspond to antibiotics normally used to treat that organism- The control measures in place to protect human health should result in minimal release of the GMM and therefore little associated environmental effects. Although the named micro-organisms are capable of infecting humans and animals the standard operating procedures described in the attached risk assessment will minimise their escape from containment and minimise the risk of exposure of workers to these pathogens.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Date of Significant Change

Project Additional Information
### Purposes of the contained use

The purpose is to study the effect of modulating the levels of proteins expressed in mammalian cells in culture either by protein over-expression or reduction in the levels.

### Recipient or parental organism

The recipient organisms will comprise various characterized mammalian cell lines maintained in tissue culture. The mammalian cell lines fall into two types:

a) A packaging/helper cell line into which retroviral DNA will be introduced, and from which infectious virus will be secreted into the medium to high titre. The media from these cell-lines poses a risk because of the high viral titre. As such this could provide a risk of infection to personnel working with the media.

b) Recipient cell lines in culture. These cells will initially be exposed to a high titre of virus to permit infection (virus derived from (a) above). However the infected cell lines will be incapable of themselves producing active virus and as such are no more dangerous than the parental cell lines i.e. a negligible risk.

### Host/vector system

The retroviral vectors which will be used are derived from either Moloney Murine sarcoma Virus (MoMLV), Mouse Mammary Tumour Virus (MMTh) or Feline Leukaemia Virus (FeLV), all of which are ACDP Hazard Group 1 biological agents.

On the other hand, the virus will be packaged by transfecting transfer vector into specific amphoteric ‘helper’ cell line (gag, poland any stably incorporated into host chromosome cells). **NOTE**: amphotropic packaging will widen the host range of the virus and allow it to infect a wide range if mammalian species (including humans) and cell types.

This means that the viruses produced for this experiment could potentially infect a number of species, including man.

However, bearing this in mind we should consider that the viruses that will be used have been modified in a number of ways which will make them safer to handle:

- The genes encoding structural and other components of the viral genome have been separated. These genes have been engineered to minimise the risk of recombination that could lead to production of a replication-competent virus.
- The packaging cell lines allow expression of proteins, required to produce progeny virus: But the transfer vector is the only genetic material transferred to the target cells, consequently these cells cannot produce the proteins which are essential for viral assembly and infectivity.
- Second, third generation or Self INactivating vectors retrovirus vectors will be used in all experiments (see SACGM compendium of guidance part2, section 2.11 (Retroviruses) ppl 17

### Origins and intended functions of the genetic material Involved

- **a.** Synthetic DNA sequences designed to code for short RNA sequences (5iRNA sequences) to cause a targeted reduction of the levels specific mRNAs and hence proteins in mammalian cells.
- **b.** Mammalian cONA sequences inserted into the retroviral vectors to result in the synthesis of ‘antisense’ RNAs complementary to specific mRNAs in the cell — resulting in selective reduction in the levels of those mRNA species and hence proteins in mammalian cells.
- **c.** Mammalian cONA sequences designed to result in over-expression of encoded proteins in target mammalian cells.

### Evaluation of foreseeable effects

Although these retroviruses are categorized at ACDP 1, a number of factors could increase the containment that will be required to work with them. We therefore need to consider worst case scenarios:

- The virus is packaged using an amphoteric system to allow transfection of human cells and this may have knock on effects when considering...
i) Biological properties of the gene product
ii) The expression characteristics and
iii) Provirus insertion (see below)

i) In the case of the introduction of retroviruses carrying DNA sequences encoding either antisense or RNA species into cells it is possible to envisage a scenario in which the knockdown of the mRNA targeted by the siRNA or antisense RNA, and hence the reduction in level of the encoded protein will have an effect on cell metabolism. Perhaps the most extreme example of this would be the reduction in levels of a protein that normally facilitates cell apoptosis, i.e., a pro-apoptotic protein. In this circumstance, cells that would normally die could survive. Even in this case the risk of a serious effect is unlikely to be high as firstly, before cells could begin to proliferate in an uncontrolled manner, accumulation of additional mutations would need to occur, and secondly a large body of previous work on siRNAs suggests that the overall level of knockdown achieved does not generally exceed 80% and hence complete growth control is unlikely to be lost. More caution is required with respect to retroviruses encoding mammalian proteins. The worst case scenario is likely to be expression of a potential oncprotein. Clearly this could result in transformation of infected cells. However, over-expression of proto-oncogenes in primary mammalian cells tends to result not in transformation; instead the result is either the induction of cellular senescence or the activation of apoptotic pathways resulting in cell death.

ii) The promoter could be highly active in a wide range of cell types (e.g., the CMV promoter).

iii) (From the SACGM compendium of guidance part 2, page 121) ‘The effects of integration upon the infected cell should be considered. For instance, promoter sequences present in the provirus might activate genes adjacent to the integration site or, alternatively, insertion may disrupt genes and prevent their expression. Therefore, retrovirus infection might induce permanent changes in a cell, resulting in tumourigenesis. It is recognized that, in humans, this appears so far only to have occurred in the context of deliberate transduction of large numbers of stem cells with a retrovirus vector. Furthermore, the transferred gene enabled the cells to proliferate in response to cytokines, and the many ensuing cycles of cell replication may have allowed additional, co-operating events to occur. High-titre inoculations are required to establish a clinically significant level of infection or gene transfer, and accidental infections of this magnitude are unlikely during standard laboratory-based manipulations of retroviruses. Nevertheless, retrovirus vectors have been shown to have transforming properties in vivo and a cautious approach to handling them is advised.’

Whilst it is possible that production of individual siRNAs or antisense RNAs could disrupt normal function in a single infected cell, it is unlikely that this effect will propagate further. The worse case scenario might be the reduction in the levels of a protein that normally facilitates cell apoptosis, i.e., a pro-apoptotic protein. In this circumstance, cells that would normally die could survive. Even in this case the risk of a serious effect is unlikely to be high as firstly, before cells could begin to proliferate in an uncontrolled manner, accumulation of additional mutations would need to occur, and secondly a large body of previous work on siRNAs suggests that the overall level of knockdown achieved does not generally exceed 80% and hence complete growth control is unlikely to be lost.

More caution is required with respect to retroviral vectors directing expression of mammalian proteins. The worst case scenario is likely to be expression of a potential oncprotein. Clearly this could result in transformation of infected cells.

The control measures in place to protect human health should result in minimal release of the GMM and therefore little associated environmental effects. Although the lentiviral vector is capable of infecting a wide range of mammalian cells the virus will be incapable of replicating in those cells and therefore no spread of the GMM is visualized.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The activity is restricted to the infection of cultured single-cell mouse embryos. As such the containment and control measures will be exactly as described for infected mammalian cells in culture.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste material will be inactivated by treatment with 1% (w/v) Virton solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (Vetspeed — Their GM authorization is GMGMS98) according to disposal notification GM1OS/41. This disposal method is expected to achieve 100% inactivation of the GMM. The data sheets describing inactivation by Virkon are attached. The activity is restricted to the infection of cultured single-cell mouse embryos. As such the containment and control measures will be exactly as described for infected mammalian cells in culture.

Project Ref 105/15.1

Date Ackn’d 25/06/2015  
CU2 Project Title Influenza A (H1N1) virus morbidity

Class 2  
CultureVolClass2 < 1 Literature

Non-GMM  
Consent Granted

Date Project Ceased 02/03/2022
Purposes of the contained use

Mice will be infected with various GM strains of influenza (altered to express marker proteins) and their ability to clear the infections and to raise effective immune responses will be monitored.

Recipient or parental organism

The recipient organisms will comprise of either:
(a) characterized mammalian cell lines maintained in tissue culture for transfection, growth and rescue of virus
(b) C57BL/6 and transgenic mice for virus morbidity studies

Host/vector system

Orthomyxoviridae, Influenza virus type A, Subtype H1 N1 (for strains see below) - All ACDP 2
• The influenza type A, subtype H1N1 and strain (WSN-OVA) ANVSN/33 virus containing the OVA 257-264 peptide was generated by reverse genetics (see D.J Topham; M.R. Castrucci; F.S. Wingo; G.T Belz and P.C. Doherty (2001) The role of antigen in the localization of naive, acutely activated and memory CD8+ T-cells to the lung during influenza pneumonia. J. Immunology, 167: 6983)
• For the generation of OVA variants flu viruses E1 (EIINFEKL) and G4 (SJIGFEKL) same reverse genetics principle was used to produce the engineered viruses (see Denton, A E et al. Affinity thresholds for naive CD8+ CTL activation by peptide and engineered Influenza A viruses. J. Immunol. 187, 5733-5744 (2011)).
• The influenza type A, subtype H1N1 virus and strain (NS1 -GFP ) AlPRl8/34 was generated using standard reverse genetics techniques of the virus NS1 gene (see Manicassamy, Bet al. Analysis of in vivo dynamics of influenza virus infection in mice using a GFP reporter virus. Proc.Nati Acad. Sci. USA 107, 11531-11536 (2010)).
• The influenza type A, subtype H1 N1 and strain (NanoLuc) AlCalifornia/04/2009 virus was generated by insertion of Gaussian luciferase gene into the NA segment of influenza virus by genetic modification. Weiqi, Pet al. Visualizing influenza virus infection in living mice. Nat. Commun. 4, 2369 (2013). Virus packaging will not be altered. The GM virus classification will be SACGM 2 (see Beare, A. S., G. C. Schild, and J . W. Craig. 1975. Trials in man with live recombinants made from AlPRl8f34 (HO N1) and wild H3 N2 influenza viruses. Lancet ii:729-732). Also, the Advisory committee on dangerous pathogens document - "Advice on Experimental working with Influenza Viruses of Pandemic Potential" - states that subtype/strains are not sufficiently different from currently circulating human viruses should be handled at higher containment - this does not apply to the subtype/strains to be used in these experiments.
Origin & function

Chicken Ovalbumin; Jelly fish (Aequorea Victoria) GFP; Marine copepod (Gaussia princeps) luciferase
Ovalbumin sequence 257-264 (SIINFEKL) and it's variants EIINFEKL (E1) and SIIGFEKl (G4); GFP gene as reporter; Gaussian Luciferase gene as reporter.

Evaluation of foreseeable effects

We classify the work with these H1 N1 influenza virus strains as SACGM 2 for the following reasons:
Strain AIWSN/33 is classified as BSL-2 by the ATCC
Strain A/PRJ8/34 is classified as BSL-2 by the ATCC
Strain A/California/04/2009 - is a currently circulating virus
Also, the Advisory committee on dangerous pathogens document - 'Advice on Experimental working with Influenza Viruses of Pandemic Potential' - states that, . Viruses with pandemic potential should be handled at higher containment (at CL3 or above as determined by risk assessment). These include subtypes H2, H1 and H3 if, in the case of the latter two, the viruses being handled are sufficiently different from currently circulating human viruses to warrant an assumption of little or no cross-reactive immunity in the human population.’
Since the H1 N1 virus strains we will be using are ‘currently circulating’ ones then this indicates containment level 2 will be adequate.
In addition the inserts are all known to be harmless.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For cells in culture the containment and control measures will be exactly as described for infected mammalian cells in culture.
For mouse infections all work will be carried out in a containment 2 area within the biological services unit. Mice will be handled within MSC II cabinets and housed in individually ventilated (HEPA filtered) sealed cages.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste material will be inactivated by treatment with 1 % (w/v) Virkon solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (Vetspeed - Their GM authorization is GMGM898) according to disposal notification GM105/4.1.
This disposal method is expected to achieve 100% inactivation of the GMM.
The data sheets describing inactivation by Virkon are attached

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The local genetic modification safely committee approved the risk assessment at a meeting on Wednesday 27th May 2015.

**Project Additional Information**

**Purposes of the contained use**

Induced pluripotent stem cells (iPSCs) are genetically reprogrammed somatic cells which exhibit a pluripotent stem cell-like state similar to embryonic stem cells. iPSCs can be derived by inducing selected gene expression via various methods including sendai virus-mediated gene transduction and chemical induction.
Recipient experimental systems are human peripheral blood mononuclear cell (PBMC), fibroblast– or other somatic
cell types. SeV vectors used in this kit consist of viral proteins NP, P, M, F (activated), HN, and L, and the SeV
genome RNA, from which the F gene is deleted. Because SeV infects cells by attaching itself to cell surface receptor
sialic acid, present on the surface of many cell types of different species, the vectors are able to transduce a wide
range of cells. However, they are no longer capable of producing infectious particles from infected cells, because the
viral genome lacks the F-gene. In addition, the presence of functional mutations such as temperature sensitivity in the
amino acid sequence of several SeV proteins (SeV/TS F, SeV/TS12 F, and SeV/TS15 F) renders the vectors easily
removable from transduced cells.

Host/vector system

The CytoTune™-IPS 2.0 Sendai Reprogramming Kit is a non-integrating system that uses Sendai virus (wild type
ACDP 1) vectors to reprogram somatic cells into induced pluripotent stem cells (iPSCs). The CytoTune TM-IPS 2.0
Sendai Reprogramming Kit contains three CytoTune™ 2.0 reprogramming vectors that are used for delivering and
expressing key genetic factors necessary for reprogramming somatic cells into iPSCs (see below).

CytoTune® Sendai hOct3/4 (Human Oct3/4; NM_002701.4) Pluripotency
CytoTune® Sendai hSox2 (Human Sox2; NM_003106.2) Pluripotency
CytoTune® Sendai hKlf4 (Human Klf4; BC029923.1) Proliferation
CytoTune® Sendai hc-Myc (Human c-Myc; K02276.1) Proto-oncogene, Proliferation

Origin & function

Human transcription factor genes used to reprogram human fibroblasts and PBMCs to produce iPSCs including:
Oct4
Sox2
Klf4
c-Myc (a known oncogene linked with several forms of cancer)
Sendai virus vector is a Cytoplasmic RNA vector. Sendai virus vector replicates its RNA genome and produces
proteins exclusively in the cytoplasm. It does not enter cell nucleus. In principle, the virus should not alter the
chromosomes in the cell nucleus.

Evaluation of foreseeable effects

SeV vectors used in this kit consist of viral proteins NP, P, M, F (activated), HN, and L, and the SeV genome RNA,
from which the F gene is deleted. Because SeV infects cells by attaching itself to cell surface receptor sialic acid,
present on the surface of many cell types of different species, the vectors are able to transduce a wide range of cells.
However, they are no longer capable of producing infectious particles from infected cells, because the viral genome
lacks the F-gene. In addition, the presence of functional mutations such as temperature sensitivity in the amino acid
sequence of several SeV proteins (SeV/TS F, SeV/TS12 F; and SeV/TS15 F) renders the vectors easily removable
from transduced cells. . . .J

Regarding the sequences being carried by this vector, some transcription factors are oncogenic e.g. c-Myc is a known
oncogene linked with several forms of cancer, therefore to minimise any potential risk of this oncogene getting into those
working with this system use SACGM containment Level 2

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Instead of autoclaving waste in the building, we propose to follow the procedure used by the Babraham Institute described in their disposal notification GM1 05/4.1 (see also above section 6 above for description). The waste disposal system used by the Babraham Institute is safe and has been running since October 2004. All liquid waste material will be inactivated by treatment with 1 % (w/v) Virkon solution prior to disposal. Solid waste material will be placed in sealed bins and incinerated by an off-site incineration company (Vetspeed - Their GM authorization is GM898) according to disposal notification GM105/4.1. Waste from our GM work at Class2 will be placed into suitably labelled hermetically sealable (red lid to distinguish them from class 1 waste) 60 litre UN approved (to Class 3) Type 3H21Y30/S/2003 bins. Sealed bins are placed into secondary 210 litre yellow labelled "Eurobins". Contents of the bin are recorded and collections by the local registered clinicalGM waste incinerator contractor will be made three times a week to prevent a buildup. The site has 24/7 Security. The contractor uses solid bodied transport and carries portable disinfection equipment in case of any spillage. Autoclave facilities will be available in an adjacent building, as required by the Regulations, in case of loss of the contractor's facilities. The type of container and the secondary Euro container, means that the risk of any spillage of active GM waste on site is negligible. However, as active waste will leave the site, the risk to the environment and health is possibly marginally higher than autoclaving prior to incineration. The only real risk of release would be as a result of a major RT A, however, the containers are designed to withstand this. This disposal method is expected to achieve 100% inactivation of the GMM.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste material will be inactivated by treatment with 1 % (w/v) Virkon solution prior to disposal. Solid waste material will then be placed in sealed bins and incinerated by an off-site incineration company (see derogation application above). Waste from our GM work at Class1 will be placed into suitably labelled hermetically sealable bins. They will be sealed by our staff and removed to a central collection point where they will be placed into 210 litre yellow labelled "Eurobins". Collections for incineration will be made by the local registered clinicalGM waste incinerator contractor. This disposal method is expected to achieve 100% inactivation of the GMM.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The scope and particular aspects of safety risks described in the risk assessment were agreed upon, and satisfactory consensus was achieved regarding the adequacy of the SOPs, COPs and risk management planning protocols. Pending notification and acknowledgement by relevant authorities.

Project Containment

Laboratory Activities

Glass Houses

Growth Rooms

02/03/2022
Adeno Associated Virus (AAV) mediated introduction of DNA sequences encoding proteins or RNA species into mammalian cells in culture and the organs/tissues of mice

The purpose is to study the effect of modulating the levels of proteins expressed in mammalian cells in culture or mouse organs/tissues either by protein over-expression or reduction in the levels.

The recipient organisms will comprise various characterized mammalian cell lines maintained in tissue culture or experimental strains of mice and transgenic mice.

The mammalian cell lines fall into two types:

a) A packaging/helper cell line into which AAV DNA will be introduced, and from which infectious virus will be secreted into the medium to high titre. The media from these cell-lines poses a risk because of the high viral titre. As such this could provide a risk of infection to personnel working with the media.

b) Recipient cell lines in culture. These cells will initially be exposed to a high titre of virus to permit infection (virus derived from (a) above). However the infected cell lines will be incapable of themselves producing active virus and
as such are no more dangerous than the parental cell lines i.e. a negligible risk.

**Host/vector system**

The AAV vector technology that we will use is based on a non-enveloped single-stranded DNA virus (Adeno Associated Virus - which are ACDP Hazard Group 1 biological agents) as vehicles to efficiently deliver and express genes in mammalian cells.

AAV viruses are taken up by endocytosis, released for transcription and expression following migration to the nucleus. Given the low pathogenicity of the recipient virus, the major hazards that will be posed by recombinant AAV vectors will depend upon the properties of the inserted genetic material and any products that it may encode.

**Origin & function**

Selectable markers – examples (but not restricted to);
- Ampicillin resistance: E.coli derived
- Neomycin resistance: bacteria derived aminoglycoside phosphotransferase gene
- Puromycin resistance (PAC) : Puromycin acetyl transferase is derived from Streptomyces alboniger
- Reporter proteins such as (but not restricted to);
- Fluorescent proteins as reporters e.g. GFP derived from the jellyfish Aequorea victoria and variants of this
- Luciferase – class of oxidative enzymes used in bioluminescence, renilla luciferase derived from the Sea pansy (Renilla reniformis), firefly luciferase derived from the firefly Photinus pyralis etc.

Open reading frames, cDNAs and gene sequences encoding proteins of interest and / or shRNAs (designed to knockdown the expression of Open reading frames, cDNAs and gene sequences encoding proteins of interest) – from various mammalian species, especially human and mouse.

This could include the expression of potentially harmful genes e.g. encoding known proto-oncogenes or genes with known oncogenic mutations or cytokines that can contribute to cellular transformation.

**Evaluation of foreseeable effects**

The AAV vectors employed in this protocol exhibit broad tropism and potential to infect human. Most work with AAV vectors would take place at containment 1 because:

i) Adeno-associated viruses (AAV) belong to the family Parvoviridae and there is no known link to any human illnesses. AAVs appear to be defective, requiring coinfection with a helper virus (for example Adenovirus or Herpes simplex virus) in order to replicate and this has led to their classification as Dependoviruses, a discrete genus within this family.

ii) The AAV-based vector systems we will use are ‘gutless’ AAV systems (of various serotypes) consisting of a plasmid containing the foreign DNA to be transduced into the cell flanked by AAV ITR sequences. Cloned rep and cap genes or expression of Adenoviral genes required for AAV replication (ie E1, E2A, E4Orf6 and VA RNA) supply helper functions.

iii) The ‘gutless’ nature of the AAV vectors we will use also mean that integration into the AAVS1 locus on human chromosome 19 will not occur, due to the lack of rep sequences in the vector backbone needed to target the genome to this locus. Long-term expression of genes transduced using AAV vectors is seen and this is thought to be mainly due to the maintenance of episomal genomes. However, the characteristics of AAV may thus have knock on effects when considering:

- Biological properties of the gene product
- The expression characteristics
  - In the case of the introduction of AAV carrying DNA sequences encoding either antisense or RNA species into cells it is possible to envisage a scenario in which the knockdown of the mRNA targeted by the siRNA or antisense
RNA, and hence the reduction in level of the encoded protein will have an effect on cell metabolism. Perhaps the most extreme example of this would be the reduction in the levels of a protein that normally facilitates cell apoptosis i.e. a pro-apoptotic protein. In this circumstance, cells that would normally die could survive. Even in this case the risk of a serious effect is unlikely to be high as firstly, before cells could begin to proliferate in an uncontrolled manner, accumulation of additional mutations would need to occur, and secondly a large body of previous work on siRNAs suggests that the overall level of “knockdown” achieved does not generally exceed 80% and hence complete growth control is unlikely to be lost.

ii) More caution is required with respect to AAV encoding mammalian proteins. The worst case scenario is likely to be expression of e.g. a potential oncprotein or cytokine. Clearly this could result in transformation of infected cells. However, over-expression of proto-oncogenes in primary mammalian cells tends to result not in transformation; instead the result is either the induction of cellular senescence or the activation of apoptotic pathways resulting in cell death.

iii) The promoter could be highly active in a wide range of cell types (e.g. the CMV promoter). (From the SACGM compendium of guidance part 2, page 121) The effects of integration upon the infected cell should be considered. For instance, promoter sequences present in the provirus might activate genes adjacent to the integration site or, alternatively, insertion may disrupt genes and prevent their expression. The ‘gutless’ nature of most AAV vectors means that integration into the AAVS1 locus on human chromosome 19 will not occur, due to the lack of rep sequences in the vector backbone needed to target the genome to this locus. Non-targeted proviral insertion is seen with AAV vectors. However, unlike the insertion events peculiar to retroviral life cycles, insertion of gutless AAV vector genomes is a passive mechanism that occurs at naturally occurring chromosomal breakpoints. Approximately 10% of all double stranded genomes are thought to integrate into host chromosomes in this way, and appear to passively target regions of transcriptionally active chromatin. Therefore the nature of most AAV vectors means that integration into the AAVS1 locus on human chromosome 19 will not occur, due to the lack of rep sequences in the vector backbone needed to target the genome to this locus. Non-targeted proviral insertion is seen with AAV vectors. However, unlike the insertion events peculiar to retroviral life cycles, insertion of gutless AAV vector genomes is a passive mechanism that occurs at naturally occurring chromosomal breakpoints. Approximately 10% of all double stranded genomes are thought to integrate into host chromosomes in this way, and appear to passively target regions of transcriptionally active chromatin.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For cells in culture the containment and control measures will be exactly as described for infected mammalian cells in culture.

For mouse infections all work will be carried out in a containment 2 area within the biological services unit. Mice will be handled within MSC II cabinets and housed in individually ventilated (HEPA filtered) sealed cages.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Instead of autoclaving waste in the building we propose to follow the procedure used by the Babraham Institute described in their disposal notification GM105/4.1 (see also section 6 above for description). Reasons for adopting this method of waste disposal are:

1. We do not have access to an autoclave within our area of the building
2. The waste disposal system used by the Babraham Research Campus is safe and has been running since October 2004.

All liquid waste material will be inactivated by treatment with 1% (w/v) Virkon solution prior to disposal. Solid waste material will be placed in sealed bins and incinerated by an off-site incineration company (Vetspeed – Their GM authorization is GM898) according to disposal notification GM105/4.1.
Waste from our GM work at Class 2 will be placed into suitably labelled hermetically sealable (red lid to distinguish them from Class 1 waste) 60 litre UN approved (to Class 3) Type 3H21Y30/S/2003 bins. Sealed bins are placed into secondary 210 litre yellow labelled "Eurobins". Contents of the bin are recorded and collections by the local registered clinical/GM waste incinerator contractor will be made three times a week to prevent a build-up. The site has 24/7 Security. The contractor uses solid bodied transport and carries portable disinfection equipment in case of any spillage. Autoclave facilities will be available in an adjacent building, as required by the Regulations, in case of loss of the contractor’s facilities. The type of container and the secondary Euro container means that the risk of any spillage of active GM waste on site is negligible. However, as active waste will leave the site, the risk to the environment and health is possibly marginally higher than autoclaving prior to incineration. The only real risk of release would be as a result of a major RTA, however, the containers are designed to withstand this. This disposal method is expected to achieve 100% inactivation of the GMM.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste material will be inactivated by treatment with 1% (w/v) Virkon solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (Vetspeed – Their GM authorization is GMGM898) according to disposal notification GM105/4.1. This disposal method is expected to achieve 100% inactivation of the GMM. The data sheets describing inactivation by Virkon are attached.

## Project Additional Information

### Purposes of the contained use

Studying the roles and regulation of cell signalling proteins.

### Recipient or parental organism

Mammalian cell cultures.

### Host/vector system

E1-deleted, replication-defective adenovirus vectors. The viruses will be generated from transfected plasmid DNA constructs, and grown, in cells that complement the E1 deficiency, e.g. HEK293 cells.

### Origin & function

The cell signalling proteins to be expressed will be derived from human or other mammalian species. In addition to the wild type forms, constitutively active or dominant negative mutants may be generated. They will have various roles (which are under investigation) in cell signalling pathways. The risk assessments included with this notification relate to Rho family proteins, and phosphoinositol-3 kinase (P13 kinase); as detailed in the risk assessments these are regulators of cell movement and proliferation.

(Risk assessments for other cell signalling proteins expressed in similar adenovirus vectors have been approved by the GMSC as class 1; these include phospholipase D, Arf family (GTPases, PIP kinases). Similar adenovirus vectors encoding other cellular signalling proteins may also be generated and used in this connected programme of work; it is our understanding that these would not require further notification to HSE if the GMSC agrees on the basis of risk assessments that there is no significant increase in the potential hazard.)
The cell signalling proteins that are to be expressed will have a variety of roles in the regulation of various cellular responses, eg inflammation, cell survival, control of apoptosis, proliferation, migration. For proteins of negligible apparent hazard, the viruses are classified as class 1. Viruses categorised as class 2 will express cell signalling proteins that have some association with harmful processes, eg. some may have been associated with a role in oncogenic transformation; however a role in cancer would only be in conjunction with many other oncogenic events, and so the degree of hazard from their transient expression in an E1-deleted adenovirus is only modest.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation applied for

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

autoclaving is preferred means of decontamination (effectively 100% kill). Liquid waste is autoclaved and disposed to drains. Disposable solid waste is also autoclaved before being removed as clinical waste, with final disposal by incineration.

The exceptions to the above are:
"Sharps", including scalpel blades, needles and disposable tips for micropipettors may be decontaminated by drawing up 1% Virkon disinfectant and soaking in Virkon for a minimum of 120 minutes. Disposable plastic pipettes may also be decontaminated by immersion in Virkon as above. Virkon has effectively 100% kill rate.

Project Additional Information

The reversible phosphorylation of tyrosine residues on proteins serves as a critical switch in the regulation of fundamental cellular processes including growth, adhesion and movement, and is controlled by the antagonistic actions of protein tyrosine kinases and protein tyrosine phosphatases (PTPs). PTPs function as critical "off" switches, antagonising oncogenic kinase signaling, and can initiate signaling cascades in their own right. The molecular mechanism of tyrosine phosphatase catalysis has been well characterised, however, the extracellular regulation and relevant substrates of many receptor tyrosine phosphatases have yet to be discovered. Recent technical developments in areas such as gene editing, organoid culturing, proteomics, and next generation sequencing mean that now is the perfect time to reveal physiological roles and regulatory mechanisms of this important protein family. We aim to understand the functional role of PTPs (specifically PTPRL) in the modulation of signal transduction, protein function and cellular/tissue responses; and their impact on physiological or disease states.

In order to ascertain such information, we will need to alter the expression of candidate genes involved in such processes, using knock-down or overexpression approaches; in addition, to manipulating their function using knock-in constructs, which harbour specific mutations, deletions and/or fusions. Although such manipulation (at least transiently) of cellular proteins structure or function in culture-adapted cell lines can be achieved using standard transfection protocols (lipofection-based, PEI or electroporation), lentiviral methods will allow long-term (stable) expression in difficult to transfect cell lines, and isolated primary cells and/or tissues.

Recipient or parental organism
Various established mammalian and human cell lines. Various primary mammalian and human cell lines. Murine tissues/explants cultured ex vivo.

Host/vector system
Lentiviral vectors based on replication-disabled HIV.

Origin & function
cDNA and/or shRNA offor genes involved in regulating the phosphorylation state of various proteins involved in signal transduction and/or the modulation of cellular function (including but not limited to members of the PTP (protein tyrosine phosphatase) family of proteins, specifically PTPR). Marker and reporter constructs that bear detectable tags for our gene of interest, such tags include but are not limited to GFP, c-myc, BirA and FLAG. Plasm ids involved in CRISPR-Cas9-mediated gene editing, which encode Cas9 variants, guide RNAs targeting our gene of interest and donor template DNA (containing a desired mutation, fusion or marker/reporter). Finally, we will target newly identified gene products that modulate or are a downstream target of protein tyrosine phosphatase activity.

Evaluation of foreseeable effects
We expect the majority of our constructs to increase decrease or otherwise alter protein phosphorylation, signal transduction and protein, cellular or tissue function; however, as the specific role of PTPs is ill-defined the exact outcome is uncertain. Despite this, PTPs are linked to regulating kinase signal transduction and therefore could possibly act as tumour suppressors. Conversely, we would not expect any cellular effects from the expression of markers or reporters.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Culture media will be disinfected with virkon or trigene
Leftover packaging cells and contaminated plastic ware will be discarded in a double bagged clear biohazard bag, sealed with red and white tape and placed in a Cfl2 waste bins for autoclaving

### Project Additional Information

#### Purposes of the contained use

Study of the function of the normal prion protein. This protein is found on the surface of all mammalian neurones, but its function is unknown, although increasing evidence suggests it may be involved in copper metabolism. We are conducting research into the possible roles of the protein using "normal" mouse prion protein as our model system. We express the protein in moderate quantity using a bacterial recombinant expression system. Following extraction, the protein is incubated with copper and its ability to bind the metal ion is measured. Part of our studies are to isolate antibodies to the protein to act as probes for the three dimensional structure of the protein. We expect to generate more data on the possible physiological roles of normal mouse prion protein. From this, we may deduce a mechanism for how the disease form of the protein causes the pathogenicity evident in the Spongiform Encephalopathies.

A broad range of agents that bind to the normal form of the prion protein may include some that have potential as diagnostics for the disease form so the generation of a panel of antibodies that bind to the wild type form is part of the proposed work.

#### Recipient or parental organism

The host for cloning the prion gene will be E.coli HB101 or E.coli XL-1 blue both non-colonising K12 derivatives.

For expression of wild type mouse prion protein, plasmids will be introduced into E.coli AD494 or BL21 (Novagen) for expression based on the T7 promoter.

#### Host/vector system

The recipient plasmid vector is a pET series vector (see www.novagen.com). The vector is based on a small multicopy non-mobilisable vector and carries the ampicillin resistance marker gene. Vector can replicate in most E.coli strains, although it is normally lost in the absence of antibiotic pressure. Expression of the prion protein cannot occur unless T7 polymerase is present through the use of specific E.coli recipients.

#### Origin & function

The incoming sequence is the Mouse prion gene (a allele) (Accession number MMPRP) - the complete coding region. No function, harmful or otherwise has been mapped to this gene product.

#### Evaluation of foreseeable effects

No harmful effects foreseen: cloning of prion protein gene sequence in E.coli XL-1 Blue or HB101 will not result in expression of the prion protein gene. Expression in E.coli BL21 or its derivative AD494 will result in prion protein accumulating in the cells, but these will be lysed after induction to release the protein for purification and study. No harmful effects have been ascribed to normal prion proteins, which are present in large quantities in the central nervous system of all mammals. Containment level 2 will suffice to prevent any dissemination of GMMs (including those residual recombinant E.coli actually containing the mouse prion protein that have escaped lysis) into the environment. Normal prion protein, unlike the protease-resistant isoform associated with "prion diseases" such as Bovine Spongiform Encephalopathy (BSE) or Creutzfeld-Jakob Disease (CJD), is fully sensitive to normal laboratory inactivation procedures.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste to be autoclaved. Waste will consist only of culture fluids and their containers. Autoclave operation routinely monitored for temperature/pressure achieved during
operation. 100% kill expected for routine operation. After autoclaving, waste to be disposed of in normal waste stream following this route of inactivation.

The advice in the Compendium of Guidance (Part 2A, Annex III) is clear that Containment level 2 is required, ie the activity is Class 2.

The Genetic Modification Safety Committee agreed with the assessment that the proposals present negligible risk to those involved, but took no note of this ACGM guidance, and agreed that Containment Level 2 was required.

Date of Significant Change

Project Additional Information

Purposes of the contained use

The human enteric caliciviruses are a major cause of viral gastroenteritis and as such pose a serious problem even in the developed world. A better understanding of how these viruses replicate and interact with their target cells is required so that we can better control outbreaks. Currently human caliciviruses cannot be grown in the lab hence in order to fully understand these viruses we need to use related animal caliciviruses that can be grown in the lab and genetically manipulated. This research aims to use the feline calicivirus as a model to dissect how the virus interacts with the host cell and how this interaction allows the virus to replicate.

Using a reverse genetic approach we are able to genetically manipulate the feline calicivirus genome to introduce mutations into the viral genes. The effects of these mutations will then be studied by looking at the phenotype of the mutant viruses. Using standard molecular approaches we also wish to identify regions of the virus genome that interact with host cell proteins and how this interaction controls genome translation and replication. The biochemical properties of calicivirus proteins will also be analysed in order to get a better understanding of how the virus replicates its genome - in particular we wish to understand how the viral RNA dependant RNA polymerase recognises the viral genome and subsequently replicates it to produce progeny virus.

We hope to achieve the following goals:
1) Understand how these viruses translate their genome into proteins by using reporter gene translation assays.
2) Characterise how the viral RNA polymerase replicates the viral genome by purifying the protein and biochemically analysing its various properties in vitro.
3) Develop cell based and cell free replication systems for these viruses to allow us to study the effects of mutations in viral genes.

Recipient or parental organism

Parental strains/ostrains to be used: Feline calicivirus (strain Urb) and human caliciviruses (HuCVs, ie Norwalk, Southampton and Manchester virus) - all ACDP HG2 pathogens.

Disabled E. coli strains DH5a, JM109 and BL21(DE3).

Disabled yeast strain EGY48 for use in yeast genetic screens.

Recombinant feline caliciviruses are unlikely to cause any greater harm than the parental strains as the mutations being introduced are likely to have a detrimental effect on replication (if any). 

Alterations of the major structural protein (orf2), thought to be main determinant of virus tropism [how these viruses infect a host cell], are specifically excluded from this project. (This exclusion however does not apply to the introduction of reporter genes into the orf2 sequence: such an insertion would replace the major part of the orf2 sequence and render the gene non-functional for virus particle formation).

In the cases where expression of calicivirus proteins occurs in E. coli or yeast, all the bacterial and yeast strains used are highly lab-adapted and carry mutations requiring the use of highly supplemented growth media. (Such strains cannot therefore survive outside the laboratory environment.)

Host/vector system

All plasmid vectors will be non-mobilisable pUC derivatives or pACT2 derivatives for propagation in yeast (non-mobiliseable, 2u origion of replication), all carrying antibiotic resistance or auxotrophic complementation markers.

Origin & function
Calicivirus genes both as altered and as mutated forms generated by PCR mutagenesis. All viral genes will be derived from either feline calicivirus (Strain Urbana from infectious virus or cloned cDNA) or from cloned non-infectious cDNA copies of human caliciviruses eg Norwalk or Southampton virus. All caliciviruses to be used are classified as category 2 pathogens - NOTE THAT THIS PROPOSAL SPECIFICALLY EXCLUDES THE USE OF RABBIT HAEMORRHAGIC DISEASE VIRUS (RHDV).

Specifically:
1) Human and feline calicivirus non-structural proteins, as both mature and precursor forms, the product of open reading frame 1 (orf1).
2) Human and feline calicivirus capsid (orf 2) and the minor structural protein encoded by orf 3.
3) Cellular proteins (of mammalian origin) known to interact with the calicivirus RNA genome. These include poly-C binding proteins, poly-A binding protein, poly-pyrimidine binding protein.

Reporter genes such as green fluorescent protein and its derivatives; luciferase and B-galactosidase.

**Evaluation of foreseeable effects**

Recombinant feline caliciviruses are unlikely to cause any greater harm than the parental strains as the mutations being introduced are likely to have a detrimental effect on replication (if any). Alterations of the major structural protein (orf2), thought to be main determinant of virus tropism [how these viruses infect a host cell], are specifically excluded from this project. (This exclusion however does not apply to the introduction of reporter genes into the orf2 sequence: such as insertion would replace the major part of the orf2 sequence and render the gene non-functional for virus particle formation).

In the cases where expression of calicivirus proteins occurs in E. coli or yeast, all the bacterial and yeast strains used are highly lab-adapted and carry mutations requiring the use of highly supplemented growth media. (such strains cannot therefore survive outside the laboratory environment).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None requested.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Lab benches will be swabbed daily with Tegodyne. Disposable plastic culture vessels (etc.) will be used where possible and autoclaved after use and before discard. All contaminated glassware will be treated with Virkon before autoclaving. Unless disposable, glassware then washed and sterilised for further use.

Powdered Virkon will be used directly to treat virus spills, before mopping up with paper towels. (Towels then enter routine waste stream, and autoclaved before disposal). Liquid waste treated with Virkon, and then autoclaved before disposal to drain. Autoclave operation routinely monitored for temperature/pressure achieved during operation; temperature of 134 degrees used on routine discard cycle; 100% kill expected under conditions of operation. Autoclaved solid waste sent to landfill.

Is an emergency plan required according to regulation 20? N

Tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The committee agreed that Containment level 2 was appropriate to minimise the risks from the proposed activity, and supported its notification to the Competent Authority.

#### Project Ref 107/08.1

- **Date Ackn’d**: 08/02/2008
- **CU2 Project Title**: Molecular analysis of Staphylococcus aureus and Streptococcus pyogenes physiology.
- **Class**: Class 2
- **CultureVolClass2**: 1-50 Litres
- **Non-GMM Consent Granted**: Not Applicable
- **Project notified under transitional arrangements**: N

#### Project Additional Information

**Purposes of the contained use**

This project aims to identify components of S. aureus and S. pyogenes that allow each organism to persist in the host environment. By assaying mutants for loss of function using in vitro model conditions, the contribution of various components to survival under stress conditions can be determined. It offers the potential for discovery of novel drug targets and strategies for treatment and prevention of S. aureus and S. pyogenes infections.

**Recipient or parental organism**
Host/vector system

Suicide vectors: pAZIO6, pMUTIN, pAULA, pMAD for use in S. aureus and S. pyogenes.
Transducing bacteriophage for S. aureus: phili, phi85
Vectors for L. lactis: pKS8O, pNZ8037; Vectors for E. coli: pUC1 8, pET2I

Origin & function

Plasmids are to be constructed and maintained in E. coli. Stable chromosomal insertions are constructed in both S. aureus and S. pyogenes by transposon mutagenesis and insertional vectors using common protocols. Antibiotic and heavy metal resistance (Cadmium, Erythromycin, Spectinomycin, Kanamycin and Tetracyclin) which are commonly used in both S. aureus and S. pyogenes will be used to construct stable chromosomal mutations where appropriate.

Methicillin-resistant strains of S. aureus [MRSA] will not be used.
Various genes of S. aureus and S. pyogenes will be expressed in E. coli and Lactococcus lactis for purposes of protein overexpression. No toxin or antibiotic resistance genes will overexpressed.

Evaluation of foreseeable effects

All E. coli clones are in a standard disabled background. Therefore they pose a low risk. L. lactis is a non-pathogenic (food grade) species.
The S. aureus and S. pyogenes mutant strains created are all stable insertions or deletions creating mutations. These are likely, if anything, to render the organism less able to survive and proliferate. Insertions are marked by antibiotic resistance markers (Erythromycin, Spectinomycin, Kanamycin and Tetracyclin) which are commonly used both S. aureus and S. pyogenes. Both organisms are opportunistic pathogens and all strains will pose no greater risk than their respective parents.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
none

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Normal microbiological practices. All contaminated waste will be autoclaved; discard autoclave has pressure/temperature probes for in-cycle monitoring. This results in total kill with no risk. Waste will consist of contaminated plasticware and glassware; culture plates and culture media; treatment by disinfection will not be used as a sole means of inactivating any viable GM Ms.
Waste will be collected from laboratories by trained staff, who will be fully informed of any risks associated with contents of the waste being collected, Waste to be stored safely pending autoclaving if not autoclaved immediately after collection.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
The members of the GMSC [known in the University as the Sub Committee for Biological Safety] agreed with the risk assessment for these proposals, and agreed that the project should be approved and notified to HSE.

Project Additional Information
### Purposes of the contained use

The purpose of this research is to understand how RNA viruses multiply in cells and form infectious particles for transmission with the aim of designing and testing new therapeutics to target these processes.

This study will investigate how virus particles are formed and devise new ways to prevent this from happening. How these viruses are able to grow inside cells will also be studied to determine precisely where and when the essential steps of the virus life cycle take place. Proteins from viruses will be expressed in mammalian cell lines by cloning into an expression plasmid in order to study the structure of virus-like particles by electron microscopy.

Using a reverse genetics approach Whale and mouse coronaviruses will be genetically manipulated to introduce mutations into the viral genes. The effects of these mutations will be studied by looking at the phenotype of the mutant viruses.

### Recipient or parental organism

#### Parental organisms:
- Arenavirus: Tacaribe, Pichinde, Junin Candid 1 vaccine strain
- Arterivirus: Equine arteritis virus
- Alphavirus - sinbis replicon
- Coronavirus, Human strains NL63, 229E, OC43, HKU1; Avian infectious bronchitis virus, Porcine TGE virus, Feline coronavirus and Whake SW1. Mouse hepatitis virus (temperature sensitive mutant)
- Torovirus: Eqire, Bovine and Porcine strains.

All viruses are ACDP HG2 with the exception of the vaccine strain of Arenavirus Junin. Junin Candid 1 vaccine strain is not listed on the ACDP list. Junin is HG4, however the vaccine strain has been classified as HG2 in the USA and has been successfully in the human population in Argentina - it is therefore proposed that this vaccine strain can be treated as HG2.

#### Recipient organisms:
- Escherichia coli K12 - Hazard group 1
- Human cell line HEK-293T - for virus and virus-like particle production
- Monkey cell line Vero-E6 - for virus growth and virus-like particle production
- Mouse cell lines DBt, 17Cl-1, L and OBL21a cells - for murine coronavirus growth

E. coli K12 is a highly lab adapted strain and cannot survive outside the laboratory environment. All mammalian cells are immortalised cell lines and cannot survive outside the laboratory environment.

### Host/vector system

- Non-infectious Sindbis virus replicase - for rescue of deletion mutants of equine arteritis virus.
- pCAGGS expression plasmid for the expression of viral proteins, cultured in both E. coli and mammalian cell lines.

Equine arteritis virus cDNA clone - for production of virions and virus-like particles.
- Mouse hepatitis virus cDNA clone - reverse genetic studies on replicase function.
- Whale coronavirus SW1 cDNA clone - reverse genetic studies on replication and pathogenesis.
CDNA clones are non infectious copies of the RNA genome.

Origin & function

For the production of Virus like particles in mammalian cells Arenavirus genes encoding Z, GP-C and NP proteins; Arterivirus genes encoding GP4 and GP2B proteins; Coronavirus genes encoding M, E, N, S and HE proteins and Torovirus genes encoding M, N, S and HE proteins will be cloned into pCAGGS. The virus like particles are not infectious.

Alphavirus (Sindbis replicon) and arterivirus will be co-transfected into a mammalian cell line to drive the expression of viable viruses.

Whale Sw1 and mouse hepatitis viruses will be mutated using a reverse genetics with debilitating mutations to the RNA replication machinery.

Alphavirus (Sindbis replicon) and arterivirus will be co-transfected into a mammalian cell line to drive the expression of viable viruses.

Evaluation of foreseeable effects

Virus like particles produced from the expression of arenavirus, coronavirus and torovirus are not infectious and are unlikely to cause any harm to the host.

The genetic modifications to MHV and SW1 coronaviruses will consist of:
1. Mutations to key replicative enzymes and motifs which are expected to attenuate virulence, and
2. Mutations which have been deliberately selected based on a debilitated or temperature-sensitive phenotype and engineered into infectious cDNA clones.

The hazards of GM strains should be less than for parental strains in both cases as the mutations introduced are likely to have a detrimental effect on replication.

Coronaviruses are highly host-restricted: MHV has only been found in mice and SW1 has only been found in one whale. Pathogenic MHV is known to circulate widely in Britain, and so these debilitated viruses are unlikely to survive in the wild in the event of an accidental release in competitions with the wild type. The university where this work will take place is not near and not directly connected with the ocean, hence accidental release of debilitated coronavirus SW1 is unlikely to spread the infection.

We will also produce both infectious and non-infectious equine arteritis virus particles using a Sindbis expression system in mammalian cells. Equine arteritis virus has, to date, only been detected in equids such as horses, and is unlikely to pose any health risk to humans. The viruses produced are less likely to produce infection in equids and there are no host reservoirs in the near vicinity of the campus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated waste will be autoclaved in a discard autoclave with the temperature probes for in-cycle monitoring. This results in total kill with no risk. Waste will consist of contaminated plasticware, culture plates and media. Treatment by disinfection will not be used as a sole means of inactivating any viable GMMs.

Waste will be placed in designated containers and collected from laboratories by trained staff, who will be fully informed of any risks associated with contents of the waste being collected. Waste will be stored safely pending autoclaving if not autoclaved immediately after collection.
Safety cabinets used for viral culture will be disinfected after use with Virkon and ethanol.

The members of the GMSC (known in the University as the Sub Committee for Biological Safety) asked for minor amendments to be made to the risk assessment. The committee agreed with the procedures specified in this risk assessment for this proposal and agreed that the project should be approved as a Class 2 project and notified to HSE.

**Project Additional Information**

**Purposes of the contained use**

Using genetic engineering techniques (point mutations and gene deletions) this project will try to produce TBEV viruses with reduced virulence in mice models with an aim of producing a potential live attenuated human vaccine.

The project also will attempt to alter the transmissibility of the TBEV (Siberian subtype) Vasilchenko. Strain between infected and non-infected ticks co feeding on mice by substitution genes or partial genes from the related TBEV (European subtype) Hypr strain.

**Recipient or parental organism**

**Parental Organisms:**
- Flavivirus: Tick borne encephalitis virus - strain Vasilchenko (Siberian sub-type) and strain Hypr (European sub-type)
- All viruses are ACDP Hazard Group 3.

**Recipient organisms:**
- Cell cultures (of porcine, human, hamster, mouse and tick origin) - Hazard Group 1
- Eschrichia coli AbleK, XL blue, DH5α and sure strains - Hazard group 1
- Spodoptera frugiperda cells (of insect origin) - Hazard group 1
- The E. coli strains used are highly lab adapted and cannot survive outside the laboratory environment.
- The S. frugiperda cells are immortalised cell lines derived from insect larva and cannot survive outside the laboratory environment.
- Other cellular lines of mammalian origin are common laboratory stocks with fastidious media requirements (listed as recipient organisms) and also cannot survive outside the laboratory situation.

**Host/vector system**

- Baculovirus AcMNPV (Hazard Group 1) - polyhedrin deleted mutant
- Plasmids pBR322, pUC118 and pTnEX1,1 - all non mobilisable small plasmids cloning vectors

**Origin & function**

The following are individual pieces of the coding region of TBEV that will be used to study individual protein structure and function; Capsid C, premembrane prM, membrane M, envelope E, nonstructural NS1, NS2A, NS2B, NS3, NS4Am, NS4B ans NS5, and untranslated regions 5'UTR of Vs and Hypr viruses. All are cloned into PBR322 or pUC118 plasmids or baculovirus AcMNPV.

These genes were derived from full length clones of the Vs and Hypr viruses. The infectious clones are cDNA copies of TBEV genomes that were previously contructed for the Vs and Hypr strains of the TBEV. The Vs infectious clone is called pGGVs and contains an entire copy of the Vs virus genome cloned in pBR322 vector.
The infectious clone for Hypr has not been constructed as a single-cloned molecule: instead the structural and nonstructural parts of the Hypr virus genome are cloned into two different plasmids both based on the pBR322 vector.

These plasmids are intended to be used to rescue the recombinant TBEV strains from infectious clone, with genetically modified individual genes listed above. The recombinant viruses will be constructed with the purpose to test the effect of the individual genes listed above on virus transmission in ticks.

The work with ticks will be carried out in Bratislava according to our long-term collaboration.

The genetically modified viruses will be used in cell culture to estimate the effect of individual genes (listed above) on the cytopathogenesis of TBEV and also for microarray analysis.

**Evaluation of foreseeable effects**

Experience gained from the early part of this work which was carried out in the Containment level 3 facilities at The Centre for Ecology & Hydrology, Oxford, where the applicant was formerly employed, is that the recombinant genetically modified viruses were never more virulent than parental viruses which are classified as ACDP Hazard Group 3 pathogens. All recombinant viruses rescued from the infectious clones previously showed either the same or a reduced replication rate in comparison with the parental viruses. Therefore no unusual adverse effects are expected in future experiments.

The natural host for the TBEV is the tick; the transmission of virus to humans in nature occurs by tick bite and this is not expected to occur in the laboratory setting (no ticks; no tick hosts in area).

The TBEV is not contagious for transmission between humans, it is not transmitted by aerosol or direct contact.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All contaminated waste will be autoclaved at 134 C for 30 mins in a discard autoclave with temperature probes for in-cycle monitoring. This results in total kill with no risk. Waste will consist of contaminated plasticware and pre-treated media. Treatment by disinfection will not be used as a sole means of inactivating any viable GMMs.

Waste will be pre-treated to a final concentration of 1% Virkon disinfectant and placed in designated containers, these will be transferred by the laboratory workers to the autoclave, loaded and the cycle started immediately. Records of cycle completion will be kept. A second autoclave is available as back-up.

Class I microbiological safety cabinets used for viral culture will be disinfected after use with 1% Virkon and 70% ethanol and will be fumigated prior to maintenance.

**Is an emergency plan required according to regulation 20?**

Project Additional Information
### Purposes of the contained use

The scope of the project is to study biologically relevant ginsenosides or metabolic derivatives in electrophysiological models of neuronal activity, to identify any effects on this activity that might correlate in any way to cognitive effects. Genetically modified human neuronal cells (ReNCell VM) will be used to establish an electrophysiological model of neuronal activity by culture on multi-electrode arrays (MEAs) enabling recording of electrical activity in response to the ginsenosides.

### Recipient or parental organism

| ReNcell VM cell line derived from human brain tissue |

### Host/vector system

ReNcell VM is a commercially available cell line derived from human foetal ventral mesencephalon and have been immortalised by the manufacturer by the incorporation of the v-myc oncogene by retroviral transduction with the murine moloney leukemia virus. The maternal donor has been screened for HepB, C and HIV and the risk of infection is considered to be low.

### Origin & function

No further modification of this cell line is proposed. Pre-modified cells will be screened for electrical activity in response to ginseng extract.

### Evaluation of foreseeable effects

No further genetic modification will occur. The neuronal cell line has been immortalized by the incorporation of the v-myc oncogene. Removal of growth factors

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All liquid waste and contaminated glassware and laboratory plastics (pipette tips etc) will be treated with 2% Trigene for 1 hr prior to autoclave treatment at 134 C for 30 mins in a discard autoclave with temperature probes for in cycle monitoring. This results in total kill with no risks. Treatment by disinfection will not be used as a sole means of inactivating waste.

The special electrode culture dishes will be treated with 2% trigene for 1hr and will then be treated with 70% ethanol, cleaned with detergent and sterilized for re-use, in line with manufacturers instructions. These dishes cannot be autoclaved.

**Is an emergency plan required according to regulation 20?** N

**Tick if you are claiming exemption from disclosure for section of the risk assessment** N

**Tick to confirm that it is attached to this form** N

**Tick to confirm that you have attached a risk assessment to this form** Y

**Tick if you are claiming exemption from disclosure for section of the risk assessment** N
The panel met with the principal investigators on the 14th of June 2012 and the panel were talked through the proposal.

BW explained that the funding body did not support research that was animal based and a human cell lines was needed for this study. Un-modified neurons do not survive for the extended culture periods required for these studies and so a genetically modified immortalized cell line would be required.

The host cell line is an undifferentiated neural cell line taken from foetal neural tissue. The maternal blood has been screened for HIV and other blood borne viruses, however, the cells themselves have not been screened and there is a low possibility that the cell lines could contain infectious material. The panel agreed that a precautionary approach should be used and Containment Level 2 facilites and that a no-sharps policy would be required.

The vector is a Mouse moloney leukaemia virus retroviral vector. Wild type MMLV is classified as ACDP Hazard Group 1. It is not clear, in the published literature or the information provided by the manufacturer whether this vector is replication deficient or whether the normal MMLV env gene has been replaced with an amphotropic env gene which can allow infection of human cell lines. Thus a cautious approach should be followed with a class 2 GM classification.

The gene insert is the human v-myc oncogene. Whilst no naked DNA will be used in this project there is a low risk of a tumour formation in the event that these immortalised undifferentiated cells are inoculated into the worker. The panel agreed that this cell line would require Containment Level 2 facilities and that a no-sharps policy would be required.

In light of these factors the technical review panel agreed that the proposal should be classified as a Class 2 GM activity.

Control measures BW and IS talked the panel through the control measures that will be implemented. Work will be carried out in a class II microbiological safety cabinet the Hopkins Containment Level 2 laboratories. No sharps (needles, scalpels or glass pipettes) will be used when working with this material. Solid Waste will be treated with 2% trigene for 2hrs before autoclaving). Liquid waste will also be treated with 2% trigene (final concentration) before autoclaving. The special culture plates will be disinfected with 2% trigene before washing and sterilisation with ethanol.

The panel agreed that these measures are proportionate to the level of risk and recommend approval of this project as a GM Class 2 activity to the SCBS, subject to minor modifications to the risk assessment. The GM safety committee agreed with this review.

**Project Ref** 107/13.1

**Date Ackn'd** 18/04/2013

**CU2 Project Title** Regulation of Neuronal and Cardiovascular cell Functions by Signal Transduction

**Class** Class 2

**Culture Vol Class** < 1 Litre

02/03/2022 Page 3132 of 15326
**Project Additional Information**

**Purposes of the contained use**

The overall aim of this programme is to discover the molecular pathways that control cardiovascular and nervous systems and their development. We are particularly interested in how certain proteins present within cells generate signals to control cell function. By elucidating the molecular mechanisms we can start to understand how the body works and what occurs during inflammation, cardiovascular and neurodegenerative diseases and in cancers. This will also allow us to find new therapeutic targets for the treatment of human disease.

The use of genetically modified microorganisms (GMMs) is essential if the goals of this research are to be realized.

**Recipient or parental organism**

Recipient organisms will include mammalian and primate cell lines from established culture collections such as epithelial cells (e.g. HEK293, CHO) and endothelial cell lines (e.g. HMEC-1).

In addition primary neuronal, cardiac and vascular cells and stem cells from rats and mice will be used. These host cells pose no threat to human health.

**Host/vector system**

**Adenovirus vector System**

The vector system is derived from the human adenovirus. The Early Region (ER) viral gene, which is essential for replication and transcription, has been deleted to make the virus safe. The E3 gene has also been deleted to allow insertion of genes of interest. The vector system consists of two plasmids. The first is a shuttle vector (pShuttle) into which the gene of interest is inserted. The second (pAdEasy-1) contains the adenovirus genome. Then using the efficient homologous recombination machinery of E. coli (e.g., BJ5183), the gene of interest is then inserted into the adenovirus genome containing plasmid. The resulting plasmid can then be used to generate infection-competent adenovirus.

Commercially available plasmids will be used e.g., pAd easy-1 and pShuttle (Stratagene) or p:E1sp1A. The plasmids are non-mobilisable themselves pose no threat to human health.

The virus produced will be a virus competent for infection, but not for replication. To become replication competent, the virus would have to recombine with wild-type virus. The probability of reversion to wild-type virus is expected to be negligible.
Adeno-associated Virus System

The vector system is derived from adeno-associated viruses, which are defective paroviruses and depend on essential helper functions provided by other viruses, such as adenovirus virus, for efficient viral replication and propagation. However E2A, E4, and VA RNA, cap and rep). The plasmids are non-mobilisable themselves pose no threat to human health.

Infection competent but replication incompetent adeno-associated viruses will be assembled by lipid-mediated transient transfection of HEK293 cells (or derivatives there of). An essential gene (E1) for the assembly of infection competent virus is expressed by HEK293 cells.

The virus produced will be a virus competent for infection, but not for replication. The virus particles are highly stable and thus, even low amounts should be identified and decontaminated appropriately. The risk to human health is low.

Lentivirus System

The vector system is derived from the human immunodeficiency virus (HIV-1). The virus has been stripped down to its minimum essential components, which have been encoded on four separate vectors. To inactivate the virus, in the unlikely event of recombination of the four plasmids, the vector is self-inactivating. This is achieved by the deletion of genetic sequence from the 3’ long terminal repeat encoding enhancer and promoter functions, resulting in the transcriptional inactivation of the provirus in the infected cell. The threat to human health is negligible.

Alternatively, commercially available plasmids will be used, that will serve the same purpose. The plasmids are non-mobilisable themselves pose no threat to human health.

Retro-X system (Clontech): The viral vector system is derived from the Moloney murine leukaemia virus (MMLV). The vectors are self-inactivating bicistronic expression vectors designed to express a target gene along with an antibiotic selection marker without the risk of promoter interference from the 5’ LTR. The self-inactivating feature of the vectors is provided by a deletion in the 3’ LTR enhancer region (U3). During reverse transcription of the retroviral transcript in the infected cell, the inactivated 3’ LTR is copied and replaces the 5’ LTR, resulting in inactivation of the 5’ LTR promoter (CMV).

Infective competent but replication competent lentiviruses will be assembled by lipid-mediated transient transfection of four plasmids into the packaging cell lines, including HEK293-based (HEK293T (human embryonic kidney cells, HEK293FT) and NIH/3T3-based.

The virus produced will be a virus competent for infection, but not for replication. The virus has been pseudotyped to utilize the envelope protein from the vesicular stomatitis virus glycoprotein (VSV-G). This is common practice with lentiviruses and will make the virus amphotropic i.e. broad tissue tropism. It is expected that host-defence mechanisms would be effective against this replication incompetent virus. The probability of reversion to wild-type virus is expected to be negligible.

Human and mammalian genes from the following categories:

A) Cell-surface receptors e.g., G protein-coupled receptors such as protease-activated receptors, cannabinoid receptors and neuropeptide receptors

B) Ion Channels e.g., transient receptor potential channels, voltage-gated ion channels, potassium channels.

C) Transporters e.g., glutamate transporters.

D) Regulatory proteins e.g., glutamate transporters.

E) Signalling proteins e.g. extracellular-regulated protein kinases, ROCO proteins.

F) Peptidases e.g., trypsins, endothelin-converting enzyme-1, matrix metallopeptidases.

G Regulators of cell cycle and survival e.g., B1, Bcl2

H) regulators of gene expression e.g., RNA processing factors, post-transcriptional regulators (e.g., exon junction complex proteins).

I) Control proteins e.g., fluorescent proteins i.e. GFP, YFP, RFP.
| J) Focal adhesion, cytoskeletal, metabolic, circadian and nucleocytoplasmic shuttling proteins. |
| K) Proteins involved in interpreting the cellular microenvironment e.g. integrins, Roc, Rho. |

**Evaluation of foreseeable effects**

Bacteria: The plasmid vectors are non-mobilisable and therefore are unlikely to escape from the host cells. Since the inserted plasmid DNA is under the control of the CMV promoter, the inserted gene will not, in any case be expressed by the bacteria. For those bacteria that are used to produce proteins, these will require IPTG to induce expression and hence these proteins will not in any case be expressed by the bacteria. For those bacteria that are used to produce proteins, these will require IPTG to induce expression and hence these proteins will not be expressed outside of the laboratory environment. The pathogenicity and toxicity of the bacteria to humans will not be altered.

Viral vectors: All viral vectors are infectious but have been modified to be replication deficient. The likelihood of ability to cause harm to humans is low.

Mammalian cells/ tissues: These cells and tissues would already express many of the genes to be introduced. The cells may become hyper-responsive to certain agonists or have exaggerated signalling responses. The likelihood of this changing the pathogenicity or toxicity to humans is negligible.

The genetically modified viral vectors are replication deficient and would not be able to be transmitted in the environment. The bacteria and final host cells/tissues are unable to survive outside the laboratory environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated waste will be autoclaved in a discard autoclave with temperature probes for in-cycle monitoring. This results in total kill with no risk. Waste will consist of contaminated plasticware, culture plates and media. Treatment by disinfection will not be used as a sole means of inactivating any viable GMOs. Waste will be pre-treated with 5% Biocleanse solution before being placed in designated containers and collected from laboratories by trained staff, who will be fully informed of any risks associated with contents of the waste being collected. Waste will be stored safely pending autoclaving if not autoclaved immediately after collection.

**Is an emergency plan required according to regulation 20?** N

**If yes, tick to confirm that it is attached to this form** N

**Tick to confirm that you have attached a risk assessment to this form** Y

**Tick if you are claiming exemption from disclosure for section of the risk assessment** N
The proposal was reviewed by a technical review panel on behalf of the SCBS (acting as GM committee). The reviewers agreed with the concept of a connected programme constituting an umbrella proposal and risk assessment with each Principal Investigator submitting a more specific application to join the project to be assessed by the GM committee.

The reviewers agreed that due to the route of infection of adenoviruses being aerosol, there was a need to control aerosols using microbiological safety cabinets. The reviewers agreed that this work constituted class 2 GM activity subject to the following revisions to the risk assessment:

- Risk assessment needs to clarify exclusion of sharps
- Recommendation to wear safety glasses to prevent mucocutaneous transmission.
- Procedures for centrifuges need clarification (specify the opening of centrifuge buckets and rotors in safety cabinet).

The reviewers discussed the intended work with lentiviral vectors, and concluded as the vectors have an extended host range due to VSV-G (i.e., could deliver to human cells e.g., through broken skin or eyes), and due to the relatively high titers proposed, classification of Class 2 would be appropriate. The need identified to restrict use of sharps and use of gloves to prevent percutaneous/mucocutaneous transmission results in classification of class 2.

Subject to minor modification and clarification, the reviewers recommended the SCBS committee approve this project as a Class 2 activity. The SCBS committee agreed with this approval.

Project Additional Information

Purposes of the contained use

The overall aims of this connected programme are:

Metal metabolism and pathogenicity.
Since iron uptake and control are key aspects of bacterial survival and pathogenicity, this aspect will focus on potential (and defined) iron transport and iron homeostasis genes in B. cepacia, P aeruginosa and P. syringae, E. coli O157 (stx-), S. typhimurium and S. gallinarium and E. coli K-12. Modifications will involve gene knock out by replacement or integration, generation of gene fusions to study expression, topology, interaction, and protein function. Some modifications will be plasmid based, others will be chromosomally integrated. Modified genes will be assembled in plasmid vectors (using E. coli K-12) before re-introduction into the source strain. Expression in response to metals and metal-regulators will be studied in E. coli mutants lacking key regulators (e.g. Fur) as well as in the original host strains. Genes will also be introduced into plasmids to enable complementation of mutants and for gene amplification. A range of common/standard antibiotic-resistance markers will be employed and inserted into the above strains. Effects of mutations on pathogenicity and/or survival will be examined in tissue culture, by invertebrate infection, by gut-model colonisation, by soil colonisation or by plant colonisation.

Plant/soil colonisation.
E. coli O157 is a potentially deadly foodborne pathogen. Infection is often achieved through contamination of food plants. E. coli O157 (and related pathogens) is able to colonise, survive and propagate on crop plants which mediates its maintenance within the herd and enhances transmission to the human host. E. coli O157 (stx-) mutants will be used to study colonisation factors on a number of plant systems. In addition, directed mutations will be generated in candidate plant colonisation genes. Phenotypes will be confirmed by complementation. Plant-adapted strains will also be subjected to targeted gene knockout and transfer of candidate-plant-colonisation genes to non-adapted strains. Mutations in metal metabolism genes will be studied. EAEC and Salmonella plant colonisation experiments will also be performed, as above.

Recipient or parental organism

E. coli O157 stx deletion mutants, Entericaggregative E. coli strains, S. typhimurium, S. gallinarium, S. enterica complex.
Burkholderia cepacia complex
Pseudomonas aeruginosa, Pseudomonas syringae, Pseudomonas fluorescens
Environmental isolates including Erwinia, Xanthomonas, Pantoea and Citrobacter species.

Host/vector system

A range of broad host vectors will be utilized in this project for cloning together with plasmids for reporter and expression studies

Origin & function

Various genes from the species listed above which are suspected of influencing the pathogenicity of bacteria or their ability to survive in the environment.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
For limited experiments a plant growth room will be required. In order to autoclave the solid waste the autoclave in a nearby building (<10 meters away) will be utilized. Waste will be transferred in sealed secondary containment.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated waste will be autoclaved in a discard autoclave with temperature probes for in-cycle monitoring. This results in total kill with no risk. Waste will consist of contaminated plasticware, culture plates and media.

Treatment by disinfection will only occur in limited circumstances where re-usable containers cannot be autoclaved. Containers will be immersed in Virkon at a final concentration of 2% for 16-18 hrs.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The proposal was reviewed by a technical review panel on behalf of the SCBS (acting as GM committee). The project to be assessed by the GM committee.

The review panel thought that the use of a E. coli 0157 mutant was justified and that the deletion of the stx from the strains (confirmed by sequencing) was consistent with a class 2 designation.

The panel agreed that none of the four projects targeted known virulence factors and there were no plans to enhance pathogenicity.

The review panel noted that the bacteria isolated from the environment would be isolated and characterised prior to any GM activity and that no enrichment for human pathogens would take place.

The panel discussed the infection models proposed with the principal investigators in some detail and agreed that the control measures were appropriate.

Subject to minor modification and clarification the reviewers recommended the SCBS committee approve this project as a class 2 activity. The SCBS committee agreed with this approval.

The overarching aim of our research is to understand the molecular pathways that occur in haematopoietic and endothelial cells to help us to understand their role in haemostasis, thrombosis, inflammation and vascular development. This research is hampered by the absence of a nucleus in platelets and the difficulty to transfect haematopoietic and primary endothelial cells with exogenous DNA constructs using standard molecular biology procedures. To overcome this obstacle we propose using the lentiviral system (third generation defective) to drive infection as an alternative to transfection. We will also use this approach in endothelial cells due to the high levels of infection which can be achieved. We will use this approach to express fluorescently tagged wild type proteins of interest, wild type and mutant proteins of interest and to knock down the expression of specific gene-products using RNA-interference, so that we can address the important roles of individual proteins involved in haematopoietic and endothelial cells. This programme covers the generation of lentivirus both to ectopically express protein as well as to knock down protein expression in both human and mouse derived haematopoietic cells or other primary cells.
Human cell lines (e.g. Dami, Hel, Meg-01) will be transduced with lentiviral particles to assess protein knock down and to investigate function of expressed full length or mutated proteins.

Primary vascular and lymphatic endothelial cells (ECs) and related cell lines (e.g. HMEC-1 and MCEC-1) will be transduced with lentiviral particles to assess protein knock down and to investigate function of expressed full length or mutated proteins.

Host/vector system

A third generation lentiviral system will be used. This is a four plasmid system. It is considered highly unlikely that recombination among all the vectors to generate replication competent viruses will occur. (Reference: A third generation lentiviral vector with a conditional packaging system, Dull T, Zufferey R, Kelly M, Mandel RJ, Nguyen M, Trono D, Naldini L. J Virol. 1998 Nov; 72(11):8463-71).

Risk of regenerating replication competent virus or the parental virus (HIV). In third generation lentiviral vectors all the regulatory/accessory proteins (Rev, Tat, Vit, Vpr, Vpu and Net) are removed, except for Rev. Rev acts at the post- transcriptional level and is necessary for HIV gag/pol expression. Rev binds to an RNA motif (Rev responsive element [RRE]) and facilitates the cytoplasmic export of gag/pol messenger. As an extra safety measure Rev is placed on a separate vector (RSV-Rev) from the transfer vector. Only 700 bp of the HIV envelope protein are present in the transfer vector, plus RRE and the packaging signal. The packaging construct contains the minimal RRE of 374 bp and the gag/pol genes. Through deletions in both L TR's and the absence of 5 of the 6 accessory proteins, including the replication essential Tat it is highly unlikely that replication competent virus is produced. In published studies replication competent virus has never been detected. The HIV-envelope protein is replaced by non-retroviral envelope protein (VSV-G). It is highly unlikely that this will be incorporated in a new hybrid replicative virus. It is impossible that wild-type HIV will be formed, because of the omission of 5 accessory proteins and HIV-env. The lentiviral vectors to be used in this study are third generation lentiviral vectors purchased from Addgene and Biosettia.

Origin & function

Fluorescent tags derived from jellyfish and coral (Section A).

Mouse and human genes of interest will be cloned from either previously cloned cDNA or form sourced IMAGE clones of wild type sequences. We will use wildtype and mutant forms of the proteins, which may be truncated or contain point mutations (Section B).

Short hairpin (shRNA) will be designed to knock down the expression of genes of interest. Clones will be purchased from Open Biosystems or other commercially available libraries (Section C).

Section A

Green Fluorescent Protein (GFP) and derivatives from Aequorea coerulescens
OsRed and derivatives from Discosoma Sp.
mEos2, a derivative from Eos from Lobophyilia hemprichii

These molecules serve as reporters and change in fluorescence upon exposure to various wavelengths of light

Fluorescent bioprobes which enable the visualisation of signalling events.

Section B

Human and mouse wild-type and mutant forms of:
The lectin receptor CLEC-2: the receptor for endothelial cell protein Podoplanin
Haematopoetic receptors: including GPVIIIFcRy, FcyRIIA, G6f, G6f-like
Actin regulatory proteins: Involved in the regulation of the morphology of haematopoietic and endothelial cells.
Signalling proteins (e.g Syk, Tec family kinases, SLP-76, PLCy2) are implicated in the assembly of signalling
complexes and function of haematopoietic cells and endothelial cells.
Adapter molecules (e.g. Spred family proteins) may be implicated in receptor signal transduction in haematopoietic 
and endothelial cells.
Inhibitory signalling molecules: Protein implicated in the inhibition of cell function such as phosphatases or ITIM 
bearing receptors
Podoplanin, ERM family of proteins, Small GTPases: Podoplanin is the endogenous ligand for the platelet receptor 
CLEC-2 and has been reported to promote cell migration through its interaction with small GTPases and ERM family 
members.
Integrins: They are involved in cell adhesion and signalling
Focal adhesion associated proteins: These provide a structural link between the actin cytoskeleton and the 
extracellular matrix.
Receptor kinases and their ligands (e.g. Eph kinases and ephrins)

Evaluation of foreseeable effects

Viral vectors: viral vectors are infectious but have been modified to be replication deficient. The likelihood of ability to 
cause harm to humans is low.
Mammalian cells: These cells would already express many of the genes to be introduced/knocked down. The 
likelihood of this changing the pathogenicity or toxicity to humans is negligible and is not thought to result in increased 
cell proliferation.
The genetically modified viral vectors are replication deficient and would not be able to be transmitted in the 
environment. The bacteria and final host cells are unable to survive outside the laboratory environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The proposed location for this work is in two buildings, the Harborne building and the Lyle building. These two 
buildings are connected by an internal bridge corridor. The Lyle building does not house its own waste autoclave and 
the intention is for waste to be transported in sealed containers from the Lyle 1st floor to the Harborne ground floor 
waste autoclave via the internal corridors.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated waste will be autoclaved in a discard autoclave with temperature probes for in-cycle monitoring. 
This results in total kill with no risk. Waste will consist of contaminated plasticware, culture plates and media. 
Treatment by disinfection will not be used as a sole means of inactivating any viable GMMs.
Waste will be pre-treated with 2% BioCleanse solution before being placed in designated containers and collected 
from laboratories by trained staff, who will be fully informed of any risks associated with contents of the waste being 
collected. Waste will be stored safely pending autoclaving if not autoclaved immediately after collection.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

02/03/2022
The committee reviewed the risk assessment in January 2016 - the committee thought the risk assessment was very well thought through and approved subject to minor amendments (use of bioclense rather than trlgene as a disinfectant). The committee thought the classification was borderline class 1/2 but that it warranted class 2 due to the relatively high titres, the need for gloves and no sharps policy.

**Project Additional Information**
**Purposes of the contained use**

The project aims to simulate the evolution of human brain metastases in vitro, using different cancer cell lines representing types of cancer that commonly metastasise to the brain. To study this evolution, we will culture these cell lines in hippocampal brain slices, the environment a metastasis would have to adapt to. Cells will be re-cultured this way repeatedly to establish successively evolved generations. Studying the evolution of these cells can give us more insight into the necessary adaptations the cells must have in order to metastasise to the brain. This characterisation will involve electrophysiology, calcium imaging (2photon) and can be later matched with genomic data and lead to new targeted therapies specific to cancer type.

In order to study the cancer cell electrophysiology whilst in the slices as well as retrieve them after culturing, the cells must be permanently tagged. For this reason we will need to create genetically modified populations of cancer cell lines, using lentiviruses containing a vector for red fluorescent protein (RFP), a fluorescent tag. Lentiviruses can be used to insert a desired gene into a cell population with long-term gene expression. The stability will mean the cells can be transfected once to last during the long-term evolution of the cancer cells. Cancer cells from a selection of cell lines will be the main tools of the project and will be transfected only to express RFP as all other functions and morphology are to be studied.

**Recipient or parental organism**

Mammalian cell lines (human): ACDP Category 1 or 2  
Lenti-X 293 (human embryonic kidney cells)  
Cancer cell lines including:  
U87-MG (human epithelial neuroglioma cell line)  
SK-MEL-28 (human malignant melanoa cell line)  
MDA-MB-231 (mammary gland adenocarcinoma cell line)  
MCF-7 (mammary gland adenocarcinoma cell line)  
A549 (lung carcinoma cell line)  
HT1080 (fibrosarcoma cell line)  
DU145 (prostate cancer cell line)

The inserted genes will be control proteins e.g., fluorescent proteins i.e. GFP, YFP, RFP, mCherry.

**Host/vector system**

**Description of Vector:**  
Expression vectors (CMV, RSV promotors) required for viral particle production including:  
Lentivirus (pCMV-dR8.74 packaging plasmid, pMD2.G envelope plasmid and pLenti6.3-CMV-mCherry2 transfer plasmid).

Plasmids do not contain mobilization genes and are rapidly lost upon removal of selecting antibiotic.

**Lentivirus:**  
1) The viral vector system is derived from the human immunodeficiency virus (HIV-1). The virus has been stripped down to its minimum essential components, which have been encoded on three separate vectors. To inactivate the virus, in the unlikely event of recombination of the three plasmids, the vector is self-inactivating. This is achieved by the deletion of genetic sequence from the 3' long terminal repeat encoding enhancer and promoter functions, resulting in the transcriptional inactivation of the provirus in the infected cell.

2) The viral vector system is derived from the Moloney murine leukaemia virus (MMLV). The vectors are self-inactivating bicistronic expression vectors designed to express a target gene along with an antibiotic selection marker without the risk of promoter interference from the 5’ LTR. The self-inactivating feature of the vectors is provided by a deletion in the 3’ LTR enhancer region (U3). During reverse transcription of the retroviral transcript in the infected cell, the inactivated 3’ LTR is copied and replaces the 5’ LTR, resulting in inactivation of the 5’ LTR promoter (CMV).

Mammalian cells/tissues: These cells will be modified to express a fluorescent tag which is not expressed naturally by these cells. However the likelihood of this changing...
the pathogenicity or toxicity to humans is negligible.

Origin & function

Lentivirus System:

GMMs required for Propagation of Plasmids
E. coli used for cloning and propagation of plasmids are standard, inherently safe and pose no threat to human health. Sub-strains of E. coli will include MACH1, DH5α, TOP10, GM2163, JM109, XL1-Blue, Stbl 3. The threat to human health is negligible.

Description of Vector System
The vector system is derived from the human immunodeficiency virus (HIV-1). The virus has been stripped down to its minimum essential components, which have been encoded on three separate vectors. To inactivate the virus, in the unlikely event of recombination of the three plasmids, the vector is self-inactivating. This is achieved by the deletion of genetic sequence from the 3' long terminal repeat encoding enhancer and promoter functions, resulting in the transcriptional inactivation of the provirus in the infected cell. The threat to human health is negligible.

Plasmids for virus particle production:
- pCMV-dR8.74 packaging plasmid (pCMVR8.74 was a gift from Didier Trono (Addgene plasmid # 22036; http://n2t.net/addgene:22036; RRID:Addgene_22036))
- pMD2.G envelope plasmid (pMD2.G was a gift from Didier Trono (Addgene plasmid # 12259; http://n2t.net/addgene:12259; RRID:Addgene_12259))

Plasmids required for gene expression:
- pLenti6.3-CMV-mCherry2 transfer plasmid (pLenti6.3 (Invitrogen) with the addition of mCherry2 gene).

Alternatively, commercially available plasmids will be used, that will serve the same purpose. The plasmids are non-mobilisable themselves pose no threat to human health.

Preparation of the Virus:
Infective competent but replication incompetent lentiviruses will be assembled by cationic polymer or lipid-mediated transient transfection of three plasmids into the packaging cell lines, including HEK293-based (HEK293T (human embryonic kidney cells)).

Description of Virus Produced:
The virus produced will be a virus competent for infection, but not for replication. The virus has been pseudo-typed to utilize the envelope protein from the vesicular stomatitis virus glycoprotein (VSV-G). This is common practice with lentiviruses and will make the virus amphotropic i.e. broad tissue tropism. It is expected that host-defence mechanisms would be effective against this replication incompetent virus. The probability of reversion to wild-type virus is expected to be negligible.

Description of Genes to be Expressed:
Genes to be expressed will be fluorescent marker proteins, ion channels, transporters and associated regulatory proteins. Some of these genes may have been modified to be fused to reporter systems to facilitate biochemical and microscopical detection e.g. by addition of epitope tags or fusion with fluorescent proteins. None of the genes inserted will be oncogenic or growth factors. Integration of the viral genome into the host genome is not specific.

Description of Final Host:
Host cells will include epithelial cells including HEK293 and cancer cell lines including U87-MG, SK-MEL-28, MDA-MB-231, MCF-7, A549, HT1080 and DU145. These host cells pose no threat to human health.

Evaluation of foreseeable effects

A) On human health:
Lentivirus System
On escape to the environment, the VSV-G viral envelope will enable the virus to infect all cell types it comes into contact with, including skin cells and cells of the respiratory tract. However, as the virus is replication incompetent, there is potential for one round of infection only. Thus, the risk to human health is low.

B) On the environment:

Lentivirus System
The virus can potentially infect all animals it comes into contact with. However, as the virus is replication incompetent, there is potential for one round of infection only. Thus, the risk following release to the environment is low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste (liquid, sharps and solid) will be placed in Biocleanse solution (3-5% final volume; located inside the cabinet) for 1-2 hours. All waste will then be autoclaved (121 C, 30 min, 15 psi) before disposal. Autoclaved liquid waste will then be disposed to drain. Biocleanse is a non-irritant, non-toxic, non-corrosive and non-hazardous bactericidal, fungicidal, virucidal, mycobacterial and sporicidal agent.

Expected degree of kill - Autoclaving waste should kill 100% of GMM's.

Spillages will be wiped up immediately and tissues disposed by autoclaving. The affected area will then be wiped with Biocleanse (diluted 5% with dH2O) followed by 70% alcohol.

Major spillages inside cabinets may require the cabinet to be fumigated (to be arranged via Building manager/AHSC).

(AHSC = Area Health and Safety Coordinator)

Please enter comments on the GM safety committee on the risk assessment

This risk assessment was reviewed by the Sub-Committee on Biological Safety (acting as GMSC) at it's Meeting on 23rd Jun 20. The committee noted that Sections 3a.6 and 3a.12 required completion and also the risk assessment required full sign off. These sections were completed post this meeting. The completed signed off risk assessment was approved, subject to HSE notification at it's meeting held on 8th Oct 20.

Project Additional Information

Purposes of the contained use
We wish to evaluate the Semliki Forest Virus (SFV) as a system for high level expression of heterologous genes in mammalian cells. This work would initially involve the expression of B-gal as a test protein standard cell lines including CHO.

From the literature SFV has been noted as particularly useful for expression of receptors and ion channels as expression takes place early in the virus replicative cycle while the cells are still intact and able to efficiently process proteins bound for the cell membrane. The aim of this experimental work extends to the expression of two receptors and one ion-channel protein in SFV for comparison of protein levels with current expression systems.

Recipient or parental organism
BACTERIAL HOSTS E coli HB101; DH5 alpha
There is a large body of literature to support the view that the K-12 strain of E. coli survives poorly outside the laboratory, particularly when faced with competition from other microflora, and has limited capacity for replication. These findings are similar to those in which the survival in the animal gut has been measured and found to be poor. Available data is consistent with the view that the K-12 strains of E. coli used in genetic modification work pose a negligible risk to both human health and safety and the environment. E. coli K-12 organisms are considered disabled in the guidance given by ACGM/HSE/DETR. Recombinant strains do not have greater capacity to survive in the environment than non-recombinants and meet the requirements for classification of the organisms as Risk Class 1.

MAMALIAN CELLS (NON-HUMAN DERIVED) BHK-21 (C13); CHO cells
Cultured animal cell lines are not free living organisms found in nature, but have been produced in the laboratory from animal tissues. Their highly specific growth requirements render animal cell lines incapable of survival outside the laboratory. They pose no risk to the environment and the laboratory procedures used to transfer genetic material into animal cells in the laboratory are depend upon conditions not found in the environment. Transfer of genetic material to another organism via an adventitious agent present in an accidentally released recombinant is theoretically possible. However, this would require the sequential occurrence of a number of separate events each of low probability. The gene products encoded by the introduced DNA are often pharmacologically active and/or may effect cell growth regulation. In some cases, they may have oncogenic properties. Their strict requirements for survival and growth result in negligible environmental risk from the cells themselves. The cells to be used in the work described in this proposal meet the criteria for an especially disabled host and the requirements for classification of the organism as Risk Class 1. Such cells cannot survive outside of laboratory culture conditions so that in themselves they pose no risk to the environment.

HUMAN CELLS HEK293
Human cell lines can be considered as especially disabled hosts provided that the cell line is unable to colonise the worker (ie. not their own cells) although there may be a low risk associated with human cancer cells. The environmental risk associated with human cell lines is considered negligible. The human cell lines described in this work meet the criteria for an especially disabled host (with respect to the GMO Regulations) and the requirements for classification of the organism as Risk Class 1. Their strict requirements for survival and growth result in negligible environmental risk from the cells themselves. However, because these cell lines are of human origin it follows that if they were to contain adventitious agents which are potentially harmful, it is possible those adventitious agents would have a host range including man. The scientist intending to use a human cell line should ensure that suitable and sufficient information is available on the previous history of the line. The presence of adventitious agents may require additional precautions for the protection of human health or the environment but unless these are directly related to the genetic modification, these should be considered under other relevant legislation and need not be taken into account in risk classification for the purposes of the Genetically Modified Organisms (Contained Use) Regulations 2000.

Host/vector system
Hosts/Vectors - Cloning Vector: pSFV-1 Host: HB101; DH5a
Additional Information for Recombinant Virus Particles
Intended virus(es): Alphavirus
"Insert" Vector(s): pSFV1 RNA Vector
Helper Plasmids: pSFV2-helper
Virus Producer Cell Line: BHK-21 (C13)cells
Expression Host Cells: HEK293, CHO

Origin & function
Details of the insert: The lac Z gene is a 3.5 kbp cDNA fragment of bacterial origin which was obtained originally from Clontech and cloned in-house vector, pGEN neo K, from which it was excised for this study, by digestion with Not 1. Full length clones of receptor and ion-channel protein from several human tissue libraries have been identified in the Incyte database. These will be obtained and full length cDNA suitable for cloning will be obtained by PCR amplification.
Nature of Gene Produce: B-galactosidase is an E. coli enzyme which catalyses the hydrolysis of lactose to galactose and glucose. The enzyme is induced by the presence of substrate in the medium; the induction is part of an adaptive process which enables E. coli to utilise alternative carbohydrates. The neuropeptide receptors can be activated by specific peptide ligands resulting in changes in intracellular cAMP or iCa2+. Expression of the proteins is restricted to brains and corticoadrenal tissue and hypothalamus in particular. Changes in intracellular levels of these second messengers in specific brain neurons are then translated into physiological responses. The ion channel protein is involved in proliferation through effects on membrane potential, Ca2+ signalling and chemokine secretion. The receptors and ion channel should be produced in an active form when introduced into mammalian cells. The receptors should undergo activation by the appropriate ligand.

Evaluation of foreseeable effects

The receptors can be activated by specific peptide ligands resulting in changes in intracellular cAMP or iCa2+. Expression of the proteins is restricted to brains and corticoadrenal tissue and hypothalamus in particular. Changes in intracellular levels of these second messengers in specific brain neurons are then translated into physiological responses. The ion channel protein is involved in proliferation through effects on membrane potential, Ca2+ signalling and chemokine secretion. The effects of over-expression of these proteins following accidental infection of a worker by activated cirrus stock are impossible to predict with certainty but there are no reports in the literature of ligand independent signalling or oncogenic transformation. Sufficient levels of circulating ligand would need to be present in peripheral tissues to activate the receptors.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

There are no special measures to be adopted for rodent or insect vector control because the recombinant organisms used on site are not likely to be transmitted by rodents or insects and moreover, the location of the recombinants in liquid nitrogen or freezers, the only activity associated with this proposal, results in these being inaccessible to such vectors. All other containment level 2 measures will be adopted with the exception of an autoclave for waste inactivation being present in every building. An exemption is requested from this requirement. An autoclave request - autoclave not present in every building. An autoclave for waste inactivation is not present in every building on site where these activities are conducted. An exemption is requested for not applying these measures. The justification for this is that the waste management measures on site (see Section 12) provide an equal standard of containment.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste management procedures at Alderley Park make use of a central autoclave facility with suitable measures for collection and transport from the site of production to the autoclave. Briefly, the standard site procedures for disposal of relevant waste are as follows: (a) Liquid wastes: In general, the site procedures involve treatment of infectious liquid waste with 2.5% Chloros or 1% Virkon (final concentrations) for at least 30 minutes. This treated liquid mixture is then flushed to drain using copious amounts of water. Hypochlorite-based solutions are effective in inactivating the SFV particles (manufacturer's validation data available and attached - 100% inactivation using 1.7% v/v of household bleach and 2 x 105 infectious units of SFV. Mammalian cells require highly specific medium to survive and grow in vitro are inactivated rapidly outside of culture medium. Any of the commonly used disinfectants will accelerate that process yet further. The K12 bacterial trains are rapidly inactivated by 2.5% v/v household bleach or 1% Virkon. Disinfection data for bacteria indicate kill in excess of 8 logs.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y
ATCC recommends Biosafety Level 2 for HEK293 cells so that it may not be entirely appropriate to indicate that there are no harmful effects associated with the recipient micro-organisms. However, since the risk, if any, is associated primarily with potential adventitious agents, it need not to be taken into account for the risk classification purposes although it should be addressed in a separate COSHH assessment. Since work with mammalian cells is routinely carried out at CL2 in a Class 2 safety cabinet, the appropriate control measures required by COSHH will be in place.

**Project Additional Information**

**Purposes of the contained use**
Generation of mammalian cells expressing recombinant chemokine X or its receptor and development of binding assays using either whole cells or membrane
preparations to detect the binding of full length chemokine X. Full-length chemokine X and N-terminally deleted chemokine X (a natural antagonist of chemokine X receptor signalling) are required as ligands in the assay. It is planned to express chemokine X and truncated mutants in E coli and mammalian cells. The receptor for chemokine X will be expressed in mammalian cells.

Recipient or parental organism

Cloning Host: E coli strain DH5 alpha - a disabled E coli K12 strain. Genotype: F^-supE44 hsdR17 recA1 gyrA96 endA1 th^-1 relA1 deoR prophage80d(lacZYA^-argF)u169(m80lacZdM15)

Bacterial Expression Host: MSD 2052: - an E coli B strain commonly used for expressing proteins with T3 & T7-type vectors. Following advice from HSE in May 2000 that BL21 can be regarded as disabled, the same is likely to apply to this strain which is a derivative. Source: Novagen 69443-1. Genotype: F^-ompT, (rB^- mB^-). Phenotype: B strain, lacks lon protease, lacks ompT protease DE3 lysogen sensitive to rifampicin, compatible with pET vectors.

Mammalian Cell Expression Hosts: CHO; MEL

CHO: Chinese hamster ovary cells posing negligible risk and safety handled at CL1
MEL: Murine erythroleukaemia cell line. Differentiate into erythrocytes upon addition of DMSO. CL1 appropriate for operator and environmental protection.

Host/vector system

Bacterial Cloning Vector: pCDNA. nic^-/mob^- and tra^-. Therefore non-mobilisable unless a derivative modified in these respects (In which case a new, separate entry should be made). Amp^r and either Neo^r, Hyg^r, or Zeocin^r. As the pCDNA series of vectors have both CMV and T7 promoters, it may be used for cloning in non-expressing strains such as HB101, DHS alpha which do not express T7 RNA polymerase and also for expression in a host strains which constitutively expresses T7 RNA polymerase. Contains SV40ori sequence as well as bacterial origin of replication permitting replication in mammalian cells expressing SV40 T.

Bacterial Expression Vectors:

pAT153: a non-mobilisable plasmid vector. ds-DNA 3658 b.p. Copy Number: 15 copies/cell. Constructed by removal of Haell-fragments B and H (pos. 1649-2353) from pBR322. There is conflicting information on the structure of pAT153. Some 200 bases may be erroneously missing from this sequence. pAT153 has properties comparable to pBR327. The bom or Mob site is lost. pAT153 has somewhat higher copy number than pBR322. pAT153 is derived from pBR322 by deletion of a 622 bp Haell fragment, bases 1730-2352.

pT7#3.3: The backbone of the vector is pZEN 0042 (pTB357): this vector contains the tetA/tetR inducible tetracycline resistance sequence from plasmid RP4 and the cer stability sequence from plasmid pKS492 in a pAT153 derived background - itself non-mobilisable. The T7 expression cassette contains a T7 gene 10 promoter flanked by two operator sequences (lac), the T7 gene 10 5' untranslated region including ribosome binding site, a tRNAarg5 transcriptional reporter element downstream of the expressed gene and a downstream T7 gene 10 terminator sequence. A T4 terminator sequence is also positioned upstream of the expression cassette and the vector contains the lac 1 gene. None of these sequences are known to increase the stability of the vector in the environment nor are they known to be mobilisable or oncogenic.

Mammalian Cell Expression Vectors: pCDNA series; pEV

pCDNA: nic^-/mob^- and tra^-. Therefore non-mobilisable unless a derivative modified in these respects (In which case a new, separate entry should be made). Amp^r and either Neo^r, Hyg^r, or Zeocin^r. As the pCDNA series of vectors have both CMV and T7 promoters, it may be used for cloning in non-expressing strains such as HB101, DHS alpha which do not express T7 RNA polymerase and also for expression in a host strains which constitutively expresses T7 RNA polymerase. Contains SV40 ori sequence as well as bacterial origin of replication permitting replication in mammalian cells expressing SV40 T. pEV: nic^-, mob^-, tra^-, therefore non-mobilisable. Ampicillin and Neomycin resistance genes. beta-globin & TK (mammalian promoters. Additional sequences include the beta-globin Locus Control Region.

Origin & function

The chemokine X cDNA will be cloned from human peripheral blood mononuclear leukocytes which have been stimulated with LPS. N-terminally deleted mutants will be generated by PCR using full length chemokine X as template. The native receptor will be cloned from the human monocyte tumour cell line THP-1. No known regulatory or transposable elements are present in the chemokine X or chemokine X receptor cDNAs.

Chemokines are a class of proteins involved in the recruitment and activation of leucocytes to areas of inflammation. Chemokine X belongs to the beta-chemokines sub-family and is more specific than other members of the family, in that it acts predominantly on a subset of leucocytes.
Themokine X mediates chemotaxis of cells (extravasation from the blood stream through vascular endothelial cells into tissues) and subsequent activation. Chemokine X (and all of the other chemokines discovered so far) act by binding to seven trans-membrane helix (STH) receptors on leukocytes. This binding triggers a series of signalling mechanisms Ca++ flux. Full length chemokine X is the natural ligand for the chemokine X-receptor expressed on the surface of leucocytes and interaction between the ligand and receptor results in changes in calcium flux within mononuclear cells. N-terminally deleted mutants of chemokine X are known to be antagonistic and compete with full-length chemokine X for binding to the chemokine X receptor.

Evaluation of foreseeable effects

The expressed genes are chemokine X, N-terminally truncated chemokine X and chemokine X receptor. These are naturally occurring molecules that have a role in the recruitment of leukocytes to areas of inflammation and the subsequent activation of leukocytes causing their differentiation into macrophages. Injection of purified chemokine X into animal tissues has been shown to initiate a slight inflammatory exudate formation (local) which subsides within several hours. This suggests that exposure to chemokine X could cause a local, short-lived immune reaction. Themokine X and mutants are soluble proteins and would be secreted into the culture media of MEL and CHO cells and should be fully-processed active proteins. E coli expressed chemokine X would require refolding and purification from inclusion bodies. There is a literature precedent for this but the proteins are unlikely to be active due to a lack of post-translational modification.

Mammalian cell generated chemokine X should be active and the highest level of expression would be expected in MEL cells with supernatants containing up to 2mg/L active protein. The highest risk of operator exposure is from accidental inhalation of aerosols when handling cell supernatants. There is no direct evidence in the literature that inhalation of chemokine X would cause an inflammatory response although there is indirect evidence linking raised chemokine X levels in lung homogenates to infiltration of leukocytes in a model of SEA-induced allergic airway inflammation in mice. There is also indirect evidence from studies with eotaxin (another chemokine that recruits eosinophils) in guinea pigs that inhalation of approx 2ng increases the sensitivity to histamine and 20ng results in eosinophilia (Am J Resp Crit Care Med 2000, 161: 1844-9). Inhalation of MEL supernatants could provide an equivalent level of exposure to chemokine X in man.

Chemokine X receptor requires expression on a cell surface in order to contribute to an inflammatory response.

Exposure to excess chemokine X receptor could possibly cause the mopping up of endogenous chemokine X but would not result in an immune reaction.

The likelihood of potentially harmful effects being realised as a consequence of exposure of the operator or environment to the final GMO is judged to be low because of the low probability of exposure to significant amounts of culture medium. With the use of a safety cabinet, this risk should be negligible.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All CL2 measures will be applied with the exception of the requirement for an autoclave to be available in each building where activities are carried out. The waste management procedures used at Alderley Park are judged to provide an equivalent level of protection. The measures used are included in the section below dealing with waste management. An exemption from the requirement for an autoclave to be present in each building is therefore requested.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

NORMAL LABORATORY OPERATIONS:

Waste management procedures at Alderley Park make use of a central autoclave facility with suitable measures for collection and transport from the site of production to the autoclave. Briefly, the standard site procedures for disposal of relevant waste are as follows:

- **a)** Liquid wastes: In general, the site procedures involve treatment of infectious liquid waste with 2.5% Chloros or 1% Virkon (final concentrations) for at least 30 minutes. This treated liquid mixture is then flushed to drain using copious amounts of water. In some instances other specified validated disinfectants are used for specific purposes including Savlon hospital concentrate. 70% ethanol is commonly employed for routine surface decontamination.
- **b)** Solid wastes (other than sharps): are placed in an autoclave bag and when sufficiently full, the neck is twisted closed and the bag placed in a second autoclave bag which is sealed with autoclave tape. The bag is then placed in a specified location in the laboratory, pending collection. The closed bags are collected daily by Shift Technicians who transport them in robust wheeled and sealed autoclave bags back to the central site.
lidded containers to an on-site autoclave for inactivation in an autoclave located in a specialised facility on site. This procedure has been validated using a 12-point
thermomcouple procedure in which probes are placed in a representative load. After autoclaving, waste is collected by a contractor for final disposal by off-site incineration.
(c) Sharps are placed in suitable purpose-designed robust containers with a lid and when full are placed for collection and final disposal by incineration by our waste
contractor.

Measures for disinfection of any accidental spills are set out in the Alderley Park Biosafety Manual and are based on appropriate use of the above disinfectants. Briefly,
liquid spills are covered with paper towels and disinfectant added from the perimeter. After the specified period required for inactivation, the towels are removed into a
container for final collection and final disposal by either autoclaving as described above, or where the disinfectant is incompatible with that process, by incineration off-site.
All waste materials are transported in sturdy leak-proof containers.

Disinfection procedures lead to at least an 8 log reduction in viable bacterial cell count. The disabled bacterial host strains used do not survive well in the environment even
if untreated. The viable count in liquid waste samples after disinfection is estimated as 0-10/ml and is likely to be at or close to the lower end of that range. With the
associated water used to flush treated liquid waste to drain, the concentration of any bacteria in such waste is negligible.

The mammalian cells used in this work cannot survive outside a narrow range of temperature and nutrient conditions and even untreated it is anticipated that none would
survive soon after disposal to drain. Given that all relevant liquid waste is treated with either 2.5% bleach (hypochlorite) or 1% Virkon, the survival rate is effectively zero.

Large-scale work.
Standard operating procedures include steam sterilisation of the fermenters at 121 degrees C for 10 minutes. The contents are then discharged to drain via the harvest
valve. The system has been validated with host strains as it is generally considered that these are more resistant to killing than recombinant organisms, particularly as
none of the recombinants are known to express proteins as a result of the modification which would confer pathogenic traits or resistance to killing by heat or by the
disinfectants utilised in this area.

Validation has been carried out on both E coli K12 and B (BL21) derivative strains, the latter in November 2000. After growth in a yeast extract-glycerol based medium
(HYE) to an OD(550nm)>100, samples are collected aseptically. The viable cell count is determined by plating of dilutions on L agar plates followed by overnight culture at
37 degrees C and counting of colonies which subsequently develop.

Samples are also taken following sterilisation procedures as indicated above. Aliquots are diluted and plated as described above and also used to inoculate 75 ml L-broth
liquid cultures which are incubated at 37 degrees C.

Typical viable populations at maximum density during such grows are 10 (to the power of 11) cfu/ml.
No colonies were observed after streaking out 10ul of the sample or after plating of a 1:100 dilution. No growth was observed in liquid cultures.

Residual waste from harvesting operations is routinely treated in a dunk tank in a Class 1 safety cabinet with Savlon Hospital Concentrate used at a dilution of 1% v/v.

Validation of this procedure for E coli strains has been carried out using concentrations of disinfectant varying from the recommended 1% to a maximum of 5%. These
concentrations are prepared by addition of appropriate volumes of concentrate to 2 litre samples of live culture dispensed in Duran bottles and left without lids overnight in a
Class 1 Safety Cabinet.

A sterile diluent is used with Asalectin (3g/l) to neutralise the disinfectant in 10 ml aliquots of the cultures in Universal tubes. 100 ul aliquots of dilutions ranging from 10 -2 to
10 -10 are then spread onto L agar plates which are then incubated at 37 degrees C overnight. No colonies were detected on any of the plates.

These data support the conclusion that the disinfection procedure leads to more than an 8 log reduction in the number of viable bacteria. For the in situ fermentor
sterilisation, this figure is greater than a 10 log reduction.

Periodic airborne monitoring has also been carried out in the fermenter hall. Data over a period of 18 months consistently resulted in the concentration of process organisms being below the limit of detection (3cfu/m (to the power of 3)) although total counts in the order of 10 (to the power of 2) (non-process organisms) were detected.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Approved at risk class 2 with the view being expressed that was taking a very precautionary approach.

Historical Significant Changes
**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

---

**Project Additional Information**

**Purposes of the contained use**

It is necessary to store for possible future use, recombinant organisms generated at Alderley Park or obtained from elsewhere. Facilities at Alderley Park include freezers where stocks of recombinant bacteria are maintained as glycerol suspensions at -80°C and also liquid nitrogen tanks for long-term storage of recombinant mammalian and insect lines.

**Recipient or parental organism**

Some cell lines may obtain adventitious agents so that laboratory activities involving these may require measures from containment level 2. The requirement for these measures is based on the provisions of COSHH rather than the GMO Regulations.

**Host/vector system**

Vectors may include some which are potentially mobilisable in an appropriate host background (i.e. mobilisation-defective) and which include antibiotic resistance genes for use as selection markers. Some vectors include transposons or encode transposase functions. They include non-expression and expression vectors. Expression vectors include those designed for expression in bacterial, yeast, mammalian and insect systems and include vectors used in the generation of recombinant viral particles. The resulting viral particles are all attenuated and replication defective as described in the original proposals for their use.

**Origin & function**

Source of Nucleic Acid - Inserts are from a wide variety of sources including rodent and human tissues and including both genomic and cDNA sequences.

Nature of Gene Product - The properties of the proteins covered by this proposal as they exist in the native organisms cover a wide range of known protein functions including enzymes, receptors, and other proteins involved in regulation of normal cellular activities including cell growth and division. Details are set out in separate risk assessments, records of which are kept in electronic or paper format, and which cover the actual use of the recombinant organisms for activities other than storage.

**Evaluation of foreseeable effects**

Some recombinant organisms are able to express products which may be oncogenic, toxic or allergenic. Where cells are capable of producing recombinant viral particles, these may be able to deliver to human cells, sequences able to express biologically active molecules. There may be harmful effects associated with these when expressed in an unregulated manner in cells in which expression is normally subject to tight control, or where they are expressed in cells in which they do not normally occur at significant concentrations. Where cells are designed to produce recombinant viral particles these are all attenuated and with the exception of recombinant baculoviruses, the viral particles are not replication competent. The likelihood of potentially harmful effects being realised as a consequence of exposure of persons to the final GMO is judged to be low. None of the organisms would be classified as greater than risk class 2 in normal operations and most are risk class 1. Having regard to the restriction of the activities covered by this proposal to storage only, and the conditions under which they are stored as described elsewhere in this proposal the potential for dissemination is negligible. Given the nature of the organisms, the negligible risk of dissemination for these storage activities, and the absence of any special features of the environment which may affect the risk, the risk of environmental harm is judged to be negligible.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

02/03/2022
There are no special measures to be adopted for rodent or insect vector control because the recombinant organisms used on site are not likely to be transmitted by rodents or insects and moreover, the location of the recombinants in liquid nitrogen or freezers, the only activity associated with this proposal, results in these being inaccessible to such vectors. All other containment level 2 measures will be adopted with the exception of an autoclave for waste inactivation being present in every building. An exemption is requested from this requirement.

Exemption request - autoclave not present in every building - An autoclave for waste inactivation is not present in every building on site where these activities are conducted. An exemption is requested for not applying these measures. The justification form this is that the waste management measures on site (see section 12) provide an equal standard of containment.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste management procedures at Alderley Park make use of a central autoclave facility with suitable measures for collection and transport from the site of production to the autoclave. Briefly, the standard site procedures for disposal of relevant waste are as follows: (a) Liquid wastes: In general, the site procedures involve treatment of infectious liquid waste with 2.5% Chloros or 1% Virkon (final concentrations) for at least 30 minutes. This treated liquid mixture is then flushed to drain using copious amounts of water. In some instances other specified validated disinfectants are used for specific purposes including Savlon hospital concentrate. 70% ethanol is commonly employed for routine surface decontamination. (b) Solid wastes (other than sharps): are placed in an autoclave bag and when sufficiently full, the neck is twisted closed and the bag placed in a second autoclave bag which is sealed with autoclave tape. The bag is then placed in a specified location in the laboratory, pending collection. The closed bags are collected daily by Shift Technicians who transport them in robust wheeled and lidded containers to an on-site autoclave for inactivation in an autoclave located in a specialised facility on site. This procedure has been validated using a 12-point thermocouple procedure in which probes are placed in a representative load. After autoclaving, waste is collected by a contractor for final disposal by off-site incineration. (c) Sharps are placed in suitable purpose-designed robust containers with a lid and when full are placed for collection and final disposal by incineration by our waste contractor. Measures for disinfection of any accidental spills are set out in the Alderley Park Biosafety Manual and are based on appropriate use of the above disinfectants. Briefly, liquid spills are covered with paper towels and disinfectant added from the perimeter. After the specified period required for inactivation, the towels are removed into a container for final collection and final disposal by either autoclaving as described above, or where the disinfectant is incompatible with that process, by incineration off-site. All waste materials are transported in sturdy leak-proof containers.

## Project Additional Information

### Purposes of the contained use

To deliver cDNAs encoding known G-protein coupled receptors to murine and human cell lines to facilitate target identification.

### Recipient or parental organism

**Cloning Hosts and Vectors**

- **Hosts**: E coli strains DH5 alpha and STBL2
  - **DH5 alpha**: Disabled E coli K12 strain. Genotype F-supE44 hsdR17 recA1 gyrA96 end/A1 th-1 relA1 deoR; prophage80d(lacZYA-argF)u169(m801acZdm15)
  - **STBL2**: Disabled E. coli K12 strain. Genotype F-mcrA del(mcrBC-hsdRMS-mrr) recA1 end A1 gyrA96 thi supE44 relA1 lambda-del(lac-proAB).

- **Mammalian Expression Host Cells**: CHO, HEK293, HeLa, NIN3T3 fibroblast

- CHO cell line initiated from a biopsy of an ovary of an adult Chinese hamster by T T Puck in 1957 posing negligible risk which can be safely handled at CL1.

- HEK-293: Human embryonic epithelial cell line stably expressing the transforming gene of human Type 5 Adenovirus. The HEK cell line supplied by ATCC is stated to be tumorigenic in nude mice and to require minimum containment at Biosafety Level 2 on the basis of the partial adenoviral sequences. There is no risk of generating...
adenovirus by recombination associated with the proposed GM activities.

HeLa: human tumour cell line. Reverse transcriptase negative. Contains residual human papilloma virus sequence with associated potential for complementation of the E1a deletion in recombinant Adenoviral systems. ATCC recommend handling at Biosafety Level 2. CL2 may therefore be required for operator protection but the modifications involved in this study are not likely to generate a risk independent or additional to that of the unmodified host line.

NIH-3T3 fibroblast cell line is a common laboratory cell line derived from murine fetal fibroblasts.

Infected cells will be regarded as stable cell lines following removal of virus containing supernatant and selection for the appropriate antibiotic marker (i.e. - G418, Hygromycin, etc.) as the integrated provirus is not able to mobilise.

Virus Producer Cell Lines: 293T-Phoenix-eco; 293T-10A1 ampho

PhiNX-Eco cells, used to produce ecotropic virus. These viral particles will infect only murine cells. PhiNX-Eco (Phoenix) are 293T cells with stable integrations of gag-pol and ecotropic env at different chromosomal loci (3rd generation packaging cells).

293-10A1 cells (Imgenex, San Diego, CA) used to produce polytropic virus. The 293-10A1 cell line contains the retroviral structural genes (gag, pol, env) on a single cDNA integrated into the host genome. While this system is not preferred, due to an increase risk of generating helper virus, it is the only stable packaging cell line currently available to AZ for generation of amphotropic virus, and will be replaced when 3rd generation systems are obtained (Phi-NX-ampho, under negotiation with Stanford University). Viral production is transient (48-72 hr) and presence of helper virus has not been detected, according to the supplier (Imgenex, CA) so actual risk for replication competent retrovirus should be considered as low. Human embryonic kidney 293T (HEK-293) cells, used to produce amphotropic or ecotropic virus by transient transfection of plasmids separately expressing gag-pol and env (amphotropic env from 4070A MuLV; eco from MMLV). In addition to using stable packaging cell lines to generate infectious virus, plasmids containing the structural genes can be transiently transfected into 293 cells along with the recombinant retroviral vector containing the gene of interest. pC-pl and pC-ampho packaging plasmids contain the MMLV gag, pol and env genes in a single cDNA, under the control of the CMV promoter. These constructs have been engineered for safety by a deletion of the enhancer region of the 3'LTR, which would render any helper virus unable to replicate. These constructs are used transiently (24-48hr), therefore the risk of generating helper virus is greatly reduced over that found in long-term culturing of virus producing cell lines.

Host/vector system

Cloning: E. coli strains DH5 alpha and STBL2 will be used for initial cloning of the vectors 293T-Phoenix-eco; 293T-10A1 ampho will be used with the following "Insert" Vector(s): pBMNZ; pGBMNZ; pBMN-SIN; pCIVA; pDIVA.

Virus Producer Cell Lines: 293T-Phoenix-eco; 293T-10A1 ampho will be used with the following "Insert" Vector(s): pBMNZ; pBMN-IP; pCIVA; pDIVA.

The pBMNZ series of vectos are high packaging efficiency vectors constructed by Gary Nolan (Stanford) and are widely used in commercial and academic laboratories. The "SIN" designation indicates a Self-Inactivating vector. During integration of the provirus the 5' LTR is inactivated (as well as the 3'LTR), which minimises the possibility of activating adjacent cellular genes. pGBMNZ is pBMNZ with GFP inserted into the vector backbone so that transfection efficiency of packaging cell lines can be easily monitored. pCIVA and DIVA are derived from pBabe-puro, which is the most commona series of retroviral vectors in use. pLNCX-2 was created in the Mulligan lab and is another commonly used retroviral vector. Derivates are modifications that modify components of the viral construct that do not alter tropism or generation of infection competent virus. For example, replacing the Neo gene with Hygro, or inserting the GFP gene into the backbone, as in pGBMNZ.

Mammalian Expression Host Cells: CHO, HEK293, HeLa, NIH3T3 fibroblasts will be used with the vectors pBMNZ; pBMN-IP; pBMN-SIN; pGBMNZ; pDIVA; pCIVA and also for expression following transfection with recombinant viral vectors produced as described above.

Origin & function

Details of the insert:
The DNA inserts will be obtained from either clones generated by Incyte (or as RT-PCR products from rat mRNA).

Nature of Gene Product:

Stimulation of G-protein coupled receptors by specific peptide ligands results in changes in intracellular cAMP, iCa++, or inositol phosphate levels. Changes in intracellular levels of these second messengers in specific cells are then translated into physiological responses.

In addition to the specified receptors other G-protein coupled receptors identified by either literature or in silico work, as being involved in the regulation of similar behavioural-associated pathways would also be considered for expression and target evaluation in this system.

The G-protein-coupled receptors will be expressed in an active form when introduced into a mammalian cell. As the receptors being used in these experiments are full-length, native receptors, ligand dependent stimulation will be maintained.

Evaluation of foreseeable effects

Recipient micro-organism(s): Some of the human cell lines are tumorigenic and contain partial viral sequences as described above. Recommendation to work at CL2 will be observed.

Vectors: The viral particle vectors can infect mammalian cells. Although replication defective, they can deliver the insert gene to, and express that gene in, cells which may be infected as the result of accidental exposure. Since the expressed gene products are able to alter intracellular signalling pathways when exposed to ligand, it is possible that cells expressing these genes at levels greater than those found in normal cells may be adversely affected. The nature and severity of such effects in individual cells is however difficult to predict.

The resulting genetically modified micro-organism(s):

Cells producing infectious viral particles will pose the same hazard as the particles themselves as considered above, although the titre of particles, and therefore the associated risk, will be lower than in concentrated vector stocks. The likelihood of potentially harmful effects being realised as a consequence of exposure to the operator or environment to the final GMO is judged to be low. The viral particles used in this GMO application are replication defective, with the only route for generating Replication Competent Retrovirus (RCR) being homologous recombination with constructs used in packaging of the viral transcripts. In every instance the risk to the operator is minimised by utilising viral vectors engineered for safety in a transient system. The replication defective nature of these vectors means that the extent of cell/tissue affected will be restricted to those cells originally infected. Given the routes of transmision of retroviral vectors, normal host responses to exposure and the anticipated titre of viral particles being worked with, the overall risk is judged to be low. Nevertheless, to reduce this risk to negligible levels, it is judged that containment level 2 measures should be used. Use of sharps is also strictly prohibited when handling infectious viral supernatants.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All CL2 measures will be applied with the exception of the requirement for an autoclave to be available in each building where activities are carried out. The waste management procedures used at Alderley Park are judged to provide an equivalent level of protection. The measures used are included in the section below dealing with waste management. An exemption from the requirement for an autoclave to be present in each building is therefore requested.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste management procedures at Alderley Park make use of a central autoclave facility with suitable measures for collection and transport from the site of production to the autoclave. Briefly, the standard site procedures for the disposal of relevant waste are as follows: (a) Liquid wastes: In general, the site procedures involve treatment of infectious liquid waste with 2.5% Chloros or 1% Virkon (final concentrations) for at least 30 minutes. This treated liquid mixture is then flushed to drain using copious amounts of water. In some instances other specified validated disinfectants are used for specific purposes including Savlon hospital concentrate. 70% ethanol is commonly employed for routine surface decontamination. (b) Solid wastes (other than sharps): are placed in an autoclave bag and when sufficiently full, the neck is...
twisted closed and the bag placed in a second autoclave bag which is sealed with autoclave tape. The bag is then placed in a specified location in the laboratory, pending collection. The closed bags are collected daily by Shift Technicians who transport them in robust wheeled and lidded containers to an on-site autoclave for inactivation in an autoclave located in a specialised facility on site. This procedure has been validated using a 12-point thermocouple procedure in which probes are placed in a representative load. After autoclaving, waste is collected by a contractor for final disposal by off-site incineration. (c) Sharps are placed in suitable purposed-designed robust containers with a lid and when full are placed for collection and final disposal by incineration by our waste contractor.

Measures for disinfection of any accidental spills are set out in the Alderley Park Biosafety Manual and are based on appropriate use of the above disinfectants. Briefly, liquid spills are covered with paper towels and disinfectant added from the perimeter. After the specified period required for inactivation, the towels are removed into a container for final collection and final disposal by either autoclaving as described above, or where the disinfectant is incompatible with that process, by incineration off-site. All waste materials are transported in sturdy leak-proof containers. Disinfection procedures lead to at least an 8 log reduction in viable bacterial cell count. The disabled bacterial host strains used do not survive well in the environment even if untreated. The viable count in liquid waste samples after disinfection is estimated as 0-10/ml and is likely to be at or close to the lower end of that range. With the associated water used to flush treated liquid waste to drain, the concentration of any bacteria in such waste is negligible. Given that retroviruses do not in general survive well in the environment and are readily inactivated by a number of disinfectants including hypochlorite based agents and Virkon (Antec) both of which are specified for use at Alderley Park. The titres of retroviruses are low and even in vector stocks are not anticipated to be greater then 10 7/ml. Routine titres in discard flasks would be two orders of magnitude less than this. The volumes of liquid waste disposed of in any experiment do not exceed 10 ml. Under the conditions of use, the disinfectant produces a log kill of at least 10 5, so that discard contains less than 10 2 infectious particles per ml. Copious volumes of water accompany disposal of waste to drains so that the titre of infectious particles presents a negligible risk of harm to human health or to the environment.

The mammalian cells used in this work cannot survive outside a narrow range of temperature and nutrient conditions and even untreated it is anticipated that none would survive soon after disposal to drain. Given that all relevant liquid waste is treated with either 2.5% bleach (hypochlorite) or 1% Virkon, the survival rate is judged to be zero.

Please enter comments on the GM safety committee on the risk assessment

The proposal was approved at risk class 2. Comments were made about the potential normal tissue distribution of receptors and ligands in the context of the potential for effects following accidental exposure. The details of these comments have been provided to the regulators in a confidential version of this document. The request for non-disclosure of this is based on the grounds that the information may disclose our position to competitors to an extent which could harm AstraZeneca's legitimate commercial interests.

Project Additional Information

Purposes of the contained use

As Jurkats and human T cells are refractory to non-viral transfection and to transfection with standard retroviral vectors, we wish to investigate the suitability of a Lentiviral vector system for transfection of these and other refractory cell types. A comparison is proposed of two-vector (SIN) and three vector lentiviral systems for future use in delivering inserted genes for expression in non-dividing cells. No candidate genes will be expressed initially with the insert restricted to an expressible mouse CD8a:EYFP fusion protein. This fusion protein is composed of the extracellular and transmembrane region of mouse CD8 fused to EYFP and is designed to facilitate magnetic purification of transduced cells from untransduced cells using mCD8 antibody coated magnetic beads.

Recipient or parental organism

HB101: A disabled E coli K12 derivative. Genotype: F-mcrB mrr hsdS20(rB,mB) recA13 supE44 ara14 galK2 lacY1 proA2 rps(L20(Smr) xy15 lamda-leu mtl1. No harmful characteristics.

HEK-293: Human embryonic epithelial cells stably expressing the transforming gene of human Type 5 Adenovirus. DNA from both the right and left ends of the viral genome is present but no adenovirus work is associated with this proposal. The HEK cell line supplied by ATCC is stated to be tumorigenic in nude mice and to require minimum containment at Biosafety Level 2. Collectively, this information indicates a requirement for CL2 although when making a risk assessment for the purposes of classifying GMOs according to the GMO (Contained Use) Regulations 2000, the presence of adventitious agents can be ignored.

Primary human T cells should be treated as potentially infected unless there is clear evidence to the contrary. This requires the adoption of CL2 measures as part of the "Universal Precautions" approach. Culture of cells derived from known or suspected cases of HIV infection beyond 100 hours of culture may require a high standard of containment. The cells used in this study will be restricted to low risk sources.

Jurkat E6.1 - ECACC accession number 88042803. The cells are derived from a human leukaemic T cell lymphoblast. This a well characterised and authenticated cell
Cloning: HB101 host with the following vectors:
PfV1-delta GPEVVVN-ires-mCD8a:EYFP Mobilisation-defective mammalian expression vector containing the ampicillin resistance gene for selection in E.coli and the bacterial original of replication. These sequences have been derived from pBluescript(KS+). This vector on its own will not produce infectious virus; two additional vectors are required. tat,rev, LTRs, mCD9a and EYFP genes will not be expressed, but will be propagated in E.coli. The 5 prime LTR viral promoter will not function efficiently in prokaryotic hosts, therefore active protein would not be expected to be produced in E.coli.

Pcsin-deltaGPEVVNT-CMV-ires-mCD8a:(EYFP or ZsGreen or ZsYellow or AsRed or AmCyan) +WPRE or -WPRE Mobilisation-defective mammalian expression vector containing the ampicillin resistance gene for selection in E.coli and the bacterial origin of replication. These sequences have been derived from pBluescript(KS+). This vector on its own will not produce infectious virus; two additional vectors are required. rev, mCD8a, EYFP and NFPS will not be expressed, but will be propagated in E.coli. The 5 prime CMV I. E promoter (which replaced the 5’ LTR) will not function efficiently in prokaryotic hosts, therefore active protein would not be expected to be produced in E.coli.

Pcsin-deltaEVVVNT-CMV-ires-mCD8a:(EYFP or ZsGreen or ZsYellow or AsRed or AmCyan)+WPRE or -WPRE Mobilisation-defective mammalian expression vector. The vector contains the ampicillin resistance gene for selection in E.coli and the bacterial origin of replication. These sequences have been derived from pBluescript(KS+). This vector on its own will not produce infectious virus, one additional vector is required. gag, pol, rev, mCD8a, EYFP and NFPS will not be expressed, but will be propagated in E.coli. The 5 prime CMV I. E promoter (which replaced the 5’ LTR) will not function efficiently in prokaryotic hosts, therefore active protein would not be expected to be produced in E.coli.

Viral producer host and vectors: Three Vector System:
Pcsin-deltaGPEVVNT-CMV-ires-mCD8a:(EYFP or ZsGreen/Yellow or AsRed or AmCyan)+WPRE or -WPRE. In addition to the deletions referred to above, this vector has tat and LTRs disabled. tat is a potent transactivator of HIV and its removal reduces concerns about its involvement in Kaposi’s Sarcoma. By abolishing the transcriptional activity of the LTR, the production of full length vector RNA in transduced cells is abolished. This minimises the risk that replication competent retroviruses (RCR) will emerge.
PcH-IHIV-PV:gag: product yields 5 proteins (matrix, capsid, p2, nucleocapsid and p6) involved in encapsulation of the viral RNA. pol: yields the protease (responsible for proteolytic maturation of the core HIV-1 proteins) reverse transcriptase (RT): produces dsDNA provirus copy upon infection of host cell.integrate: facilitates insertion of the provirus DNA into the host cell chromosomes.
VpCas-VSG-G encodes the VSV-G (vesicular stomatitis virus G protein) envelope protein required for pseudotyping. This renders the lentivirus infectious via non-specific adsorption to host cell glycoproteins. The result is a retrovirus with an extremely broad host cell range and lentivirus particles that are able to transduce human T-cells and Jurkats more efficiently. SIN Two Vector System:
Pcsin-deltaEVVVNT-CMV-ires-mCD8a:(EYFP or ZsGreen or ZsYellow or AsRed or AmCyan)+WPRE or -WPRE. This system is similar to the above but the gag-pol genes will not be supplied in trans by a separate vector. This increases the chances of recombination, but the fact that the transcriptional activity of the LTR has been abolished reduces these concerns, because the production of full-length vector RNA in transduced cells is also abolished.
PvPack-VSV-G(see above).

Mammalian expression systems: Primary human T-cell cultures and Jurkats cell lines transfected with the recombinant viral particles described above.

Recombinant viral vectors in expression hosts: Production of marker genes (fluorescent proteins)

Mammalian expression systems: Primary human T-cell cultures and Jurkats cell lines transfected with the recombinant viral particles produced in HEK293 cells transfected with the above.

**Origin & function**

**EYFP:** encodes a mutant form of the jelly fish green fluorescent protein that has been approved and used extensively on site and will be cloned immediately upstream of the IRES sequence. It is expressed in order that FACS analysis can be carried out to calculate transduction efficiency.

**mCD8a:** made up of the extracellular and transmembrane region of mouse CD8. It is expressed in order to facilitate magnetic purification of transduced cells from untransduced cells using mCD8 antibody coated magnetic beads.
The mCD8a ND EYFP will be expressed as a fusion protein. The AmpR gene confers resistance to ampicillin and is required for propagation of the vectors in E.coli. The rev gene product facilitates RNA export to the cytoplasm and the tat gene product activates the LTR promoter. The following are genes carried on pCI-(HIV1)-PV: 
- gag: product yields 5 proteins (matrix, capsid, p2, nucleocapsid and p6) involved in encapsulation of the viral RNA.
- pol: yields the protease (responsible for proteolytic maturation of the core HIV-1 proteins).
- reverse transcriptase (RT): produces dsDNA provirus copy upon infection of host cell.
- integrase: facilitates insertion of the provirus DNA into the host cell chromosomes.
pVPack-VSV-G encodes the VSV-G (vesicular stomatitis virus G protein) envelope protein required for pseudotyping. This renders the lentivirus infectious via non-specific adsorption to host cell glycoproteins. The result is a retrovirus with an extremely broad host cell range and lentivirus particles that are able to transduce human T-cells and Jurkats more efficiently.

**Evaluation of foreseeable effects**

**Identification of Potentially Harmful effects:**
(i) the recipient micro-organism(s) - possible adventitious agents in human primary cell culture - COSHH matter to be controlled by the adoption CL2 according to the University Principles approach.
(ii) the vector(s) - there is a risk associated with handling naked DNA because the LTR would be able to drive expression of functional viral genes such as tat in mammalian cells. The risk to the operator is minimised by safe handling of the DNA i.e. all operators will wear gloves and needles or sharps will not be used and the generation of aerosols will be avoided.
(iii) the resulting genetically modified micro-organism(s) - the recombinant viral particles are infectious with a broad animal host range including man. Most of the expressed proteins are unlikely to be deleterious but where tat expression is possible, the association between the tat gene product and Kaposi's sarcoma suggest that such expression may be harmful. (Blood, 1999, vol94, pp663-672) although the mechanisms involved are unclear. A number of papers over the past year indicate that the key factor underlying Kaposi's sarcoma is likely to be infection with HHV-8, although there are still some indications that the tat gene product may have synergistic effects in association with HHV8.

The risk of accidental production of replication competent retroviruses is negligible in these systems. However, the pseudotyping with VSV-G protein is predicted to increase survival of the viral vector and may permit transmission via an airborne route in addition to the usual route of direct contact (e.g. percutaneous injury). The use of sharps will be prohibited and wearing gloves will be mandatory. The production of aerosols will be minimised to prevent accidental contamination of surfaces. Given the broad anticipated host range of the vector, there is the potential for similar harm to animals which may be exposed to the recombinant viral particles as that described above regarding risk to human health. However, the proposed containment measures should prevent such exposure. Even if such exposure should occur, the replication-defective status of the particles would restrict any harm to the animals which were directly exposed and the vector could not be transmitted beyond any animals directly affected. There are no special features of the environment which is likely to be exposed, which affect the risk. All activities which can be adequately controlled by standard laboratory procedures. The overall risk to the environment is thus negligible.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

All CL2 measures will be applied with the exception of the requirement for an autoclave to be available in each building where activities are carried out. The waste management procedures used at Alderley Park are judged to provide an equivalent level of protection. The measures used are included in the section below dealing with waste management. An exemption from the requirement for an autoclave to be present in each building is therefore requested.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Waste management procedures at Alderley Park make use of a central autoclave facility with suitable measures for collection and transport from the site of production to the autoclave. Briefly, the standard site procedures for disposal of relevant waste are as follows: (a) Liquid wastes: In general, the site procedures involve treatment of
infectious liquid waste with 2.5% Chloros or 1% Virkon (final concentrations) for at least 30 minutes. This treated liquid mixture is then flushed to drain using copious amounts of water. In some instances other specified validated disinfectants are used for specific purposes including Savlon hospital concentrate. 70% ethanol is commonly employed for routine surface decontamination. (b) Solid wastes (other than sharps): are placed in an autoclave bag and when sufficiently full, the neck is twisted closed and the big bag placed in a second autoclave bag which is sealed with autoclave tape. The bag is then placed in a specified location in the laboratory, pending collection. The closed bags are collected daily by Shift Technicians who transport them in robust wheeled and lidded containers to an on-site autoclave for inactivation in an autoclave located in a specialised facility on site. This procedure has been validated using a 12-point thermocouple procedure in which probes are placed in a representative load. After autoclaving, waste is collected by a contractor for final disposal by off-site incineration. (c) Sharps are placed in suitable purpose-designed robust containers with a lid and when full are placed for collection and final disposal by incineration by our waste contractor. Measures for disinfection of any accidental spills are set out in the Alderley Park Biosafety Manual and are based on appropriate use of the above disinfectants. Briefly, liquid spills are covered with paper towels and disinfectant added from the perimeter. After the specified period required for inactivation, the towels are removed into a container for final collection and final disposal by either autoclaving as described above, or where the disinfectant is incompatible with that process, by incineration off-site. All waste materials are transported in sturdy leak-proof containers. Disinfection procedures lead to at least an 8 log reduction in viable bacterial cell count. The disabled bacterial host strains used do not survive well in the environment even if untreated. The viable count in liquid waste samples after disinfection is estimated as 0-10/ml and is likely to be at or close to the lower end of that range. With the associated water used to flush treated liquid waste to drain, the concentration of any bacteria in such waste is negligible. The recombinant viral vector particles are anticipated to be readily inactivated by the hypochlorite based agents and Virkon (Antec) both of which are specified for use at Alderley Park. Both lentiviruses and VSV, the parent viruses for the construct, are known to be susceptible. The titres of the recombinant particles are anticipated to be not greater than 10-7 IU/ml and the total volume in any one experiment will be approximately 100 ml. Viral particles are to be collected by centrifugation at 23000g for 2 hours. It is anticipated that only a very small proportion will remain in the discard supernatant. Reports obtained from the manufacturer of Virkon suggest that this is an effective disinfectant against lentiviruses under the recommended conditions of use (reports typically indicate at least 5 logs reduction in infectious dose). The volumes of liquid waste disposed of in any experiment are expected to be in the order of 100 ml. Assuming that 1% of the vector particles remain in the supernatant, this would leave the numbers of surviving particles at less than 1 per ml. Given the infectious dose and the dilution of any disinfectcd waste when discharged to drain, the presence of any residual infectious particles is judged to present a negligible risk of harm to human health or to the environment. The mammalian cells used in this work cannot survive outside a narrow range of temperature and nutrient conditions and even untreated it is anticipated that none would survive soon after disposal to drain. Given that all relevant liquid waste is treated with either 2.5% bleach (hypochlorite) or 1% Virkon, the survival rate is judged to be zero.

Is an emergency plan required according to regulation 20? N  
If yes, tick to confirm that it is attached to this form N

- DH10B: Disabled E. coli strain. Genotype: F^- mcrA(mrr^-hsdR17mcrBC) prophage 80dlacZD15 lacX74 deoR recA1 endA1 AraD139d(ara,leu)7697 galU galK lambdab^- rpsL nupG
- BJ5183 Especially disabled E. coli K-12 derivative with partial recombination capability to allow the recombination of pAdEasy-1 and pAdTrack-CMV. It is ampicillin and kanamycin sensitive.

**Virus Producer Cell Line:** HEK293

HEK 293 is a human embryonic kidney cell line of widespread use. It has the adenovirus E1A region integrated into its genome stably expressing the transforming gene of human Type 5 Adenovirus and thus provides complementation to E1A deficient adenovirus constructs allowing their replication - this is used as the packaging cell line.
DNA from both the right and left ends of the viral genome is present. When used as a helper cell line production of recombinant adenoviral particles, production of wild-type virus (an ACDP Hazard Group 2 pathogen) can occur albeit at a low frequency. Two specific non-homologous recombination events would be required to generate replication-competent virus. In a supemant rescue assay performed on the virus stock to check for replication competent adenovirus (ref: Dion et al J. of Virol Methods 1996 vol56 p99-107) no replication competent virus was detected in 1x10e9 infectious particles. If virus stocks are repeatedly passaged in HEK293 cells replication-competent virus can appear after 9 passages. Methods to produce virus using pAdEasy-1 only require a maximum of three passages in HEK293 cells. Given this data, the risk of generating wild-type adenovirus is considered to be negligible using these procedures.

Expression Host Cells: HEK293, MCF, T47D
HEK-293: see description above.
MCF-7: The MCF7 line is derived from a human mammary gland adenocarcinoma and retains several characteristics of differentiated mammary epithelium contains the Tx-4 oncogene. CL2 following UKCCCR guidelines.

T47D cells: ECACC Ref No: 85102201 Established from the pleural effusion of a ductal carcinoma of the breast of a 54 year old female. The cells carry receptors for a variety of steroids. ATCC refer in an entry for a mouse myeloma cell line (HB-8630) to human mammary tumor virus particles isolated from the T47D clone-10 mammary cancer cell line. CL2 following UKCCCR guidelines. No reason to suspect that the modification will have any effect on the hazard posed by any such endogenous virus.

Host/vector system

Cloning Vectors (used with DH5alpha, DH5alpha, DH10B and BJ5183 bacterial hosts):
pShuttle: this is identical to pAdTrack-CMV except it does not contain a CMV promoter or the GFP element. It is used in conjunction with pAdEasy, to generate recombinant adenoviral plasmids in E. coli. The resulting recombinant plasmid can be used to generate infective but replication-defective adenoviral particles following transfection into suitable mammalian host cells (ie. HEK 293 cells) able to provide the E1A sequence in trans. PadTrack-CMV is a 9.2 kbp vector obtained from Bert Vogelstein (He et al PNAS 1998 vol 95 p2509-2512) and is used in conjunction with pAdEasy-1 to generate recombinant adenoviral plasmids in E. coli. The resulting recombinant plasmid can be used to produce infective but replication-defective adenoviral particles following transfection of suitable mammalian host cells (eg HEK293) above to provide the E1a sequence in trans. pAdEASY-1: A33.4 kbp vector obtained from Bert Vogelstein (He et al PNAS 1998 vol 95 p2509-2514) which contains all the adenovirus type 5 sequences except nucleotides 1-3533 (encompassing the E1 genes) and 28, 130-320, 820 (encompassing E3 region). The vector also contains an ampicillinR gene and an origin of replication for pBR322, hence the plasmid is mobilisation defective (Hom+ Tra- Mob-). The vector is used in conjunction with pAdTrack vectors to generate recombinant adenoviral plasmids in E. coli. (eg when co-transformed into a bacterial host with the pAdTrack-CMV shuttle vector containing an insert sequence, recombination of the host leads to production of a recombinant pAdEasy-1 containing insert sequences. That plasmid can be used to transfect appropriate mammalian cells (eg HEK293) to generate recombinant E1α-deletion adenoviral particles. Additional information for Recombinant Viral Vectors

"Insert" Vector(s): recombinant pAdEASY-1 used with packaging cell line (HEK) and resulting viral particles used to transfect mammalian expression host cells (MCF-7 and T47D).

Origin & function

This is an artificial construct containing: a nuclear localisation signal - NLS (derived from SV40 large T), hER2.0/1.1 ZFP DNA binding domain (synthetic), either a KRAB transcriptional repression domain (derived from Drosophila Kruppel) or a VP 16 transcriptional activation domain (derived from a fragment of Herpes Simplex Virus) and a FLAG domain (synthetic) in pcDNA3. This artificial construct is under the control of the Tet Repression system (Tet Off). This comprises two cassettes which have been PCRd from commercially available vectors: Cassette 1 consists of a Tet repressor under the control of a CMV IE promoter linked to VP16 followed by an IRES-EGFP element and Bovine growth hormone Poly A. Cassette 2 comprises a 7 x Tet Operon with a CMV IE minimal promoter, followed by a multiple cloning site (into which the above ZFP constructs will be inserted) and an SV40 Poly A. The two cassettes are inserted back to back into the pSHUTTLE expression plasmid. (See Vogelstein et al. PNAS., Vol. 95, pp. 2509-2514, March 1998) The two proteins to be expressed are artificial constructs. Each consists of zinc fingers which are expected to bind specifically to an 18-bp sequence in the hERα promoter. In the presence of tetracycline their expression will be switched off. However, in the absence of tetracycline they are expected to be highly expressed. The proteins will contain a Nuclear Localisation Signal and will therefore be targeted largely to the nucleus of hER2.0/1.1 NKF/NVF expressing cells, where the KRAB transcriptional repressor domain and VP16 transcriptional activator domain will assert their effects on hERα transcription within 1kb of the hERα Sp1 binding site. The expressed proteins are expected to be biologically active but are designed to exert their effects only in cells expressing endogenous hERα.
Since ERa is a transcription factor, over-expression will have no effect unless the cells are exposed to estrogens, in which case the consequence will be to activate expression of estrogen responsive genes.

**Evaluation of foreseeable effects**

Taking a very precautionary approach, the likelihood of potentially harmful effects being realised as a consequence of exposure of the operator or environment to the viral vectors was judged to be low. Risks associated with other GMOs are judged to be negligible.

The greatest risk of accidental infection arises during the preparation of concentrated virus stocks. Since the use of sharps may be necessary in the viral purification steps, there is chance of the user being injected with virus particles containing the genetic material. It is conceivable that infection may induce an immune response against the viral vector if large numbers of cells are infected initially. After aliquotation only small aliquots are handled at any one time and effectively, the complete aliquot would have to be ingested to generate a significant infection.

There is no evidence that the expression of the inserted gene could have an additional harmful effect in vivo. It is possible that infection with the virus containing the constructs may lead to a localised expression of ZFPs. Constructs to be expressed will be biologically active and are designed to exert their effects only in cells expressing endogenous hERa.

They are designed to bind specifically to the human ER alpha promoter where they will act as either inhibitors or activators of ERa transcription. Since ERa is a transcription factor, over-expression will have no effect unless the cells are exposed to estrogens, in which case the consequence will be to activate expression of estrogen responsive genes. Most cells which are exposed to estrogen express ERa at a level sufficient to activate gene expression on exposure to ligand, thus overexpression of ER will be of little consequence. It is difficult to predict the effects of switching off hERa expression in cells which normally express the protein. Since the function of these ZFPs is to up or down-regulate ERa expression, it is possible that infection may lead to ERa-responsive genes being switched on or off in the immediate area.

Since the ZFP sequences are to be introduced into viral vectors designed to target human cells, it will be necessary to control exposure to viral particles containing this genetic material. However, since the virus is replication-defective, the risk of widespread infection is very low. Thus, expression of the inserted genetic material should be restricted to cells which have received the initial dose of the virus.

The protein is very unlikely to bind productively to other functional Sp1 sites in the human genome than that referred to above since the Sp1 binding site comprises only 8 of the 18bp required for binding. However, binding to other sites with sufficient homology may be possible. There is evidence in the literature (liu et al, PNAS 94, 5225-5530, 1997) which suggests that the binding of synthetic ZFPs to their target sequences may not be absolute, and that there may be a risk of the ZFPs binding to sequences other than those intended. Since these synthetic ZFPs have transcriptional activation and repression domains attached to them, it is possible that when they are introduced into a viral vector which targets human cells, there is the potential for inadvertent transcriptional activation of oncogenic sequences or inhibition of tumor suppressor sequences, respectively. The protein is expected to be immunogenic but autoimmune effects are not likely because they are artificial proteins that are not present normally in humans.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

n/a

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

All CL2 measures will be applied with the exception of the requirement for an autoclave to be available in each building where activities are carried out. The waste management procedures used at Alderley Park are judged to provide an equivalent level of protection. The measures used are included in the section below dealing with waste management. An exemption from the requirement for an autoclave to be present in each building is therefore requested.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Waste management procedures at Alderley Park make use of a central autoclave facility with suitable measures for collection and transport from the site of production to the autoclave. Briefly, the standard site procedures for disposal of relevant waste are as follows: (a) Liquid Chloros or 1% Virkon (final concentrations) for at least 30
minutes. This treated liquid mixture is then flushed to drain using copious amounts of water. In some instances other specified validated disinfectants are used for specific purposes including Savlon hospital concentrate. 70% ethanol is commonly employed for routine surface decontamination. (b) Solid wasts (other than sharps) are placed in an autoclave bag and when sufficiently full, the neck is twisted closed and the bag placed in a second autoclave bag which is sealed with autoclave tape. The bag is then placed in a specified location in the laboratory, pending collection. The closed bags are collected daily by Shift Technicians who transport them in robust wheeled and lidded containers to an on-site autoclave for inactivation in an autoclave located in a specialised facility on site. This procedure has been validated using a 12-point thermocouple procedure in which probes are placed in a representative load. After autoclaving, waste is collected by a contractor for final disposal by off-site incineration. (c) Sharps are placed in suitable purpose-designed robust containers with a lid and when full are placed for collection and final disposal by incineration by our waste contractor.

Measures for disinfection of any accidental spills are set out in the Alderley Park Biosafety Manual and are based on appropriate use of the above disinfectants. Briefly, liquid spills are covered with paper towels and disinfectant added from the perimeter. After the specified period required for inactivation, the towels are removed into a container for final collection and final disposal by either autoclaving as described above, or where the disinfectant is incompatible with that process, by incineration off-site. All waste materials are transported in sturdy leak-proof containers.

Disinfection procedures lead to at least an 8 log reduction in viable bacterial cell count. The disabled bacterial host strains used do not survive well in the environment even if untreated. The viable count in liquid waste samples after disinfection is estimated as 0-10/ml and is likely to be at or close to the lower end of that range. The associated water used to flush treated liquid waste to drain, the concentration of any bacteria in such waste is negligible.

Adenoviruses are inactivated by a number of disinfectants including hypochlorite based agents and Virkon (Antec) both of which are specified for use at Alderley Park. The titres of recombinant adenoviral vectors in concentrated stocks can approach 10 pfu. Routine titres in discard flasks would be at least two orders of magnitude less than this and probably substantially less than this. Contaminated liquid waste is diluted into at least a 10-fold excess of Virkon such that the final concentration of the disinfectant is at least 1%, the concentration recommended by the manufacturer. The maximum concentration of viral particles in the disinfectant solution is estimated to be 10 (to the power of 6) particles per ml. Under the conditions of use, the disinfectant produces a log kill of at least 10 (to the power of 5), so that the material discarded to drain contains (less than or equal to) 10 infectious particles per ml. Copious volumes of water accompany disposal of waste to drains so that the titre of infectious particles is less than 1 per ml. The presence of any residual infectious particles, which are anyway replication defective, thus presents a negligible risk of harm to human health or to the environment.

The mammalian cells used in this work cannot survive outside a narrow range of temperature and nutrient conditions and even untreated it is anticipated that none would survive soon after disposal to drain. Given that all relevant liquid waste is treated with either 2.5% bleach (hypochlorite) or 1% Virkon, the survival rate is effectively zero.

Approved as risk class 2 following a precautionary approach.

Project Containment
Hepatocyte growth factor (HGF) and its receptor c-met are both known to be upregulated in a number of human cancers including breast cancer and contribute to disease progression; HGF is normally produced by cells of mesenchymal origin and acts in a paracrine manner on epithelial cells expressing c-met. In normal physiology, HGF/c-met provide one mechanism for controlled cell proliferation and expression of other gene products that effect tissue repair processes including, cell migration and proliferation, and expression of proteolytic enzymes to facilitate tissue remodelling. The recombinant MDA MB435 H1 cell line which expresses high levels of HGF, has a more aggressive phenotype than the parental cell line, and gives rise to substantially more lung metastases when implanted into the mammary fat pad. The cell line will be grown in vitro and implanted in vivo for use in the study of tumour invasion and angiogenesis.

Recipient or parental organism

MDA MB435: One of several human breast tumour cell lines (see also MDA MB231) in routine use as xenograft models. Tumourigenic in animals, although not likely to survive outside of defined culture medium.
MDA MB435 cells have been modified by the introduction of the human hepatocyte growth factor gene in an expression plasmid, pBAT which contains a full length (~2.2kb) cDNA encoding HGF. Expression is driven from sequences in that plasmid which encode the chicken beta actin promoter. The cells have also been transformed with another plasmid, pSV2neo, which encodes sequences for neomycin resistance (for in vitro selection). The expression construct allows for the secretion of a pro-HGF molecule which is proteolytically cleaved to the active heterodimer.

Origin & function

The expression plasmid pBAT contains a full length (~2.2kb) cDNA encoding human hepatocyte growth factor. The cDNA sequence contains the appropriate signal sequences for processing of secreted proteins. The transfected cells have been shown to secrete HGF as reported by Meiners et al (Oncogene. 1998 Jan 8;16(1):9-20). It is anticipated that the product will be produced in an active form. Hepatocyte growth factor (HGF) is a 92kDa heterodimeric growth factor, secreted as a single chain pro-form from cells of mesenchymal origin. Proteolytic cleavage to the mature heterodimer is thought to occur at sites of tissue damage in the adult, and is associated with tissue remodelling in the developing embryo. HGF binds to and activates the tyrosine kinase receptor c-met, the expression of which is largely confined to epithelial cells. Thus in the adult body, HGF is secreted as a pro-form and is activated as required for tissue repair, and through activation of c-met, initiates epithelial pathways needed for repair processes such as cell migration, proliferation and the secretion of proteolytic enzymes. The intended function is to confer relevant properties on the cell line as a model for the study of tumour invasion and angiogenesis.

Evaluation of foreseeable effects

The modification is anticipated to confer a more aggressive and more metastatic phenotype on the recombinant than is exhibited by the parental cell line. It was judged unlikely that any harmful effects other than localised immune response would occur if in the worst case scenario of accidental injection while transplanting the tumour cells into mice. The probability of the cells establishing a tumour in a healthy non-syngeneic person in the case of accidental inoculation was judged to be negligible. The consequences of handling the cells detailed herein are no more severe than those considered for many other human tumour cell lines. The UKCCCR recommend that all work with human tumour cells is conducted at level 2 but the Health and Safety Executive (HSE) have indicated that this requirement can in general be treated as a COSHH issue and disregarded for the purposes of risk classification. However, after consultation, HSE have indicated that as a human tumour cell line, with anticipated increased aggressiveness and metastatic potential associated with the modification, and the potential for accidental inoculation, this work should be categorised as risk class 2. The resulting risk categorisation has arisen as a consequence of this advice.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All other relevant measures required at Cl2 will be applied except for the presence of an autoclave in the building. At Alderley Park, autoclaves are not present in each and every building where work with Risk Class 2 organisms may be conducted. In some buildings, autoclaves are present, but are available only for media and glassware sterilisation. As described in full below, the waste management system involves a central autoclave facility and a collection and transport process which we judge to provide an equivalent level of protection.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste management procedures at Alderley Park make use of a central autoclave facility with suitable measures for collection and transport from the site of production to the autoclave. Briefly, the standard site procedures for disposal of relevant waste are as follows: (a) Liquid wastes: In general, the site procedures involve treatment of infectious liquid waste with 2.5% Chloros or 1% Virkon (final concentrations) for at least 30 minutes. This treated liquid mixture is then flushed to drain using copious amounts of water. In some instances other specified validated disinfectants are used for specific purposes including Savlon hospital concentrate. 70% ethanol is commonly employed for routine surface decontamination. (b) Solid wastes (other than sharps): are placed in an autoclave bag and when sufficiently full, the neck is twisted closed and the bag placed in a second autoclave bag which is sealed with autoclave tape. The bag is then placed in a specified location in the laboratory, pending collection. The closed bags are collected daily by Shift Technicians who transport them in robust wheeled and lidded containers to an on-site autoclave for inactivation in an autoclave located in a specialised facility on site. This procedure has been validated using a 12-point thermocouple procedure in which probes are placed in a
representative load. After autoclaving, waste is collected by a contractor for final disposal by off-site incineration. (c) Sharps are placed in suitable purpose-designed robust containers with a lid and when full are placed for collection and final disposal by incineration by our waste contractor.

Measures for disinfection of any accidental spills are set out in the Alderley Park Biosafety Manual and are based on appropriate use of the above disinfectants. Briefly, liquid spills are covered with paper towels and disinfectant added from the perimeter. After the specified period required for inactivation, the towels are removed into a container for final collection and final disposal by either autoclaving as described above, or where the disinfectant is incompatible with that process, by incineration off-site. All waste materials are transported in sturdy leak-proof containers.

Disinfection procedures lead to at least an 8 log reduction in viable bacterial cell count. The disabled bacterial host strains used do not survive well in the environment even if untreated. The viable count in liquid waste samples after disinfection is estimated as 0-10/ml and is likely to be at or close to the lower end of that range. With associated water used to flush treated liquid waste to drain, the concentration of any bacteria in such waste is negligible.

The mammalian cells used in this work cannot survive outside a narrow range of temperature and nutrient conditions and even untreated it is anticipated that none would survive soon after disposal to drain. Given that all relevant liquid waste is treated with either 2.5% bleach (hypochlorite) or 1% Virkon, the survival rate is effectively zero.

Approved at risk class 2 after consultation with the Health and Safety Executive. The risk classification of this particular proposal posed some particular difficulties. For this reason, the advice of HSE was sought. Their view was that the potential increased hazard associated with the modification, in conjunction with the UKCCR recommendation regarding CL2 measures as a minimum requirement for work with human tumour cells meant that risk Class 1 was inappropriate.

**Project Ref** 108/01.7
Adenoviral mediated expression of human AKT that has been modified such that it is no longer oncogenic. The aim of the experiment is to deliver modified human AKT to all cells in a culture and measure the effect on apoptosis, cell proliferation and protein phosphorylation profiles.

Recipient or parental organism

CLONING HOSTS:
DH10B: Disabled E coli strain. Genotype: F^-mcrAd(mrr^-hsdRMS^-mcrBC) prophage 80lacZdM15 lacX74 deoR recA1 araD139 ara,leu)7697 gaiU galKlamdEl^-rpsL nupG.

BJ5183 Especially disabled E coli K-12 derivative with partial recombination capability to allow the recombination of pAdEasy-1 and pAdTrack-CMV. It is ampicillin and kanamycin sensitive.

EXPRESSION HOSTS:
A549: Authenticated human lung tumour cell line. ATCC Number: CCL-185. Reverse Transcript: negative. ATCC recommend BL1

Calu-6: ATCC Number: HTB-56. Derived from a human anaplastic carcinoma, probably lung. No special risk factors known with respect to patient origin. Tumorigenic in nude mice; forms poorly differentiated carcinoma; epithelial morphology in vitro. References date back to 1975. ATCC refer to Biosafety Level 1 but CL2 may be more appropriate given the tumorigenicity (albeit only cited in respect of nude mice).

HeLa: Human tumour cell line. Reverse transcriptase negative. Contains residual human papilloma virus sequence with associated potential for complementation of the E1a deletion in recombinant Adenoviral systems. ATCC recommend handling at Biosafety Level 2.

HT29: ATCC Number: HTB-38. Human colorectal adenocarcinoma; Tumorigenic in nude mice; forms well differentiated adenocarcinoma consistent with colonic primary (grade 1); tumors also from in steroid treated hamsters. No virus particles observed. Oncogene: myc +; ras +; myb +; fos +; sis +; p53 +; abl -; src -. The line is positive for expression of c-myc, K-ras, H-ras, N-ras. N-myc oncogene expression was not detected. The p53 antigen is overproduced. ATCC recommend BioSafety Level 1.

LNCaP: clone FGC [LNCaP.FCG] Available from ATCC. References date from at least 1980. Tissue: human carcinoma; prostate; from metastatic site: left
supraclavicular lymph node. Tumorigenic in nude mice. 

MCF7: The MCF7 line is derived from a human mammary gland adenocarcinoma and retains several characteristics of differentiated mammary epithelium Contains the Tx-4 oncogene. 

OVCA-3: The NIH:OVCA-3 line was established in 1982 by T C Hamilton, et al. From the malignant ascites of a patient with progressive adenocarcinoma of the ovary. Tumorigenic in nude mice. Described by ATCC as appropriate for work at Biosafety Level 1. 

PC-3: ECACC Ref No: 90112714. Established from a grade 4 prostatic adenocarcinoma from a 62 year old male Caucasian. 

Cloning Vectors: 

pAdTrack-CMV: A 9.2 kbp vector obtained from Bert Vogelstein (He et al PNAS 1998 vol 95 p2509-2514) and is used in conjunction with pAdEasy-1 to generate recombinant adenoviral plasmids in E. coli. The resulting recombinant plasmid can be used to produce infective but replication-defective adenoviral particles following transfection of suitable mammalian host cells (eg HEK293) able to provide the E1a sequence in trans. 

pAdEASY-1: A 33.4 kbp vector obtained from Bert Vogelstein (He et al PNAS 1998 VOL 95 P2509-2514) which contains all the adenovirus type 5 sequences except nucleotides 1-3533 (encompassing the E1 genes) and 28, 130-30,820 (encompassing E3 region). The vector also contains an ampicillinR gene and an origin of replication from PBR322, hence the plasmid is mobilisation defective (Bom+ Tra- Mob-). The vector is used in conjunction with pAdTrack vectors to generate recombinant adenoviral plasmids in E. coli (eg when co-transformed into a bacterial host with the pAdTrack-CMV shuttle vector containing an insert sequence, recombination in the host leads to production of a recombinant pAdEasy-1 containing insert sequences. That plasmid can be used to transfect appropriate mammalian cells (eg. HEK293) to generate recombinant E1a-deleted adenoviral particles. 

Recombinant Virus Particles: Recombinant adenoviral vector based on: 

"Insert" Vector(s): recombinant pAdEASY-1; Virus Producer Cell Line: HEK293. 

HEK-293: Human embryonic epithelial cells stably expressing the transforming gene of human Type 5 Adenovirus. DNA from both the right and left ends of the viral genome is present. When used as a helper cell line production of recombinant adenoviral particles, production of wild-type virus (an ACDP Hazard Group 2 pathogen) can occur albeit at a low frequency. Two specific non-homologous recombination events would be required to generate replication-competent virus. In a supernatant rescue assay performed on the virus stock to check for replication competent adenovirus (ref: Dion et al J of Virol Methods 1996 vol56 p99-107 no replication competent virus was detected in 1x10e9 infectious particles. If virus stocks are repeatedly passaged in HEK293 cells replication-competent virus can appear after 9 passages. Methods to produce virus using pAdEasy-1 only require a maximum of three passages in HEK293 cells. Given this data, the risk of generating wild-type adenovirus is considered to be negligible using these procedures. The HEK cell line supplied by ATCC is tumorigenic in nude mice and ATCC recommend minimum containment at Biosafety Level 2. 

The resulting recombinant viral particles will be used for transfection of, and subsequent expression of products in, the mammalian host cells referred to above. 

Origin & function 

Origin of insert: The expression vector containing the modified human AKT construct was obtained from Dundee University. The original insert was derived initially by PCR from a human cdNA library. The modification is of the coding sequence such that the resulting protein will contain alanine residues in place of threonine at 308 and serine at 473 and will therefore be inactive. 

Intended function: When native AKT is expressed the phosphorylation of Threonine 308 and Serine 473 act synergistically to activate AKT. Here the modified human AKT protein contains alanine residues in place of Threonine 308 and Serine 473 and therefore when expressed should not be phosphorylated at these residues hence should not be active. The modified human AKT protein should act as a dominant-negative when expressed in mammalian cells and inhibit endogenous AKT, with possible effects.
on cell proliferation, apoptosis and intracellular protein phosphorylation profiles. These effects are those that are to be analysed as part of this work however effects on other pathways eg glycogen synthesis pathway are also possible. The modification of the threonine and serine residues to alanine residues results in a functional protein that acts as a dominant negative. The protein is not active as a kinase. The activity anticipated is inhibition of endogenous AKT kinase.

**Evaluation of foreseeable effects**

Taking a very precautionary approach, the likelihood of potentially harmful effects being realised as a consequence of exposure of the operator or environment to the viral vectors was judged to be low. Risks associated with other GMOs are judged to be negligible.

The greatest risk of accidental infection arises during the preparation of concentrated virus stocks and aliquotation. Before that the virus is present in a very diluted state and large volumes would have to be involved to produce a significant infection. After aliquotation only small aliquots are handled at any one time and effectively, the complete aliquot would have to be ingested to generate a significant infection.

It is conceivable that infection may induce an immune response if large numbers of cells are infected initially. There is no evidence that the expression of the inserted gene could have an additional harmful effect in vivo. The protein should act as a dominant negative when expressed in mammalian cells and inhibit endogenous Akt, with possible effects on cell proliferation, apoptosis and intracellular protein phosphorylation profiles. Normal AKT is expressed in all tissues throughout the body. Hence in tissues that require cell division for normal function, in theory, if the handling of the dominant negative virus stock resulted in an accidental infection eg. through aerosols, this could lead to an abnormal hypoplastic status. The risk of this however is considered to be very low due to the containment measures put in place. Because normal AKT appears to have several functions within the cell an accidental infection could also result in the perturbation of other pathways apart from proliferation, but again this risk is considered to be very low. Because AKT is an intracellular serine/threonine kinase and is highly unlikely to be secreted by the host cells, the target is inaccessible in cells other than those in which it is expressed. Any effects would thus be restricted to the cells initially infected.

A further possible risk which has also been taken into consideration is the chance of homologous recombination between the insert sequence and the wild-type gene following transfection of the HEK293 cells to produce a replication-defective recombinant but one able to express the non-mutated form of the gene. If this did occur and if such expression was abnormally high or non-regulated the resulting expressed protein could be oncogenic. The chance of this happening is very low.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

n/a

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Measures for which an exemption is claimed: All CL2 measures will be applied with the exception of the requirement for an autoclave to be available in each building where activities are carried out. The waste management procedures used at Alderley Park are judged to provide an equivalent level of protection. The measures used are included in the section below dealing with waste management. An exemption from the requirement for an autoclave to be present in each building is therefore requested.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Waste management procedures at Alderley Park make use of a central autoclave facility with suitable measures for collection and transport from the site of production to the autoclave. Briefly, the standard site procedures for disposal of relevant waste are as follows. (a) Liquid wastes: In general the site procedures involve treatment of infectious liquid waste with 2.5% Chloros or 1% Virkon (final concentrations) for at least 30 minutes. This treated liquid mixture is then flushed to drain using copious amounts of water. In some instances other specified validated disinfectants are used for specific purposes including Savlon hospital concentrate. 70% ethanol is commonly employed for routine surface decontamination. (b) Solid wastes (other than sharps): are placed in an autoclave bag and when sufficiently full, the neck is twisted closed and the bag placed in a second autoclave bag which is sealed with autoclave tape. The bag is then placed in a specified location in the laboratory, pending collection. The closed bags are collected daily by Shift Technicians who transport them in robust wheeled and lidded containers to an on-site autoclave for inactivation in an autoclave located in a specialised facility on site. This procedure has been validated using a 12-point thermocouple procedure in which probes are placed in a representative load. After autoclaving, waste is collected by a contractor for final disposal by off-site incineration. (c) Sharps are placed in suitable purpose-designed robust containers with a lid and when full are placed for collection and final disposal by incineration by our waste contractor.

Measures for disinfection of any accidental spills are set out in the Alderley Park Biosafety Manual and are based on appropriate use of the above disinfectants. Briefly,
Liquid spills are covered with paper towels and disinfectant added from the perimeter. After the specified period required for inactivation, the towels are removed into a container for final collection and final disposal by either autoclaving as described above, or where the disinfectant is incompatible with that process, by incineration off-site. All waste materials are transported in sturdy leak-proof containers.

Disinfection procedures lead to at least an 8 log reduction in viable bacterial cell count. The disabled bacterial host strains used do not survive well in the environment even if untreated. The viable count in liquid waste samples after disinfection is estimated as 0-10/ml and is likely to be at or close to the lower end of that range. With the associated water used to flush treated liquid waste to drain, the concentration of any bacteria in such waste is negligible. Adenoviruses are inactivated by a number of disinfectants including hypochlorite based agents and Virkon (Antec) both of which are specified for use at Alderley Park. The titres of recombinant adenoviral vectors in concentrated stocks can approach 10 (to the power of 11) pfu. Routine titres in discard flasks would be at least two orders of magnitude less than this and probably substantially less than this. Contaminated liquid waste is diluted into at least a 10-fold excess of Virkon such that the final concentration of the disinfectant is at least 1% the concentration recommended by the manufacturer. The maximum concentration of viral particles in the disinfectant solution is estimated to be 10(to the power of 6) particles per ml. Under the conditions of use, the disinfectant produces a log kill of at least 10(to the power of 5), so that the material discarded to drain contains <10 infectious particles per ml. Copious volumes of water accompany disposal of waste to drains so that the titre of infectious particles is less than 1 per mil. The presence of any residual infectious particles, which are anyway replication defective, thus presents a negligible risk of harm to human health or to the environment. The mammalian cells used in this work cannot survive outside a narrow range of temperature and nutrient conditions and even untreated it is anticipated that none would survive soon after disposal to drain. Given that all relevant liquid waste is treated with either 2.5% bleach (hypochlorite) or 1% Virkon, the survival rate is effectively zero.

Project Ref  108/01.8
GENERATION OF RECOMBINANT ADENOVIRUS CODING FOR A NATIVE AND MODIFIED HUMAN KINASE AND TRANSIENT EXPRESSION IN MAMMALIAN CELLS.

Purposes of the contained use
To deliver the kinase gene to all cells in a culture and to measure the effect of expression of this gene on transcript expression profiles.

Recipient or parental organism
Cloning hosts:
Disabled E. coli K12 strains:
DH5alpha: Genotype: F^-supE44 hsdR17 recA1 gyrA96 endA1 thi-1 relA1 deoR pro phage 80d(lacZYA^-argF)u169(m801acZdM15)
DH10B: Genotype: F^-mcrAd(mrr^-hsdRMD^-mcrBC) prophage 80dlacZdM15 dlacX74 deoR recA1 endA1 araD139d(ara,leu)7697 galU galKlambda^-rpsL nupG

BJ5183 Especially disabled E. coli K-12 derivative with partial recombination capability to allow the recombination of pAdEasy-1 and pAdTrack-CMV. It is ampicillin and kanamycin sensitive.

Virus Producer Cell Line: HEK293
Expression Host Cells: HeLa, primary human aortic endothelial cells (HAEC); primary human umbilical vein endothelial cells (HUVEC)

Host/vector system
pAdrack-CMV: A 9.2 kbp vector obtained from Bert Vogelstein (He et al PNAS 1998 VOL 95 P2509-2514) and is used in conjunction with pAdEasy-1 to generate recombinant adenoviral plasmids in E.coli. The resulting recombinant plasmid can be used to produce infective but replication-defective adenoviral particles following transfection of suitable mammalian host cells (eg HEK293) able to provide the E1a sequence in trans.

pAdEASY-1: A 33.4 kbp vector obtained from Bert Vogelstein (He et al PNAS 1998 vol 95 p2509-2514) which contains all the adenovirus type 5 sequences except nucleotides 1-3533 (encompassing the E1 genes) and 28, 130-30,820 (encompassing E3 region). The vector also contains an ampicillinR gene and an origin of replication from pBR322, hence the plasmid is mobilisation defective (Bom+ Tra-Mob-). The vector is used in conjunction with pAdTrack vectors to generate recombinant adenoviral plasmids in E.coli (eg when co-transformed into a bacterial host with the pAdTrack-CMV shuttle vector containing an insert sequence, recombination in the host leads to production of a recombinant pAdEasy-1 containing insert sequences. That plasmid can be used to transfect appropriate mammalian cells (eg. HEK293) to generate recombinant E1a-deleted adenoviral particles.
Additional information for Recombinant Virus Particles.

Intended virus(es): Adenovirus

*Insert* Vector(s): recombinant pAdEASY-1.

PadE

Inserts originate from human cDNA from the Incyte collection. The proteins encoded by the inserts are serine/threonine kinases which are involved in a signalling pathway which, in response to extra-cellular factors, activates a transcription factor leading to ultimate expression of pro-inflammatory genes. The precise role of the kinases in linking the various extracellular signals with pro-inflammatory gene expression is unclear, though expression of a dominant negative mutant of these kinases is anticipated to inhibit - activation of a key pathway. Expression of the kinases will allow associated transcript profiles to be studied.

**Origin & function**

Generation of wild-type virus: Human embryonic epithelial cells stably expressing the transforming ene of human Type 5 Adenovirus are used to allow replication of viral particles by complementation of the vector defect. DNA from both the right and left ends of the viral genome is present. When used as a helper cell line production of recombinant adenoviral particles, production of wild-type virus (an ACDP Hazard Group 2 pathogen) can occur albeit at a low frequency. Two specific non-homologous recombination events would be required to generate replication-competent virus. In a supernatant rescue assay performed on the virus stock to check for replication competent adenovirus (ref: Dion et al J of Virol Methods 1996 vol56 p99-107 no replication competent virus was detected in 1 x10e9 infectious particles. If virus stocks are repeatedly passaged in HEK293 cells replication-competent virus can appear after 9 passages. Methods to produce virus using pAdEasy-1 only require a maximum of three passages in HEK293 cells. Given this data, the risk of generating wild-type adenovirus is considered to be negligible using these procedures.

Recombinant adenoviral particles:

The vector is a recombinant adenovirus type 5 capable of infecting human cells expressing adenovirus receptor in a non-productive manner, ie no replication of the virus is possible, however, for a limited period of time, the inserted gene will be expressed in infected cells at potentially high levels. No systemic adverse effect is expected should local infection occur although a localised immune response is conceivable.

The inserts encode serine/threonine kinases which are involved in the signalling pathway which, in response to extra-cellular factors, activates a target transcription factor leading to expression of pro-inflammatory genes. The precise role of these kinases in linking the various extracellular signals with pro-inflammatory gene expression is unclear, although expression of dominant negative mutants is anticipated to inhibit cytokine-mediated activation of the relevant pathway.

The greatest risk of accidental infection arises during the preparation of concentrated virus stocks and aliquotation. Before that the virus is present in a very diluted state and large volumes would have to be involved to produce a significant infection. After aliquotation only small aliquots are handled at any one time and effectively, the complete aliquot would have to be ingested to generate a significant infection. It is conceivable that infection may induce an immune response if large numbers of cells are infected initially. There is no evidence that the expression of the inserted gene could have an additional harmful effect in vivo. However, in vitro, certain cell types are sensitised to cytokine mediated apoptosis in the presence of inhibitors of the target a key constituent of the relevant pathway (ie dominant-negative form of the kinase of interest). Thus, both a large number of cells susceptible to sensitisation would have to be infected and a high concentration of cytokine would have to be present to induce apoptosis so this particular risk is negligible to low.

The only variants of the kinases which are being studied are the dominant negatives. There are no constitutively active forms proposed or made. Endothelial cells in tissue culture can be sensitised to apoptosis after cytokine treatment when all activity of the critical pathway target is inhibited. It is not clear whether this would also happen in vivo and whether inhibition of one kinase by a dominant negative would completely abolish activation of the target. The cytokine level required in vitro is much higher than would ever occur in vivo, with the exception of local production. In order to get an adverse effect, local cytokine production and recombinant adenovirus infection would have to occur simultaneously which is highly unlikely. In addition, apoptosis in vivo will be occurring naturally and it is likely that the effect of infection at anticipated levels even in the case of accidental exposure, will lead to marginal effects at worst.
The kinases are ubiquitously expressed but normally inactive unless the cells are stimulated by cytokines or bacterial lipopolysaccharide. It is unclear which isoform is rate limiting in which cells. The only imaginable effect would be if high amounts of wild-type kinase were expressed such that there could be activation of the target which would trigger an inflammatory response if enough cells were activated at the same location. The dominant-negative kinase would not have any effect in normal cells unless these cells were triggered to activate the target which one would then expect to be inhibited and suppress whatever process was triggering activation of the target.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

n/a

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

All CL2 measures will be applied with the exception of the requirement for an autoclave to be available in each building where activities are carried out. The waste management procedures used at Alderley Park are judged to provide an equivalent level of protection. The measures used are included in the section below dealing with waste management. An exemption from the requirement for an autoclave to be present in each building is therefore requested.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Waste management procedures at Alderley Park make use of a central autoclave facility with suitable measures for collection and transport from the site of production to the autoclave. Briefly, the standard site procedures for disposal of relevant waste are as follows:

a) Liquid wastes: In general, the site procedures involve treatment of infectious liquid waste with 2.5% Chloros or 1% Virkon (final concentrations) for at least 30 minutes. This treated liquid mixture is then flushed to drain using copious amounts of water. In some instances other specified validated disinfectants are used for specific purposes including Savlon hospital concentrate. 70% ethanol is commonly employed for routine surface decontamination.

b) Solid wastes (other than sharps): are placed in an autoclave bag and when sufficiently full, the neck is twisted closed and the bag placed in a second autoclave bag which is sealed with autoclave tape. The bag is then placed in a specified location in the laboratory, pending collection. The closed bags are collected daily by Shift Technicians who transport them in robust wheeled and lidded containers to an on-site autoclave for inactivation in an autoclave located in a specialised facility on site. This procedure has been validated using a 12-point themocouple procedure in which probes are placed in a representative load. After autoclaving, waste is collected by a contractor for final disposal by off-site incineration. (c) Sharps are placed in suitable purpose-designed robust containers with a lid and when full are placed for collection and final disposal by incineration by our waste contractor.

Measures for disinfection of any accidental spills are set out in the Alderley Park Biosafety Manual and are based on appropriate use of the above disinfectants. Briefly, liquid spills are covered with paper towels and disinfectant added from the perimeter. After the specified period required for inactivation, the towels are removed into a container for final collection and final disposal by either autoclaving as described above, or where the disinfectant is incompatible with that process, by incineration off-site. All waste materials are transported in sturdy leak-proof containers.

Disinfection procedures lead to at least an 8 log reduction in viable bacterial cell count. The disabled bacterial host strains used do not survive well in the environment even if untreated. The viable count in liquid waste samples after disinfection is estimated as 0-10/ml and is likely to be at or close to the lower end of that range. With the associated water used to flush treated liquid waste to drain, the concentration of any bacteria in such waste is negligible.

Adenoviruses are inactivated by a number of disinfectants including hypochlorite based agents and Virkon (Antec) both of which are specified for use at Alderley Park. The titres of recombinant adenoviral vectors in concentrated stocks can approach 10 (to the power of 11) pfu. Routine titres in discard flasks would be at least two orders of magnitude less than this and probably substantially less than this. Contaminated liquid waste is diluted into at least a 10-fold excess of Virkon such that the final concentration of the disinfectant is at least 1%, the concentration recommended by the manufacturer. The maximum concentration of viral particles in the disinfectant solution is estimated to be 10 (to the power of 6) particles per ml. Under the conditions of use, the disinfectant produces a log kill of at least 10 (to the power of 5), so that the material discarded to drain contains <10 infectious particles per ml. Copious volumes of water accompany disposal of waste to drains so that the titre of infectious particles is less than 1 per ml. The presence of any residual infectious particles, which are anyway replication defective, thus presents a negligible risk of harm to human
health or to the environment. The mammalian cells used in this work cannot survive outside a narrow range of temperature and nutrient conditions and even untreated it is anticipated that none would survive soon after disposal to drain. Given that all relevant liquid waste is treated with either 2.5% bleach (hypochlorite) or 1% Virkon, the survival rate is effectively zero.

That plasmid can be used to transfect appropriate mammalian cells (eg. HEK293) to generate recombinant E1a-deleted adenoviral particles.

Additional Information for Recombinant Virus Particles

*Insert* Vector(s): recombinant pAdEASY-1
Virus Producer Cell Line: HEK293
Recombinant viral particles used for transfection of mammalian expression host cells.

### Origin & function

**Source of Nucleic Acid:** Human cDNAs

**Intended functions:** The receptors are ligand-activated hormone receptors which when activated regulate expression of target genes. Endogenous expression of the receptors is limited to only some cell types. Expression of the receptors in mammalian cells has been shown to yield biologically active proteins with potential for evaluation of the effects of compounds with potential antagonist properties and to determine receptor selectivity.

**Expression of the receptors in mammalian cells has been shown to yield biologically active proteins.** There is the potential for accidental infection with the recombinant viral particles. The greatest risk is judged to arise during the preparation of concentrated virus stocks and aliquotation. Before that the virus is present in a very diluted state and large volumes would have to be involved to produce a significant infection. After aliquotation only small aliquots are handled at any one time and effectively, exposure to the complete aliquot would have to be ingested to generate a significant infection. Since the vector is not replication competent, any harmful effects will be limited to cells directly infected following accidental exposure. Depending on the titre, this could be a greater or lesser number. It is conceivable that infection may induce an immune response if large numbers of cells are infected initially. There is no evidence that the expression of the inserted gene could have an additional harmful effect in vivo. There is no evidence that expression of the receptor is deleterious to cells (ie. transient expression of the receptor in cultured cells in the presence of hormone does not kill cells nor does it induce oncogenic effects. However, induction of inducible genes may change the normal physiology of a cell. It is not known how extensive exactly those changes would be because it is uncertain whether receptor expression alone is sufficient for induction of - hormone-dependent genes. Some genes may be inhibited by the presence of the receptor which may change the physiology of the cell to an unknown extent. The recombinant adenoviral vector could confer similar altered properties on cells accidentally infected with this vector. Although expression of the receptor in cells which may be accidentally infected is likely to be transient, it could persist for days/weeks. Taking a very precautionary approach, the likelihood of potentially harmful effects being realised as a consequence of exposure of the operator or environment to the viral vectors was judged to be low. Risks associated with other GMOs are judged to be negligible.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

All CL2 measures will be applied with the exception of the requirement for an autoclave to be available in each building where activities are carried out. The waste management procedures used at Alderley Park are judged to provide an equivalent level of protection. The measures used are included in the section below dealing with waste management. An exemption from the requirement for an autoclave to be present in each building is therefore requested.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Waste management procedures at Alderley Park make use of a central autoclave facility with suitable measures for collection and transport from the site of production to
the autoclave. Briefly, the standard site procedures for disposal of relevant waste are as follows:

a) Liquid wastes: In general, the site procedures involve treatment of infectious liquid waste with 2.5% Chloros or 1% Virkon (final concentrations) for at least 30 minutes. This treated liquid mixture is then flushed to drain using copious amounts of water. In some instances other specified validated disinfectants are used for specific purposes including Savlon hospital concentrate. 70% ethanol is commonly employed for routine surface decontamination.

b) Solid wastes (other than sharps): are placed in an autoclave bag and when sufficiently full, the neck is twisted closed and the bag placed in a second autoclave bag which is sealed with autoclave tape. The bag is then placed in a specified location in the laboratory, pending collection. The closed bags are collected daily by Shift Technicians who transport them in robust wheeled and lidded containers to an on-site autoclave for inactivation in an autoclave located in a specialised facility on site. This procedure has been validated using a 12-point themocouple procedure in which probes are placed in a representative load. After autoclaving, waste is collected by a contractor for final disposal by off-site incineration. (c) Sharps are placed in suitable purpose-designed robust containers with a lid and when full are placed for collection and final disposal by incineration by our waste contractor.

Measures for disinfection of any accidental spills are set out in the Alderley Park Biosafety Manual and are based on appropriate use of the above disinfectants. Briefly, liquid spills are covered with paper towels and disinfectant added from the perimeter. After the specified period required for inactivation, the towels are removed into a container for final collection and final disposal by either autoclaving as described above, or where the disinfectant is incompatible with that process, by incineration off-site. All waste materials are transported in sturdy leak-proof containers.

Disinfection procedures lead to at least an 8 log reduction in viable bacterial cell count. The disabled bacterial host strains used do not survive well in the environment even if untreated. The viable count in liquid waste samples after disinfection is estimated as 0-10/ml and is likely to be at or close to the lower end of that range. With the associated water used to flush treated liquid waste to drain, the concentration of any bacteria in such waste is negligible.

Adenoviruses are inactivated by a number of disinfectants including hypochlorite based agents and Virkon (Antec) both of which are specified for use at Alderley Park. The titres of recombinant adenoviral vectors in concentrated stocks can approach 10^11 pfu. Routine titres in discard flasks would be at least two orders of magnitude less than this and probably substantially less than this. Contaminated liquid waste is diluted into at least a 10-fold excess of Virkon such that the final concentration of the disinfectant is at least 1%, the concentration recommended by the manufacturer. The maximum concentration of viral particles in the disinfectant solution is estimated to be 10^6 particles per ml. Under the conditions of use, the disinfectant produces a log kill of at least 10 (to the power of 5), so that the material discarded to drain contains <10 infectious particles per ml. Copious volumes of water accompany disposal of waste to drains so that the titre of infectious particles is less than 1 per ml. The presence of any residual infectious particles, which are anyway replication defective, thus presents a negligible risk of harm to human health or to the environment. The mammalian cells used in this work cannot survive outside a narrow range of temperature and nutrient conditions and even untreated it is anticipated that none would survive soon after disposal to drain. Given that all relevant liquid waste is treated with either 2.5% bleach (hypochlorite) or 1% Virkon, the survival rate is effectively zero.

Is an emergency plan required according to regulation 20?  
If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Approved at risk class 2 following provision of further information requested from the proposer and which has been incorporated into the above.
Purposes of the contained use

Development and application of recombinant viral vectors for target identification, drug discovery and development using procedures involving:

- production of human sense or anti-sense cDNA or genomic libraries for screening using functional cloning studies with transfected mammalian cells. The latter will be recombinants of the following types:
  - reporter constructs (eg genes encoding marker proteins such as fluorescent proteins, linked to specific promoters eg associated with various cell signalling pathways).
  - library constructs eliciting biological effects, such as responses to specific hormones or other signalling molecules, which will be monitored after transfection.
- production of recombinant mammalian cells expressing wild-type and altered human genes to investigate mechanism of action of the gene products by monitoring the
effects of specific alterations on the predicted biological effect(s).

* production of recombinant mammalian cells expressing products of defined human genes of suspected by uncertain function to investigate the nature of potential substrates (e.g., where protein substrates are suspected, by studying incorporation of labelled precursors into those molecules in control and transfected cells).

* production of recombinant mammalian cells incorporating human transcription factors which may have a role in differentiation and monitoring the recombinants for subsequent development of specific differentiation markers.

* production of recombinant cells expressing tagged human proteins to investigate protein-protein interactions by immunoprecipitation and identification of tag-associated proteins.

In some cases, expression of products will be regulated using specific inducible expression systems (e.g., tetracycline-responsive elements).

Recipient or parental organism

Initial cloning studies will be carried out using E. coli strains such as DH5a, BJ5183 or DH10B which are all disabled as defined by ACGM and are unable to survive in the environment outside of laboratory culture conditions for extended periods. They are not pathogenic nor are they likely to colonise the gut of humans or of animal species.

A variety of human and rodent cells will be used as mammalian expression hosts. Human cells will be primary cell cultures and established cell lines. Any harm associated with these cells is restricted to potential adventitious agents or, in the case of human tumour cells, to the very low risk of establishment in the case of accidental inoculation. None of the cells to be used are derived from persons who will be working with these so that this risk is judged to be very low indeed. None of the mammalian cells are able to survive in the environment.

In some cases, mammalian cells will be used for the generation of recombinant adenoviral or retroviral particles. These particles can infect a wide range of mammalian cells but they are not replication competent so that any effect is restricted to cells which are initially transfected. Given the volumes and anticipated titre in culture media or in suspensions of the viral particles titres there are no likely environmental effects.

Accidental exposure of persons working with viral vector systems could lead to infection of a limited number of cells in exposed tissues. In such cases, foreseeable effects due to viral components of the vectors are restricted to inflammatory effects associated with immune responses. These are likely to be mild and transient given foreseeable accidental exposure. The effects associated with expression of the insert sequences are less predictable but if any, would be anticipated to vary according to the specific insert as set out below.

Host/vector system

The specified bacterial hosts will be used with the following vectors:

pLNCX
pLPCX
pCI
pVPACK
pAdEasy-1
pAdTrack-CMV
pAdTrack
pCDNA
pRevTet-On
pVPACK-VSV-G
pVPACK-ampho
pVPACK-10A1
Mammalian cells will be modified using either recombinant viral vectors (please see below) or directly with the following:

- pAdTrack-CMV
- pCDNA

Replication-defective recombinant tetroviral or adenoviral particles will be used to transfect the mammalian cells hosts. These particles are constructed using the following vectors in appropriate packaging cells or in cells otherwise complementing the replication defects:

Recombinant pAdEasy-1  293

pLNCX: A non-mobilisable expression vector, derived from Moloney murine leukemia virus (MoMuLV), and Moloney murine sarcoma virus (MoMuSV) designed for retroviral gene delivery and expression. Upon transfection into a packaging cell line, pLNCV can transiently express, or integrate and stably express, a transcript containing psi+ (the extended viral packaging signal), the gene of interest, and a selectable marker. The 5' viral LTR in this vector contains promoter/enhancer sequences which control expression of the neomycin resistance (Neo r) gene for antibiotic selection in eukaryotic cells. A gene of interest can be cloned into the multiple cloning site immediately down stream of the human cytomegalovirus (CMV) immediate early promoter (PCMV). pLNCX also includes the E coli ColE1 origin of replication and ampicillin resistance gene for propagation and selection, respectively, in E. coli.

pLPCX: as for pLNCX but with a puromycin selection marker replacing neomycin resistance.

pCl: mobilisation-defective vector (contains minimal pBR322 nic site) from Promega. Strong CMV IE enhancer sequence, an optimized chimeric intron composed of the
donor site from the first intron of the human beta-globin gene and acceptor site from an immunoglobulin gene intron which increases expression from some cDNAs. Also includes SV40 late polyadenylation signal. These three elements combine to yield strong, constitutive expression of the cloned genes in mammalian cells. pC-neo (5474 bp) also contains neo r gene as a dominant selectable marker driven from the SV40 enhancer/early promoter. The vectors also contain a T7 promoter, an f1 origin of replication, and an Amp r gene.

pAdEasy-1: 33.4 kbp mobilisation defective vector (he et al PNAS 1998 vol 95 p2509-2514) which contains all the adenovirus type 5 sequences except nucleotides 1-3533 (encompassing the E1 genes) and 28, 130-30,820 (encompassing E3 region). The vector also contains an ampicillinR gene and an origin of replication from pBR322. The vector is used in conjunction with pAdTrack vectors to generate recombinant adenoviral plasmids in E. coli (eg when co-transformed into a bacterial host with the pAdTrack-CMV shuttle vector containing an insert sequence, recombination in the host leads to production of a recombinant pAdEasy-1 containing insert sequences. That plasmid can be used to transfect appropriate mammalian cells (eg HEK293) to generate recombinant E1a-deleted adenoviral particles.

pAdTrack-CMV: 9.2 kbp (He et al PNAS 1998 vol 95 p2509-2514) and is used in conjunction with pAdEasy-1 to generate recombinant adenoviral plasmids in E. coli. The resulting recombinant plasmid can be used to produce infective but replication-defective adenoviral particles following transfection of suitable mammalian host cells (eg HEK293) able to provide the E1a sequence in trans. The vector contains a polylinker surrounded by adenoviral sequences ("arms") that allow homologous recombination with pAdEasy-1. The left arm contains Ad5 nucleotides 34,931-35,935 and inverted terminal repeat and packaging signal sequences (nucleotides 1-480 of Ad5) required for viral production in mammalian cells. The right arm contains Ad5 nucleotides 3534-5790. The plasmid has a kanamycinR gene from pZero2.1 (Invitrogen) and an origin of replication from pBR322, hence the plasmid is mobilisation-defective (Bom+ Tra- Mob-). The vector contains a CMV promoter for expression of heterologous genes and a GFP expression cassette driven by a second CMV promoter, to track virus production. Potential for generation of "wild-type" Type 5 Adenovirus (a Category 2 human pathogen) in cells expressing E1a gene (eg HEK 293).

pAdTrack: 8.3 kbp shuttle vector (He at al PNAS 1998 vol 95 p2509-2514) and is used in conjunction with pAdEasy-1 to generate recombinant adenoviral plasmids in E. coli. The resulting recombinant plasmid can be used to produce infective but replication-defective adenoviral particles following transfection of suitable mammalian host cells (eg. HEK293) able to provide the E1a sequence in trans. The vector contains a polylinker surrounded by adenoviral sequences ("arms") that allow homologous recombination with pAdEasy-1. The left arm contains Ad5 nucleotides 34,931-35,935 and inverted terminal repeat and packaging signal sequences (nucleotides 1-480 of Ad5) required for viral production in mammalian cells. The right arm contains Ad5 nucleotides 3534-5790. The plasmid has a kanamycinR gene from pZero2.1 (Invitrogen) and an origin of replication from pBR322, hence the plasmid is mobilisation-defective (Bom+ Tra- Mob-). The vector lacks the CMV promoter present in pAdTrack-CMV promoter, to track virus production. Potential for generation of "wild-type" Type 5 Adenovirus (a Category 2 human pathogen) in cells expressing E1a gene (eg HEK 293).
